**Effects of Visual Linguistic Feedback on Parents of Infants and Toddlers in Korea**

Journal:	<i>First Language</i>
Manuscript ID	FLA-15-0044.R2
Manuscript Type:	Original Manuscript
Keywords:	adult words, child words , turns, feedback , Korea
Abstract:	<p>The objective was to investigate changes in the natural language environments of families with typically-developing infants receiving language feedback in South Korea. Volunteer parents of 99 children aged 4–16 months were randomly divided into experimental and control groups. During six months intervention, the experimental group recorded weekly day-long automatically-analyzed LENA measures of language environment and viewed feedback, while the control group recorded only baseline, mid-period and post-test without feedback. LENA Adult Word Counts (AWC) and Conversational Turn (CT) counts correlated reasonably well with human transcripts. At baseline groups were not significantly different. At post-test there was no significant overall difference between experimental and control groups, but AWC and CT differences were significant for families below the 50th percentile at baseline. Korean parents whose linguistic environment was below average adapted their communicative interaction in response to linguistic feedback. The intervention has promise for use with at-risk families in many countries.</p>

Running Head: EFFECTS OF LANGUAGE FEEDBACK

Financial Disclosure: The authors have no relevant financial relationships to disclose.

Conflict of Interest: Dr. Gilkerson, Mr. Richards and Dr. Ma are employed by the LENA Research Foundation. The specific results of this study do not create a conflict of interest for them. The other authors have no conflicts of interest relevant to this article to disclose.

### Acknowledgments

We gratefully acknowledge Terrance Paul for conceiving of the LENA technology, his wife Judith for funding its development, and the LENA Research Foundation for funding the current study. We would also like to express our deep appreciation to the families who participated.

## Effects of Feedback on Parent-Child Language with Infants and Toddlers in Korea

### Abstract

The objective was to investigate changes in the natural language environments of families with typically-developing infants receiving language feedback in South Korea. Volunteer parents of 99 children aged 4–16 months were randomly divided into experimental and control groups. During six months intervention, the experimental group recorded weekly day-long automatically-analyzed LENA measures of language environment and viewed feedback, while the control group recorded only baseline, mid-period and post-test without feedback. LENA Adult Word Counts (AWC) and Conversational Turn (CT) counts correlated reasonably well with human transcripts. At baseline groups were not significantly different. At post-test there was no significant overall difference between experimental and control groups, but AWC and CT differences were significant for families below the 50<sup>th</sup> percentile at baseline. Korean parents whose linguistic environment was below average adapted their communicative interaction in response to linguistic feedback. The intervention has promise for use with at-risk families in many countries.

## Effects of Feedback on Parent-Child Language with Infants and Toddlers in Korea

Few carefully evaluated parental involvement initiatives have focused on developing child language in the early years of life, from 0 to 2 years of age. Even fewer of these studies have used an automatic computer-based method for analyzing full-day audio recordings of parent-child interactions, such as the LENA (Language ENvironment Analysis) technology. None of these studies in the English language literature have taken place in South Korea, a fascinating location for such investigations. The present study addresses these gaps. The paper explores pre-post changes resulting from facilitating language development with feedback in a group of families randomly divided into experimental and control groups.

### Context of the Present Study

In Korea, the single language Korean is used. While the Korean alphabet (hangul) may appear logographic, it is actually a phonemic alphabet organized into syllabic blocks. Each block consists of at least two of the 24 letters: at least one each of the 14 consonants and 10 vowels (Song, 2005). The language is thus more similar to English than say Chinese, so it was expected that English-based LENA algorithms might work for Korean.

Korean families are of various sizes, typically 3-6 people. Parental motivation for child success is very high. Kim (2008) studied parents' and adolescents' reports of parenting styles and found mothers were more aggressive/hostile, behaviorally controlling and psychologically controlling than fathers. Parents tend to expect to express their support for their child's education by buying extra materials and tuition for the child, rather than actually doing something with the child themselves. Thus Korean parents with preschool children seem to have different parenting beliefs from parenting practices (Park & Kwon, 2009).

1  
2  
3 South Korea's science education, math and literature are ranked highly in international  
4 comparisons. However, the education system is criticized for emphasizing passive learning and  
5 memorization, and being hierarchical (suppressing innovation) and competitive. Additionally,  
6 there are many private academies or cram schools (*hagwons*) which further emphasize passive  
7 memorization (Center on International Educational Benchmarking, 2015; Janda, 2013).  
8  
9

### 15 **Aim of the Present Study**

16  
17 The quantity and quality of adult-child interaction in developing the language of children  
18 in the early years using real-time day-long audio recordings and automatic analysis has never  
19 before been explored in such a highly education-oriented society as Korea, which nonetheless  
20 has issues of pedagogical style and high competition. The present study aimed to investigate the  
21 effect of feedback generated from the LENA technology on parent-child language interaction in  
22 such a society - with improvements on previous studies - a larger sample size, the use of  
23 experimental and control groups and random allocation to conditions. (Further information on  
24 the LENA technology will be found under Measures and further information on the nature of the  
25 feedback will be found under Procedure below.) The study further explored differences between  
26 families who were given feedback from baseline recordings that their child's language  
27 environment was above or below average in relation to norms.

### 44 **Adult Interaction in Early Child Language Development**

45  
46 Evidence of the critical role of adult interaction in child language development strongly  
47 supports the capacity of very young children to respond to rich stimulation (Chapman, 2000;  
48 Hart & Risley, 1995; Huttenlocher, Haight, Bryk, Seltzer & Lyons, 1991; Rowe, 2008). The  
49 properties of adult caregiver language are predictive of metrics of child language development.  
50  
51  
52  
53  
54

55  
56 We know that there is a relationship between adult language input to children and their  
57  
58  
59  
60

1  
2  
3 subsequent development of vocabulary. For example, Boyce et al. (2013) investigated 120 Latino  
4 dual language learners of low socio-economic status. Language was assessed in both English and  
5 Spanish. The home language and literacy environments were significantly related to child  
6 language status at 24 and at 36 months, and indeed had predictive value. However, on average  
7 these socio-economically disadvantaged children performed well below average age levels for the  
8 whole (non-disadvantaged) population. When performance in both English and Spanish was  
9 aggregated, scores were raised nearer to this criterion, but still below it.

10  
11 We also know that there is a measurable quantitative relationship between parental  
12 language input and child acquisition of language over time. The acquisition of discourse  
13 connectives in relation to parental language input was studied by Van Veen et al. (2009).  
14 Obviously, increasing child age and cognitive ability are factors which need to be taken into  
15 account. The researchers looked at the effects of parental input within one recording, but also at the  
16 effects of cumulative parental input over a longer period of time. They subsequently developed a  
17 growth curve incorporating all these variables which accounted for and predicted child language  
18 development over time in relation to parental input. Sample size for development of this growth  
19 curve was rather small, so replication of this study is needed.

20  
21 Further, infant language behavior is shaped by parental language input but can also shape  
22 that input. Masur et al. (2013) analyzed infant language behaviors before and after four  
23 categories of maternal utterance: responsive utterances, supportive behavioral directives,  
24 intrusive behavioral directives, and intrusive attentional directives. These were investigated  
25 longitudinally during dyadic free play at ages 13, 17, and 21 months. Children's positive social  
26 and object-directed behaviors increased both before and after maternal speech. When mothers  
27 engaged in language interaction with their child, this often resulted in disengagement with play

1  
2  
3 and toys, but after the language interchange engagement with play and toys was resumed at a  
4  
5 higher level. The researchers identified different patterns of interaction depending on the nature  
6  
7 of the maternal utterance.  
8  
9

10 Beyond this, we also know that parental word choices tend to be reflected in preschoolers'  
11  
12 phonological and vocabulary development. For example, Hohenstein (2013) focused on  
13  
14 parent-child talk about motion while playing a board game. Spanish-speaking (21) and  
15  
16 English-speaking (24) families were examined for lexical and syntactic differences in motion  
17  
18 event expressions. English-speaking parents used more manner verbs and Spanish-speaking  
19  
20 parents used more specific path verbs. English-speaking parents also used more general path  
21  
22 verbs than did Spanish speakers. These differences mapped onto children's production of motion  
23  
24 event language.  
25  
26  
27

28  
29 Taking a different slant, Reese et al. (2015) investigated the development of pre-school  
30  
31 children's phonological awareness (an important predictor of later reading skill) as a function of  
32  
33 parental talk. Parents who used more sound talk had children with more advanced phonological  
34  
35 awareness, even after controlling for children's language skills and sociodemographic factors.  
36  
37 Thus there are many reasons for the presumption that parental input increases child language,  
38  
39 although this may be a reciprocal relationship. Parent word choices enhance vocabulary and  
40  
41 parent sound talk enhances phonological awareness.  
42  
43  
44

45  
46 The responsiveness of parents to their child's vocalizations in conversational turns  
47  
48 (Tamis-LeMonda, Bornstein & Baumwell, 2001; Topping, Dekhinet & Zeedyk, 2013) correlate  
49  
50 particularly well with growth in child vocabulary. There is further evidence that turn taking  
51  
52 impacts on early infant vocalizations. Bloom et al. (1987) investigated very young (3-month-old)  
53  
54 children, one group of 20 participants experiencing conversational turn taking and another 20  
55  
56  
57  
58  
59  
60

1  
2  
3 random adult responsiveness. Infant vocalizations were categorized as speech-like (syllabic) or  
4 nonspeech-like (vocalic). Turn-taking yielded higher quality of infant vocal sounds. When the  
5  
6 adult maintained a give-and-take pattern, the infant produced a higher ratio of syllabic/vocalic  
7  
8 sounds.  
9  
10

11  
12 The frequency of turns does increase with age during the toddler years. Rutter and Durkin  
13 (1987) reported laboratory studies of vocal coordination and gaze in mother–infant play. They  
14  
15 were interested in the use of gaze by children to signal that they had completed their vocalization  
16  
17 and to indicate attention when the other person is speaking – highly related to turn-taking. Active  
18  
19 structuring of vocal interaction was found by the end of the second year, and gaze began to  
20  
21 approximate the typical adult pattern of signaling as early as 18 months. There were marked and  
22  
23 consistent individual differences, however.  
24  
25  
26  
27  
28

29 The converse has also been observed, in which deprivation in quality or quantity of  
30  
31 language input leads to delayed language acquisition, lowered IQ, and reduced subsequent  
32  
33 academic achievement (Huttenlocher, Vasilyeva, Cymerman & Levine, 2000; Landry, Smith,  
34  
35 Swank, & Miller Loncar, 2000; Topping, Dekhinet & Zeedyk, 2011). Thus, many aspects of  
36  
37 language acquisition are driven by factors within caregiver intervention.  
38  
39  
40

#### 41 **Automatic Assessment of Language**

42

43 There are many different ways of assessing child language performance, although many  
44  
45 studies only use one way. Gatt et al. (2014) however examined expressive vocabulary  
46  
47 development in children aged one to two and a half years through three methods: picture naming,  
48  
49 caregiver report and language sampling. Expressive vocabulary reported by caregivers was  
50  
51 compared to word use elicited through picture naming and sampled naturalistically during play.  
52  
53 Analyses revealed commonalities between pairs of measures which suggested their co-validity.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 However, commonalities between all three measures were fewer. Data collection methods did to  
4  
5 some extent influence the nature of the data collected. The author recommended the routine use  
6  
7 of multiple measures in language assessment, but of course this is very time consuming and  
8  
9 usually possible only with small participant numbers or short samples of language.  
10  
11

12  
13 In the development of pre-term infants, the relationship between *adult word counts* (AWC)  
14  
15 and the frequency of child vocalizations has been noted (Caskey, Stephens, Tucker & Vohr,  
16  
17 2011). Moreover, rates and durational properties of AWCs, child vocalizations and  
18  
19 *conversational turns* (CTs) have been shown to be useful in distinguishing the language  
20  
21 environments of some clinical populations (Wiggin, Gabbard, Thompson, Goberis &  
22  
23 Yoshinaga-Itano, 2012; Dykstra, et al., 2013; Warren, et al., 2010; Warlaumont, et al., 2010; Oller,  
24  
25 et al., 2010).  
26  
27

28  
29 These interaction measures have recently become more easily studied through automatic  
30  
31 means of assessing daylong audio samples of language. Such a means (e.g., the LENA  
32  
33 technology) yields not only descriptive tools to characterize language environments, but also a  
34  
35 potential source of intervention in the form of feedback to adult caregivers on their performance.  
36  
37 A much longer sample of language is analyzed than is possible with human transcription (a  
38  
39 minimum of eight hours per day is specified for LENA analysis, but the whole recording of up to  
40  
41 16 hours is analyzed). The recording is then analyzed by computer, enabling distinction between  
42  
43 adult speech, child vocalization, conversational turns (adult speech immediately followed by  
44  
45 child vocalization or vice versa), television, noise, and other environmental factors. Elements of  
46  
47 this analysis are then fed back to the caregivers.  
48  
49  
50  
51  
52

53  
54 Greenwood et al. (2011) made LENA recordings with 30 middle to upper socio-economic  
55  
56 status families with typically developing children. There were vast differences in individual  
57  
58  
59  
60

1  
2  
3 children's home language environments (adult word count, children's vocalizations, and  
4 conversational turns). Suskind, et al. (2013) reported significant, positive results in utilizing  
5 automated linguistic analysis (and specifically AWC and CT) to measure the progress of  
6 non-familial caregivers of typically-developing children in setting and meeting goals to increase  
7 their speech in interactions with children.  
8  
9

10  
11  
12  
13  
14  
15 Suskind, et al. (2015) followed this up with a study of 23 low socio-economic status  
16 parents and their children (aged 18 – 36 months) with automated analysis, although there was a  
17 good deal of attrition. Twelve experimental and 11 control children allocated randomly to  
18 condition received eight weekly home visits. For the experimental group these were hour-long  
19 and focused on parent-child interactions to promote language development and included video  
20 modeling by the visitor and of the parent. For the control group they were much shorter (10  
21 minutes) and focused on nutrition. In the experimental group parent knowledge of language  
22 development increased significantly one week and four months after the intervention, but not in the  
23 control group. For the experimental group, adult word counts (Cohen's  $\delta = 0.34$ ), conversational  
24 turn counts ( $\delta = 0.66$ ), and child vocalization counts ( $\delta = 0.43$ ) from the LENA technology  
25 increased significantly during the intervention. At post-intervention the scores were still somewhat  
26 elevated, but not statistically significant. Thus the intervention showed effects, but not all of these  
27 were significantly maintained post-intervention.  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45

46 In another continent, Zhang, et al. (2015) used the LENA technology to investigate  
47 changes in the natural language environments of families receiving quantitative language  
48 feedback in Shanghai. Measures of adult word count and conversational turns with children were  
49 collected regularly over six months from volunteer parents of 22 children aged 5–30 months.  
50  
51  
52  
53  
54  
55 Feedback reports to caregivers included individual family plus group counts. Overall, families  
56  
57  
58  
59  
60

1  
2  
3 increased word/turn counts significantly during the first three months then regressed to baseline  
4 levels during the summer months. However, parents whose word count output was below  
5 average at baseline significantly increased word count output to study conclusion. Increases in  
6 adult word and conversational turn counts were related to a subset of language development  
7 measures.  
8  
9

10  
11  
12  
13  
14  
15 Although the majority of previous work has been with typically-developing children in  
16 American English-speaking (AE) households, one previous study reported on the validity of the  
17 LENA technology with a small number of Spanish-speaking families of young children aged up  
18 to 60 months (Weisleder & Fernald, 2013), finding a correlation between automated estimates  
19 and transcriber-based word counts of  $r = .80$ . A more recent study correlated automated  
20 estimates and transcriber-based counts for children aged up to 60 months in Mandarin and  
21 Shanghai Dialect (Gilkerson, et al., 2015) with similar results ( $r = .73$ ), although again the  
22 sample was small. Canault et al. (2015) investigated the reliability of the LENA technology in  
23 French. Eighteen native French-speaking children were divided into six age groups ranging from  
24 3 to 48 months old and recorded for three days per week. Six 10-min chunks of recordings (a  
25 total of 324 samples) were transcribed and aligned to LENA Adult Word Count and Child  
26 Vocalization Count. AWC and CVC estimates were reasonably reliable ( $r = .64$  and  $.71$ ,  
27 respectively). These studies suggest that further research in other languages merits exploration.

### 46 **Research Questions**

47  
48 The present study is about the use of LENA technology as a primarily home-based  
49 intervention in a novel culture. It was with typically developing children, had a fairly large sample,  
50 and experimental and control groups. The literature review suggests that parental language input  
51 is key to the development of pre-schoolers' own language, and that turn-taking is an important  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 component of this. We sought to investigate whether Adult Word Count (AWC) and  
4  
5  
6 Conversational Turns (CT) generated by automated analysis were important in the development of  
7  
8 language in a sample of children in an alternative culture.  
9

10  
11 Two research predictions were made. Firstly, that receiving automated feedback would  
12  
13 enable participant families to increase their adult word and conversational turn counts from  
14  
15 baseline. Secondly, that such increases would be greater for the below-50<sup>th</sup> percentile group of the  
16  
17 participant pool (who were expected to be more motivated on becoming aware of their  
18  
19 “below-average” status, although it is accepted that this is purely speculative), as in the previous  
20  
21 Chinese study (Zhang, et al., 2015).  
22  
23

## 24 25 **Method**

26  
27 Ethical approval was obtained from Hallym University prior to study participation.  
28

### 29 **Participants**

30  
31 The area chosen for this study was the capital city of Seoul and two coterminous provinces  
32  
33 in the north of South Korea containing a total of 23.5 million people. To recruit participants,  
34  
35 flyers and brochures were distributed to those pediatric clinics and baby daycare centers which  
36  
37 agreed to inform families interested in the program. Initially 428 families expressed interest from  
38  
39 12 facilities. Of these, 132 gave informed consent. Subsequently 99 of these actually participated.  
40  
41 These were self-selected volunteers. The majority were recruited from one pediatric clinic, one  
42  
43 church, one work place parent group, two baby centers and three daycare centers.  
44  
45  
46  
47

48  
49 All families spoke Korean at home (there are few local dialects in South Korea). Each had a  
50  
51 baby aged between 4 months and 16 months. There were 45 boys (45%) and 54 girls (55%).  
52  
53 Fourteen (14%) attended daycare centers. Most families were middle class: 36 (36%) made  
54  
55 2-3,000 US dollars a month, 35 (35%) 3-5,000 US dollars a month and 24 (24%) more than  
56  
57  
58  
59  
60

1  
2  
3 5,000 US dollars a month. These are average to above-average salaries for South Korea.

4  
5 Considering maternal education levels, only one mother (1%) did not graduate from high school,  
6  
7  
8 5% had graduated from high school, 74% were college graduates and 20% had a masters and/or  
9  
10 doctoral degree. Almost half the mothers (43%) had a full-time job.

11  
12 Participants were offered involvement in a longitudinal study using the LENA recording  
13  
14 and feedback technology along with language development assessments. The 99 families were  
15  
16 then randomly assigned either to experimental or control groups, yielding 49 in the experimental  
17  
18 group and 50 in the control group. Each child in the experimental group was matched with a child  
19  
20 of similar age in the control group, since language from a 5-month-old is very different to that with  
21  
22 a 30-month-old, and each recording was thereby controlled for the child's age at baseline.  
23  
24  
25

26  
27 Results from experimental families were split into two groups depending on whether they  
28  
29 were above or below the 50<sup>th</sup> percentile at baseline compared to the normative sample from the  
30  
31 United States. It was assumed that families who saw they were "below average" would be more  
32  
33 motivated to change their behavior.  
34  
35

36  
37 Some attrition ensued over the course of the study, reducing the experimental group to 40  
38  
39 and the control group to 44. Four out of nine withdrawing experimental families failed to show at  
40  
41 the first meeting after baseline recordings. Others had difficulty recording regularly because  
42  
43 some daycare centers did not allow recording in the center, some working mothers did not have  
44  
45 time to record and some had sick infants. There was no evidence of socio-economic bias in the  
46  
47 pattern of withdrawal.  
48  
49

## 50 **Measures**

51  
52 The main measures were language environment estimates obtained automatically using  
53  
54 LENA technology (Ford, Baer, Xu, Yapanel & Gray, 2008; Gilkerson & Richards, 2008), in which  
55  
56  
57  
58  
59  
60

1  
2  
3 a small digital recorder is worn by the child in a front chest pocket of clothing designed to optimize  
4 microphone placement and minimize clothing friction noise. Data are collected in children's  
5 natural environments: homes, parks, playgrounds, and anywhere else children use or hear  
6 language. The recorder can hold 16 hours of audio, optimally recorded within a 6-10 foot radius at  
7 16 kHz. Recordings were then computer analyzed with a digital sound analyzer that parses out the  
8 child's speech-related vocalizations and exposure to adult speech, the speech of other children,  
9 overlapping talk, silence, general noise, and television. Algorithms enable the discarding of crying  
10 or vegetative sounds (e.g., from respiratory or digestive systems) and automatically generate adult  
11 word, child vocalization and conversational turn estimates. Further details of the LENA  
12 technology (e.g. on how words are estimated and turns identified) will be found in Richards, et al.  
13 (2008). LENA has previously been shown to be both valid and reliable when compared with  
14 trained human transcribers in American English (Xu, Yapanel & Gray, 2009).

15  
16 In addition, parents completed a Korean adaptation of the LENA Developmental Snapshot  
17 (KSNAP), a standardized measure of parent self-report of expressive and receptive language skills  
18 in children aged 2-36 months (Gilkerson & Richards, 2008). This 52-item inventory yields a total  
19 score, a developmental quotient, a developmental age, an expressive vocabulary raw score, and a  
20 percentile score. Gilkerson & Richards (2008) report a three-month test-retest reliability  
21 of .93-.97 and an average correlation of .93 with various other language measures.

22  
23 Parents also completed a locally normed version of Korean adaptation of the  
24 MacArthur-Bates Communication Development Inventories (K M-B CDI) (Pae & Kwak, 2011),  
25 which assess early language and communication. The K M-B CDI assesses expressive  
26 vocabulary for 8-36 month old children, gesture and play for 8-17 month old children and  
27 expressive vocabulary and grammar for 18-36 month old children. Heilmann, Weismer, Evans,

3 and Hollar (2005) report concurrent validity of .63-.84 with mean length of utterance, .56-.82  
4  
5 with number of different words spoken and .54-.77 with the Bayley Scales. The K M-B CDI  
6  
7 appeared a valid and useful instrument to discriminate late-talking toddlers in the Korean  
8  
9 population (Kim, et al., 2014; Pae, 2003).  
10  
11

### 12 13 **Procedure**

14  
15 At the outset, experimental and control children were assessed on the two language  
16  
17 development measures. Four certified and experienced speech language pathologists  
18  
19 administered the Korean versions of these instruments after receiving specific training in their  
20  
21 administration. Then the experimental group made baseline LENA recordings and weekly  
22  
23 recordings for six months. They also completed a daily activity log (especially regarding instances  
24  
25 of book reading) on the same day as the recording. The control group made recordings only at  
26  
27 baseline and Months 3 and 6. Participants who completed recordings at baseline and Months 3  
28  
29 and 6 were analyzed. (The control group was actually a wait list condition and received the  
30  
31 intervention after the six months reported here).  
32  
33  
34  
35

36  
37 The experimental group received a single workshop the second month after starting. Thirty  
38  
39 one families participated; about 7-10 families in each of three parallel workshops. In the  
40  
41 workshop, the group viewed six short (two-minute) video clips (which were displayed in the  
42  
43 internet café after the workshop), participated in discussions of parental experiences, and received  
44  
45 advice about enhancing the home language environment. The nine families who did not attend  
46  
47 received in depth individual phone guidance and were directed to the videos in the internet café.  
48  
49

50  
51 Individualized LENA reports were explained in detail. Feedback centered on LENA Reports,  
52  
53 which displayed bar graphs of counts of AWC and CT (see Figure 1). The analysis showed the  
54  
55 pattern of Adult Word Counts and Conversational Turns. Given their own individual AWC and  
56  
57  
58  
59  
60

1  
2  
3 CT for each recording, parents were encouraged to set an individual goal to do better at the next  
4  
5 recording. However, details of parental goals were not analyzed. Parents could also see how their  
6  
7 and their child's performance compared to the US norms for LENA in terms of percentiles, and  
8  
9 consequently whether they and their child were below or above average and by how much. This  
10  
11 feedback was delivered to the parent's home computers and was viewable after the LENA data  
12  
13 had been analyzed.  
14  
15

16  
17  
18 INSERT FIGURE 1 ABOUT HERE  
19

20 Weekly recordings fed into the LENA technology were analyzed for the first six months  
21  
22 for the experimental group. Every month the experimental group families were also telephoned by  
23  
24 one of two research assistants in order to check whether they had any technical problems and to  
25  
26 give encouragement. Experimental parents also had constant access to the Internet café, to  
27  
28 communicate with each other and discuss issues which they had in common. (However, parents  
29  
30 preferred to talk over the phone and reported that they did not have time to access the café.) At  
31  
32 the sixth month, the experimental participants were given five storybooks for babies and an  
33  
34 online book-reading guide.  
35  
36  
37

38 All experimental and control parents knew their child's language development status  
39  
40 based on K M-B CDI percentile rank and Developmental Snapshot Development Quotients. The  
41  
42 control group received no feedback, support, workshops or storybooks. The control group  
43  
44 recorded at the third month and at the end of the six month period to add to their baseline  
45  
46 recording. At the end of six month period, all children were reassessed on language  
47  
48 development.  
49  
50  
51

### 52 53 **Triangulation of Implementation Integrity** 54

55 Although the LENA technology automatically yields data about implementation integrity  
56  
57  
58  
59  
60

1  
2  
3 in terms of parent and child behaviors, an additional check was made on this through an alternative  
4  
5 procedure. Two research assistants in contact with the families made judgments of the  
6  
7 experimental mother's attitude toward the LENA recordings on a 5-point Likert scale (1 = no  
8  
9 interest or relatively very small number of recordings, 2 = very little interest or small number of  
10  
11 recordings, 3 = average interest or average number of recordings, 4 = high interest or high number  
12  
13 of recordings, 5 = very high interest or very high number of recordings). Of the 40 experimental  
14  
15 mothers, there were 10 who were judged 5, four judged as 4.5, 16 judged as 4.0, four judged as 3.5,  
16  
17 five judged as 3.0 and one mother as 2.5. Thirty mothers (75%) seemed to be participating  
18  
19 sincerely. Six mothers (15%) seemed to have difficulties or less interest in study participation  
20  
21 (judged 3.0 or less). Some parents reported that weekly recording was difficult and their babies  
22  
23 refused to put on LENA vests.  
24  
25  
26  
27  
28

29  
30 Among the 10 mothers who were extremely interested in getting quantitative language  
31  
32 feedback via LENA technology, there were three mothers who had babies at risk of language  
33  
34 development at basal assessment (below 10th percentile on K M-B CDI on any of receptive,  
35  
36 expressive vocabulary, gesture and play). After the six month intervention all these children were  
37  
38 in the normal range of language development and above the 25th percentile on K M-B CDI. These  
39  
40 families increased and sustained their language environment during six month intervention period.  
41  
42 However, there was no relationship between judgments of attitude and membership of  
43  
44 above-average or below-average groups.  
45  
46  
47

### 48 **Statistical Analyses**

49  
50 Firstly, the validity and reliability of LENA measures for Korean-speaking families were  
51  
52 analyzed via comparisons with human transcription in correlation terms. Then LENA recording  
53  
54 counts (AWC and CT) were analyzed in terms of raw scores and standardized scores. Chi-squared  
55  
56  
57  
58  
59  
60

1  
2  
3 was used to test for significance with nominal variables. Two-way repeated-measures analyses of  
4  
5 variance were conducted to evaluate groups' differences in LENA measures at baseline, three  
6  
7 months, and six months. Post hoc tests were conducted where the analysis of variance yielded  
8  
9 significant results, either independent or paired t-tests.  
10  
11

## 12 Results

### 13 Equivalence of LENA in Korean Language

14  
15 We had two sources of data to investigate the relationship of LENA counts to human  
16  
17 transcripts in Korean language: 27 transcripts (about 10 minutes each) from infants aged 3-15  
18  
19 months in home environments and 36 transcripts from infants aged 11-22 months in a clinic (in a  
20  
21 10 minute book reading and play context). Overall, human AWC counts were significantly  
22  
23 correlated with LENA AWC counts ( $r = .72, p < .001$ ). However, human CT counts were initially  
24  
25 not significantly correlated with LENA CT counts ( $r = -.03, p > .05$ ). When we excluded the data of  
26  
27 five babies containing abundant overlaps or whining noises, there were significant correlations  
28  
29 between human and LENA CT counts ( $r = .67, p = .001$ ) (overlaps are human vocalizations  
30  
31 confused with other sound sources). When a child is very young or has frequent whining sounds  
32  
33 and/or overlapped speech, LENA CT counts might need to be interpreted cautiously. The data for  
34  
35 10 babies (28%) were assessed by two transcribers for inter-rater reliability. Agreement rate was  
36  
37 98.5% for AWC and 95% for CT. Overall it seemed that LENA AWC and CT counts could be  
38  
39 applied to the Korean language context.  
40  
41  
42  
43  
44  
45  
46  
47

### 48 Experimental and Control Groups At Baseline

49  
50 There were no significant differences between the experimental and control groups at  
51  
52 baseline on child chronological ages, gender (chi-squared = .01,  $p = .912$ ), or the dependent  
53  
54 measures of LENA counts on AWC or CT or language development measures (see Table 1). At  
55  
56  
57  
58  
59  
60

1  
2  
3 baseline there was also no significant difference on the dependent measure of KSNAP between  
4  
5 the above-50<sup>th</sup> percentile and below-50<sup>th</sup> percentile experimental subgroups (see below for  
6  
7 analysis).  
8  
9

10 INSERT TABLE 1 ABOUT HERE

### 11 **Experimental and Control Group Differences over Three and Six Months**

12  
13 For the dependent measure of AWC, a two-way repeated-measures ANOVA of treatment  
14  
15 x time over six months showed that there was no significant interaction ( $F(2,164) = .58, p = .56,$   
16  
17 partial eta squared = .007) (table 2) (partial  $\eta^2$  effect sizes are categorized:  $\geq .01$  small,  $\geq .06$   
18  
19 medium,  $\geq .14$  large.). Nor was there any significant difference between the groups ( $F(1, 82)$   
20  
21 = .153,  $p = .696$ , partial eta squared = .006). There was a significant difference in the time factor  
22  
23 ( $F(2,164) = 3.62, p = .029$ , partial eta squared = .042). Follow-up paired-samples  $t$ -tests showed  
24  
25 that for both experimental and control groups, AWC increased in month 3 but decreased in  
26  
27 month 6. From month 3 to month 6, the experimental group AWC decreased significantly ( $t(39)$   
28  
29 = -2.29,  $p = .027$ ), while the decrease of the control group was not significant.  
30  
31  
32  
33  
34  
35

36 For the dependent measure of CT, a two-way repeated-measures ANOVA of treatment x  
37  
38 time over six months showed that there was a significant interaction ( $F(2,164) = 3.14, p = .046,$   
39  
40 partial eta squared = .037). As for AWC, there was no significant difference between groups ( $F(1,$   
41  
42  $82) = .079, p = .779$ , partial eta squared = .001). As for AWC, there was a significant difference  
43  
44 in the time factor ( $F(2,164) = 15.47, p < .001$ , partial eta squared = .159). Follow-up  
45  
46 paired-samples  $t$ -tests showed that for the experimental group the mean CT in months 3 and 6  
47  
48 was significantly higher than baseline CT ( $t(39) = 3.828/2.467, p < .001$  or = .018). However, the  
49  
50 CT in month 6 was significantly lower than in month 3 ( $t(39) = -2.210, p = .033$ ). For the control  
51  
52 group, the mean CT in months 3 and 6 was also significantly higher than the baseline ( $t(43) =$   
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 3.164/4.065,  $p = .003$  or  $< .001$ ).

4  
5  
6 INSERT TABLE 2 ABOUT HERE

### 7 8 **Relative Performance of Above/Below 50<sup>th</sup> Percentile Families Overall**

9  
10 On the dependent measure of AWC, the below-50<sup>th</sup> percentile group numbered 36 and the  
11 above-50<sup>th</sup> percentile group 48, while on the dependent measure of CT the below-50<sup>th</sup> percentile  
12 group numbered 27 and the above-50<sup>th</sup> percentile group 57. Thus the total sample was in general  
13 above average compared to US norms. Two-way repeated-measures ANOVA showed that for  
14 AWC there was a significant interaction between time and above/below average group  
15 membership ( $F(2,164) = 14.35, p < .001$ , partial  $\eta^2 = .149$ ). There was also a significant  
16 difference between the above average group and the below average group ( $F(1, 82) = 23.21, p$   
17  $< .001$ , partial  $\eta^2 = .221$ ). Additionally, there was a significant difference in the time factor  
18 ( $F(2,164) = 4.75, p = .010$ , partial  $\eta^2 = .550$ ).

19  
20 Similarly, two-way repeated-measures ANOVA showed that for CT there was a  
21 significant interaction between time and above/below average group membership ( $F(2,164) =$   
22  $6.33, p = .002$ , partial  $\eta^2 = .072$ ). There was also a significant difference between the above  
23 average group and the below average group ( $F(1, 82) = 15.05, p < .001$ , partial  $\eta^2 = .155$ ).  
24 Additionally, there was a significant difference in the time factor ( $F(2,164) = 21.89, p < .012$ ,  
25 partial  $\eta^2 = .211$ ) (Table 3). Thus, the analyses showed that the AWC and CT trajectories of the  
26 above average and below average groups were different across six months.

47  
48 INSERT TABLE 3 ABOUT HERE

49  
50 Post paired t-tests indicated that for the below AWC or CT average groups, AWC and CT  
51 scores in both months 3 and 6 were significantly higher than the baseline scores (for AWC,  $t(35)$   
52  $= 5.05/4.73, p < .001$ ; for CT,  $t(26) = 6.77/6.97, p < .001$ ). However, for the above AWC  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 average group, AWC scores in months 3 and 6 were lower or significantly lower than their  
4  
5 baseline scores ( $t(47) = -.77/-3.38, p = .51/.001$ ). For the above CT average group, CT scores in  
6  
7 Months 3 and 6 were significantly higher than the baseline scores ( $t(56) = 2.31/2.08, p$   
8  
9  $= .024/.042$ ). These results suggest that the below average group was more likely to increase  
10  
11 their talk with children.  
12  
13

### 14 15 **Relative Performance of Above/Below Average Families in Experimental Group**

16  
17 The difference between the above/below AWC/CT average talk groups within the  
18  
19 experimental group was then examined. There was no significant difference between the groups  
20  
21 at baseline on KSNAP raw score, although the effect size was quite large (AWC below average  
22  
23 group  $n = 13$ , mean = 16.31,  $SD = 5.12$ ; above average group  $n = 27$ , mean = 14.37,  $SD = 4.62$ ;  
24  
25  $t(38) = 1.20, p = .24$ , Cohen's  $\delta = .40$ . CT below average group  $n = 14$ , mean = 14.50,  $SD = 4.00$ ;  
26  
27 above average group  $n = 26$ , mean = 15.27,  $SD = 5.25$ ;  $t(38) = .48, p = .64$ , Cohen's  $\delta = .17$ ). Once  
28  
29 becoming aware of their position in the overall group, the below average group was considered  
30  
31 likely to have higher motivation to perform.  
32  
33  
34  
35

36  
37 Two-way repeated-measures ANOVA showed that for the above-average and  
38  
39 below-average groups' AWC there was indeed a significant interaction between time and  
40  
41 above/below average performance ( $F(2,76) = 5.65, p = .005$ , partial  $\eta^2 = .129$ ). This was also true  
42  
43 for CT ( $F(2,76) = 3.20, p = .046$ , partial  $\eta^2 = .078$ ). Of course, sample size was small.  
44  
45

46  
47 Post hoc paired-samples t-tests indicated that for the below average talk group, AWCs in  
48  
49 months 3 and 6 were significantly higher than the baseline scores ( $t(12) = 2.89/3.20, p = .014/.008$ ).  
50  
51 For the above average talk group, AWC in month 3 was lower than the baseline score (but not  
52  
53 significantly), while AWC in month 6 was significantly lower than baseline scores ( $t(26) = -3.29, p$   
54  
55  $= .003$ ). For CT in the below average group, in both months 3 and 6 scores were significantly  
56  
57  
58  
59  
60

1  
2  
3 higher than baseline ( $t(13)= 4.80/4.58, p \leq .001$ ). For the above average group, CT in both months  
4  
5 3 and 6 was slightly higher than the baseline score but not significantly. These results provided  
6  
7 evidence that feedback worked better for the below average group than the above average group.  
8  
9

11 INSERT TABLE 4 ABOUT HERE  
12

### 13 **Developmental Language Measures**

14  
15 On the K M-B CDI, only the Expressive Vocabulary (EV) Scale was relevant to all the  
16  
17 children. The small numbers for the other three scales were disregarded. As one would expect,  
18  
19 within each treatment group, the scores on both the dependent measures of K M-B CDI EV and K  
20  
21 SNAP increased significantly from baseline to month three and to month six. However, there were  
22  
23 no significant differences between the experimental and control groups at months three or six on  
24  
25 either of these language development measures (Table 5).

### 32 **Discussion**

#### 33 **Summary of Results**

34  
35 Human and LENA AWC counts correlated at  $r = .72$ , but human and LENA CT counts  
36  
37 correlated only at  $.67$  after exclusion of outlier cases. Overall it seemed LENA AWC and CT  
38  
39 counts could be applied to the Korean language context, with caution in respect of the latter. There  
40  
41 were no significant differences between experimental and control groups at baseline on child age,  
42  
43 gender, LENA AWC and CT counts or language development measures. The experimental group  
44  
45 was divided into those above average at baseline and those below average (compared to US  
46  
47 norms). There was no significant difference between these subgroups.  
48  
49

50  
51 Overall over six months there was no significant effect of treatment over time between  
52  
53 experimental and control groups in AWC. However, for CT there was evidence of an intervention  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 effect. However, both AWC and CT showed a significant effect of treatment over time in relation  
4  
5 to above/below average group membership. For the below average group, AWC in both months 3  
6  
7 and 6 was significantly higher than baseline scores, but for the above average group AWC was  
8  
9 lower than baseline scores. The pattern was similar for CT.  
10  
11

### 12 **Implications for the Literature**

14  
15 Parental responsiveness is a key factor across a broad range of child development indices  
16  
17 (Warren & Brady, 2007; Zimmerman, al., 2009). We know that very young children respond to  
18  
19 rich language stimulation, particularly in terms of Adult Word Count and Conversational Turns  
20  
21 (Rowe, 2008; Topping, et al., 2013). Using American English, Suskind, et al. (2013) and Suskind,  
22  
23 et al. (2015) reported significant positive results from automated linguistic feedback with  
24  
25 non-parental care-givers of typically developing children and the natural parents of  
26  
27 socio-economically deprived children. Zhang, et al. (2015) did the same with 22 families of  
28  
29 typically developing children using Shanghai Dialect and Mandarin. The present study extends  
30  
31 the latter work to a new Asian language and culture (Korean), with a larger sample and random  
32  
33 allocation to experimental or control groups. Zhang, et al.'s (2015) 22 families came from two  
34  
35 centers and enjoyed interaction with each other at regular workshops, while the present study  
36  
37 recruited much more widely and had only one workshop. Consequently the present study did not  
38  
39 have any impact of regular parental face-to-face meetings. However, both Zhang, et al. (2015)  
40  
41 and the present study only reported persistently enhanced language interaction for the  
42  
43 below-average section of the participant group (although in the case of Zhang, et al. (2015) this  
44  
45 was below the baseline average of the experimental group).  
46  
47  
48  
49  
50  
51  
52

53 The increase in conversational turn counts is promising in that previous studies have  
54  
55 shown this measure to be positively correlated with child receptive language (VanDam, Ambrose  
56  
57  
58  
59  
60

1  
2  
3 & Moeller, 2012) and school readiness (Huttenlocher et al., 2007; Zimmerman et al., 2009). In  
4  
5 this typically-developing group, the experimental parents received feedback which always  
6  
7 indicated their own family's status in relation to the average for the US. This gave a clear signal,  
8  
9 and to parents who were notoriously highly competitive. However we accept that there may be  
10  
11 other explanations for this.  
12  
13

14  
15 One of the features of the LENA technology is its potential for application in studying  
16  
17 variations across the various contexts of language use. For example, Hoff (2010) reported two  
18  
19 studies. One was of 20 children aged 1;5 - 2;2 in conversation with their mothers: at mealtime, in  
20  
21 toy play, and at book reading. The other was of 16 children aged 1;9 - 3;0 in dyadic toy play  
22  
23 interaction with three different conversational partners: a 5-year-old sibling, an 8-year-old sibling,  
24  
25 and their mother. In both studies the contextual effects had differential effects on children's  
26  
27 vocabulary use and discourse cohesion. Book-reading yielded the richest child vocabulary and  
28  
29 produced more topic-continuing contributions. They used a richer vocabulary and produced more  
30  
31 responses to questions in conversation with their mothers than in conversation with their older  
32  
33 siblings. However, again there were persistent differences between children which endured over  
34  
35 time.  
36  
37  
38  
39

40  
41 Similarly, Leech and Rowe (2014) compared five-year-old children's (N=33) discussions  
42  
43 with their parents during picture book and chapter book reading (chapter books tell the story  
44  
45 primarily through the text, although they tend to be profusely illustrated). There was variation in  
46  
47 the amount and type of discussion between contexts. Children needed more narrative skill to  
48  
49 participate in chapter book reading. It seems there is much scope for micro-analyzing LENA data  
50  
51 in relation to the social context in which it was used. For instance, research could compare  
52  
53 language interactions of parents with those of other care-givers, such as grandparents or day-care  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 staff. It could also directly compare language during book-reading with language during other  
4  
5 activities. It could also identify key times of the day which have high potential for language  
6  
7 interaction.  
8  
9

### 10 **Limitations of the Research**

11  
12 Although the participant group was divided into experimental and control groups  
13  
14 randomly, their initial selection was purely on the basis of self-selected volunteering. The  
15  
16 participants were all of middle to high socio-economic status, so we do not know if the results  
17  
18 would be true of other sections of the population. The participants were drawn principally from  
19  
20 eight centers, the number of parents from each center was small, and the opportunities for  
21  
22 face-to-face discussions between parents thereby limited. The broad span of child ages reflected  
23  
24 very different normal language inputs at different ages. The study also somewhat confounded the  
25  
26 effects of feedback and the effects of a parent workshop and telephone calls, although the point  
27  
28 of the study was to test the intervention as a whole. Further, the rate of attrition was quite high.  
29  
30 In addition, implementation fidelity of the intervention was not gathered by direct observation.  
31  
32  
33  
34  
35

36  
37 The control group performed at an unexpectedly high level, which we might attribute to  
38  
39 the novelty for them of conducting a recording. Also, both experimental and control participants  
40  
41 knew their child's language development status from the language assessment program at  
42  
43 pre-test. Discovering their baby's initial language status was low could have triggered increased  
44  
45 efforts to interact with their child. In future studies all these factors need to be remedied.  
46  
47

48  
49 Despite these limitations, the results show benefits for below-average families, in line  
50  
51 with results of Zhang, et al. (2015) in China, but using random allocation to conditions and a  
52  
53 control group, in a different cultural and linguistic context. The participants were strenuously  
54  
55 followed up by a vigorous and enthusiastic research team, but this follow-up was not so intense  
56  
57  
58  
59  
60

1  
2  
3 as to compromise sustainability of the program. These results have strong implications for  
4  
5 onward research and practice.  
6  
7

### 8 **Future Research, Practice and Policy**

9

10 In the future, a study which recruits participants from one locality or one center should be  
11 used coupled with face-to-face interaction to see if this makes any difference. This would also  
12 facilitate home visits by project staff if needed. The number of workshops could also be varied.  
13 We know from previous studies that parents greatly value the opportunity to discuss with other  
14 parents. Future studies could also vary the feedback with respect to nature, frequency and content  
15 in an adaptive manner that better utilizes the information available from the automated system.  
16 Comparisons could be made of reports outlining a timeline of parent-child interactions during the  
17 course of the day with simpler and more complex forms of feedback. However, increasing the  
18 complexity of feedback may also have unwanted side-effects. As additional samples are obtained  
19 in this language and culture, representative normative standards can be derived to provide better  
20 estimates of individual family performance.  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 LENA technology seems to be able to decode Korean at an acceptable level of accuracy  
37 (with cautions about CT), and consequently it can be used in other studies in the future. This  
38 study was the third to extend automatic measurement of the language environment to a  
39 non-English language, and only the fourth to examine the effects of automatically generated  
40 feedback to parents on adult word counts and conversational turns with children. This positive  
41 result demonstrates the potential for further cross-linguistic extension of automatic assessment of  
42 child-caregiver interactions to a much broader range of populations.  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52

53 It could be argued that more intensive and active coaching was needed. On the other hand,  
54 attendance at the workshop was markedly less than 100%, and there seems no guarantee that  
55  
56  
57  
58  
59  
60

1  
2  
3 parents would attend more intensive coaching. A higher intensity of coaching would also be  
4  
5 more difficult to sustain once the program was generalized to a larger population.  
6  
7

8 The intervention was effective, but only effective in the longer term with below-average  
9  
10 families. Of course, this is exactly the group who are most in need - those experiencing an  
11  
12 impoverished language environment.  
13  
14

### 15 **Conclusions**

16  
17 This study was conducted to determine whether adult-child interaction practices could be  
18  
19 assessed in a novel culture and language using tools developed on American English in the U.S.,  
20  
21 and whether Korean-speaking parents would respond positively to language feedback concerning  
22  
23 their interaction behavior. A family's relative ranking in the quality of participant home language  
24  
25 environments was seen as a key principle. LENA measures were collected over 6 months with 40  
26  
27 experimental and 44 control families.  
28  
29  
30

31  
32 Results suggested that LENA can assess adult word counts and conversational turns fairly  
33  
34 accurately in Korean, with some caution regarding CT. LENA technology performance in the  
35  
36 Korean language was adequate to ensure reasonable language use estimates. Overall, experimental  
37  
38 and control families showed few differences in AWC, but the experimental group performed better  
39  
40 in CT. Receiving automated feedback resulted in participant parents raising their adult word  
41  
42 counts from baseline to three months, although it then went down again. Likewise, conversational  
43  
44 turns increased, then slipped back, but not as far as baseline levels.  
45  
46  
47

48 Over the six months of the intervention, families below average at baseline responded  
49  
50 significantly better to feedback than families above average. Increases in both AWC and CT were  
51  
52 statistically significant for the below-average half of the participant pool (who were expected to be  
53  
54 more motivated on becoming aware of their "below-average" status on feedback reports).  
55  
56  
57  
58  
59  
60

1  
2  
3 However, this study had several limitations, which should be addressed in the future.  
4

5 Both China and Korea have now shown below-average parents sustain improved language  
6 interaction over six months in response to LENA feedback. It could be argued that giving  
7 feedback in relation to the child's baseline status capitalizes on a degree of parental  
8 competitiveness which may be a feature in Asian countries but is less prominent in the West.  
9 Consequently a study exploring the comparative use of this kind of feedback with above and  
10 below-average families in the West might be timely. However, this kind of research is  
11 increasingly focusing on families of low socio-economic status, a great many of whom could be  
12 construed as "below-average" in relation to the general population, so this question may be  
13 answered in a different way.  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26 It seems that LENA feedback can have a positive effect on language interactions between  
27 parents and children in several different cultures with different language systems, and is  
28 particularly potent with families who are below-average in language interactions – exactly the  
29 population who need it. Using LENA with families at risk of low language interaction seems  
30 likely to have the most profound effects on the future functioning of the children concerned.

Table 1  
 Experimental and Control Equivalence at Baseline on Age, LENA and Language Measures

	Experimental			Control			<i>t</i>	<i>p</i>	<i>d</i>
	<i>n</i>	Mean	<i>SD</i>	<i>n</i>	Mean	<i>SD</i>			
Child Age	49	10.29	2.85	50	10.10	2.97	.32	.75	.07
LENA AWC	45	14125	6313	54	13727	4827	.36	.72	.06
LENA CT	45	396	180	54	393	141	.08	.94	.02
KSNAP DQ	40	97.39	35.86	44	99.56	27.54	-.32	.75	-.06
K M-B CDI	40	4.34	7.00	44	6.45	8.76	-1.03	.31	-.30

*Note:* KSNAP DQ = Korean version of SNAP, Developmental Quotient  
 K M-B CDI = Korean MacArthur-Bates Communication Development Inventories  
*d* = effect size (Cohen's  $\delta$ ). Only the last *d* is substantial

Table 2  
*Scores on AWC & CT at Baseline & Months 3 & 6 for Experimental/Control*

	Experimental			Control			Total		
	<i>n</i>	Mean	<i>SD</i>	<i>n</i>	Mean	<i>SD</i>	<i>n</i>	Mean	<i>SD</i>
AWC_0	40	14719.23	5536.25	44	13447.89	5916.08	84	14053.29	5739.55
AWC_3	40	15678.68	8098.66	44	15403.43	6758.99	84	15534.50	7382.77
AWC_6	40	13667.57	5754.51	44	13878.27	5975.61	84	13777.94	5836.97
CT_0	40	382.33	164.00	44	372.95	126.94	84	377.42	144.95
CT_3	40	476.56	207.16	44	459.86	185.77	84	467.81	195.23
CT_6	40	434.63	190.36	44	503.28	237.69	84	470.59	217.89

*Note:* 0 = baseline, 3 = the 3rd month, 6 = the 6th month

Table 3  
*Whole Sample AWC/CT at Baseline & Months 3 & 6 in Above/Below Average Groups*

	Below AWC/CT50%			Above AWC/CT50%		
	<i>n</i>	Mean	<i>SD</i>	<i>n</i>	Mean	<i>SD</i>
AWC_0	36	9008.58	2276.61	48	17836.81	4494.74
AWC_3	36	13398.89	5466.05	48	17136.21	8239.62
AWC_6	36	12585.52	4836.54	48	14672.26	6390.70
CT_0	27	231.87	57.90	57	446.35	120.56
CT_3	27	400.57	160.86	57	499.67	203.14
CT_6	27	411.87	161.41	57	498.41	236.27

*Note:* 0 = baseline, 3 = the 3<sup>rd</sup> month, 6 = the 6<sup>th</sup> month

Below AWC/CT50% = below average, Above AWC/CT50% = above average

Table 4

*Experimental Group Difference in AWC & CT between Baseline & Months 3/6 by Above/Below Average Group*

Group	AWC/CT	n	Difference 1 (Baseline - Month 3)					Difference 2 (Baseline - Month 6)				
			Value	SD	t	p	d	Value	SD	t	p	d
Below AWC50%	AWC	12	3689.62	4608.89	2.89	<b>.014</b>	.96	3049.98	3437.49	3.20	<b>.008</b>	.81
Above AWC50%	AWC	26	-355.06	6883.43	-0.27	.791	.05	-3026.51	4782.55	-3.29	<b>.003</b>	.58
Below CT50%	CT	13	155.10	120.97	4.80	<b>&lt;.001</b>	1.31	117.39	95.86	4.58	<b>.001</b>	1.23
Above CT50%	CT	25	61.46	164.39	1.91	.068	.34	17.25	140.08	0.63	.536	.10

*Note.* Below AWC/CT50% = below average, Above AWC/CT50% = above average

The figures emboldened are significant at  $p < .05$

$d$  = effect size (Cohen's  $\delta$ )

Table 5  
 Experimental/Control Groups at Baseline and Months 3 & 6 on Snapshot and K M-B CDI EV

		Experimental			Control			<i>t</i>	<i>p</i>	<i>d</i>
		<i>n</i>	Mean	<i>SD</i>	<i>n</i>	Mean	<i>SD</i>			
Baseline	KSNAP DQ	40	15.00	4.81	44	15.11	4.58	-.11	.91	-.02
	K M-B CDI	40	4.34	7.00	44	5.87	8.18	-.77	.45	-.21
Month 3	KSNAP DQ	40	22.75	6.75	44	21.98	5.68	.56	.58	.11
	K M-B CDI	40	23.47	33.39	44	26.82	36.65	-.42	.67	-.10
Month 6	KSNAP DQ	40	26.89	6.57	44	26.07	6.55	.55	.58	.12
	K M-B CDI	40	57.31	72.91	44	62.07	76.20	-.28	.78	-.06

Note: K SNAP DQ = Korean version of SNAP, Developmental Quotient

K M-B CDI = Korean MacArthur-Bates Communication Development Inventories, Expressive Vocabulary

*d* = Effect Size (Cohen's  $\delta$ )

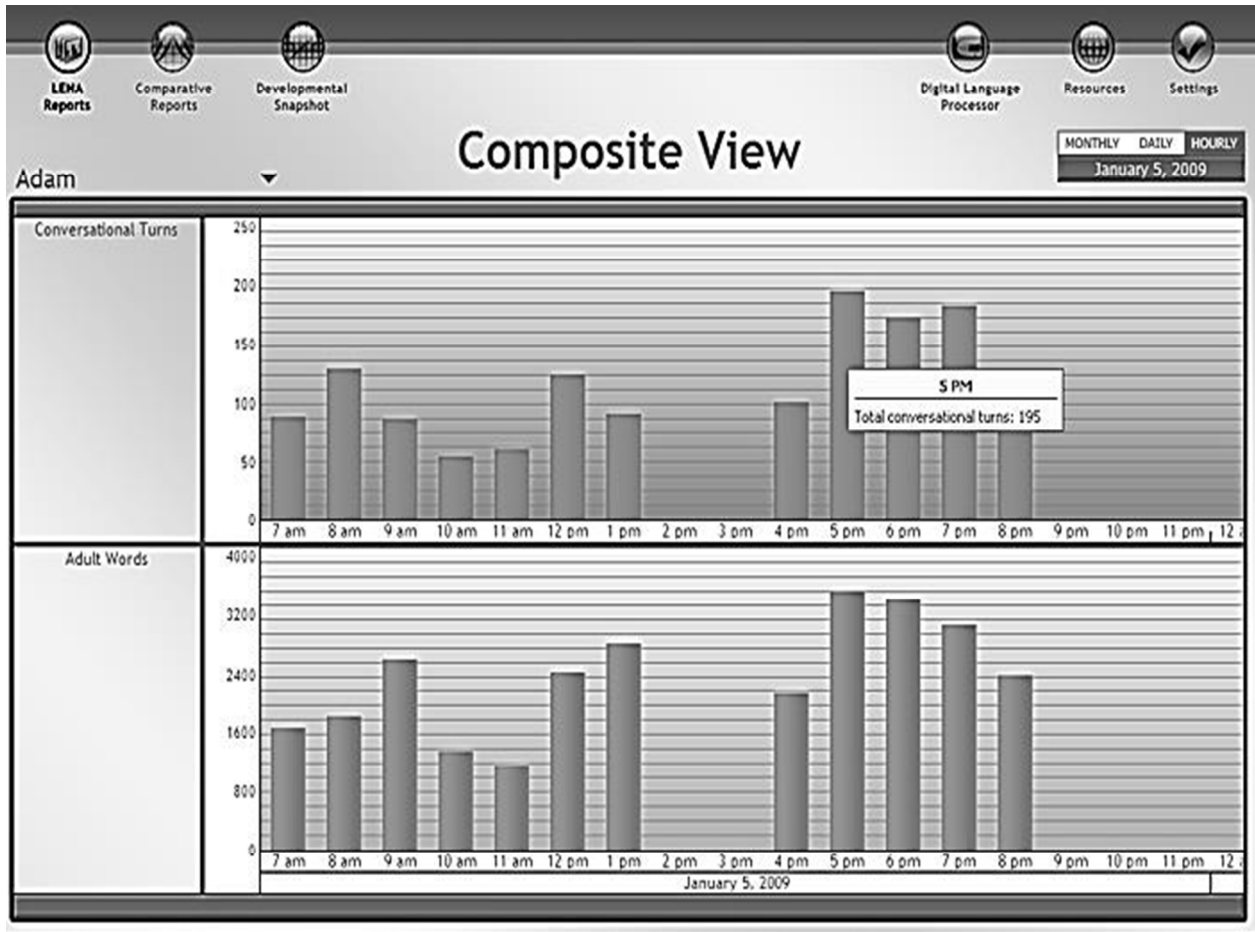

Figure 1. LENA feedback report
