Abstract

20 Eye-tracking is widely used throughout the scientific community, from vision science and
21 psycholinguistics, to marketing and human-computer interaction. Surprisingly, there is little
22 consistency and transparency in preprocessing steps, making replicability and reproducibility
23 difficult. To increase replicability, reproducibility, and transparency, a package in R (a free and
24 widely used statistical programming environment) called gazeR was created to read in and
25 preprocess two types of data: gaze position and pupil size. For gaze position data, gazeR has
26 functions for: reading in raw eye-tracking data, formatting it for analysis, converting from gaze
27 coordinates to areas of interest, and binning and aggregating data. For data from pupillometry
28 studies, the gazeR package has functions for: reading in and merging multiple raw pupil data
29 files, removing observations with too much missing data, eliminating artifacts, blink
30 identification and interpolation, subtractive baseline correction, and binning and aggregating data.
31 The package is open-source and freely available for download and installation:
32 <https://github.com/dmirman/gazer>. We provide step-by-step analyses of data from two tasks
33 exemplifying the package's capabilities.

36

37 GazeR: A package for processing gaze position and pupil size data

38 **Introduction**

39 Recent advances in eye-tracking technology make it a highly powerful and relatively
40 inexpensive tool to gather fine-grained measures of the temporal dynamics of cognitive
41 processing. Because of this, a growing number of fields from vision science and
42 psycholinguistics, to marketing and human-computer interaction, have adopted this methodology.
43 Despite its growing presence, there is a lot of variability in how eye-tracking data are processed.
44 With increased attention on replicability, reproducibility, and transparency, there is a need for a
45 cross-platform, fully free implementation of standard practices in eye-tracking data processing. R
46 (R Core Team 2018) is a widely-used, free, cross-platform, and open-source statistical
47 programming language that provides the tools needed to meet those needs. In R, there are few
48 established pipelines for handling pupil and fixation data from the visual world paradigm and
49 pupillometry, especially contained in one package (see Tables 1 and 2). To meet this need, we
50 created the gazeR package. The gazeR package is meant to facilitate the end-to-end handling of
51 eye-tracking data within a single programming environment (R) – from reading in raw data files
52 to statistical analysis and generating figures. The gazer package is also designed to be as familiar
53 as possible for the regular R user, thus handling data in formats and functions that will be
54 accessible for most users.

55 In this paper, we provide a step-by-step walk-through of how to use the gazeR package to
56 analyze data from experiments in which the primary outcome measure is gaze position or pupil
57 size. There are several conceptual or theoretical discussions on best practices when analyzing
58 pupil and gaze data available elsewhere (see Mathôt et al., 2018; Winn, Wendt, Koelewijn, and

59 Kuchinsky, 2018; Salverda & Tanenhaus, 2018). The main aim of the present paper is to
60 illustrate and explain how to analyze gaze and pupil data in a more standardized way using
61 gazeR, such that it may be used by researchers to analyze their own data. While there exist
62 various packages and online resources to get started with eye-tracking, such materials are
63 typically limited to the analysis of a single participant and do not represent what researchers
64 typically want to do with their data. A secondary aim is to facilitate reproducible and transparent
65 preprocessing of these types of data, using conventional practices in eye-tracking data processing,
66 and smoothing the transition from data preprocessing to data analysis and visualization. In the
67 remainder of this report, we provide a step-by-step walk through of the installation and core
68 functionality of the gazeR package.

Binning Time data	Yes	Yes	Yes	No

90 Package Installation and Setup

91 Reading in Data

92 GazeR is meant to work on data in a relatively raw format, where each row is a sample
 93 corresponding to the sampling rate of the eye tracker. This allows gazeR to maximize
 94 compatibility: data from any eye-tracker can be used as long as the file contains information such
 95 as x and y coordinates, pupil size, and/or relevant event messages. For the examples contained
 96 herein, we will discuss how to preprocess data collected with one of the most popular commercial
 97 eye-trackers on the market—the SR EyeLink. Keeping with the spirit of open-access and
 98 transparency, however, we will highlight how to read in raw edf files for use with gazeR, so the
 99 proprietary SR software DataViewer is not necessary¹.

¹ Although not necessary, some EyeLink users nevertheless find it convenient to use the Fixation Reports or Sample Reports generated by DataViewer. A walkthrough for Sample and Fixation reports can be found here: <https://psyarxiv.com/gvcxb/>

100 **Package Installation**

101 The gazeR package can be installed along with helper packages using the remotes

102 package:

```
103 remotes::install_github("dmirman/gazer")
104 #installs gazeR package from github
105 remotes::install_github("tmalsburg/saccades/saccades")
106 #install saccades package from github Needed the master version
107 remotes::install_github("jashubbard/edfR")
108 #install package if using edfs from SR
```

109 Once this has been completed, gazeR can be loaded along with additional useful packages:

```
110 library(gazer)
111 library(tidyverse)
112 library(zoo)
113 library(knitr)
114 library(edfR)
115 library(saccades) #use master version from github
116
```

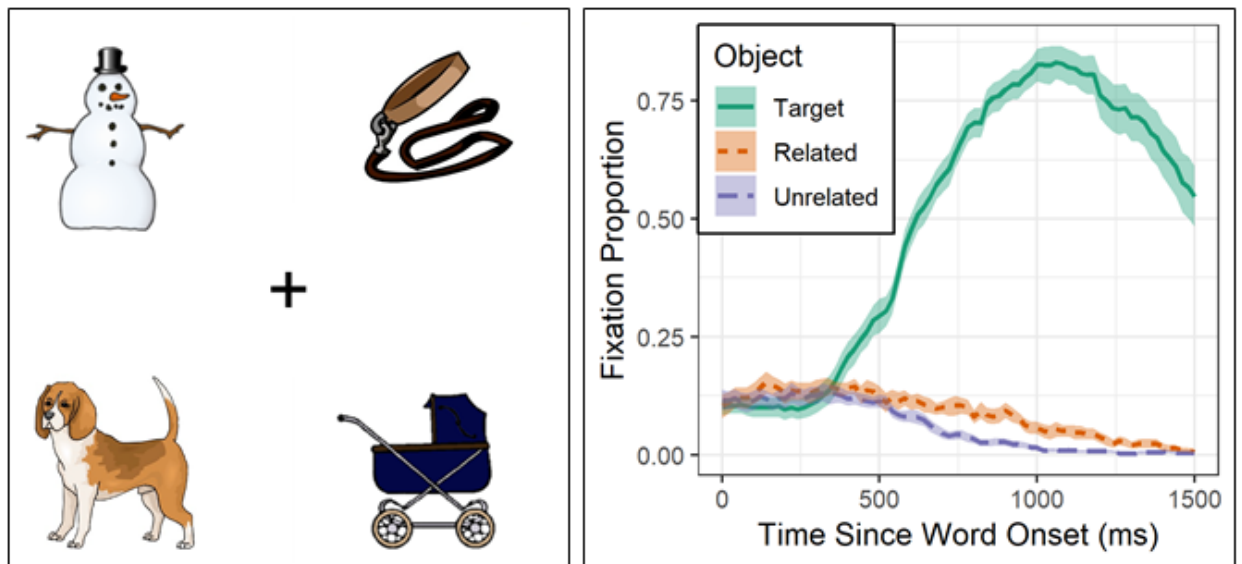

117 Once gazeR and other helper packages have been installed and loaded the user is ready to start

118 preprocessing data.

119 **Preprocessing Gaze Position Data from the Visual World Paradigm**

120 In a typical instantiation of the Visual World Paradigm (VWP), participants hear spoken
121 instructions to manipulate or select one of several images on a computer screen or objects in the
122 real world (Cooper, 1974; Tanenhaus, Spivey-Knowlton, Eberhard, & Sedivy, 1995). Decades of
123 research have shown that the time course of fixation proportions – that is, the probability of
124 fixating a particular object at a particular time – reflects the activation of that object’s mental
125 representation. Figure 1 illustrates a typical VWP task. In this example (from Mirman &

126 Graziano, 2012), the study examined semantic competition: the display contained a critical
 127 distractor that was related to the target either thematically (associates; e.g., *dog-leash*; shown in
 128 the left panel of Figure 1) or taxonomically (e.g., *apple-pear*). On each trial, the display
 129 contained a target object image, a semantic competitor (taxonomically or thematically related),
 130 and two unrelated distractors. The outcome measure was the probability of looks (fixation
 131 proportion) to a particular object at each point in time (example data shown in the right panel of
 132 Figure 1).

133
 134 Figure 1. Left: Example display from a VWP experiment. The target is dog, the critical
 135 semantic competitor is leash (thematically related to the target), and snowman and carriage are
 136 unrelated distractors. Right: Example data showing the time course of target word recognition
 137 (solid line) and semantic competition: the semantically related competitor (dotted line) was
 138 fixated more than the unrelated distractors (dashed line).

139 Gaze preprocessing requires three main steps:

- 140 (1) Reading in the data
- 141 (2) Eliminating trackloss (out-of-bounds) data
- 142 (3) Assigning areas of interest
- 143
- 144 (4) Samples to bins (optional)

145 **Reading in Gaze Data**

146 In order to process the edf files generated by the EyeLink system you will need to first
147 install the edf API provided by SR-Research, which is free of charge² and required for the ‘edfR’
148 package (Hubbard, 2014), which gazeR uses to read in edf files. In order to read in the edf files,
149 for both pupil and visual world data, two folder paths must be specified: one path where the edf
150 files are located and one where the raw .csv files should be saved.

```
151 directory_edf = ""  
152 # path to edfs  
153 directory_csv_from_edf_conversion = ""  
154 # path where csv files should be stored  
155  
156 file_list_edf <- list.files(path=directory_edf, pattern=".edf")  
157 # extract the edfs from the directory_edf path
```

158 Once folder paths are specified, you can call the `parse_edf` function. This function
159 imports the sample data from the edf files. The `type` argument must be specified as either “pupil”
160 or “vwp”, depending on experimental design used. The `parse_edf` function merges the sample
161 and message data from your raw edf files and wrangles them into a format suitable for
162 preprocessing with gazeR. Specifically, the function places time in milliseconds, adds participant

² <https://www.sr-support.com/forumdisplay.php?17-EyeLink-Display-Software>

163 ids, trials, and sample messages, and computes the mean x and y gaze coordinates and diameter
 164 values for a monocular eye variable (the left, right, or mean of both eyes).

165 The `parse_edf` function generates a csv file from each edf file in a directory specified by
 166 the user. The `merge_gazer_files` function can then aggregate those new csv data files stored in
 167 the `directory_csv_from_edf_conversion` path specified above. For files that were processed with
 168 `parse_edf`, you need to set the `filetype` argument to “edf.”

```
169 parse_edf(file_list=file_list_edf,
170 directory_csv_from_edf_conversion,
171 type="vwp"))
172 # parses each edf file. Path to pupil edf files and where you want csv files
173 stored needed
174 file_list_csv <- list.files(path=directory_csv_from_edf_conversion, pattern="
175 .csv")
176 # Save csv files from specified directory
177 sampled_gaze_data <- merge_gazer_files(file_list_csv, filetype = "edf")
178 # merges all the sample files from the csv folder specified.
179
```

180 Behavioral Data

181 When using raw edf files, relevant behavioral message variables (e.g., conditional
 182 variables, RTs , and accuracy) are usually sent outside the sampling frequency of the eye tracker.
 183 To get the relevant trial variables in a nice table, you can run the `find_messages_edf` function,
 184 which will produce a csv file from each edf file. In order for the function to work properly the
 185 user must specify specific variable names (`varnames`) and the patterns that need to be replaced
 186 (`patterns`). SR prepends a “TRIAL VAR” marker to behavioral variables. After running this
 187 function, you can merge each participant’s behavioral report with the `merge_gazer_files`
 188 function. The behavioral report can then be joined to the gaze sample reports.

```
189 find_messages_edf(file_list= file_list_edf, varnames= c("TRIALID", "TRIAL_VAR
190 Condition", "TRIAL_VAR StimSlide.ACC", "TRIAL_VAR StimSlide.RT", "TRIAL_VAR C
191 orrectPort", "TRIAL_VAR CompPort"), patterns=c("TRIALID", "TRIAL_VAR Condition
```

```

192 ", "TRIAL_VAR StimSlide.ACC", "TRIAL_VAR StimSlide.RT", "TRIAL_VAR CorrectPor
193 t", "TRIAL_VAR CompPort"),output_dir)
194 #Need to know what your variable names are called these will be specific to
195 the experiment.
196 #use the edf path and csv path specified above
197 file_list_messages <- list.files(path = directory_csv_from_edf_conversion,
198                               full.names = TRUE, pattern = '.csv')
199 messages <- merge_gazer_files(file_list_messages filetype = "edf")
200

```

201 A pre-read version of this data set is included in gazeR to demonstrate what the sample

202 data should look like after merging the message information:

```

203 gaze_path <- system.file("extdata", "vwp_data_raw_edf.xls", package = "gazer"
204 )
205 gaze_raw <- data.table::fread(gaze_path) # reads in large datasets quickly
206
207 gaze_data <- as_tibble(gaze_raw) # save as tibble
208
209 head(gaze_data)
210 ## # A tibble: 6 x 14
211 ##   subject trial  time pupil      x      y target  acc comport  rt
212 ##   <int> <int> <int> <int> <dbl> <dbl> <chr>  <int> <chr>  <int>
213 ## 1   9061     1     0   199  507.  358. pillow     1 image1  4000
214 ## 2   9061     1     2   199  506.  358. pillow     1 image1  4000
215 ## 3   9061     1     4   199  506.  359. pillow     1 image1  4000
216 ## 4   9061     1     6   199  506.  359. pillow     1 image1  4000
217 ## 5   9061     1     8   199  506.  359. pillow     1 image1  4000
218 ## 6   9061     1    10   199  506.  359. pillow     1 image1  4000
219 ## # ... with 4 more variables: correctport <chr>, condition <chr>,
220 ## #   TargetLocation <int>, CompLocation <int>
221

```

222 For this example data set the sample gaze data contains eye-tracking variables and experiment-

223 specific values (positions of different objects, trial condition, participant accuracy and response

224 time) that were extracted from the raw edf files.

```

```

255 Trackloss

256 Once the data are loaded in, some researchers might prefer to remove trials with excessive

257 trackloss (instances where the eyes travel outside of the viewing screen). This can be determined

258 by the X and Y coordinates at each sample relative to the size (resolution) of the screen.

259 Trackloss from the EyeLink systems use $1e+08$. The `get_trackloss` function determines the on/off

260 screen status of each sample, computes the proportion of trackloss by trial and participant, and

261 filters out trials and subjects that pass a user-defined threshold (this filtering can be omitted by

262 setting the threshold to 1.0). The `screen_size` argument must be supplied as a numeric vector of

263 the X and Y dimensions of the computer screen used during the experiment. In this example, we

264 will not be throwing out data due to trackloss.

```

265
266 gaze_track <- get_trackloss(gaze, screen_size=c(1024, 768), missingthresh=.2)

```

267 Parsing areas of interest

268 The following preprocessing assumes that the interest areas (locations of objects) were
 269 static and that the fixation report includes columns indicating the location of each object for each
 270 trial. For this example, the objects were always presented in the four corners of the screen, though
 271 which object was in which corner was randomized. The four possible image locations are labeled
 272 as image1, image2, image3, and image4. The TargetLoc variable identifies which of those
 273 locations was the target object and the CompPort variable identifies which of those locations was
 274 the critical semantically related competitor. The gaze position was recorded in terms of (X,Y)
 275 coordinates. In order to determine which (if any) of the objects were being fixated, first identify
 276 the locations of the target and competitor images, then use gaze coordinates to determine which
 277 image location (if any) was being fixated, then compare gaze location to target and competitor
 278 locations. If gaze location has already been coded in terms of interest areas (many experiment
 279 programs do this dynamically, as the data are being collected), then this step can be skipped.

280 The `assign_aoi` function will match gaze positions to numbered areas of interest (AOI)
 281 based on screen coordinates (by default, 400x300 rectangles in the corners of the 1024x768
 282 screen), which will need to be matched to image location labels:

```
283 gaze_aoi <- assign_aoi(gaze, screen_size=c(1024, 768), aoi_size=c(400, 300),
284 aoi_loc=NULL, X="x", Y="y")
285

```

320 Now determine which object was being fixated by matching AOI codes with target and
321 competitor locations:

```

322 gaze_oi$Targ <- gaze_oi$AOI == gaze_oi$TargetLocation
323 gaze_oi$Comp <- gaze_oi$AOI == gaze_oi$CompLocation
324 gaze_oi$Unrelated <-
325   ((gaze_oi$AOI != as.numeric(gaze_oi$TargetLocation)) &
326    (gaze_oi$AOI != as.numeric(gaze_oi$CompLocation)) &
327    (gaze_oi$AOI != 0) & !is.na(gaze_oi$AOI))

```

328

329 **Gathering Data**

330 The specifics of data organization and aggregation will depend on the design and
331 hypotheses of the specific study. For this example, the fixation locations need to be “gathered”
332 from separate columns into a single column (see Supplemental Figure for a demonstration of this)
333 and “NA” values need to be re-coded as not-fixations:

```

334 gaze_obj <- gaze_aoi %>%
335   dplyr::gather(key = "object", value = "fix",
336     Targ, Comp, Unrelated, factor_key = TRUE) %>%
337   dplyr::mutate(Fix = replace_na(fix, FALSE)) # recode NA as not-fixating
338
339 ## gather: reorganized (Targ, Comp, Unrelated) into (object, fix) [was 104857
340 5x18, now 3145725x17]
341 ## mutate: new variable 'Fix' with 2 unique values and 0% NA
342

382 **Samples to Bins (Optional)**

383 You can downsample your data, if you choose, into larger time bins using the
 384 `downsample_gaze` function. This function will aggregate the set of samples into a time series
 385 consisting of standardized time bins with a size specified by the user (default is 50ms). In
 386 addition, it will drop columns that are no longer necessary. The user needs to specify a list
 387 columns (`aggvars`) that define the aggregation level (e.g., individual trials) and should be kept
 388 after the binning is done. If you would like to keep the raw data unbinned, you can skip this part.

```
389 bin_gaze <- downsample_gaze(gaze_obj, bin.length = 50, timevar = "time", aggv
390 ars = c("subject", "condition", "target", "trial", "object", "timebins"))
391 ## mutate: new variable 'timebins' with 525 unique values and 0% NA
392
393 head(bin_gaze)
394
395 ## # A tibble: 6 x 9
396 ##   subject condition target trial object timebin   acc   rt Fix
397 ##   <int> <chr>      <chr> <int> <fct>   <dbl> <int> <int> <lgl>
398 ## 1   9061 associate anchor   18 Targ     0     1  3493 FALSE
399 ## 2   9061 associate anchor   18 Targ    50     1  3493 FALSE
400 ## 3   9061 associate anchor   18 Targ   100     1  3493 FALSE
401 ## 4   9061 associate anchor   18 Targ   150     1  3493 FALSE
402 ## 5   9061 associate anchor   18 Targ   200     1  3493 FALSE
403 ## 6   9061 associate anchor   18 Targ   250     1  3493 FALSE
```

404 **Aggregating Data**

405 In the final stage of preprocessing, the error and practice trials can be removed and the
 406 time window can be restricted, to make the data ready for aggregation. For this example, we
 407 group the trials by Subject, Condition, and Object type to calculate number of valid trials in each
 408 cell. Then also group by time point to calculate the number of object fixations and mean fixation
 409 proportion at each time point; that is, the time course of fixation. These are the subject-by-
 410 condition time courses that would go into an analysis.

```
411 gaze_subj <- bin_gaze %>%
412   filter(acc == 1, condition != "practice", timebins < 3500) %>%
413   # calculate number of valid trials for each subject-condition
```

```

414   group_by(subject, condition, object, timebins) %>%
415   summarize(meanfix = mean(Fix, na.rm=TRUE)) # fixation proportion
416 # there were two unrelated objects, so divide those proportions by 2
417 gaze_subj$meanfix[gaze_subj$object == "Unrelated"] <-
418 gaze_subj$meanfix[gaze_subj$object == "Unrelated"] / 2
419
420 ## filter: removed 28,158 rows (22%), 99,387 rows remaining
421 ## group_by: 3 grouping variables (subject, condition, object)
422 ## mutate (grouped): new variable 'nTrials' with 5 unique values and 0% NA
423 ## group_by: 4 grouping variables (subject, condition, object, timebins)
424 ## summarize: now 5,634 rows and 7 columns, 3 group variables remaining (subject, condition, object)
425
426
427 summary(gaze_subj)
428 ##      subject      condition      object      time
429 ## Min.   :9061  Length:140703  Targ     :46901  Min.    :  0
430 ## 1st Qu.:9092  Class :character  Comp     :46901  1st Qu.: 868
431 ## Median :9146  Mode  :character  Unrelated:46901  Median :1736
432 ## Mean   :9121
433 ## 3rd Qu.:9153

```

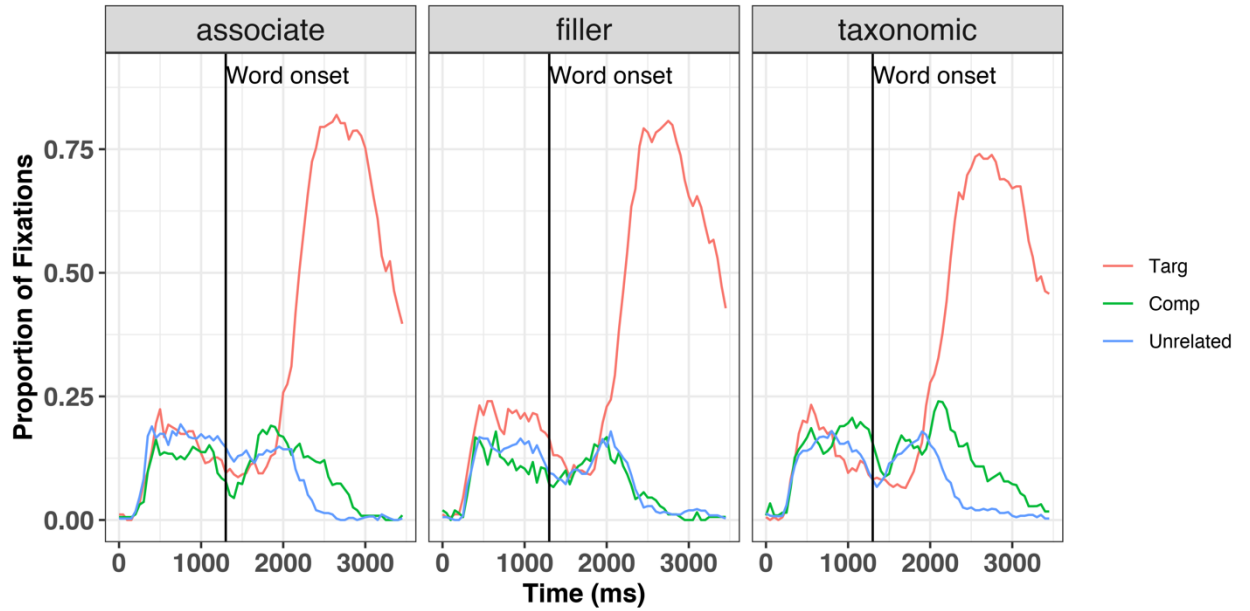

442 Plot fixation time course

443 After the fixations have been assigned to the object type and converted to time bins, they
444 are ready for visualization and statistical analysis. Below is a plot of the time course of fixation
445 proportions for each target type.

```

446 ggplot(gaze_subj)+
447   aes(time, meanfix, color = object) +
448   facet_wrap(~ condition) +
449   theme_gray() +
450   labs(x = "Time (ms)", y = "Proportion of Fixations") +
451   stat_summary(fun.y = mean, geom = "line") +
452   geom_vline(xintercept = 1300) +
453   annotate("text", x=1300, y=0.9, label="Word onset", hjust=0)

```

454

455 Figure 2. Time course of fixation proportions by condition. These data have been pre-
 456 processed and are ready for statistical analysis.

457 Preprocessing Pupil Data from a Lexical Decision Task

458 Recent advances in eye-tracking technology have lead to a burgeoning interest in
 459 cognitive pupillometry (i.e., measurement of changes in pupil size as it relates to higher-level
 460 processing). According to a recent PubMed search (see Figure 3), the number of studies
 461 employing pupillometry has grown exponentially since the first modern boom more than a half a
 462 century ago. The reason for this is quite simple: pupil size has been shown to be a reliable and
 463 valid index of cognitive effort or arousal across many domains, including word recognition
 464 (Geller, Still, & Morris, 2016), normal and impaired auditory perception (Zekveld et al., 2018),
 465 semantic cognition (Geller, Landrigan, & Mirman, 2019), attention allocation (Endogenous
 466 attention: Mathôt, Van derLinden, Grainger, Viti, 2013), working memory load (Granhölm,
 467 Asarnow, Sarkin, & Dykes, 1996; Van Gerven, Paas, Van Merriënboer, & Schmidt, 2004), face
 468 perception (Goldinger, He, and Papesh, 2009), and general cognitive processing (Murphy et al.,

469 2014). While there are a number of good open-source programs available in R to analyze pupil
470 data (see Forbes, 2019; Tsukahara, 2018), there are not many walk-throughs demonstrating how
471 to go from raw data to fully pre-processed data. A recent methods review by Winn et al. (2018)
472 describes and illustrates general principles like blink detection, interpolation, and filtering. The
473 gazeR package includes functions for implementing these steps and here we demonstrate their
474 use.

Interest in pupillometry research from 1940-2019

475
476 Figure 3. PubMed search for the keyword [pupillometry] from 1940-2019.

477 To demonstrate analysis of pupil data, we will be using an example data set containing
478 data from a lexical decision task. For this walkthrough, participants ($N=3$) judged the lexicality
479 (i.e. “was this a word or not a word?”) of printed and cursive stimuli while pupil diameter was

480 recorded. Because cursive stimuli are non-segmented and could be ambiguous, it was predicted
481 that recognizing cursive stimuli would require more effort than printed words would (cf.,
482 Barnhart & Goldinger, 2010; Geller, Still, Dark, & Carpenter, 2018), resulting in larger pupil
483 dilation.

484 Preprocessing pupil data requires the following steps:

485 (1) Read in data

486 (2) De-blinking

487 ○ Extending blinks

488 ○ Smoothing and interpolation

489 (4) Baseline correction

490 (5) Re-scaling

491 (7) Artifact Rejection

492 ○ Missing data

493 ○ Unlikely pupil values

494 ○ Median absolute deviation (MAD)

495 (8) Event time alignment

496 (9) Samples to bins

497 **Reading in Pupil Data**

498 In this example, we consider data from several subjects – the typical experimental
499 scenario. For your own data (that includes many individual files), the function `parse_edf` with
500 the `type` argument set to “pupil” will produce the necessary columns needed for gazeR to work.
501 For non-edf files, you can use the `make_gazer` function to make your data suitable for gazeR.

502 This will return a data frame with column names changed to: subject, trial, blink, x, y, pupil,
503 time, and message.

504 Once each edf file is saved as a .csv with the `parse_edf` function (explained above), you can
505 call the `merge_gazer_files` function to aggregate all your pupil sample files.

```
506
507 directory_edf = ""
508 # path to edfs
509 directory_csv_from_edf_conversion = ""
510 # path where csv files should be stored
511
512 file_list_edf <- list.files(path=directory_edf, pattern=".edf")
513 # get list of edf files
514 parse_edf(file_list=file_list_edf,
515 output_dir = directory_csv_from_edf_conversion,
516 type="pupil"))
517 # parses edfs and saves them into directory
518 # folder path to csv folders from parse_edf
519
520 file_list_pupil_samp <- list.files(path=directory_csv_from_edf_conversion,
521 pattern=".csv")
522 # extract the processed csv files from directory_csv_from_edf_conversion
523
524 pd <- merge_gazer_files(file_list_pupil_samp, type = "edf")
525 # merges all the files from file_list_pupil_samp object
```

526 Behavioral Data (Optional)

527 For those interested in analyzing behavioral data, the `find_messages_edf` function can be
528 used to cull the important behavioral data and merge with the sample data.

```
529 find_messages_edf(file_list= file_list_samp, varnames=c("TRIALID", "script", "
530 TRIAL_VAR item", "TRIAL_VAR RT", "ACCURACY", "alteration", "block"), patterns
531 =c("TRIALID", "!V TRIAL_VAR script", "!V TRIAL_VAR item", "!V TRIAL_VAR RT", "!
532 V TRIAL_VAR ACCURACY", "!V TRIAL_VAR alteration", "!V TRIAL_VAR block"),
533 output_dir)
534 # use edf and csv paths from above
535 #find out what variable names are called these will be specific to the experi
536 ment.
```

```

537 file_list_messages <- list.files(path = directory_csv_from_edf_conversion,
538                               full.names = TRUE, pattern = '.csv')
539
540 messages <- merge_gazer_files(file_list_messages filetype = "edf")
541 # rbind all the file_list_message files
542
543 pupil_behav_merge <- full_join(pupil_files, messages, by=c("subject", "trial"
544 ))
545 # merge behave with full sample report
546     Due to processing constraints, we are using a data file that includes data from a few

```

547 participants with all behavioral data included. The `parse_edf`, `merge_gazer_files`, and
 548 `find_messages_edf` functions can be tested using example data that is available to download
 549 from the Open Science Framework (OSF): <https://osf.io/fzu38/>. While reading in the data is fast
 550 (even with many participants), some of the functions performed on the data can be
 551 computationally intensive.

```

552 pupil_path <- system.file("extdata", "pupil_sample_files_edf.xls" , package =
553 "gazer") # get the file from gazer
554 pupil_raw <- data.table::fread(pupil_path) # reads in large files quickly
555 pupil_files <- as_tibble(pupil_raw) # saves the .xls file as tibble
556 summary(pupil_files)

587

```

588 Once merged the `behave_data` function will cull the important behavioral data from the

589 sample report. The function will return a data frame without errors when `omiterrors=TRUE` or a

590 data frame with errors for accuracy/error analysis when `omiterrors=FALSE`. The columns

591 relevant for your experiment need to be specified within the `behave_col` names argument. This

592 function does not eliminate outliers; you must use your preferred method. Grange's (2015) `trimr`

593 package implements multiple standard methods of outlier exclusion

594 (<https://github.com/JimGrange/trimr>). The overall item and subject accuracy can be merged into

595 the pupil sample report.

```

596 behave_data<-
597 behave_pupil(pupil_files, omiterrors = FALSE, behave_colnames = c("subject",
598 script","alt", "trial", "item","acc","rt", "block"))
599 behave_data

616 acc_by_item <- behave_pupil%>%
617   group_by(item) %>%
618   summarise(meanitemacc = mean(acc[block>0 & alt=="word"])) # overall item ac

```

```

619 curacy
620
621 acc_by_subject <- behave_data %>%
622   group_by(subject) %>%
623   summarise (meansubacc = mean(acc[block>0 & alt=="word"]))# subject accuracy
624
625 data_to_process <- pupil_files %>%
626   full_join(acc_by_item) %>% # merge item accuracy
627   full_join(acc_by_subject) # merge subject accuracy

```

628 In our data, we want to remove subject accuracy lower than 75% and item accuracy below 60%.

629 We can use the data frame generated above to calculate this when argument `omiterrors=FALSE`.

630 We then merge accuracy by items and subjects into the main pupil file.

631 We can now restrict preprocessing to valid trials by removing practice blocks, trials with
632 incorrect responses, conditions that are not words, subjects with accuracy below 75%, and items
633 with accuracy below 60%.

```

634 pupil_files1 <-data_to_process %>%
635   filter(block>0, acc==1, alt=="word",
636   meanitemacc >.60, meansubacc>.74) %>%
637   arrange(subject,trial, time)

```

638 Pupil Preprocessing is now ready to begin!

639 **De-blinking**

640 An important step in preprocessing pupil data is de-blinking. A major artifact in pupil data
641 comes from blinking. When the eye blinks, the pupil momentarily becomes smaller as it is
642 occluded more and more by the eyelids, making it difficult to compute the center of the pupil.
643 Eye-trackers interpret this as a fast shift in pupil position and might erroneously classify it as a
644 saccade. Additionally, the estimate of pupil size will rapidly decrease as the pupil occupies less of
645 the camera image. This process happens in reverse (albeit a bit more slowly) as the eye is
646 opening, so blinks are always flanked by an artifact that includes a false saccade and/or false

647 change in pupil size. Occasionally there will be some additional artifacts, such as short fixations
648 preceding or following the blink. It is thus advisable to de-blink the data, which involves
649 identifying blinks, removing data during the blink, removing data slightly before and after the
650 blink, and then interpolating data during the period that was removed. In gazeR, blinks are
651 identified automatically when importing raw edfs using the saccades package (Malsburg, 2015).
652 For data in another format, the `detect_blink` function can be used to identify blinks. Blink
653 detection from the saccades package uses a velocity-based algorithm taken from Engbert &
654 Kliegl (2003). Blink events are identified as anything that looks like a fixation but has much
655 lower dispersion than the typical fixation. In the saccades package, a blink is an event with a
656 dispersion that is smaller than the median dispersion minus four times the median absolute
657 deviation of the dispersion and only if this is the case for horizontal and vertical dispersion.³

658 A less trivial matter in pre-processing pupil data is deciding how many data points to
659 remove before and after the blink. It has generally been recommended that data 100 ms before
660 and after the blink should be eliminated. There are several ways one can deal with blinks (see
661 Hershman, Henik, & Cohen, 2018). One method is to eliminate all blinks from a trial. This is
662 generally not recommended as it can eliminate too much data, resulting in a loss of power. A
663 more acceptable approach, and the one implemented in gazeR, is to extend the time window
664 around the blinks so the interpolation starts 100-200 ms before the blink and continues after the
665 blink (Nyström, Hooge, & Andersson, 2016; Satterthwaite et al., 2007). Extending the time

³ A comparison of results using the blink detection algorithm in the saccades package and the SR-EyeLink algorithm resulted in negligible differences, at least on grand averaged data. However, more extensive testing should be done. .

666 window around the blinks eliminates spurious samples caused by the closing and opening of the
667 eyelids. The `extend_blinks` function implements this method, with the `fillback` argument
668 specifying how far blinks should extend back in time (before the blink) and the `fillforward`
669 argument specifying how far blinks should extend forward in time (after the blink). This
670 function is robust to different sampling rates as long as the eye-tracker sampling rate is specified
671 in the `hz` argument. For this experiment, the tracker sampled at 250Hz (once every 4 ms) and
672 blinks were extended 100 ms forward and backward in time.

```
673 pup_extend<- pupil_files1 %>%  
674   group_by(subject, trial) %>%  
675   mutate(extendpupil=extend_blinks(pupil, fillback=100, fillforward=100, hz=2  
676   50))  
677 ## group_by: 2 grouping variables (subject, trial)  
678 ## mutate (grouped): new variable 'extendpupil' with 1,617 unique values and  
679 23% NA  
680
```

681 Smoothing/Filtering and Interpolation

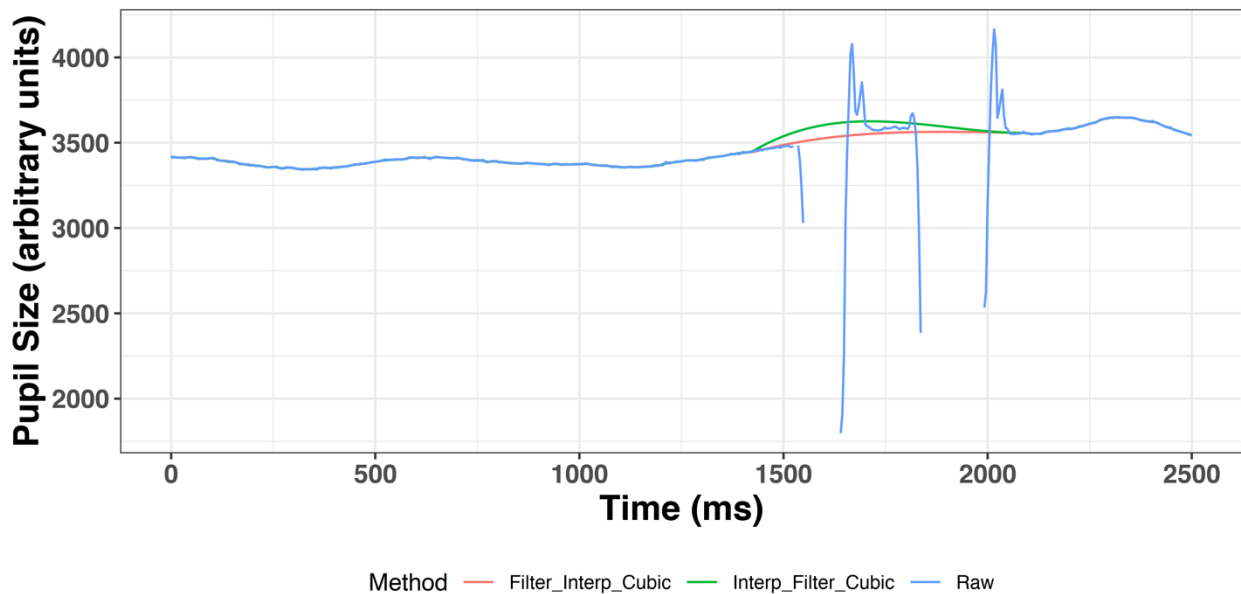

682 Pupil data can be extremely noisy. To remove some of this noise, filtering and
683 interpolation are commonly done. In gazeR this is done in one step using the
684 `smooth_inteprolate_pupil` function. With the `step.first` argument users can choose to
685 either smooth the data first with a n-moving average, and then interpolate (`step.first =`
686 `“smooth”`) or vice versa (`step.first = “interp”`). Depending on which methods are selected,
687 the order of the steps can have negligible or substantial effects (see Figures 4 and 5); if applying
688 cubic-spline interpolation, smoothing before interpolation is generally advisable. The gazeR
689 package currently implements two common ways to smooth pupil data: n-point moving average
690 and Hanning window (we plan to include more smoothing options in future updates to the
691 package). To smooth the data, you must specify the column that contains the pupil information
692 and the size (in samples) of the moving average window. In this example, we use a 5-point
693 moving average ($n=5$) which, at a sampling rate of 250 Hz, corresponds to a 1250 ms moving
694 average.

695 Missing data stemming from blinks or failure of the eye tracker need to be interpolated.
696 The `smooth_interpolate_pupil` function searches the data and reconstructs the smoothed
697 pupil size for each trial from the relevant samples using either linear interpolation (Bradley,
698 Miccoli, Escrig, & Lang, 2008; Cohen et al., 2015; Siegle, Steinhauer, Carter, Ramel, & Thase,
699 2003) or cubic-spline interpolation (Mathôt, 2018). Considering the short duration of blinks and
700 the relatively low speed of blinks, the choice of linear versus cubic interpolation will ultimately
701 have negligible effect. If `extendblinks= FALSE`, samples with blinks are turned into NAs and are
702 then interpolated. This function returns a tibble object with a column called `pup_interp` which
703 contains interpolated values from the moving averaged pupillary data. There are also options to
704 denote the max number of gaps to interpolate over (the `maxgap` argument is set to `Inf` by default).
705 This requires the sampling rate (hz) of the eye tracker be specified. As an important note, if the
706 Data Viewer was used to extend blinks, the `extendblinks` argument should be set to `FALSE`. If
707 the `extend_blinks` function was used, the `extendblink` argument should be set to `TRUE`. It is
708 important to note that SR only extends the blink column and does not set pupil size estimates
709 during blinks to “NA” in the Sample Report. For this example, we will set `extendblinks` to
710 `TRUE` and use linear interpolation. You can use cubic interpolation by changing type to “cubic.”

```
711 smooth_interp <- smooth_interpolate_pupil(pup_extend, pupil="pupil", extendpu  
712 pil="extendpupil", extendblinks=TRUE, step.first="interp", filter="moving", m  
713 axgap=Inf, type="linear", hz=250, n=5)  
714  
715 ## Performing linear interpolation  
716 ## Smoothing the pupil trace with moving average  
717  
718
```

719
720 Figure 4. Linear interpolation for one trial. The blink extension was successful: the isolated
721 points (blue line) have been removed. In this example, for linear interpolation, it does not matter
722 whether the interpolation was done first (green line) or the smoothing was first red line).

723
724 Figure 5. Cubic interpolation for one trial. The blink extension was successful: the isolated points
725 (red line) have been removed. In this example, for cubic interpolation, somewhat different results
726 are obtained if the interpolation step is first (green line) versus if the smoothing step is first
727 (red line).
728

729 **Baseline correction**

730 To control for variability in overall pupil size arising from non-task related (tonic) state of

731 arousal, baseline correction is commonly used (but see Attard-Johnson, Ó Ciardha, &
732 Bindemann, 2019). The two most popular types of baseline correction to identify task-evoked
733 *dilation* are subtractive (pupil size - baseline) and divisive (change in pupil size - baseline /
734 baseline). Subtractive baseline correction is more common in the literature (cf., Beatty, 1982;
735 Laeng et al., 2012; Zekveld, Koelewijn, & Kramer, 2018), and this practice has been argued by
736 Reilly, Kelly, Kim, Jett, and Zuckerman (2018) to be reflective of the linearity of the pupil
737 response independent of baseline size, although the basis of that argument has been questioned⁴.
738 The `baseline_correction_pupil` function finds the median pupil size during a specified
739 baseline period for each trial and performs a subtraction baseline correction by default (see
740 Mathôt et al., 2018, for argument that baseline correction should be done using the median, and
741 not the mean, baseline value). By changing the `baseline_method` argument to “div”, you will
742 get proportion change from baseline. In this example, subtractive baseline correction is applied
743 to pupil size in arbitrary units (`pupil_colname = "pup_interp"`) though the same can be done for
744 pupil size in mm or z-score. The baseline time window can be set with numerical values using the
745 `baseline_window` argument from the `baseline_correction_pupil` function if events are fixed
746 or static.

⁴ Reilly et al. varied luminance in order to elicit different baseline sizes, but that is not the typical source of baseline pupil size differences. Tonic baseline pupil size differences due to arousal, age, or other variables may affect the range of dilation reactivity in ways that differ from changes that are elicited by changes in luminance. Additionally, Wang et al. (2018) suggested that brighter lighting condition elicit *larger* dilations, on account of suppression of the parasympathetic suppressive influence on dilations. These factors can be used to motivate divisive baseline correction.

```

747 baseline_pupil <- baseline_correction_pupil(smooth_interp, pupil_colname='pup
748 _interp', baseline_window=c(500,1000))
749 ## Calculating median baseline from:500-1000
750 ## Merging baseline
751 ## Performing subtractive baseline correction
752

```

753 If events in your experiment occur dynamically, the `baseline_correction_pupil_msg`
754 function can be used. This function takes a user-specified baseline period immediately preceding
755 a stimulus onset message. In the below example, we set the `baseline_dur` argument to 100 ms
756 and the `event` argument to “target.” This will calculate the median baseline value for 100 ms
757 preceding target onset. The choice of baseline duration appears to largely inconsequential (Winn
758 et a., 2018).

```

759 baseline_pupil<-baseline_correction_pupil_msg(smooth_interp, pupil_colname='p
760 up_interp', baseline_dur=100, event="target", baseline_method = "sub")

796

797 **Re-Scaling**

798 So far, the analysis steps have used arbitrary pupil units. It is advised that these be
799 transformed into a standardized unit in order to make comparisons between individuals.
800 Numerous options have been used in prior studies: z-scores (see Cohen, Moyal, & Henik, 2015;
801 Einhauser, Stout, Koch, & Carter, 2008; Kang & Wheatley, 2015), absolute changes in mm (e.g.,
802 Beatty, 1982; Geller, Landrigan, & Mirman, 2019; Geller et al., 2016), proportional change
803 relative to baseline (Winn, 2016), proportional change relative to peak (Winn, 2016; Winn &
804 Moore, 2018), and absolute change relative to dynamic range of pupil reactivity elicited by the
805 light reflex (Piquado, Isaacowitz, & Wingfield, 2010). To convert arbitrary pupil size to mm, we
806 measured the scaling factor by running a short experiment with an artificial pupil (5 mm in size)
807 and calculated the average pupil size in arbitrary units. At a fixed camera-to-pupil distance of 90
808 cm, the 5mm pupil was coded as 5570 arbitrary pixel units. This information was entered into the
809 equation below to convert arbitrary units to mm. Specifically, the smoothed pupil size value is
810 multiplied by 5/5570 to re-scale the values to mm.

```

811 timebinsmm <- baseline_pupil %>%
812   mutate(pupilmm = (pup_interp * 5)/5570.29)

```

813 Alternatively, the arbitrary pupil units can be converted to a z-score using the scale
814 function.

```
815 timebinsz <- baseline_pupil %>%
816   group_by(subject, trial) %>%
817   mutate(pupilz = scale(pup_interp))
818
```

819 For the rest of the walkthrough, arbitrary pupil size will be used.

820 **Artifact Rejection**

821 **Missingness.** The `count_missing_pupil` function will remove subjects and items that
822 have a large amount of missing data – the threshold for “a large amount” is specified by the
823 researcher. It has been recommended by Winn et al. (2018) that a reasonable threshold is 20%,
824 but that the exact importance of missing data might be weighted by specific timing landmarks in
825 the experiment trials. For this example, we have set the `missingthresh` argument to `.2` and the
826 `pupil` argument to the raw, non-interpolated, pupil dilation column in our dataset. The
827 `count_missing_pupil` function returns the percentage of subjects and trials that have been
828 excluded for reporting.

```
829 pup_missing <- count_missing_pupil(baseline_pupil, pupil= "pupil", missingthr
830   esh = .2)
831
832 ## % trials excluded:0.07
833 ## subjects taken out:
```

834 **Spurious pupil values.** Unlikely pupil values that are too small and too large should be
835 removed from the data (Mathôt et al., 2018; Winn et al., 2018). Mathôt (2018) recommended
836 against removing data based on a subject-independent fixed criterion (e.g., above or below a SD
837 cut-off or a specified lower and upper pupil boundary). This is due to the inherent heterogeneity
838 of pupil sizes across experiments. Instead, Mathôt (2018) recommend visual inspection to
839 determine unlikely pupil values. This can be done using a simple histogram to plot the
840 pupillometric data. Based on the histogram below, it seems reasonable to remove pupil sizes less
841 than 2500 and greater than 5000.

```

842 puphist <- ggplot(baseline_pupil aes(x = pup_interp)) +
843   geom_histogram(aes(y = ..count..), colour = "green", binwidth = 0.5) +
844   geom_vline(xintercept = 2500, linetype="dotted") +
845   geom_vline(xintercept = 5100, linetype="dotted") +
846   xlab("Pupil Size") +
847   ylab("Count") +
848   theme_bw()
849
850 print(puphist)

```

851

852 Figure 6. Histogram of recorded pupil sizes.

```

853 pup_outliers <- pup_missing %>%
854   # based on visual inspection
855   dplyr::filter(pup_interp >= 2500, pup_interp <= 4000)
856

```

857 **Median absolute deviation (MAD).** After interpolation, it is a good idea to perform a
858 second pass to make sure that the data are not contaminated by rapid pupil size disturbances.
859 These artifacts can be detected using the median absolute deviation, which is a more robust
860 variability metric than traditional measures of variability (e.g., standard deviation; Hampel, 1974;
861 Kret & Sjak-Shie, 2018). For each time point, the `speed_pupil` function calculates the
862 normalized dilation speed, which is the absolute change in pupil size between samples divided by

863 the temporal separation between them. To detect outliers, the MAD is calculated from the
 864 dilation speed variable and multiplied by a constant (in this case 16, which is the value used in
 865 Kret & Sjak-Shie, 2018). The constant controls the sensitivity threshold: The higher the constant,
 866 the more extreme a value needs to be in order to be marked for removal. The MAD is added to
 867 the median dilation speed variable using the `calc_mad` function; values above this threshold are
 868 then removed.

```
869 mad_removal <- pup_outliers %>%
870   group_by(subject, trial) %>%
871   mutate(speed=speed_pupil(pup_interp,time_zero)) %>%
872   mutate(MAD=calc_mad(speed, n = 16)) %>%
873   filter(speed < MAD)
```

874 Event Time Alignment

875 In most psychological experiments, each trial includes several events. In the example
 876 experiment, each trial began with a fixation screen (small cross in the center of the screen) and
 877 the stimulus of interest appeared on screen 1s after trial onset. These events are documented in
 878 the data file: the onset of the target is denoted by the trial message “target.” We can use this
 879 information to align the data so that `time=0` corresponds to stimulus onset (i.e., the analysis
 880 window of interest) rather than trial onset. The `onset_pupil` function performs this alignment
 881 using three arguments: time column, sample message column, and the event of interest (“target”
 882 in our example). In the output below, we can see that our experiment now starts at zero, when the
 883 target was displayed on screen.

```
884 baseline_pupil_onset <- mad_removal %>%
885   dplyr::group_by(subject, trial) %>%
886   dplyr::mutate(time_zero=onset_pupil(time, message, event=c("target"))) %>%
887   ungroup() %>%
888   dplyr::filter(time_zero >= -100 & time_zero <= 2500) %>%
889   select(subject, trial, time_zero, message, baseline, baselinecorrectedp, pu
890 pil, pup_interp, script)
891 ## select: dropped 13 variables (time, x, y, blink, acc, ...)
```

921 Samples to Bins

922 If the data are recorded at a relatively high sampling frequency (e.g., 250Hz in this
923 example), it may be useful to aggregate the data into time bins that are somewhat larger than the
924 sample rate (users can specify a time bin size to use). The `downsample_gaze` function will
925 aggregate the set of samples into a time series consisting of standardized time bins with a size
926 specified by the user for pupil data when the `type` argument is set to “pupil”. In addition, it will
927 drop columns that are no longer necessary. The user needs to specify a vector of column names
928 (`aggvars`) that define the aggregation level (e.g., individual trials) and should be kept after the
929 binning is done. This produces an average baseline-corrected pupil diameter for each subject,

930 condition, and timebin. If you would like to keep the raw data unbinned, you can skip this part.

931 This function returns a tibble with an added column called timebins, which can be used for

932 aggregation (e.g., calculating the mean pupil size in each time bin).

```

933 timebins1<- downsample_gaze(baseline_pupil_onset, bin.length=100, timevar = "
934 time_zero", aggvars = c("subject", "script", "timebins"), type="pupil")
935

954 Pupillary Data Visualization

955 After baseline-correction and artifact rejection, the data are ready for visualization and

956 statistical analysis. The pre-processed data produced by gazeR are highly flexible and compatible

957 with different visualization strategies.

```

958
959 cursive_plot <- ggplot(timebins1)+
960   aes(timebins, aggbaseline, linetype=script, color=script) +
961   stat_summary(fun.y = "mean", geom = "line", size = 1)
962   theme_bw() +
963   labs(x = "Time (ms)",y = "Pupil Dilation (change from baseline (a.u.))") +
964   geom_hline(yintercept=0.0)
965
966 cursive_plot

```

969

Data Analysis

970 The gazeR package is deliberately agnostic to how researchers should analyze their data,

971 leaving the data in a format that is flexible and compatible with a variety of statistical modeling

972 strategies. For instance, various curve-fitting strategies such as growth curve analysis, general

973 additive models and/or functional data analysis (Jackson & Sirois, 2009; Mirman, 2014;

974 Seedorff, Oleson, and McMurray, 2018; van Rij et al., 2019). In the absence of a field-standard

975 statistical approach, we leave it up to the researcher to choose what statistical analysis to use.

976 For those interested in growth curve modeling, the gazeR package does contain a helper

977 function (`code_poly`) to facilitate growth curve analysis (GCA) using orthogonal polynomials

978 (Mirman, 2014). The `code_poly` function takes your time column and adds polynomial

979 transformations of time up to a user-specified order. The polynomial transformation can be

980 natural or orthogonal; the orthogonal version can be useful because it makes the time terms

981 uncorrelated and scales them to the same range (for a discussion of natural vs. orthogonal
 982 polynomials see Mirman, 2014).

```
983 code_poly(df = gaze_subj, predictor = "time", poly.order = 4, orthogonal = TR
984 UE, draw.poly = TRUE)

```

1015 The gazeR package also includes a function (`get_ranef`) for extracting random effects
1016 from a growth curve model in a format that is convenient for quantifying individual differences
1017 (see Mirman, 2014, Chapter 7) and a function for estimating p-values for linear mixed effects
1018 models using the normal and/or Kenward-Roger approximations (`get_pvalues`).

1019 Discussion

1020 While there are a number of viable solutions available to process eye-tracking data, not all
1021 are suitable for research purposes:

- 1022 • An all-graphical interface seldom provides information about the underlying data
1023 analysis and can be difficult to reproduce.
- 1024 • File formats are sometimes proprietary and undocumented, lacking detailed
1025 annotation necessary for replicability.
- 1026 • Source code and description of the algorithms are not always accessible to the
1027 user.
- 1028 • Some implementations rely on expensive proprietary software.

1029 The research community needs solutions that are completely open, with the possibility of directly
1030 manipulating and annotating the code, data, and parameters so that others may replicate or
1031 critique the methods. This article summarized and demonstrated the functionality of gazeR -- a
1032 free, open-source package written in R. We walked through important functions needed to pre-
1033 process both gaze position and pupil size data and make it suitable for analysis. This provides a
1034 generalized, replicable, and transparent method for preprocessing raw eye-tracking data.

1035 **How does gazeR compare to other existing solutions?**

1036 While there exist several packages in R to analyze pupillometry data or visual world paradigm
1037 data (see Table 1), gazeR has several advantages over existing solutions. First, gazeR is currently
1038 the only package that allows one to analyze pupillometric and gaze data all in one package.
1039 Second, many of the R packages rely on proprietary software and algorithms for key analysis
1040 steps (such as fixation/saccade parsing and blink detection). GazeR avoids this by allowing users
1041 to read in edf files directly and by using open-source event detection algorithms. Third, when
1042 deciding on a package to use, it is important the package be well documented and supported.
1043 Many of the packages listed in the table were developed and updated several years ago, and it is
1044 unclear if the package developers are still servicing the packages. Most crucially, the source code
1045 and descriptions for many of the packages are not well explained. Lastly, a significant problem
1046 for the standardization of analyses, especially with the implementation of a package, is that with
1047 constantly changing software environments results likely differ. For example, different R
1048 versions could change the results, as could differences between platforms (Windows, macOS, or
1049 Linux). To this end, a containerized version of gazeR is available via Binder on Github, which
1050 allows users to follow along with this walkthrough in the exact environment where it was created,
1051 thus supporting reproducibility. Our hope is this encapsulated environment will help facilitate use
1052 of our pipeline to users' own data. In the future we hope to host gazer on Docker, similar to other

1053 preprocessing pipelines (e.g., fmriprep; Esteban et al., 2019). Overall, we feel that this
1054 walkthrough, end-to-end implementation in the free, cross-platform environment of R, and the
1055 fact that gazeR conforms to best practices for pupillometry laid out in recent reviews (Winn et al.,
1056 2018; Mathot et al., 2018) makes gazeR a valuable tool for analyzing your pupillometry and gaze
1057 data.

1058 **Limitations**

1059 The gazeR pre-processing pipeline is not exhaustive. The implemented set of functions
1060 should suffice for researchers to pre-process their gaze and pupil data based on recent
1061 recommendations, but there are factors that are not included yet. For example, gaze position is
1062 known to influence pupil size (Brisson et al., 2013; Gagl, Hawelka, & Hutzler, 2011), called the
1063 pupil foreshortening effect. This effect occurs when rotations of the eyes change the angle at
1064 which the camera records the pupil, and therefore also the pupil's apparent size. As such, this
1065 manifestation of gaze position in pupil size should ideally be controlled or corrected for. A
1066 simple way to do this would be to include X and Y gaze coordinates into the analysis model as a
1067 co-variate. If reading in edf files, the X-Y gaze coordinates are included and can easily be
1068 included in this analysis. Additionally, various aspects of pupil dilation might be more or less
1069 important to the analysis, which might benefit from examination of additional features such as
1070 onset and offset slopes (c.f., Winn & Moore, 2018). Because the gazeR package is open-source,
1071 modifications can always be made to incorporate additional functionality. Suggestions and
1072 contributions from users are encouraged and can be submitted through the package github page:
1073 <https://github.com/dmirman/gazer>.

1074 Finally, the current instantiation of gazeR has only been tested with data files from the SR
1075 EyeLink (i.e., raw edfs and sample reports). Much of the gazeR functionality is easily compatible

1076 with other eye-trackers with the addition of functions for reading data and renaming columns
1077 (variables) to match the gazeR conventions. Future updates to the package will include added
1078 support for Tobii and Gazepoint eye trackers.

1079 To summarize, the gazeR package provides general, open-source tools for replicable and
1080 transparent processing of gaze and pupillometry data. GazeR grew out of in-house preprocessing
1081 code in several research groups and is already being used by several additional research groups. It
1082 is our hope that more researchers will use it and will contribute to its improvement.
