CORE

Interpretation of modern art masterpieces: no motor reflection

* Department of Bioengineering of International Centre for Mechanical Sciences (CISM), Udine, Italy ** Department of Bioengineering, University of Udine, Italy

x1 SUMMARY: In the article we present conceptual counter-arguments to the embodiement role claim, even when x2 motor areas of the brain are activated and, as a pilot case, resume and reproduce the experiment at the base of one of the seminal work about mirror neurons and neuroaesthetics, slightly modifying its measurement protocol х3 and considerably increasing its statistical population. This new study suggests that the aesthetic experience is x4 so strongly affected by cultural and experiential backgrounds of the beholder that somato-motor resonance x5 effects, if any, seem to be undetectable and, so far, unprovable. Recent trends in neuroaesthetics postulate a x6 х7 nexus between dramaticity, sense of movement, in static works of visual art, beholder's aesthetic experience and x8 embodied simulation mechanisms, the rationale being an asserted twofold motor resonance induced in the x9 observer by the dynamic content of the works and by recognizable traces of the artist's creative gestures. Trying x10 to cope with the effects of the subjective cultural conditioning, some pioneering studies have focused on the beholder's differential response to works of abstract art compared to less motor-evocative, computer-made x11 images. Using the same method reported by Umiltà et al. (2012) in Frontiers in Human Neuroscience, as a x12 x13 major result, those investigations don't contradict the embodied simulation hypothesis but they also don't prove x14 it definitively. Here the authors present conceptual counter-arguments to the embodiement role claim, even x15 when motor areas of the brain are activated and, as a pilot case, resume and reproduce the experiment at the base of one of the seminal work, slightly modifying its measurement protocol and considerably increasing its x16 x17 statistical population. This new study suggests that the aesthetic experience is so strongly affected by cultural x18 and experiential backgrounds of the beholder that somato-motor resonance effects, if any, seem to be undetectable and, so far, unprovable. x19

x20 KEY WORDS: Embodied simulation, Experiment, Falsification, Mirror neurons, Neuroaesthetics.

□ INTRODUCTION

1

2 3 Apart from their possible top-down relationships, theoretical neuroaesthetics^(19,23), embodied simulation⁽⁹⁾ 4 and mirror neuron system⁽²⁰⁾ share several common 5 6 points as cognitive paradigms in that, they all try to 7 put in relation neurophysiological evidence with 8 superior concepts which, from the bottom up, can be summarized as action goal understanding (assuming 9 neuronal motor resonance), building-up of high level 10 mental constructs like empathy and language 11 12 (assuming cognitive representations that are bodily rooted in the motor and perceptual system) and 13 aesthetic experience (assuming balanced network 14 cooperation involving functionally specialized areas 15 of the brain). Also, all these three theories are quite 16

y1 *LIST OF ACRONYMS AND ABBREVIATIONS:* ANOVA = Analysis Of Variance; EEG = ElectroEncephaloGram; **EMG = Electro**-V2 **MyoGraphy; F = manca???**; HSD = honestly significant difference; MNS = Mirror Neuron System; **MS = manca???**.

recent; they face similar epistemological problems, 17 exemplified by the difficult applicability of the 18 falsification criterion^(5,12,15,18); finally, they are trendy 19 due to the apparent simplicity of the mechanisms they 20 21 postulate. 22 In 2007, pivoting on the concept of empathy, a 23 seminal work⁽⁷⁾ explicitly connected for the first time 24 neuroaesthetics, embodied simulation and MNS. In 25 that occasion two major ingredients where claimed to 26 participate in the build up of the aesthetic experience 27 in front of visual works of art: first, "the relationship between embodied empathetic feelings in the observer 28 29 and the representational content of the works" (sic); second, "the relationship between embodied empa-30 thetic feelings in the observer and the quality of the 31 work in terms of the visible traces of the artist's 32 creative gestures" (sic). While that work "did not 33 suggest that the activation of mirror or canonical 34 neurons was sufficient for esthetic appraisal or for 35 judgments about artworks"(2,7), nevertheless it put 36 embodied simulation at center stage, differentiating 37 between "aesthetic appraisal", "aesthetic attitude", 38 39 "aesthetic experience" (where embodiment should occur) and "aesthetic judgment"^(1,6). 40

In the wake of such claims and in an attempt to 41 uncouple as much as possible cultural and 42 experiential factors from those ones attributed 43 44 directly to the embodiement mechanism, subsequent investigations concerned the case of non-figurative 45 art or of comparable visual works, for which one 46 47 could expect a sharpest evidence for at least the second, supposed, ingredient, that is a motor 48 49 resonance evoked in the beholder by the traces left by the artist in her creative act (affecting, for instance, 50 brushworks style, patterns or trajectories). In this line 51 52 of research, here are recalled three significant researches that deal with the differential experience 53 54 that could arise during the observation of both true 55 hand-made visual works and some not human reproductions of them. The first one⁽²²⁾, in the 56 57 following referred as the "reference work", focused on artworks of the artist Lucio Fontana, compared 58 59 with some simplified computer-graphics replicas; in this case up to 14 volunteers, exposed to random 60 sequences of originals and simplified copies, were 61 62 recorded by means of EEG, EMG and an ad-hoc questionnaire; following ANOVA calculations 63

showed significant correlation between originality of 64 the image, activation of motor related area of the 65 brain and subjective perception of "amount of 66 movement" inside the image and its "artistic nature". 67 The second investigation⁽⁴⁾ focused on robot-made 68 abstract drawings and their hand-made counterparts 69 made by a sculptor and by a computer-graphics artist; 70 differentiating from images with salient kinematic 71 72 cues or not (based on the presence of geometrical shapes that are hard to naturally reproduce by hand, 73 74 as the case of complete circles), ANOVA calculations 75 concerned the answers of 12 volunteers about the guessed human or robotic nature of the sketcher; in 76 77 this case the correct recognition of the maker type was found to be highly correlated to the absence of 78 geometric salient cues but, even if at a minor extent, 79 also to the presence of subtle kinematics cues (such 80 as smudging in the sketch). In a similar fashion, but 81 in a slightly different context, the third investigation 82 here recalled⁽¹⁶⁾ focused on the recognition of hand-83 written and typed alphabet letters; in that case, 84 measurements on 11 volunteers clearly showed 85 correlation between changes in the MEG oscillatory 86 activity originating from the motor cortex and 87 88 changes in the nature of the displayed letters. All these three investigations appear to show an 89 enhanced activation of motor related areas of the 90 brain when the observer is exposed to clearly hand-91 made works and they seem not to rule out a possible 92

role for the embodiement mechanism in the aesthetic 93 experience. Nevertheless, till now no satisfactory and 94 uncontroversial explanation has been advanced for 95 the operating details of this mechanism. Even worst, 96 97 a quite lively scientific community disagrees also with some core claims of the embodied simulation 98 and MNS theories themselves^(3,10,14,16). 99 On the basis of experimental, conceptual and 100 epistemological issues, the author endorses this 101 criticism and he highlights two major problems with 102 embodiement theories. First, low level neural mir-103 roring and high level cognitive experiences belong to 104

different domains that can relate to each other only105through matching functions that till now no one has106been able to detail. Second, even if many of the107pertinent claims seem to rely on experimental results,108they appear to fail or at least ignore falsification109methods (even when in weak form).110

111 (For a better comprehension of the problem the reader can be see a similar experiment⁽¹⁷⁾ where "The Ado-112 ration of the Mystic Lamb" of Jan van Eyck and 113 114 "Concetto spaziale" of Lucio Fontana are compared 115 on the basis of the theory of mirror neurons, the first, 116 on the basis of simple neuronal plasticity, the second). In order to submit the hypothesis of the embodied 117 118 aesthetic experience to a falsification test, the author 119 performed an independent verification of the results 120 obtained in the reference work. Pivot of this current 121 investigation is the possibility that the cultural and 122 experiential attitude of the beholder could overwhelm 123 any motor attributable mechanism in her aesthetic experience (rationale: if these were the case, the 124 125 claim of the embodied simulation applied to art 126 would have been yet to be proven).

127 In this new research only the questionnaire survey 128 was considered, although in a slightly modified 129 version, while special care was taken of the selection 130 of a wider population of volunteers, differentiated by 131 their personal background. Instead, no EEG or EMG 132 recordings were taken, due to their squareness to the 133 scope of this work and the above cited controversial 134 relationship between such measurements and the true 135 role of mirroring mechanisms. This experiment takes for example in its methods the seminal works of 136 137 Parma's Group to allow us to falsify them really; 138 otherwise the work would have expressed conclu-139 sions but not the falsification of previous ones'. As a 140 major result, this work clearly shows the importance 141 of the cultural and experiential attitude of the 142 beholder in hiding any supposed effect due to 143 empathetic motor resonance with the artwork and, 144 through it, with the creative act of the artist.

145 146

147 **METHODS** 148

149 ■ PARTICIPANTS. Two groups of volunteers participated in the experiment. The first one included 150 ninety-six healthy subjects, equally represented by 151 152 gender and of comparable age (mean: 18.03 years), 153 coming from different high schools according to an 154 equal partition between art students, building sur-155 veyor students, mechanical students and students of 156 professional institutes, the latter ones (vocational students) without specific skills in art and design; in 157 158 detail: 24 students, twelve female and twelve male, 159 for each school type. The second group included four-160 teen healthy subjects (seven females and seven males, mean age: 28.28 years) recruited with no explicit care 161

to their cultural background but in analogy with the 162 protocol followed in the reference work. 163

The study was ethically approved by the manage-164 ments/ethical committees of all the high schools 165 involved and of the University of Udine; all experi-166 ments were performed in accordance with relevant 167 guidelines and regulations; informed consent was 168 obtained from all participants; all the collected data 169 (questionnaires, recordings, images) was processed 170 171 and stored in a strictly anonymous way, irreversibly 172 hiding the identity of the involved subjects.

173 ■ **PROCEDURE.** Apart some improvements, high-174 lighted in the following, the experimental protocol 175 was a strict replica of the one exhaustively described 176 in the reference work. Accordingly, participants were 177 exposed to random sequences of abstract images displayed on a 60 cm far, 17-inch size screen. Each 178 image (stimulus) was shown for 1000 ms preceded by 179 180 a start marker (a sub-sequence consisting of a 4500. 181 4000 or 5500 ms lasting black background, anticipating a 450, 500 or 550 ms lasting attention 182 symbol) and it was followed by a 500 ms lasting stop 183 184 marker. After each stimulus was shown, participants 185 were asked to score it according to: "Q1 familiarity" with the image (semantic differential range: [0,10]); 186 "Q2 aesthetic appraisal" of the image (range: 187 188 [-10,10]); "Q3 amount of movement" perceived in the image (range: [0,10]); "Q4 artistic nature" of the 189 stimulus (that is, is the image a true artwork? - range: 190 191 ["no","yes"]). In addition to what was done in the reference work, an open-answer question was added 192 193 to let the subjects freely express their impressions, 194 sensations and comments. In the reference work the images were selected so as to represent two classes of 195 stimulus. The first class (original stimulus) was fea-196 tured by 3 black and white, high resolution digitized 197 images of different artworks of Lucio Fontana (one, 198 two and three physical cuts on light color canvasses); 199 the second one (control stimulus) was featured by 3 200 201 black and white, high resolution digitized images of graphically modified and simplified versions of the 202 original artworks (an example of a paired stimuli 203 concept is depicted in Figure 1). These stimuli (each 204 one displayed 15 times in a randomly shuffled man-205 206 ner) were adopted also in this work but here they were integrated by additional pairs of original 207 paintings of abstract art and control counterparts. The 208 new entries where excerpts from: "Convergence" by 209 Jackson Pollock (1912-1956), coupled with "Exca-210 vation" by Willem De Kooning (1904-1997) (pairing 211 criterion: paintings that are similar in colors and 212

F1 **Figure 1.** Original and control stimulus. Example of stimuli pair for a Fontana's artwork. *On the left*: original stimulus; *on the right*: smoothed control stimulus.

shapes but made impulsively the first one and quietly
the second one); "Number 11" by Jackson Pollock,
coupled with a false Pollock (pairing criterion:
similar paintings made in different techniques);
"Number 14" by Jackson Pollock, coupled with an
inkblot pattern by Hermann Rorschach (1884-1992)

219 (pairing criterion: dominance of white and black).

220 This choice of artworks (Fontana's and Pollock's) 221 was driven by their recurrent pairing within abstract 222 art research and critique, their supposed connection 223 to empathy as stated in one of the seminal works on 224 neuroaesthetics⁽⁸⁾ and, as for Pollock, their ability to 225 convey structured information like fractal patterns⁽¹¹⁾. 226 The actual stimuli for the Fontana's case are depicted

- 227 in Figure 1 of the reference work; those one for the
- 228 Pollock's case are shown in Figure 2 of this work.

STATISTICAL ANALYSIS. After a preliminary tuning 229 230 analysis, all differential semantic scores were normalized to boolean values, according to the following 231 mappings: for "Q1 familiarity", logical true values 232 233 were set on scores greater than or equal to 3, as in the 234 reference work; for "Q2 aesthetic appraisal", true 235 values were set on scores greater than 0; for "Q3 amount of movement", true values were set on scores 236 greater than or equal to 3 (answers to "Q4 artistic 237 238 nature" were already gathered in boolean form). A 239 brief summary of the collected data is given in Table 240 1 as well as in Figure 3.

Answers to the "Q1 familiarity" question were studied first, also due to the focus given to them in the reference work. While in the present case about 40% of the people declared to be somewhat familiar with the shown artworks, open form remarks provided by the respondents highlighted that, when asserted, this acquaintance was often far from any direct artistic discourse. For instance, Fontana's cuts sometimes 248 evoked female silhouettes (especially in male, aged 249 eighteen, students), blades of grass or simple just 250 another sample of broken fabric: in other words, not 251 really art but somewhat one can experience almost 252 every day. Due to its poor selectivity within the scope 253 of this research, familiarity was thus discharged as a 254 not significant category; instead, in this work the 255 influence of the subjective cultural backgrounds was 256 studied through the lens of the different school 257 specializations. 258

Accordingly, participants were sorted to form a 259 category (people) explicated by six groups, namely: 260 art students, mechanical students, surveyor students, 261 vocational students (from professional schools), 262 aggregate students (that is, all 96 students) and finally 263 the control, undifferentiated group (14 subjects, aged 264 28 on average). A second, category (target) was de-265 fined according to the nature of the artworks 266 displayed, resulting in four groups: Fontana's original 267 stimuli, synthetic replicas of Fontana's original 268 (control stimuli), Pollock's original stimuli and 269 counterparts to Pollock's originals (control stimuli). 270 A last category (topic) was defined according to 271 which question was asked to the participants, re-272 sulting in three groups ("Q2 aesthetic appraisal", "Q3 273 amount of movement" and "Q4 artistic nature"). Our 274 analysis focused on the role and interactions of these 275 three categories when coupled in a pair-wise fashion 276 as in people versus target and in people versus topic. 277 The statistical analysis consisted in a batch of two-278 way ANOVA's ($p \le 0.05$), each one accompanied by 279 pertinent post-hoc Tukey HSD tests (here preferred to 280 the less conservative Newman-Keuls comparisons 281 used in the reference work). 282

207

F3 Figure 2. Stimuli around Pol-F4 lock's artworks. Upper row: F5 original stimuli; from the left to the right: details from "Conver-F6 F7 gence", "Number 11", "Number F8 14". Lower row. control stimuli; F9 from the left to the right: details F10 from "Excavation" by Willem F11 De Kooning, false Pollock, F12 inkblot pattern by Hermann F13 Rorschach.

283 \Box RESULTS

284

285 GENERALITY. For the reader's convenience, this 286 work details only a selection of the obtained results: 287 first, outcomes regarding the aggregate students and 288 the control group are not shown due to their strongly 289 uncorrelated response against the various questions 290 and due to the low nvalue for the control group (here 291 introduced for an assessment of this aspect as ad-292 dressed in the reference work); second, when people 293 versus target is of concern, Tukey test results are 294 reported only when significant variation was obtained 295 for the same people group on different target groups 296 (that is, people intragroup results are not shown in the 297 following); finally, only significant variations (p \leq 298 0.05) are reported; anyway, almost no pvalue was 299 found within the neighboring interval [0.05, 0.10].

questions. The order of the questions was not 572 573 randomized, but they were the criteria used in the paper that we are challenging. We used change 574 575 position of questions only in the last test (14 participants), to have a correct support for our analysis. 576 Our results from tests T1 and T4 suggest that art 577 578 students are far more sensitive in decreasing their perception of movement when exposed to the control 579 580 images instead of the original artworks; conversely, mechanical students show an opposite behavior (at 581 least when Fontana's subjects are of concern); finally, 582 583 building surveyors and vocational students seem to 584 be quite unconcerned about the nature of the stimuli. This differential outcome, not detectable in the 585 reference work, strongly fades away any apparent 586 effect due to an universal motor resonance between 587 588 drama expression inside artworks and motor realization in the beholder. Not only at high cognitive 589

levels this claimed resonance appears to be totally 590 undetectable (but still not denied) but it seems that 591 determinant focus should be given to the cultural 592 background of the observer instead. Indeed, art 593 students are specifically educated through theory and 594 exercise in both the recognition and execution (or 595 reproduction) of artworks details and, accordingly, 596 they own a repertoire of techniques that they are also 597 used to embody in form of physical actions and 598 movements. When exposed to original, impetuously 599 made artworks as in the Fontana's or Pollock's case, 600 art students can smartly exploit even the finest details 601 to reverse engineering the artist's creative act; 602 instead, when exposed to more aseptic images, as in 603 the control stimuli case, the same subjects cannot 604 605 take advantage of landmarks so useful for the expert perception of impressed movements. In a different 606 way, mechanical students are educated to deal with 607

608 geometrically exact and clean trajectories as well as to plan and program the operation of devices like 609 Computer Numerical Control routers. For these 610 students, those subtle details so useful to art students 611 612 are instead likely to be treated as disturbing noise that 613 could obfuscate expected motion patterns inside the 614 image. Among other factors, similar cues could rea-615 sonably play a significant role in the recorded 616 differential response: not denied in the reference work, here the author claims their observable pre-617 618 ponderance over a somewhat vague, asserted motor 619 resonance between artist and beholder. Furthermore, 620 it should be recalled that also artists get educated through theory and exercise, as pointed out by 621 622 common sense and pioneering neurophysiological 623 researches⁽¹¹⁾. Coherently, if universal mirroring mech-624 anisms are accepted for the comprehension of subtle 625 movements, as impressed in artworks, one should 626 explain how they could keep on operating between 627 eventually diverging neural systems, on the learning 628 artist and on the (not educated) beholder side.

629 Results from tests T2 and T5 suggest that, when 630 dealing with the artistic appraisal, the transition from 631 the original artworks to the control stimuli induces a 632 coherent variation in the response of all groups 633 (especially the art students one) except the building 634 surveyors students group. In Italy, building surveyors 635 are usually educated to the handling of essential 636 architectural or technical drawings free of smudges 637 and of not geometric decorations. Anyway, in this 638 case the volatility of the concept dealt with, the small 639 amount of variation and the (yet small) size of the 640 statistical population suggest even greater caution in 641 interpreting data.

642 Results from tests T3 and T6 tests suggest that, when 643 dealing with the artistic nature of the displayed 644 subject, original artworks are better appreciated by all 645 groups, except for the art and vocational students in 646 the Fontana's case. This differential outcome seems 647 to unearth two complementary implications of the 648 subjective cultural background. On one side, personal 649 experience is likely to affect personal sensitivity to 650 expressions of art; on the other one, education could 651 interfere with the understanding itself of the "artistic 652 nature" concept, eventually triggering different 653 mental processes in front of the posed question. 654 While the latter possibility here is only guessed, it 655 seems to be corroborated by the fact that openform 656 remarks given by the participants suggest a strong 657 variability in the perceived (artistic or physical) 658 subjects of the displayed images.

Results from tests T7 and T9 suggest that the 659 perception of movement and the aesthetic appraisal 660 are more correlated for art students than for the other 661 groups (eventually with the exception of the building 662 surveyors students in front of Fontana's originals 663 artworks). 664

Recalling the considerations just exposed for the 665 outcomes of tests T1, T2, T4 and T5, one can hardly 666 express this correlation in terms of mutual 667 dependency; rather, it seems that, independently, art 668 students show improved attitudes in both movement 669 recognition and aesthetic appraisal. 670

Tests T8 and T10 suggest similar correlation between671perception of movements and recognition of the artistic672nature of the subject displayed. Again, the answers of673the art students show more coherent variations.674As already mentioned, the aggregate students group675

and the control group, when compared, have 676 highlighted a variable, different behavior depending on 677 the question that, from time to time, was asked. On one 678 side, the aggregate group synthesizes and averages 679 different scholar backgrounds that have proved to 680 matter; on the other side, the control group, in the 681 image and likeness of that one studied in the reference 682 work, appears to be too much small for any robust sta-683 tistical investigation. This outcome suggests that fur-684 ther investigation on the topic could take effective ad-685 vantage by larger statistical populations, carefully 686 categorized in order to better control cultural, emotio-687 nal and other subjective conditions. Studies suggest, 688 judging by the position and functionality of the pre-689 motor cortex investigated with respect to the rest of 690 the cerebral cortex, that, if they exist, mirror neurons 691 could help in the reproduction of works of art 692 depending on the experience of each one rather than 693 in the judgment of the same except in the case in 694 which details such as "the brushstroke" or other 695 similar details of a particular artist are taken. It should 696 be noted, however, that in this case the normal 697 function of the premotor cortex and of the F5 area 698 would be indistinguishable from what passed into 699 literature before the phantom discovery of this new 700 class of neurons(13). 701

In this case, thinking about an inhibition of the action702of the premotor cortex could be sufficient to explain703the activation of the areas of the premotor cortex704called mirrors both in the precedent study or in the705more or less competent evaluation of artworks.706

707 708

$709 \square$ **CONCLUSIONS**

710

711 The results obtained throughout this research shed a 712 different light on some claims and results exposed in 713 previous studies about the embodied simulation role 714 in neuroaesthetics. While no neurophysiological 715 measurements have been taken here due to their 716 problematic linkage to the high level perception of 717 impressed movements and the aesthetic experience, 718 attention was paid to isolate critical factors like 719 personal experiences and cultural backgrounds. On 720 this basis it was found that subjective education, in 721 the broadest sense, deeply modulates our individual 722 mental disposition in front of works of visual art, 723 even subverting what one would expect from the 724 application within art experience of debated para-725 digms like the somatomotor resonance. Strictly 726 speaking, while a possible role for these paradigms 727 cannot be excluded yet, this work suggests the need 728 for finer experimental protocols where affecting 729 factors, like personal culture and actual mood, are 730 better explained and studied over wider statistical 731 populations.

- 732 Until today and in the absence of further evidence,
- 733 what one can reasonably say is that if the artistic
- 734 experience is a matter of resonance then this resonance
- 735 should be of cultural, and not motor, nature.
