1 Interpretative Summary

2 **Effect of Jersey milk on Cheddar cheese.**

3 *By Bland et al.,*

4 Jersey milk is believed to improve cheese yield but to reduce cheese quality. Thus, the  
5 effect of Jersey milk used at different inclusion rates on Cheddar cheese production was  
6 examined. Jersey milk increased cheese yield, cheese fat content and decrease the level  
7 of moisture in proportion to inclusion rate. Jersey milk also increased the total grading  
8 score in winter and the yellowness of the cheeses in summer, however no effect on  
9 cheese texture was detected and quality was not decreased. Including Jersey milk is thus a  
10 valid way of improving Cheddar cheese yield.

EFFECT OF JERSEY MILK ON CHEDDAR CHEESE

**Effect of blending Jersey and Holstein-Friesian milk on Cheddar Cheese Processing,  
Composition and Quality.**

26 **ABSTRACT**

27 The effect of Jersey milk use solely or at different inclusion rate in Holstein-Friesian milk  
28 on Cheddar cheese production was investigated. Cheese was produced every month over  
29 a year using non- standardized milk consisting of 0%, 25%, 50%, 75% and 100% Jersey  
30 milk in Holstein-Friesian milk in 100L vat. Actual, theoretical and moisture adjusted  
31 yield increased linearly with percentage of Jersey milk. This was also associated with  
32 increased fat and protein recoveries and lower yield of whey. The composition of whey  
33 was also affected by the percentage of Jersey milk with lower whey protein and higher  
34 whey lactose and solids. Cutting time was lower when Jersey milk was used but the  
35 cutting to milling time was higher due to slower acidity development, hence overall  
36 cheese making time was not affected by the use of Jersey milk. Using Jersey milk  
37 increased cheese fat content in autumn, winter and spring and decreased cheese moisture  
38 in spring and summer. Cheese protein, salt and pH levels were not affected. Cheese was  
39 analyzed for texture and color and it was professionally graded at 3 and 8 months. The  
40 effect of Jersey on cheese sensory quality was an increase in cheese yellowness during  
41 summer and a higher total grading score at 3 month in winter, no other difference in  
42 cheese quality was found. The study indicates that using Jersey milk is a valid method of  
43 improving Cheddar cheese yield.

44 **Key Words:** Jersey, Cheddar, cheese yield, cheese quality.

45

## INTRODUCTION

46

47 Milk composition has an important influence on the technical and economic efficiency of  
48 cheese making (Storry et al., 1983; Sundekilde et al., 2011). Milk suitability is modified  
49 by many factors such as diet, breed, protein genetic variant, health, season and rearing  
50 condition. The effects of breed and protein genetic variants, which are inter-related, have  
51 been subject to increased interest (Barowska et al., 2006). The Jersey, Brown Swiss,  
52 Montbéliarde and other high milk solids yielding breeds have been shown to have a  
53 positive impact on cheese-making (Lucey and Kelly, 1994).

54 The Jersey (J) breed is the second most important dairy breed in the world and it has been  
55 suggested that using J milk would improve the efficiency of the cheese making sector in  
56 Canada (Thompson, 1980), Wales (Hayes, 1983) and the USA (Capper and Cady, 2012)  
57 due to improved longevity, superior udder health, higher cheese yield, reduce feed and  
58 water requirement, and an overall reduction in the carbon footprint of Cheddar cheese  
59 production.

60 However, the use of J milk for Cheddar cheese production, while common, is still limited  
61 both in terms of the quantity used by individual cheese makers and the number of cheese  
62 makers using it. This could be linked to the lack of information available to cheese  
63 makers on the effects of using J milk on the cheese making process and cheese yield.

64 Estimates of cheese yield from J were based mainly on theoretical cheese yield equations  
65 and theoretical increases ranged from 21% to 32% compared to Holstein-Friesian (H-F)  
66 (Lundstedt, 1979; Geary et al., 2010; Capper and Cady, 2012). The only practical study  
67 measuring the actual improvement in yield did so using standardized milk and showed an  
68 increase of only 10% (Auldism et al., 2004).

69 There also appears to be a presumption in the industry that J milk has a negative impact  
70 on cheese quality. Cheese quality can be firstly defined as the compliance to legislation  
71 (International Food Standards, 2003) which specifies a minimum level of fat and  
72 maximum moisture. Secondly quality can be defined as the cheese having the desirable  
73 organoleptic properties at the time of consumption, which is commonly, assessed using  
74 grading at the cheese factories. In the case of J cheese, it is believed to have a higher  
75 moisture content due to the lower protein to fat ratio, resulting in lower syneresis (Bliss,  
76 1988) and a buttery, weaker texture and rancid taste due to the higher fat content and  
77 larger, more fragile fat globules, causing early lipolysis (Cooper et al., 1911). However,  
78 these fears of negative impact were not supported by past data. Auld et al. (2004) found  
79 that the moisture content and composition of J and H-F Cheddar cheeses made with  
80 standardized milk were not different with the exception of a higher salt concentration and  
81 lower pH and ash concentration for J cheese. On the other hand, Whitehead (1948) found  
82 that Cheddar cheese from non-standardized J milk had a lower moisture content and the  
83 cheese was also firmer. However, the cheese making process also had to be adapted to  
84 account for differences in acidity development and syneresis. Unfortunately, no  
85 information regarding yield was provided. Thus there is a lack of information on the  
86 effect of J milk on Cheddar cheese making, composition and sensory properties limiting  
87 its use on a commercial scale.

88 This study therefore investigated the effect of J milk, and blends of J and H-F, on  
89 Cheddar cheese production with the objective of finding the optimal inclusion rate of J  
90 milk in H-F milk for improving yield without reducing the quality of the cheese.

91

## MATERIALS AND METHODS

92

### *Experimental Design*

93

94 The experiment was carried out three times each season between September 2012 and  
95 November 2013. The seasons were defined as autumn (September, October and  
96 November), winter (December, January and February), spring (March, April, May) and  
97 summer (June, July, August).

98 Samples from the combined evening and morning milking were obtained from the  
99 University herd of H-F cows (CEDAR, Reading, UK) and two J farms (Brackley and  
100 Slough, UK) and transported to the pilot-scale cheese making facility at the University of  
101 Reading. J milk was blended with H-F milk at 0%, 25%, 50%, 75% and 100% J in H-F  
102 milk. Due to time limits, the ratios 25% and 75% were performed on alternate repeats.  
103 Thus, 4 samples were analyzed on each repeat, giving a total of 48 observations.

### *Milk Composition*

104

105 Analysis for fat, protein, lactose, casein, urea content and freezing point depression and  
106 Somatic Cell Count (SCC) were performed by the National Milk Laboratory (Glasgow,  
107 UK) using an infrared milk analyzer. The ratio of protein to fat (P/F) and casein to protein  
108 (C/P) were calculated from this data. Size of casein micelles (CMS) and size of fat  
109 globules (mean volume D(4.3), mean surface area D(3.2), average size D(0.5) and span)  
110 were determined using a Zetasizer 500 (Malvern Instruments Ltd, Worcestershire, UK)  
111 and a Mastersizer S 2000 (Malvern Instruments Ltd, Worcestershire, UK) respectively.  
112 Calcium ion concentration ( $\text{Ca}^{2+}$ ) was determined using a Ciba Corning 634 ISE  $\text{Ca}^{2+}$ /pH  
113 Analyzer (Bayer Ltd, Newbury, UK) using the method of Lin (2002). Milk pH was  
114 measured using a FE20 desktop pH meter (Mettler-Toledo Ltd., Leicester, UK) and

115 titratable acidity was measured using an acid-base titration with a Titalab automatic  
116 titrator (Radiometer Analytical, Villeurbanne, France) titrated with 0.1 M NaOH until pH  
117 8.70 was reached, and expressed as Dornic acid (°D). All analyses were performed  
118 within 24 h of milk collection.

### 119 *Cheese making process*

120 On each occasion four vats of cheese were made over two days. Bulk milk was  
121 pasteurized, but not standardized, as standardization was not carried out by the large  
122 commercial cheese plant on which the cheese making process is based. Approximately 80  
123 kg of milk was placed into each vat and warmed to 33°C. Starter (RSF 638, Chr. Hansen  
124 Laboratories A/S, Hørsholm, Denmark) was added at 0.0269 g/kg of milk and left to  
125 ripen for 35 min. Coagulant Marzyme 15 PF (Danisco, Dupont Company, Hertfordshire,  
126 UK) was then added at 0.2566 ml/ kg after being diluted fivefold with water. Curd was  
127 cut at the cheese maker's judgment. The curd and whey was heated to 39°C in 45 min  
128 and then left to scald at this temperature for 50 min. Whey was then drained and the  
129 cheddaring process started when the TA reached  $0.20 \pm 0.05$  °D. Curd was milled at TA  
130  $0.30 \pm 0.05$  °D and salt added at 24 g/ kg of curd. Salted curds were left to cool and then  
131 filled into round moulds of 5 kg and prepressed at 3 Pa up to 7 Pa, and left to press  
132 overnight at 7 Pa.

133 The yield and composition of the whey was determined from the whey collected between  
134 drainage until milling (Lactoscope, Advanced Instruments Inc., Drachten, Netherlands).  
135 Yield was calculated from the weight of milk placed in the vat, and the weight of cheese  
136 after pressing and vacuum packing. Yield was expressed both in actual yield kilo of  
137 cheese per 100kg of milk, and adjusted yield using a fixed moisture content of 37%.

138 Theoretical yield was also calculated using milk composition data and the Van Slyke  
139 equation (Van Slyke and Price, 1949). Finally cheese yield efficiency was calculated  
140 using the actual yield as percentage of theoretical yield.

141 Additionally, fat and protein recoveries and losses were calculated using the composition  
142 and quantity of milk and whey based on the principle described by Banks et al. (1981).  
143 Time of addition of rennet to cutting, cutting to milling and starter to milling was  
144 recorded.

#### 145 *Cheese composition*

146 Cheese was analyzed for fat, protein, moisture, pH and salt 1 month after production. Fat  
147 content analysis was carried out using the Gerber method as described by Grandison and  
148 Ford (1986) and the ISO standard 2446/IDF 226 using an Astell Hearson Gerber  
149 centrifuge (Astell Scientific, London, United Kingdom).

150 Protein content was determined by the Kjeldahl nitrogen method based on the ISO  
151 17837:2008 using the BÜCHI digestion K-424 unit (BÜCHI Labortechnik AG, Postfach,  
152 Switzerland) and a BÜCHI distillation unit 323 (BÜCHI Labortechnik AG, Postfach,  
153 CH). The moisture content was determined by weighing  $10 \pm 0.005$ g of ground cheese into  
154 a dish with  $20 \pm 0.5$ g of sand, along with lid and rod, which had been previously dried for  
155 1 hour at  $105^\circ\text{C}$  and then pre-weighed ( $\pm 0.0001$  g). The sample was then put into an oven  
156 to dry for 23h hours at  $105^\circ\text{C}$  and the loss in weight recorded. A Titralab automatic  
157 titrator (Radiometer Analytical, Villeurbanne, France) was used to assess salt  
158 concentration in cheese. A sample ( $5 \pm 0.001$  g) of ground cheese was mixed with 100ml  
159 of water at  $40^\circ\text{C}$  and a 50 ml aliquot was sampled. To this aliquot 5ml of 1M nitric acid  
160 was added and then it was titrated using a combined silver / mercurous sulphate metal

161 probe MC609/Ag (Radiometer Analytical, Villeurbanne, FR) with silver nitrate 0.1M to  
162 an endpoint of -100Mv. The pH of cheese samples was measured with a Thermo Orion  
163 star A111 benchtop pH meter (Thermo Fisher Scientific Ltd, Loughborough, UK) using  
164 a specially designed cheese FoodCare pH combination pH probe FC240B (Hanna  
165 Instruments Ltd, Leighton Buzzard, UK). All analyzes were carried out in triplicate at  
166 room temperature ( $20 \pm 0.5^{\circ}\text{C}$ ).

### 167 *Sensory analysis*

168 The cheese sensory properties were evaluated after 3 months of ageing. The texture of the  
169 cheese was analyzed using Texture Profile Analysis (TPA) as developed by Szczesniak  
170 (1963) and Friedman et al. (1963) with a texture analyzer (Model TA-XT2, Stable Micro  
171 Systems, Godalming, U.K.). Samples were cut into cylinders of 22 mm diameter and 22  
172 mm height (Halmos et al., 2003) after being tempered to room temperature in a vacuum  
173 pack overnight. The TPA parameters recorded were: hardness, cohesiveness, springiness,  
174 and resilience. The parameters were 30% compression at a speed of 50mm/s (Shama and  
175 Sherman, 1973) and 5 s delay between compressions, this was done in triplicate.

176 Color was analyzed using a ColorQuest II spectrophotometer (HunterLab, Virginia, US).  
177 Cheese samples were prepared into cubes (5x5x3 cm) and analyzed using the  
178 Commission on Illumination Standard (CIE) Illuminant D65 lamp. Results are given as a  
179 CIE  $L^*a^*b$  color scale and color differences ( $\Delta E^*_{ab}$ ) were calculated (Fernández-  
180 Vázquez et al., 2011). Analysis was carried out in triplicate

181 Cheese grading was carried out at 3 and 8 months according to the standard UK grading  
182 scheme (NACEPE) awarding points for flavor and aroma, body and texture, color and

183 appearance with regard to standard Cheddar cheese required by retailers. On each  
184 occasion a minimum of three graders were used.

### 185 *Statistical analysis*

186 Data were subject to ANOVA and Tuckey HSD using SPSS PASW Statistics 21.0 to  
187 detect any statistical differences between inclusion rates. Seasonal variation effects were  
188 tested the same way. Differences were considered significant at  $P < 0.05$ .

189

## 190 **RESULTS AND DISCUSSION**

### 191 *Milk composition*

#### 192 **(Table 1)**

193 Means, ranges and SE for each blends are presented in Table 1. The range and differences  
194 in composition are in agreement with others studies (Auldust et al., 2004; Barowska et al.,  
195 2006; Czerniewicz et al., 2006). The J milk contained significantly higher levels of all  
196 components except lactose, urea, calcium ions, D(3.2), fat globule size span and pH  
197 which were not significantly different. In addition, the protein to fat and the casein to  
198 protein ratio and CMS were higher in H-F milk. This difference in protein to fat and  
199 casein to protein ratio would not be representative of all cheese milk due to the  
200 increasingly common standardization of milk to a set protein to fat or casein to fat ratio.  
201 However, not standardizing enabled the evaluation of the effect of increased fat  
202 proportion in the cheese, which is often believed to be the cause of poor cheese quality.  
203 In terms of the effect of season on milk composition (Table 1), only the fat and protein  
204 content was modified, for both breeds, with the lowest level found of both components in  
205 summer and the highest level in winter but no difference in spring and autumn ( $P < 0.05$ ).

206 *Cheese making process*

207 **(Table 2)**

208 Table 2 presents the results of the effect of J milk on the cheese making process. The  
209 actual, theoretical and moisture adjusted yield of cheese were significantly improved by  
210 the inclusion of J milk. Actual yield was increased by up to 34.6% more when using  
211 100% J milk compared to H-F (Table 2). This is consistent with the deterministic model  
212 based on a yield equation of Lundstedt (1979) which found an increase of approximately  
213 32%, but was higher than the estimates of Geary et al. (2010) and Capper and Cady  
214 (2012) which found respectively increases of 21% and 23%. However, this was due to  
215 the J milk composition being lower in protein and fat content than in the previous  
216 deterministic model. Auld et al. (2004) showed an increase in yield of 10% when  
217 using standardized J milk. Theoretical yield predicted a smaller increase in yield  
218 (17.74%) which is lower than the results of the previously cited research (Lundstedt,  
219 1979; Geary et al., 2010; Capper and Cady, 2012). This could be due to the way casein  
220 was measured. In the current study casein level was analyzed whereas in the deterministic  
221 model it was calculated from protein level using higher casein to protein ratio (0.8) than  
222 what was found in the current study (0.73-0.77). Seasonality variations were found for  
223 the theoretical yield, in winter and spring no difference in theoretical yield between  
224 inclusion rates were found, while in autumn and summer the theoretical yield increased  
225 with increased J milk percentage. This disagrees with actual yield values where the  
226 difference between H-F and J was constant throughout the year (Figure 1) due to similar  
227 seasonal effect on actual yield for both breeds.

228 **(Figure 1)**

229 Differences between actual yield and yield moisture adjusted to 37% were found only for  
230 H-F cheese which had lower moisture adjusted yield.

231 Yield of whey was decreased when J milk was added to H-F milk at rate of 50% or over,  
232 with the exception of summer where no difference in whey quantity was found. This is  
233 consistent with Whitehead (1948) who found J curd to have improved syneresis  
234 compared to H-F. Following the same cheese-making process, J curd retained 25% more  
235 whey. This is in accordance with a higher casein content improving syneresis. However,  
236 the higher content of fat and bigger globules would be expected to decrease syneresis rate  
237 (Guinee et al., 2007). This indicates that protein concentration and size of micelles  
238 compensate for the higher fat content and bigger fat globules found for J milk.

239 Composition of whey was modified by a high inclusion of J milk with protein decreasing  
240 and lactose and solid increasing with inclusion of J milk. However, there was some  
241 seasonal variation in the phenomenon, in particular, the level of protein was found not to  
242 be different in spring and summer, while the level of lactose was not significantly  
243 different in autumn and winter and level of solids not different in autumn and summer.  
244 The concentration of fat in whey was not affected by inclusion of J milk overall, but was  
245 found to be higher in autumn and winter.

246 The recovery rate of protein and fat was improved when J milk was used solely, but this  
247 was highly affected by season, in agreement with the study of Banks et al. (1984a) for fat,  
248 but not for protein. This study also found higher recovery value than in the present study  
249 which is believed to be due to a lower efficiency on small scale production.. No  
250 differences in recoveries were found in autumn and in winter.

251 The time to cutting was lower when J milk was added at 50% or higher throughout the  
252 year. This is in accordance with the shorter coagulation time and higher curd firming rate  
253 of J milk reported in several other studies (Okigbo et al. 1985; Barłowska et al. 2006;  
254 Kielczewska et al. 2008; Frederiksen et al. 2011; Jensen et al. 2012). The time from  
255 cutting to milling was increased for 100% J milk due to a lower acidity development,  
256 which was also reported by Whitehead (1948) who advised the use of more starter to  
257 overcome this problem. However, this only occurred in the summer, which is in  
258 agreement with Banks et al. (1984a). Overall, the total cheese making time was not  
259 different between inclusions rates, the faster coagulation time with J milk compensating  
260 for the longer acidification time.

261 Including J milk significantly modified the Cheddar cheese process. The increase in  
262 Cheddar cheese yield was linear and was at its maximum when J milk was used solely.  
263 The fat and protein recoveries were also improved but no statistical differences were  
264 found when more than 25% of J milk was used. Whey quantity and composition was  
265 modified by J milk inclusion as was the cutting and acidification time, but this was not  
266 deemed to affect negatively the cheese making process. From these results the use of J  
267 milk solely seemed to be the most efficient way of producing Cheddar cheese.

### 268 *Cheese composition*

#### 269 **(Table 3)**

270 The cheeses were analyzed for fat, protein, moisture, salt and pH, and only fat and  
271 moisture were modified by the inclusion of J milk (Table 3). This is in agreement with  
272 the study of Auld et al., (2004) which found little difference in cheese composition,

273 however, changes in pH and salt were observed, which were not seen in the current study.  
274 All cheeses were above the legal minimum standard for fat content and below the legal  
275 maximum standard for moisture content and the fat in dry matter was also always above  
276 the recommended 50% for good quality Cheddar cheese (Lawrence and Gilles, 1980).  
277 However at 100% J milk, the fat in dry matter ( $58.21 \pm 0.54\%$ ) was slightly above the  
278 recommended range 50-57%, which could increase the chance of downgrading  
279 (O’Riordan and Delahunty, 2003). Fat increased with the inclusion of J milk in autumn,  
280 winter and spring (Figure 1). This is consistent with a higher level of casein and larger  
281 MFG improving fat retention as well as seasonal effects (Banks et al., 1984b, 1986).

282 **(Figure 2)**

283 Moisture was reduced when J milk was used in spring and summer (Figure 2). Whitehead  
284 (1948) also found moisture to be decreased when J milk was used, due to higher  
285 syneresis, and noted that similar moisture could readily be achieved through the  
286 adaptation of the scalding temperature. The moisture in non-fat substance was not found  
287 to be different between inclusion rates, but the levels were slightly higher than that  
288 considered as optimal for Cheddar cheese (50-56%) by Banks et al. (1984b).

289 **(Figure 3)**

290 Cheddar cheese made from J milk complied with current legislation on Cheddar cheese  
291 composition.

292 ***Cheese sensory properties***

293 From all the sensory properties studied, including texture, color and professional grading,  
294 only the color and total grading scores were modified by the inclusion of J milk. This lack

295 of difference in sensory properties is supported by Whitehead (1948), except that the  
296 latter study found firmness to be greater in J cheese which was not the case in our study.  
297 The lack of effect of J milk on texture is surprising as a the increase in fat in dry matter  
298 (Table 3) should have decreased cheese firmness (Martin et al., 2000). Still, as texture  
299 was both monitored instrumentally (TPA) and through grading, it can be concluded that  
300 in our study this was not the case. Figure 3 presents the  $b^*$  value in summer, which  
301 correspond to the color yellow, and showed when J milk was included the cheese was  
302 more yellow. However, the color differences ( $\Delta E^*_{ab}$ ) were not different ( $P < 0.05$ ) and  
303 the ranges were lower than the normal eye tolerances, which require a difference of 2.8 to  
304 5.6 (Fernández-Vázquez et al., 2011) to be noticeable by consumer. This was proved by  
305 no difference being found in the grading for color.

306 **(Figure 4)**

307 The total grading scores in winter increased with the inclusion of J milk (Figure 5),  
308 however this difference was not sustained at 8 months and no significant difference in  
309 graded flavour, texture, appearance and color was detected at either 3 or 8 months. This is  
310 in contradiction with the belief of a negative effect of J milk on cheese quality. Not  
311 standardizing, while increasing cheese fat, fat in dry matter and moisture in non-fat  
312 substance, did not affect negatively cheese quality, and is thus a viable way of producing  
313 Cheddar cheese with J milk. Further research should investigate the effect of J milk on  
314 the grading of cheese, after 8 month as the bigger fat globules could still lead to early  
315 lipolysis and thus bitter taste (Cooper et al., 1911).

317

318

## CONCLUSIONS

319 This study showed that including J milk improved the yield of non-standardized Cheddar  
320 cheese in direct proportion to the rate of inclusion, and thus, without affecting negatively  
321 the sensory quality of the cheese. In addition the change in the cheese making process  
322 and cheese composition does not hinder its use. Therefore using J milk is a valid way of  
323 improving the yield of Cheddar cheese with the optimal inclusion rate being 100% J milk.

324

325

## ACKNOWLEDGEMENT

326 Funding for this research was provided by UK Jersey, the Dartington Cattle Breeding  
327 Trust, the Royal Bath and West of England Society, West Country Dairy Award and the  
328 Pocock Memorial trust.
