ABSTRACT

Background: Observational studies comparing ticagrelor and prasugrel in this setting have yielded contradictory results but often do not consider differential censoring (e.g., for treatment switching or insurance disenrollment) or confounding by time dependent factors.

Objective: Our objective was to conduct a comparative effectiveness and safety analysis of ticagrelor and prasugrel in patients who underwent PCI after being hospitalized for an acute coronary syndrome.

Methods: This study used the Optum's de-identified Clinformatics® Data Mart Database and included patients aged 18 years or older with an index hospital admission between May 2012 and December 2015, a diagnosis of acute coronary syndrome managed with percutaneous coronary intervention, and treatment with either ticagrelor or prasugrel. The primary composite outcome was defined as the first occurrence all-cause death, myocardial infarction, or ischemic stroke. The secondary composite outcome included the first occurrence of gastrointestinal bleed, intracranial hemorrhage, or other major bleeds requiring hospitalization. Weighted Cox proportional hazard models and robust variance estimation were implemented to adjust for baseline comorbidities, time-varying exposure, time-dependent confounders, and differential censoring.

Results: Included in the analysis were 2,559 patients initiated on ticagrelor and 4,456 patients initiated on prasugrel following PCI. Patients initiated on ticagrelor were 10% more likely to have eligibility disenrollment (Ticagrelor: 57%, Prasugrel: 47%, $P < .01$) and 7 percentage-points more likely to switch medication (Ticagrelor: 35%, Prasugrel:

1
2
3 28%, $P < .01$). After adjusting for multiple factors, including time-varying exposure, and
4
5 censoring imbalance, ticagrelor use was associated with a higher risk of all-cause death,
6
7 MI, or stroke when compared to prasugrel (HR: 1.33; 95%CI: 1.04-1.68). Similarly,
8
9 ticagrelor was associated with a higher risk in bleeding events when compared with
10
11 prasugrel (HR: 1.61; 95%CI: 1.19-2.17).
12
13

14 **Conclusion:** When compared with ticagrelor, prasugrel use following PCI for ACS
15
16 was associated with a lower risk of death, MI, or stroke. as well as with a reduced risk
17
18 of major bleeding.

INTRODUCTION

Dual antiplatelet therapy (DAPT), with aspirin and a P2Y₁₂ agent, reduces the risk of subsequent ischemic events and is a mainstay in treatment in patients with acute coronary syndrome undergoing percutaneous coronary intervention (PCI).¹⁻³ In the TRITON-TIMI-38 trial, less ischemia but more bleeding occurred in the prasugrel than clopidogrel group. In contrast, in the PLATO trial comparing ticagrelor and clopidogrel, both agents reduce CV death, MI, and stroke by the same magnitude and both agent increase non-CABG TIMI major bleeding by the same magnitude.. The Intracoronary Stenting and Antithrombotic Regimen: Rapid Early Action for Coronary Treatment (ISAR-REACT) 5 trial, a randomized, open-label study evaluating ticagrelor versus prasugrel in patients with acute coronary syndrome (ACS) in whom an invasive evaluation was planned, found that patients receiving ticagrelor had a significantly higher incidence of death, myocardial infarction, or stroke but similar rates of major bleeding over 1 year of follow up.⁴ Observational studies comparing ticagrelor and prasugrel in this setting have yielded contradictory results,⁵⁻⁹ but have not taken into account the possibility of differential censoring (e.g., for treatment switching or insurance disenrollment), nor of confounding by time dependent factors, both of which can affect study outcomes.¹⁰

We conducted a comparative effectiveness and safety analysis of ticagrelor and prasugrel in patients who underwent PCI for an acute coronary syndrome. We implemented marginal structural models and employed inverse probability censoring weighting to adjust for post-treatment selection bias caused by imbalance in treatment

1
2
3 switching and insurance disenrollment between comparison groups. We hypothesized
4 that after adequate adjustment for confounding and selection bias, a real-world
5 comparative effectiveness and safety study would yield results similar to those observed
6 in the ISAR-REACT 5 trial.

13 14 15 **METHODS**

16 17 **Data Source**

18
19 We utilized Optum's de-identified Clinformatics® Data Mart Database (Optum Inc.,
20 Eden Prairie, MN), a large, nationwide, managed care, administrative claims dataset
21 comprised of longitudinal medical billing information in the United States. Insurance
22 claims for all pharmacy, inpatient, and outpatient services are included for the enrolled
23 13 million yearly-members.¹¹ This project was designated as “research not involving
24 human subjects” by the University of Rhode Island Institutional Review Board, as all
25 data were de-identified prior to analyses.

34
35
36
37

38 39 **Study Cohort**

40 Patients aged 18 years and older hospitalized between May 2012 and September 2015
41 with a diagnosis of ACS managed with PCI and treated with either prasugrel or
42 ticagrelor were included. This period was selected to align with the FDA approval of
43 ticagrelor in July 2011, allowing for delayed acceptance into insurance formularies.
44 ACS was identified using the International Classification of Diseases, Ninth Revision,
45 Clinical Modification (ICD-9-CM) codes (ICD-9-CM: *410.x [acute myocardial*
46 *infarction] and 411.x[other acute and subacute forms of ischemic heart disease]*).¹²

51
52
53
54
55
56
57
58
59
60

1
2
3 PCI was identified by ICD-9-CM and Current Procedural Terminology (CPT-4)
4 procedure codes (*ICD-9-CM: 00.66, 36.01, 36.02, 36.05, 36.06, 36.07, and 36.09;*
5
6
7
8 *CPT-4: 92980, 92981, 92982, 92984, 92920, 92921, 92924, 92925, 92928, 92929,*
9
10 *92933, 92934, 92937, 92938, 92941, 92943, 92944, 92973*) occurring during the index
11 hospitalization.⁹ At least one pharmacy prescription claim for either ticagrelor or
12 prasugrel within 14 days of discharge was required.⁹ Patients with prior dispensing of
13 ticagrelor or prasugrel, history of stroke, fibrinolytic therapy within one day of
14 hospitalization, prior dispensing of oral anticoagulants, or dispensing of strong
15 Cytochrome P-450 3A inhibitors/inducers identified during the baseline period were
16 excluded.^{4,13} Additionally, patients with claims for more than one or any non-study
17 antiplatelet agents during the 14-day initiation window were excluded.

28 **Outcomes Assessments**

29
30 The primary composite outcome was defined as the first occurrence of one of any of the
31 following: all-cause death, myocardial infarction, or ischemic stroke. All-cause death
32 was identified utilizing the Social Security Administration's Death Master File. Since
33 only the month and year of death were included in these data, a day of death was
34 randomly assigned within each month for death events occurring after hospital
35 discharge. Myocardial infarction and stroke were identified by ICD-9-CM diagnosis
36 codes (*MI: 410-412 [excluding 410.x2]; Stroke: 430-434, 436*) occurring during
37 hospitalization.^{14,15} The secondary composite outcome was defined as the first
38 occurrence of one of the following: gastrointestinal bleed, intracranial hemorrhage, or
39 other major bleeding requiring hospitalization.¹⁶ Patients were followed from index

3 hospitalization discharge until primary endpoint occurrence, loss of insurance eligibility,
4
5 or for 365 days; whichever occurred first.
6
7
8
9

10 **Censoring Assessment**

11
12 Censoring events included insurance disenrollment, treatment switching, treatment
13
14 discontinuation, or end of data window on September 30, 2015. Insurance disenrollment
15
16 was identified by eligibility end or a gap of 30 days or more in insurance enrollment.
17
18 Treatment switching was classified by the discontinuation of the initially prescribed
19
20 antiplatelet therapy and initiation of an alternative medication, as identified via
21
22 prescription pharmacy claims. Patients who switched to ticagrelor or prasugrel were not
23
24 censored at switch date consistent with the time-varying exposure analysis described
25
26 below. However, patients that switched to clopidogrel were censored. Therapy
27
28 discontinuation was defined as a greater than 45 days of gap between prescription end
29
30 of supply and refill. Since treatment duration of 6 to 12 months is recommended in this
31
32 clinical setting, gaps greater than 45 days occurring after 6-months of follow-up were
33
34 not evaluated.¹⁷
35

2
3 pump inhibitor, or diabetes medication use. These are time-fixed potential confounding
4 factors specified by previous studies.^{17,18} A time variable was generated for each
5 person-time interval when the exposure was assessed. Angina, prior interval treatment,
6 and interval time were included as time-dependent covariates assessed during each
7 month of follow-up.
8
9
10
11
12
13

14 15 16 17 **Statistical Analysis**

18
19 Categorical variables are presented as frequencies (%) and compared using chi-square
20 tests. Continuous variables are presented as mean \pm standard deviation (SD) and were
21 compared between two drug groups using student t-test. Marginal-structural models
22 (MSM) were fit using inverse probability weights (IPW) to adjust for confounding with
23 time-dependent variables.^{19,20} Possible violations of positivity and misspecification
24 were assessed in all models by inspecting the estimated stabilized weight distribution to
25 check for extreme values and to confirm that the mean was approximately equal to
26 one.²¹ The proportional hazards assumption was assessed graphically by examining the
27 IPW log cumulative hazard function estimates to ensure that the hazard curves remained
28 parallel over time.

44 45 *Time-Dependent Exposure (TD)*

46
47 Weighted Cox proportional hazard models and robust variance estimation were
48 implemented to adjust for baseline and time-dependent confounders.^{22,23} The robust
49 variance estimator was required to account for the additional variability introduced by
50 estimating the IPWs. The time-dependent weights were constructed to adjust for fixed
51
52
53
54
55
56
57
58
59

1
2
3 baseline and time-varying confounding factors. Exposure was assessed at monthly
4 intervals of prescription dispensing for each patient following initial assignment and
5 continued until loss of eligibility, switching to clopidogrel, treatment discontinuation,
6 event occurrence, or study end. Weights for each person-time interval were created by
7 the ratio of the probability that each patient received their observed treatment
8 conditional on time, and past treatment divided by the probability that the patient
9 received the observed treatment given time, past treatment, baseline covariates, and
10 prognostic (time-dependent) factors.²⁴

13
14
15
16
17
18
19
20
21
22
23

24 *Censoring Weighting (CW)*

25
26 The censor-weighting accounted for possible informative censoring (e.g., insurance
27 disenrollment) due to measured confounding factors. These weights were estimated as
28 the ratio of the probability of remaining enrolled in the insurance program for 12-months
29 following index hospitalization given time of the exposure assessed, prior treatment
30 divided by the conditional probability of remaining enrolled given time, prior treatment,
31 baseline variables, and time-dependent confounding factors.^{24,25} The time-dependent
32 exposure and censoring weights were multiplied together for each person-time interval
33 of follow-up for each patient.

39
40
41
42
43
44
45
46

47 **Sensitivity Analyses**

48 *Intention-To-Treat Analysis (ITT)*

49
50 A conventional ITT analysis was conducted to better enable comparison with the
51 approaches used in previously published observational studies. Patients were censored
52
53
54
55
56
57
58
59
60

1
2
3 if loss of follow-up due to insurance disenrollment but were not censored based on
4 treatment discontinuation, adherence, or switching. The IPWs were derived by a ratio
5 of the marginal probability of exposure and the probability of exposure given baseline
6 covariates.²⁶ The weights were used to create a pseudopopulation in which the measured
7 covariates and treatment assignment were independent of each other. No adjustments
8 were made for time-dependent confounding factors. We hypothesized that not adjusting
9 for dropout or switching imbalances between exposure groups would bias results toward
10 the null.

17
18
19
20
21
22
23

24 *Clopidogrel Naïve Population*

25
26 To determine if clopidogrel exposure during baseline period was associated with the
27 study outcomes, we narrowed the population to antiplatelet-naïve patients by
28 excluding those with clopidogrel exposure during the baseline period. While the
29 ISAR-REACT 5 trial did not exclude patients with a history of clopidogrel use, we
30 hypothesized that the results would be similar for a population that was naïve to
31 P2Y₁₂-antiplatelet therapy.

43 **RESULTS**

44 **Study Population**

45
46 There were 91,682 individuals admitted with an ACS who underwent PCI during the
47 study period. Of these, 71,287 had 6-months of insurance eligibility prior to index
48 hospitalization. After applying the exclusion criteria, there were 2,559 initiated on
49
50

52
53
54
55
56
57
58
59
60

1
2
3 ticagrelor and 4,456 initiated on prasugrel following PCI who were included in this
4
5 analysis (**Figure 1**).
6
7

8
9
10 The ticagrelor group had significantly higher incidences of comorbidities at baseline as
11 compared with those who initiated prasugrel (**Table 1**). The ticagrelor group was older,
12 had higher rates of hypertension, chronic kidney disease, anemia, chronic obstructive
13 pulmonary disease, congestive heart failure, and atrial fibrillation. Patients initiated on
14 ticagrelor were 10% higher on eligibility disenrollment and 7% higher on medication
15 switching (absolute differences in **Table 2**). The ticagrelor group had a 2 percentage-
16 point higher use of clopidogrel during baseline compared to the prasugrel group
17 (absolute differences in **Table 2**). Treatment discontinuation was balanced between
18 groups.

32

33 **Comparative Effectiveness Results**

34
35 In the unadjusted analysis, the composite outcome, death, myocardial infarction, or
36 ischemic stroke, occurred numerically more often in the ticagrelor group (**Table 3**). The
37 rates of gastrointestinal bleeding, intracranial hemorrhage, and other major bleeding
38 requiring hospitalization were also numerically greater in the ticagrelor group, however
39 neither difference in composite endpoint rates was statistically significant. After
40 adjusting for multiple confounding factors, time-varying exposure, and censoring
41 imbalance, ticagrelor was associated with a higher risk of the composite all-cause death,
42 MI, or stroke, when compared to prasugrel (HR: 1.33; 95%CI: 1.04-1.68; p=0.02)
43
44
45
46
47
48
49
50
51
52
53
54 (**Table 4**). Similarly, ticagrelor was also associated with a higher risk of bleeding events
55
56
57
58
59
60

(HR: 1.61; 95%CI: 1.19-2.17; $p<0.01$). Figures 2 and 3 show the survival curves for outcomes in the IPW estimated pseudopopulation.

Sensitivity Analysis Results

Intention-To-Treat Analysis (ITT)

The conventional ITT analysis that did not adjust for the disenrollment or switching imbalance between groups derived estimates in the opposite direction. With the ITT approach, ticagrelor was associated with numerically fewer all-cause death, MI, and stroke events (HR: 0.78; 95%CI: 0.58-1.06; $p=0.11$) and numerically fewer bleeding events (HR: 0.84; 95%CI: 0.58-1.20, $p=0.33$), but these differences were non-significant.

Clopidogrel Naïve Population

Results for the sensitivity analyses that excluded patients dispensed clopidogrel during baseline were similar to those from the ISAR-REACT 5 study population, where prior clopidogrel use was allowed. The TD-CW method for ischemic (HR: 1.28; 95%CI: 0.99-1.66; $p=0.06$) and bleeding (HR: 1.63; 95%CI: 1.19-2.23, $p<0.01$) composite outcomes remained consistent. Similarly, ITT results for the primary composite outcome (HR: 0.81; 95%CI: 0.59-1.11; $p=0.19$) and secondary composite outcome (HR: 1.05; 95%CI: 0.73-1.51; $p=0.79$) were similar in direction although not significantly different.

DISCUSSION

1
2
3
4
5
6
7
8 In this real-world study using a national claims dataset we compared the incidence of
9
10 composite ischemic and bleeding events between hospitalized patients prescribed
11
12 ticagrelor or prasugrel after PCI for an ACS. Two analytic methods were applied. In
13
14 TD-CW analyses with Marginal Structural Models, ticagrelor was associated with a 33%
15
16 increased hazard of all-cause death, MI, or stroke, as well as a 61% greater hazard for
17
18 ICH, GI bleed, or major hemorrhage. However, in traditional ITT analyses there were
19
20 no significant differences in ischemic or bleeding outcomes between treatments.
21
22
23
24
25

26 Our findings from the TD-CW analysis were consistent with the ISAR-REACT 5 trial
27
28 which found that prasugrel was associated with a lower risk of ischemic and bleeding
29
30 events in patients treated for ACS. While treatment guidelines recommend prasugrel or
31
32 ticagrelor equally following PCI, many clinical and non-clinical factors can influence
33
34 treatment selection, potentially explaining the observed imbalances in disenrollment
35
36 and antiplatelet switching.^{17,27} While observational studies can adjust for baseline
37
38 imbalances between groups, post-exposure events are not often evaluated. We
39
40 implemented a time-dependent exposure and censor weighted model to adjust for the
41
42 censoring imbalances identified in Table 2. In order to replicate/mimic findings from
43
44 the RCT, we need to conduct a study in which adherence is similar. To do this, we need
45
46 to account for time-varying confounding and censoring to get an accurate ‘on treatment’
47
48 effect. Thus, we applied methods for time-dependent confounding, drug switching and
49
50 discontinuation to account for differences in adherence/discontinuation between the
51
52
53
54
55
56
57
58
59
60

1
2
3 real-world data and RCT. Accounting for these factors within the observational cohort
4
5 resulted in dropout and treatment switching rates that were similar to the ISAR-REACT
6
7 5 trial. The results from this analysis were in the same direction as the trial results.
8
9

10
11
12 The observational literature regarding outcomes of antiplatelet use have conflicting
13
14 results.^{5-9,18,28} Differences in how study designs address variability in follow-up time,
15
16 inclusion and exclusion criteria, approaches for addressing covariates may lead to
17
18 divergent conclusions. Using a conventional ITT analytic approach that fails to address
19
20 censoring events that are imbalanced between treatment groups, and differential
21
22 censoring can lead to different interpretations of the estimates. Dawwas et al. evaluated
23
24 the comparative effectiveness and safety of ticagrelor versus prasugrel in patients with
25
26 ACS.²⁸ Their results indicated that ticagrelor was associated with a decreased risk of
27
28 recurrent nonfatal CVD events (HR: 0.80, 95%CI: 0.70-0.92), and major bleeding
29
30 events (HR: 0.54, 95%CI: 0.41-0.70). In contrast, some observational studies suggested
31
32 a benefit with prasugrel over ticagrelor. For example, Larmore et al. found that major
33
34 adverse cardiovascular and major bleeding events were lower at 30-days in the
35
36 prasugrel-treated group when compared to the ticagrelor-treated group.²⁹ However,
37
38 most observational studies found no significant difference in the incidence of adverse
39
40 cardiovascular and bleeding events when comparing these agents.⁷⁻¹¹ Our ITT
41
42 sensitivity analysis provided results that were consistent with recent observational
43
44 studies evaluating these agents and that were contrary to the ISAR-REACT 5 trial.
45
46 Ignoring differential post-assignment imbalances between exposure groups produced
47
48 results in the opposite direction. The variability of results in observational studies may
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 be attributed to different study populations, and most likely unaddressed post-treatment
4
5 selection bias as none of these studies assessed or compared medication switching or
6
7 disenrollment rates in comparison groups during study follow-up.
8
9

10
11
12 While there was a statistically significant 2% higher clopidogrel exposure rate in the
13
14 ticagrelor group during the baseline period , narrowing the population to antiplatelet-
15
16 naïve patients by excluding those with prior clopidogrel exposure produced similar
17
18 results with a slight loss in power. This suggests that clopidogrel use at baseline period
19
20 did not impact the estimated treatment effect.
21
22

23
24
25
26 The key difference between the analysis methods lies in adjusting for confounding that
27
28 results in incomplete adherence to the assigned treatment. It has been noted in clinical
29
30 trials that loss to follow-up may be affected by clinical or demographical factors
31
32 occurring after randomization. Our results further confirmed that the imbalance of
33
34 medication switching or insurance disenrollment between exposures could bias the
35
36 results. Adjusting for post-assignment factors can help improve the precision of effect
37
38 estimates. After adjusting for time-varying confounding and treatment in the TD-CW
39
40 analysis, our findings were consistent with the ISAR-REACT 5 trial where the post-
41
42 treatment selection bias was addressed.
43
44
45
46
47
48

49 **LIMITATIONS**

50
51 First, this study is based on claims data and could be biased by unmeasured confounding
52
53 factors (e.g., over-the-counter medications, antiplatelet loading-dose, or other details of
54
55
56
57
58
59
60

1
2
3 inpatient procedures). Second, a substantial number of patients were excluded for not
4
5 having an outpatient dispensing of the study treatment within 14-days of index PCI.
6
7 Subsequent analysis of the 27,049 patients excluded indicated that the majority did not
8
9 have pharmacy dispensings of the study agents. The 14-day window captured >83% of
10
11 the patients with pharmacy dispensing of the study treatments in the database. We
12
13 presume that most of the patients with no dispensings of antiplatelet agents following
14
15 PCI were treated and recorded using a different payment system. Increasing this window
16
17 to 30 and 90 days did not greatly improve the number of patients identified. However,
18
19 these effects are thought to be non-differential as we are comparing two drugs from the
20
21 same drug class. Third sub-codes differentiating between types of myocardial events
22
23 such as STEMI or NSTEMI were not reliably utilized in the data to differentiate as
24
25 outcomes. Fourth, our results pertain to patients enrolled in a managed care plan and
26
27 may not be generalizable to other populations. Additionally, the death file included
28
29 within this dataset is the Social Security Administration Death Master file. Since 2013
30
31 it was no longer mandatory for states to report death events to the Social Security
32
33 Administration. As such, death events are expected to be non-differentially
34
35 underreported.³⁰ Lastly, there are several key assumptions that must be made to obtain
36
37 correct causal inferences from the time-varying approaches. We assumed that the
38
39 measured covariates, including baseline and time-varying factors, were sufficient to
40
41 adjust for both confounding and post-treatment selection bias. This assumption is not
42
43 testable in retrospective observational studies; however, we relied on comprehensive
44
45 literature review and clinical expertise to bolster this assumption. While many of the
46
47 covariates were selected to mimic previous clinical trials, information regarding
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 gastrointestinal disorders or abnormalities may be factors of interest for future studies.
4
5 We also assumed that the models implemented were suitably specified, including the
6
7 MSM comparing average treatment effects conditional on time-varying exposure,
8
9 baseline covariates, and time-varying confounders. While these assumptions are not
10
11 testable, we fit the same covariates in all models to make these results comparable.
12
13
14
15
16

17 **CONCLUSION**

18
19 After adjusting for confounding factors, time-varying exposure, and censoring
20
21 imbalance using marginal structural models with TD-CW, results from our
22
23 observational data mirrored those from a contemporary randomized controlled trial
24
25 asking the same question; application of such statistical methods may augment future
26
27 comparative effectiveness and safety analyses using observational data.

Table 2. Censoring Frequencies by Initial Exposure

Censoring Criterion	Ticagrelor (%)		Prasugrel (%)		P Value
	n =	2,639	n =	4,566	
Days of follow-up					
Mean (\pm SD)	278	(\pm 113)	294	(\pm 109)	
Median (IQR)	365	(190-365)	365	(231-365)	
Insurance Disenrollment During Follow-up	1493	(57)	2139	(47)	<0.01
Medication Switch	931	(35)	1278	(28)	<0.01
Switch to Clopidogrel	815	(88)	1273	(100)	
Treatment Discontinuation	230	(9)	439	(10)	0.22

Table 3. Primary and Secondary Composite Outcome Frequencies by Initial Exposure.
(Unadjusted)

Outcomes	Ticagrelor (%) n = 2,639		Prasugrel (%) n = 4,566		P value
Primary Outcomes					
All-cause Death	33	(1.3)	60	(1.3)	0.82
Myocardial Infarction	109	(4.1)	150	(3.3)	0.06
Stroke	29	(1.1)	24	(0.5)	<0.01
Death, MI, Stroke	119	(4.5)	172	(3.8)	0.12
Rate per 100 person-years	7.1 per 100 person-years		5.3 per 100 person-years		
Secondary Outcomes					
Gastrointestinal Bleed	63	(2.4)	84	(1.8)	0.11
Other Major Bleed	29	(1.1)	41	(0.9)	0.40
Intracranial Hemorrhage	11	(0.4)	17	(0.4)	0.77
Bleeding Outcomes	72	(2.7)	98	(2.1)	0.12
Rate per 100 person-years	4.7 per 100 person-years		3.3 per 100 person-years		

Table 4. Adjusted Hazard Ratios for Ischemic and Bleeding Events by Analysis Methods

Time-Dependent Censor-Weighted (TD-CW)	HR	95% CI	P
All-cause death, MI, Stroke	1.33	(1.04 - 1.69)	0.02
ICH, GI Bleed, Major Hemorrhage	1.61	(1.19 - 2.17)	<0.01
Intention-to-Treat (ITT)			
All-cause death, MI, Stroke	0.78	(0.58 - 1.06)	0.11
ICH, GI Bleed, Major Hemorrhage	0.84	(0.58 - 1.20)	0.33
Clopidogrel-Naive TD-CW			
All-cause death, MI, Stroke	1.28	(0.99 - 1.66)	0.06
ICH, GI Bleed, Major Hemorrhage	1.63	(1.19 - 2.23)	<0.01
Clopidogrel-Naive ITT			
All-cause death, MI, Stroke	0.81	(0.59 - 1.11)	0.19
ICH, GI Bleed, Major Hemorrhage	1.05	(0.73 - 1.51)	0.79

Note: Myocardial infarction (MI), intracranial hemorrhage (ICH), gastrointestinal bleed (GI bleed)

For Peer Review

05-Jan-2021

Dear Dr Wen:

Manuscript ID 12-20-0746 entitled "Comparative Effectiveness and Safety of Prasugrel versus Ticagrelor following Percutaneous Coronary Intervention: A Real-World Data Study" which you submitted to Pharmacotherapy, has been reviewed. The comments of the reviewers are attached to this letter.

The reviewers have concerns with your paper, and major revisions would be needed to make it acceptable. Therefore, if you choose to make such changes to your paper and resubmit it, you must respond to the reviewers' comments and revise your manuscript accordingly. Your paper may be acceptable for publication provided you can satisfactorily respond to the reviewers' comments.

Please be mindful of word and reference counts when preparing your revision. You should refer to the author instructions for more information regarding word and citation limits.

Wiley Editing Services Available to All Authors

Should you be interested, Wiley Editing Services offers expert help with manuscript, language, and format editing, along with other article preparation services. You can learn more about this service option at https://urldefense.proofpoint.com/v2/url?u=http-3A_www.wileyauthors.com_eeo_preparation&d=DwlFaQ&c=dWz0sRZOjEnYSN4E4J0dug&r=132BPCjAOTejTEebG8o5vFDgJj9BGfyfjtxESqsz3yc&m=_knkB6GLMGH6Im-nMxWLsELuOsr_U9fK5XtkzoAnTkk&s=CPOjnlqCjxgcqx7wIVUzH-BZo9ZtEiNkm7to5JQtD3Q&e= . You can also check out Wiley's collection of free article preparation resources for general guidance about writing and preparing your manuscript at https://urldefense.proofpoint.com/v2/url?u=http-3A_www.wileyauthors.com_eeo_prepresources&d=DwlFaQ&c=dWz0sRZOjEnYSN4E4J0dug&r=132BPCjAOTejTEebG8o5vFDgJj9BGfyfjtxESqsz3yc&m=_knkB6GLMGH6Im-nMxWLsELuOsr_U9fK5XtkzoAnTkk&s=7h3hf-8FNVGFKo0ZsLsJ_o_iSlyEZ3M2VyNLUvFKN4c&e= .

When submitting your revised manuscript, please upload a Word file that includes a copy of the reviewers' comments and your responses to these comments (highlighted). Please name this file "Response to Comments" and upload it as a "Supplementary" file. You can use this file to document any changes you make to the original manuscript. In order to expedite the processing of the revised manuscript, please be as specific as possible in your response to the reviewers' comments.

You will be unable to make your revisions on the originally submitted version of the manuscript. Instead, revise your manuscript using a word processing program and save it on your computer.

To submit your revised manuscript, log into https://urldefense.proofpoint.com/v2/url?u=http-3A_mc.manuscriptcentral.com_pharmacotherapy&d=DwlFaQ&c=dWz0sRZOjEnYSN4E4J0dug&r=132BPCjAOTejTEebG8o5vFDgJj9BGfyfjtxESqsz3yc&m=_knkB6GLMGH6Im-

4 [y7WIsVyduR3Uto30WM5D4g3cAU&e=](https://doi.org/10.1093/ptp/ptaa000) and enter your Author Center, where you will find your
5 manuscript title listed under "Manuscripts with Decisions." Under "Actions," click on "Create a
6 Revision." Your manuscript number has been appended to denote a revision.
7

8
9 Once the revised manuscript is prepared, you can upload it and submit it through your Author
10 Center.
11

12 I would very much appreciate it if you could upload your revision by **06-Mar-2021**. If it is not
13 possible for you to submit your revision in a reasonable amount of time (i.e., within 4 months)
14 we may have to consider your paper as a new submission.
15

16
17 Once again, thank you for submitting your manuscript to Pharmacotherapy and I look forward to
18 receiving your revision.
19

20
21 Cordially,
22

23 James Tisdale, PharmD
24 Scientific Editor, Pharmacotherapy
25 jtisdale@purdue.edu
26
27

28
29 **Response: We sincerely appreciate the reviewer's constructive comments and editor's**
30 **consideration. We will address all comments and resubmit the revised manuscript and**
31 **point-to-point responses.**

33

34 Reviewer(s)' Comments to Author:
35 Reviewer: 1
36

37 Comments to the Author

38 This manuscript is a real-world comparative effectiveness study of prasugrel and ticagrelor for
39 ACS with PCI.
40

41 1. Abstract: Please include a brief Background section.
42

43 **Response: Added a background section to abstract**
44

45
46 2. Page 8: Methods, Covariate Assessment - why wasn't STEMI, NSTEMI or unstable angina
47 NOT included in the analysis? It is a predictor of outcome. If you were not able to discern from
48 the database, describe in the limitations.
49

50 **Response: Sub-codes differentiating between types of myocardial events such as STEMI**
51 **or NSTEMI are not reliably utilized to differentiate as outcomes.¹**
52
53

54 3. Limitations Page 16: Exclusion Criteria/Figure 1: I calculated that 38% of patients in the
55 database were excluded for lack of 14-day dispensing which is capturing 72% not 83%. Please
56 reconcile.
57
58

1
2
3 **Response:** Updated the language in the limitations section to make clearer. The 14-day
4 window identified 83% of the patients within the database that had a pharmacy
5 dispensing for the study treatment following PCI. During post-hoc analysis of the 27,049
6 patients excluded, only 10% had prescription dispensing for study agents at anytime
7 following PCI, with 3-5% having dispensings within 15 to 90-days. Thus, using the 14-day
8 window, we identified most of the patients with evidence of initiation of study treatment
9 following PCI. Most of the 27,049 excluded did not have claims for the therapies of
10 interest.
11
12
13

14 4. Figure 1: Where are those patients with PRIOR dispensing (page 7 line 15) in your figure?
15

16 **Response:** There were 70, 27, and 35 patients in prasugrel, ticagrelor, and clopidogrel
17 groups that had prior dispensings to either prasugrel or ticagrelor respectively. These
18 patients were grouped with prior antiplatelet exclusion. Figure 1 has been updated to
19 reflect this.
20
21

22 5. Exclusion Criteria/Figure 1: What were the strong CYP3A inducers and inhibitors prescribed?
23 Figure 1 indicates 5-10% of patients were excluded. In practice those amount to clarithromycin
24 and rifampin. Neither of which in my experience are prescribed often. Please re-evaluate these
25 medications. Or did you mean moderate and strong?
26

27 **Response:** Patients taking strong CYP inducers or inhibitors were excluded (any CYP
28 isoenzyme, not just 3A4). A list is provided at the end of this document. The language
29 was fixed in the manuscript.
30
31
32

33 6. Table 1: Please include whether the patient had STEMI, NSTEMI or unstable angina.
34

35 **Response:** STEMI and NSTEMI cannot be precisely assessed in the claims data.
36 Sentence added in the limitations section.. No evidence has shown that STEMI, NSTEMI,
37 or unstable angina significantly related to prescribing of two study drugs.
38
39

40 7. Table 3: You need to either define Composite Outcomes or change the labels. Consider
41 redefining primary outcome as primary efficacy outcomes and secondary as secondary bleeding
42 outcomes. As is, you have two labels: Composite Outcome that have different meanings.
43

44 **Response:** Edited table 3 so that outcomes are clearer.
45
46

47 8. All patients were followed for various times, correct? What was the median for each group?
48 Add to the results. More importantly, why aren't the results presented in annualized events or
49 per patient per some time period? (Tables 2 and 3) If it is taken into consideration in the
50 analysis, please explain it more clearly in the methods.
51

52 **Response:** FU time is Added to table 2. Results as rate per person-time added to table 3.
53
54
55
56
57
58
59
60

1
2
3
4 9. Figures 2 and 3 are not mentioned in the manuscript. Should they be? If not, delete.

5 **Response:** Sentence added at the end of the results section.
6
7

9

10 Comments to the Author

11 General comments to the authors:
12
13

14 I would like to congratulate the authors on an interesting and timely manuscript. Overall, the
15 paper is well written with some specific revisions discussed below. Here are some general
16 comments on the manuscript:
17

18
19 1. The major issue with the manuscript is a thorough explanation of how and why their
20 specific time exposure and censoring weighting methods impact the data findings. The data
21 presented shows that it changes the interpretation of the data, but the reader does not gain an
22 understanding of why and how the data changed. I would highly recommend more explanation
23 of these methods, possibly providing an example of how and why these methods change the
24 findings in the introduction or discussion.
25

26 **Response:** Thank you for your important suggestion. We have added a sentence at the
27 end of the second paragraph of the discussion section: “In order to replicate/mimic
28 findings from the RCT, we need to conduct a study in which adherence is similar. To do
29 this, we need to account for time-varying confounding and censoring to get an accurate
30 ‘on treatment’ effect. Thus, we applied methods to account for time-dependent
31 confounding, drug switching and discontinuation to account for differences in
32 adherence/discontinuation between the real-world data and RCT. Accounting for these
33 factors within the observational cohort resulted in dropout and treatment switching rates
34 that were similar to the ISAR-REACT 5 trial. The final results from this analysis were in
35 the same direction as the trial results We also have explained in detail the time-
36 dependent exposure and censoring weighting in the methods section.
37
38

39
40 2. Suggest changing the title to use “an observational study” instead of “a real-world data
41 study”. Although the use of real-world seems to be popular lately, especially by pharmaceutical
42 manufacturers, these are plain and simply observational studies.
43

44 **Response:** changed to “Real-world data study”.
45
46

47
48 3. Throughout the manuscript the “12” in P2Y12 should be subscript. Also, the correct term is
49 acute coronary syndrome and not acute coronary syndromes. It is a single syndrome. It
50 appears in both forms throughout the manuscript.
51

52 **Response:** Fixed both typos.
53
54

55 Specific comments for the authors:
56
57
58
59
60

1
2
3 Page 5, lines 15-19: The statement about there not being a difference in bleeding in the
4 PLATO trial is misleading. In practically all trials of P2Y12 inhibitors, the consistent definition of
5 major bleeding is non-CABG TIMI major bleeding. This is what was used in TRITON-TIMI 38
6 and CURE. In PLATO the definition was manipulated to include all TIMI major bleeds. Since
7 approximately 75% of patients going to CABG surgery have a major bleed, this dilutes the
8 difference between the arms. When the consistent definition of non-CABG TIMI major bleeding
9 is evaluated in PLATO, there is a significant increase compared to clopidogrel, with the same
10 absolute increase as seen in TRITON. Both agents increase this consistent definition of major
11 bleeding. Therefore, it would be appropriate to state that both agents reduce CV death, MI, and
12 stroke by the same magnitude and both agent increase non-CABG TIMI major bleeding by the
13 same magnitude.
14
15

16 **Response: Changed the statement to “both agents reduce CV death, MI, and stroke by**
17 **the same magnitude and both agents increase non-CABG TIMI major bleeding by the**
18 **same magnitude.”**
19

20
21 Page 6, top: So there was no equipoise in the evaluation of your data? Then did you do a one-
22 tailed statistical analysis?
23

24 **Response: In this observational study, there was no equipoise like there was in the RCT.**
25 **Since as physicians perceived that Ticagrelor was superior to Prasugrel, there was**
26 **confounding by indication which we attempted to account for through proper analysis.**
27 **before ISAR-REACT 5 trial. ²⁻⁶The final estimates are adjusted HR, which is similar as the**
28 **one-tailed statistical analysis that shows the higher risk in one agent.**
29
30

31 Page 7, lines 10-13: It would seem more appropriate to include pharmacy claims within 30 or
32 45 days of discharge instead of 14 days. With many hospitals using meds-to-beds programs,
33 the first month of medication is often provided to patients before they leave the hospital, and
34 therefore, would not be captured in your data. Both ticagrelor and prausgrel also often gave the
35 first month of medication for free, which would also have limited your ability to capture these
36 patients. One of the main strengths of a comparative effectiveness study is the ability to capture
37 larger numbers of patients than a randomized controlled trial. By limiting your pharmacy claims
38 window, you reduce the power and impact of your results. You do mention this is your
39 limitations, but seems to be an easy fix. It is someone confusing in your limitations discussion
40 where you lose almost 25% of the study population because of this exclusion, but then state by
41 changing the pharmacy claims date you did not gain many patients? These two statements do
42 not seem to be consistent unless most of the patients did not have any claim until beyond 90
43 days.
44
45

46 **Response: We sincerely appreciate reviewer’s important suggestion. We actually have**
47 **examined 30 days and 45 days and didn’t observe a substantial increase in sample size.**
48 **Also, patients may have events within 30 days or 45 days. The 14-day window identified**
49 **83% of the patients within the database that had a pharmacy dispensing for the study**
50 **treatment following PCI. During post-hoc analysis of the 27,049 patients excluded, only**
51 **about 10% had prescription dispensing for study agents at any time following PCI, with**
52 **3-5% having dispensings within 15 to 90-days. Thus, using the 14-day window, we**
53 **identified most of the patients with evidence of initiation of study treatment following**
54 **PCI. Most of the 27,049 excluded did not have claims for the therapies of interest.**
55
56
57
58
59
60

1
2
3
4
5 Page 7, lines 38-43: The assigning of a random day in the month for each death seems odd.
6 This reads as each death was given its own random day. It would seem more prudent to just
7 give all deaths the same day of the month, such as the 1st, 15th, or 30th. This way is would be
8 consistent for all deaths.
9

10
11
12 **Response: We sincerely appreciate reviewer's insightful comments. We considered the**
13 **random date assignment a more suitable approach than using a same mid-month date.**
14 **We also measured day of death using the first and last day of the month and this did not**
15 **change the study results.**
16

17
18 Page 8, lines 22-24: Why were patients switched to only clopidogrel censored? Anytime a
19 patients was switched, the data for that drug should end.
20

21 **Response: Patients that switched to ticagrelor or prasugrel were not censored. The risk-**
22 **time attributed to the 'switched to' agent was included in estimating the**
23 **pseudopopulation consistent with the time-varying exposure methods described in the**
24 **statistical analysis section.**
25

26
27 Page 8, line 42: Not sure why COPD (or asthma in your table) are included. They are not
28 risk factors for CVD or bleeding.
29

30 **Response: These baseline covariates have been included in other observational studies**
31 **for these therapies.**
32

33 Results: Please add the mean and median follow up times for each agent.
34

35 **Response: Added to table 2.**
36

37 Limitations: It would seem that the third limitation on the counting of subsequent events could
38 be fixed by matching additional codes with hospitalizations and not clinic visits. As well
39 requiring a primary code for ACS on subsequent admissions. This is actually critical to the
40 internal validity of your data.
41

42 **Response: From the reviewer's comments, we removed this limitation. The outcomes**
43 **were identified via validated algorithms cited in the text evaluating hospitalizations and**
44 **not clinic visits.**
45

46
47 References: In Pharmacotherapy the journal names are not italicized and do not have a
48 period after them. DOI numbers are also not used by the journal. Please be sure to review the
49 instructions to authors before your submission. In references 3-5, 8, 9, 17, 18, 25, 28, and 29 all
50 of the words in the title are capitalized, which is not appropriate for referencing. This
51 inconsistency should have been caught by the lead or senior authors prior to submission.
52

53 **Response: The references in the word document have no capitalizations. Perhaps this**
54 **occurred during uploading or converting to PDF. I will check to be sure that this does not**
55 **occur again.**
56
57
58
59

1
2
3
4 Table 2: Please add the actual event rates to this table in addition to the HR and 95% CI.
5 Also, the HR and 95% CI do not need to all be in separate columns. This is awkward to read.
6 They can all go in the same column.
7

8 **Response: Added event rates to table 3. Reformatted the columns in table 4.**
9

10 Figure 2 and 3: Is it appropriate to label the y-axis “estimated probability of survival” when you
11 are not evaluating survival. Figure 2 is the composite ischemic endpoints and Figure 3 is major
12 bleeding. May be better to label as “estimated probability event free survival”
13
14
15

16 **Response: Updated axis titles.**
17
18

19 Reviewer: 3
20

21 Comments to the Author
22 Statistical and Methodological Review
23
24

25 This study uses contemporary pharmacoepidemiologic methods to overcome limitations of prior
26 studies that have evaluated the comparative effectiveness and safety of prasugrel and
27 ticagrelor. It has many strengths. I believe a few things need to be further discussed or specified
28 and have some relatively minor concerns about other aspects of the methods.
29

30 **Response: We sincerely appreciate the reviewer’s positive comments. We will address all**
31 **your comments diligently.**
32

33 The time-period of the data is not entirely clear, and this is important because of the use of ICD-
34 9 codes to identify outcomes. The censoring criteria do not mention September 2015, the end of
35 the study period, as a reason for censoring.
36
37

38 **Response: Added Data end window in the ‘censoring’ section of methods.**
39

40 Please comment on validation studies and the performance characteristics of the outcome
41 definitions, i.e. PPV. I’m not entirely sure why 412, old MI, was included in that definition. 436
42 also is not a particularly valid code for stroke since guidance on stroke coding changed in the
43 mid-2000s with instructions not to code strokes this way. The impact may be minimal since it is
44 used less often, but using a study using recent data as a reference for its validity is important. It
45 may also be useful to indicate the proportion of MIs and strokes identified with these more
46 questionable codes. [https://urldefense.proofpoint.com/v2/url?u=https-

3 Please comment on the limitations of Social Security Death Index data for capturing mortality,
4 and any validation studies vs. the National Death Index that may have been done in this data
5 source. This data source has changed to no longer include state death data and sensitivity now
6 appears to be limited.
7

8 **Response: The death file included within this dataset is the Social Security**
9 **Administration Death Master file. Since 2013 it was no longer mandatory for states to**
10 **report death events to the Social Security Administration. As such, death events are**
11 **expected to be non-differentially underreported.⁷ This is added to the limitations with the**
12 **citation.⁶**
13
14
15

16 Why is angina being treated as a time-varying covariate? It seems to me that it's likely on the
17 causal pathway from drug choice to MI since the purpose of these drugs is to prevent ischemic
18 events. It seems reasonable to include in the analysis of bleeding since it may lead to other
19 drugs that increase bleeding risk, but it's not clear to me why it would be considered a
20 confounder with MI as an outcome.
21

22 **Response: If a patient has an ACS, this will sometimes lead to a change in the agent**
23 **used for DAPT (e.g. from prasugrel to ticagrelor).**
24
25

26 A sensitivity analysis using only primary position MI codes may be beneficial for dealing with the
27 challenges of differentiating visits related to prior MI and new acute MI.
28

29 **Response: We utilized a validated claims algorithm for outcomes. This included MI-**
30 **related hospitalization with length of stay ≥ 3 days. Since we are not evaluating MI-**
31 **related outpatient claims we believe that there is minimal opportunity for misclassifying**
32 **historical MI event for a new MI event. We have removed this language from the**
33 **limitations section.**
34
35

36 The covariate list doesn't seem optimal for bleeding events, as it lacks peptic ulcer disease,
37 inflammatory bowel disease, and some other GI abnormalities that pose bleeding risk. PPI use
38 may handle peptic ulcer disease to some extent, but many people without peptic ulcer disease
39 take PPIs. I'm not sure this necessitates redoing all the analyses, but can you comment on why
40 these weren't included?
41

42 **Response: We appreciate the reviewer's important suggestion. We acknowledge that**
43 **these suggestions would improve the analysis. While many of the covariates were**
44 **selected to mimic previous clinical trials, information regarding gastrointestinal**
45 **disorders or abnormalities may be factors of interest.**
46
47

48 Please include an appendix that specifies the ICD codes used to define different covariates, as
49 this is necessary for reproducibility of the work and assessment of the appropriateness of the
50 methods.
51

52 **Response: Thank you for your important suggestion. We have added an eTable that**
53 **present all ICD codes to define the covariates.**
