<b>Abstract:</b>	Comparative genomics approaches are broadly used for analysis of transcriptional regulation in bacterial genomes. In this work, we identified binding sites and reconstructed regulons for 33 orthologous groups of transcription factors (TFs) in 196 reference genomes from 21 taxonomic groups of Proteobacteria. Overall, we predict over 10,600 TF binding sites and identified more than 15,600 target genes for 1,896 TFs constituting the studied orthologous groups of regulators. These include a set of orthologs for 21 metabolism-associated TFs from <i>Escherichia coli</i> and/or <i>Shewanella</i> that are conserved in five or more taxonomic groups and several additional TFs that represent non-orthologous substitutions of the metabolic regulators in some lineages of Proteobacteria. By comparing gene contents of the reconstructed regulons, we identified the core, taxonomy-specific and genome-specific TF regulon members and classified them by their metabolic functions. The detailed analysis of ArgR, TyrR, TrpR, HutC, HypR and other amino acid-specific regulons demonstrated remarkable differences in regulatory strategies used by various lineages of Proteobacteria. The obtained genomic collection of <i>in silico</i> reconstructed TF regulons contains a large number of new regulatory interactions that awaits future experimental validation. It provides a framework for future evolutionary studies of transcriptional regulatory networks in Bacteria. It can be also used for functional annotation of putative metabolic transporters and enzymes that are abundant in the reconstructed regulons.

### ABSTRACT

Comparative genomics approaches are broadly used for analysis of transcriptional regulation in bacterial genomes. In this work, we identified binding sites and reconstructed regulons for 33 orthologous groups of transcription factors (TFs) in 196 reference genomes from 21 taxonomic groups of Proteobacteria. Overall, we predict over 10,600 TF binding sites and identified more than 15,600 target genes for 1,896 TFs constituting the studied orthologous groups of regulators. These include a set of orthologs for 21 metabolism-associated TFs from *Escherichia coli* and/or *Shewanella* that are conserved in five or more taxonomic groups and several additional TFs that represent non-orthologous substitutions of the metabolic regulators in some lineages of Proteobacteria. By comparing gene contents of the reconstructed regulons, we identified the core, taxonomy-specific and genome-specific TF regulon members and classified them by their metabolic functions. The detailed analysis of ArgR, TyrR, TrpR, HutC, HypR and other amino acid-specific regulons demonstrated remarkable differences in regulatory strategies used by various lineages of Proteobacteria. The obtained genomic collection of *in silico* reconstructed TF regulons contains a large number of new regulatory interactions that awaits future experimental validation. It provides a framework for future evolutionary studies of transcriptional regulatory networks in Bacteria. It can be also used for functional annotation of putative metabolic transporters and enzymes that are abundant in the reconstructed regulons.

### DATA SUMMARY

33

34 Inferred transcription factor binding sites and reconstructed regulons have been deposited in the  
35 RegPrecise database (URL – [http://regprecise.lbl.gov/RegPrecise/project\\_proteobacteria.jsp](http://regprecise.lbl.gov/RegPrecise/project_proteobacteria.jsp)).

36

37 **We confirm all supporting data, code and protocols have been provided within the article or**  
38 **through supplementary data files.**

40

41 **IMPACT STATEMENT**

42 Bacteria in most ecological niches are constantly exposed to variations in many factors  
43 including nutrient availability. Changes in gene expression using transcription factors allow  
44 bacteria to adapt to these variations. Knowledge of transcriptional regulatory networks is  
45 essential for understanding cellular processes. Comparative genomics is the analysis and  
46 comparison of genomes from different species. Thousands of sequenced bacterial genomes  
47 open an opportunity to reconstruct transcriptional regulatory networks using the  
48 comparative genomics. Despite the importance of transcriptional regulation of the central  
49 metabolism for systems-level metabolic modelling of Bacteria, our understanding of the  
50 respective transcription factor regulons is limited for the majority of sequenced bacteria. In  
51 this study, the researchers have applied the comparative genomics approach to describe  
52 regulatory networks of genes involved in the central metabolism in four major classes of  
53 Proteobacteria. The reconstructed regulatory networks involve 33 groups of orthologous  
54 transcription factors with different DNA recognition motifs. Large-scale phylogenomic  
55 analysis of the reconstructed TF regulons reveals and classifies various evolutionary  
56 processes that shape regulatory networks in Bacteria. The reconstructed regulon contents  
57 suggest numerous novel functional associations between both known and uncharacterized  
58 genes encoding enzymes and transporters thus providing testable hypotheses for future  
59 experimental studies. This study demonstrates the power of comparative genomics for the  
60 reconstruction of transcription factor regulons in bacteria.

## 61 INTRODUCTION

62 Regulation of gene expression is an important mechanism for fast adaptation of prokaryotic  
63 metabolism to changing environmental conditions. Transcription factors (TFs) repress or activate  
64 gene transcription via specific binding to TF binding sites (TFBSs) in regulatory gene regions. Binding  
65 ability of many bacterial TFs depends on the presence or absence of an effector such as intracellular  
66 metabolites, inorganic chemicals or physical stimuli (Browning and Busby 2004). A set of genes  
67 directly controlled by a single TF is called a regulon. Global TF regulons in bacteria contain large sets  
68 of genes (operons) that share similar TFBSs in their promoter regions, while local TFs control one or  
69 several operons that are often co-localized with a TF gene (Rodionov 2007).

70 Experimental studies built a foundation for understanding mechanisms laying behind  
71 transcription regulation (Minchin and Busby 2009). However even with high throughput  
72 technologies as ChIP-Seq or RNA-Seq, these approaches still consume a lot of time and resources  
73 and therefore are restricted by few model organisms (Grainger, et al. 2009). At this point  
74 comparative genomics studies of growing number of sequenced bacterial genomes provide a  
75 successful approach to extend our knowledge of known TF regulons to wide range of bacterial  
76 lineages, as well as to perform *ab initio* prediction of novel TF regulons (Rodionov 2007).  
77 Comparative genomics-based regulon reconstruction combines identification of conserved *cis*-acting  
78 TFBSs, their genomic and metabolic context analysis in a set of closely-related genomes. Finally, it  
79 results in determination of a regulog that is a set of genes/operons co-regulated by orthologous TFs  
80 in closely related organisms. Implementation of this approach in the RegPredict web tool  
81 (Novichkov, et al. 2010) produced numerous computational reconstructions of TF regulogs across a  
82 wide range of bacterial taxa (Ravcheev, et al. 2011; Rodionov, et al. 2011; Leyn, et al. 2013;  
83 Ravcheev, et al. 2013; Rodionov, et al. 2013). This substantial amount of data on regulon  
84 reconstructions captured in the RegPrecise database (Novichkov, et al. 2013) provides the basis for  
85 description of most common types of events associated with evolution of TF regulons in bacteria  
86 such as duplications and losses of TFs and their TFBSs that result in expansions, shrinkages, mergers  
87 and split-ups of regulons (Gelfand 2006; Rodionov, et al. 2006; Ravcheev, et al. 2014). New non-  
88 orthologous TFs could be introduced to control equivalent pathways or, vice versa, orthologous TFs  
89 could control distinct pathways in related taxonomic groups of bacteria (Yang, et al. 2006; Rodionov,  
90 et al. 2008; Kazakov, et al. 2009; Leyn, et al. 2014).

91 We recently conducted a comprehensive comparative genomics analysis of regulatory systems  
92 for methionine metabolism in near 200 representative genomes from 22 taxonomic groups from the  
93 phylum Proteobacteria (Leyn, et al. 2014). In  $\gamma$ -proteobacteria, two TFs, MetJ and MetR, are  
94 implicated in the control of methionine metabolism, whereas this function is taken by other TFs  
95 (SahR and SamR) or RNA regulatory systems (e.g., SAH and SAM riboswitches) in other lineages of  
96 Proteobacteria. The core of MetJ regulons includes a large numbers of genes that are highly  
97 conserved in most lineages of  $\gamma$ -proteobacteria. In contrast, the core of MetR regulons includes only  
98 two genes, *metE* and *metR*, whereas regulatory interactions between MetR and other target genes  
99 are mostly lineage-specific. Regulatory system replacement and lineage-specific regulon expansions in  
100 Proteobacteria were also observed in the comparative genomics analyses of TF regulons involved in  
101 fatty acid degradation (FadR, PsrA, FadP), branched-chain amino acid utilization (LiuR, LiuQ), N-  
102 acetylglucosamine utilization (NagC, NagR, NagQ) (Yang, et al. 2006; Kazakov, et al. 2009), biotin  
103 biosynthesis (BirA, BioR) (Rodionov and Gelfand 2006) and central carbohydrate metabolism (HexR)  
104 (Leyn, et al. 2011).

105 Here, we extended these observations toward large-scale regulon reconstructions for 21 known  
106 TFs that have orthologs in a wide phylogenetic range of Proteobacteria. By comparing the metabolic  
107 context of the reconstructed TF regulons, we identified the core, taxonomy-specific and genome-  
108 specific members of regulons, and proposed evolutionary scenarios for regulation of several  
109 pathways involved in metabolism of amino and fatty acids, nucleotides and co-factors in  
110 Proteobacteria. Additionally, we predicted novel regulators of aromatic amino acid metabolism  
111 replacing the TyrR/PhrR and HmgR regulons in Alteromonadales and Pseudomonadales (named  
112 HmgS and HmgQ), and a novel regulator of NAD metabolism in  $\beta$ - and  $\alpha$ -proteobacteria, named  
113 NadQ. The obtained regulatory reconstructions for both known and new TF regulons across 196  
114 reference genomes of Proteobacteria will be useful for development of theoretical models for the  
115 evolution of microbial regulatory networks.

116

## 117 METHODS

118 For regulon reconstruction, we selected 196 reference genomes of  $\alpha$ -,  $\beta$ -,  $\gamma$ - and  $\delta$ -  
119 proteobacteria and subdivided them into 21 sets of evolutionary related genomes (Table S1). Closely  
120 related strains and species were excluded from the analysis because they skew the TFBS training set  
121 and thus decrease the sensitivity of the TFBS recognition rule. Genomes and the phylogenetic  
122 species tree were downloaded from MicrobesOnline database (Dehal, et al. 2010). Each taxonomic  
123 group includes 4 to 16 genomes of bacteria. Orthologs of TFs in the selected genomes were  
124 identified as bidirectional best hits using protein BLAST search (Altschul, et al. 1997) and were  
125 additionally confirmed via phylogenetic trees using precomputed protein trees in MicrobesOnline.  
126 The genomes of  $\epsilon$ -proteobacteria were not analyzed because of the absence of orthologs for target  
127 TFs.  $\zeta$ -proteobacteria, which is represented by a single genome in the MicrobesOnline database, was  
128 not suitable for the comparative genomic analysis.

129 Genes in the reconstructed regulons were considered orthologs if they were classified as specific  
130 tree-based orthologs in MicrobesOnline. Conservancy of the genomic context through related  
131 genomes was considered as an additional support for gene orthology. Comparative analysis of  
132 conserved gene neighborhoods was conducted in MicrobesOnline. Biological functions of genes  
133 were predicted by BLAST search against the SwissProt/Uniprot database (UniProt 2014), domain  
134 architecture analysis in the Pfam database (Finn, et al. 2014), and by using gene function  
135 assignments in the PubSEED database (Overbeek, et al. 2005). Known metabolic pathways were  
136 taken from KEGG (Kanehisa and Goto 2000) and EcoCyc (Karp, et al. 2014). Sequence logos for TF  
137 binding sites were drawn using the WebLogo package (Crooks, et al. 2004).

138 For regulon reconstruction we used an established comparative genomics approach implemented  
139 in the RegPredict interactive tool (Novichkov, et al. 2010). This approach is based on construction of  
140 positional weight matrices (PWMs) for TFBS motifs, and further genomic searches for additional  
141 regulon members on the basis of predicted TFBSs in upstream gene regions (Rodionov 2007).  
142 Bioinformatics workflow used for regulon reconstruction is described in Figure S1. Two main  
143 workflows were applied for regulon reconstructions: (i) propagation and expansion of known TF  
144 regulons that were previously experimentally studied in model organisms (Table S2) and/or  
145 computationally reconstructed in *Shewanella* spp. (Rodionov, et al. 2011); and (ii) *ab initio* prediction  
146 of novel TF regulons for sets of potential target genes involved in the same metabolic pathway. To  
147 find conserved TFBS motifs for the known TFs in each taxonomic group where their orthologs are  
148 present, we used initial training sets of genes that are orthologous to previously established regulon

149 members in model species, and then updated each set by potential regulon members confirmed by  
150 the comparative genomics checks. For novel TF regulons, the original training sets included genes  
151 from the respective metabolic pathways and/or conservative chromosomal gene neighborhoods  
152 around analyzed TFs.

153 A simple iterative procedure implemented in the Discover Profile tool in RegPredict was used for  
154 identification of conserved palindromic DNA motifs and construction of PWMs. For most of the  
155 analyzed TFs, their DNA motifs have palindromic structure and length between 15 and 25 nt,  
156 whereas the TFBS motifs of NagQ and BirA represent tandem and inverted repeats, respectively. The  
157 obtained PMWs (both known and *ab initio* predicted) were further used for identification of  
158 additional candidate sites in upstream gene regions as previously described (Leyn, et al. 2014;  
159 Ravcheev, et al. 2014). Each predicted regulatory interaction was analyzed for conservation within  
160 the analyzed groups of genomes using the Clusters of co-Regulated Orthologous operoNs (CRONs)  
161 approach in RegPredict. Further analysis of functional and genomic context and curation of each  
162 CRON resulted in the final TF regulon model. All reconstructed TF regulons including TFBS motifs and  
163 sets of TF-regulated genes/operons with their functional annotations are accessible in the latest  
164 release of the RegPrecise database (Novichkov, et al. 2013) (Data Citation 1). Each TF regulon in  
165 RegPrecise belong to two types of regulon collections classified by either taxonomy of studied  
166 bacteria, or by the name of TFs.

167

## 168 RESULTS AND DISCUSSION

### 169 Statistics of reconstructed regulons and regulogs

170 A set of 196 representative genomes of  $\gamma$ -,  $\beta$ -,  $\alpha$ -, and  $\delta$ -proteobacteria selected from the  
171 MicrobesOnline database was classified into 21 taxonomic groups by analyzing the phylogenetic  
172 species tree (Table S1). For the analysis of evolution of transcriptional regulation, we selected a set  
173 of 21 transcriptional regulators of the central metabolism that are present either in *E. coli* and/or  
174 *Shewanella* spp. and that are conserved in five or more taxonomic groups of Proteobacteria (Table 1;  
175 Figure S1). The selected TFs include the previously known regulators that control  
176 biosynthesis/utilization of amino acids (ArgR, HutC, HypR, LiuR, MetJ, MetR, TrpR, TyrR), fatty acids  
177 (FabR, FadR, PsrA), nucleotides (NrdR, RutR), and vitamins (BirA, NrtR), as well as nitrogen and  
178 carbon metabolism (HexR, GlcC, LldR, NagC, NtrC, PdhR). Sixteen of these TFs are present in *E. coli*,  
179 of them twelve regulators are also shared by *Shewanella* spp., whereas the remaining five TFs (LiuR,  
180 HutC, HypR, NrtR, PsrA) are unique for *Shewanella* spp. We also studied 12 additional TFs that  
181 appear to substitute some of the above TFs in the control of specific metabolic pathways, and thus  
182 can be assumed as non-orthologous TF replacements. These include known and predicted regulators  
183 that control metabolism of amino acids (HmgQ, HmgR, HmgS, LiuQ, SahR, SamR) and fatty acids  
184 (FadP), vitamin biosynthesis (BioR, NadR, NadQ), and N-acetyl-glucosamine metabolism (NagQ,  
185 NagR) (marked with asterisk in Table 1).

186 Application of the comparative genomics procedure to 33 analyzed groups of orthologous TFs  
187 resulted in reconstruction of 283 regulogs containing 1896 regulons that are unevenly distributed  
188 across 21 taxonomic groups of Proteobacteria (Figure S2). Each regulon includes a set of target  
189 genes/operons that are co-regulated by the same TF in a particular genome. A regulog represents a  
190 set of regulons under control of orthologous TFs in a specific taxonomic group of Proteobacteria. The  
191 most widespread orthologous groups of analyzed TFs are NrdR (186 regulons, 20 regulogs), NtrC

192 (169 regulons, 19 regulogs), MetR (117 regulons, 14 regulogs), HutC (113 regulons, 18 regulogs), LiuR  
193 (104 regulons, 16 regulogs), HexR (95 regulons, 13 regulogs), and BirA (94 regulons, 11 regulogs).

194 The taxonomical distribution of analyzed TF regulogs across four subdivisions from the  
195 Proteobacteria phylum is summarized in Figure 1. Overall, 30 out of 33 analyzed TFs are present in  $\gamma$ -  
196 proteobacteria, and 14 of these regulators do not have orthologs in other classes of Proteobacteria.  
197  $\alpha$ -proteobacteria totally possess 15 studied TFs, including one regulator (BioR), which is unique for  
198 this class. Among 17 studied TFs in  $\beta$ -proteobacteria, two regulators (LiuQ, FadP) are unique for this  
199 class.  $\delta$ -proteobacteria that represent the most taxonomically diverged subdivision of Proteobacteria  
200 have orthologs for only five studied TFs. Several TFs (such as LldR, GlcC, RutR) that are present in  
201 several classes of Proteobacteria show a mosaic distribution across the analyzed genomes and taxa,  
202 while other TFs (such as ArgR, FabR, FadR, MetJ, TrpR, TyrR) are highly conserved in many taxonomic  
203 groups of  $\gamma$ -proteobacteria but are absent in other classes. The diverse distribution of TFs suggests  
204 different evolutionary pathways for the studied metabolic regulons.

205 The detailed descriptions of reconstructed regulons and regulogs are captured in the RegPrecise  
206 database (Data Citation 1), whereas the complete list of regulatory interactions between the studied  
207 TFs and their target genes is provided in Table S3. Overall, the obtained regulons included 10,663  
208 candidate TFBSs and 15,690 target genes (Table 1). The largest average number of target genes per  
209 genome (more than 10 genes per genome) was observed for regulators of amino acid metabolism  
210 (ArgR, LiuR, MetJ, TyrR), the fatty acid degradation regulators FadP and PsrA, the carbohydrate  
211 metabolism regulators HexR, NagC and NagR, and the pyrimidine utilization regulator RutR.

212 For most of the studied TFs, their cognate DNA binding motifs are generally conserved across the  
213 analyzed taxonomic groups (see the RegPrecise database for detailed lists of taxonomy-specific TFBS  
214 motifs, Data Citation 1). However, for several TFs including FabR, HypR, NrtR, RutR, SahR and TrpR,  
215 we observed taxon-specific substitutions in their cognate DNA motifs, whereas the GlcC-binding DNA  
216 motifs in  $\alpha$ - and  $\beta$ -/ $\gamma$ -subdivisions of Proteobacteria are characterized by different length of the  
217 spacer between the conserved palindromic half-sites (Figure 2). Finally, the HexR and NagQ motifs in  
218 several taxonomic groups of  $\gamma$ -proteobacteria have different consensus sequences and structures  
219 (Yang, et al. 2006; Leyn, et al. 2011).

220

## 221 Conservation of reconstructed regulons

222 To analyze conservation of regulatory interactions in the reconstructed regulogs, we calculated  
223 the conservation score as a number of gene occurrence in a regulog divided by a number of regulons  
224 in a regulog. Average of these taxonomy-specific conservation scores was calculated for all  
225 orthologous groups of target genes across analyzed lineages of Proteobacteria. For each group of  
226 orthologous TFs, we plotted the average conservation score of a target gene against the number of  
227 taxonomic groups, in which this gene is regulated. The obtained plots visualize average conservation  
228 of regulatory interactions and thus help to determine the core, taxonomy-specific and genome-  
229 specific target genes within the reconstructed TF regulons (Figure S3).

230 The core regulon members determined by this approach represent regulatory interactions with  
231 high average conservation scores that are conserved in more than half of reconstructed TF regulogs.  
232 The core members of most of the analyzed regulons are consistent with major biological functions  
233 and molecular effectors of their cognate TFs (Table S4). For instance, the arginine repressor regulon  
234 ArgR in  $\gamma$ -proteobacteria has a conserved core that includes genes involved in arginine biosynthesis  
235 (*argABCEFGH*, *carAB*), transport (*artPIQM*), and degradation (*astAD*), as well as the *argR* gene itself

236 (Figure 3). The cores of most other reconstructed TF regulons include their cognate TF genes.  
237 Exceptions from this observation include the FabR, FadR and NadQ regulons that include their  
238 cognate TF genes only in some taxonomic groups of Proteobacteria; the biotin repressor BirA, which  
239 is autoregulated only in *Desulfobacteriales*, and the deoxyribonucleotide reductase regulator NrdR,  
240 which was never found under autoregulation. Negative autoregulation of a TF gene is a common  
241 feature of bacterial regulatory networks. Here, we demonstrate that this type of regulatory  
242 interaction is highly conserved in the evolution of regulatory networks of Proteobacteria.

243 The remaining members of reconstructed regulons were classified into the taxon- and genome-  
244 specific groups depending on their average conservation scores. The taxonomy-specific regulon  
245 members are characterized by strong conservation of regulatory interactions restricted to a half or  
246 less taxonomic groups containing an orthologous TF. At that the **taxon-specific regulon members**  
247 were defined as genes that **are regulated in more than 65% of genomes in at least one taxonomic**  
248 **group**. In contrast, the genome-specific regulon members are characterized by low conservation of  
249 regulatory interactions, when in each taxonomic group conservation of a regulatory interaction is  
250 less than 65%. The groups of taxonomy-and genome-specific TF regulon members with assigned  
251 metabolic pathways are often involved in the same major biological process as the core regulon  
252 members (Table S4). However, in some TF regulons these categories also involve genes that  
253 participate in other metabolic pathways or biological processes. For example, the taxon-specific  
254 members of ArgR regulons include genes involved in arginine biosynthesis (*argD*) and transport (*artJ*,  
255 *argW*, *omp*), arginine degradation (*astBC*), as well as genes from glutamate (*gltBD*) and branched-  
256 chain amino acid (*ilvMGDA*) biosynthesis, putrescine transport (*potFGHI*), and pyruvate metabolism  
257 (*oadABG*) (Figure 3). The genome-specific ArgR regulon members include arginine degradation genes  
258 (*arcABCD*, *astE*), proline (*proVWX*) and histidine (*hisJMPQ*) transporters and putrescine metabolism  
259 genes (*speF*, *potE*). Likewise, in our previous analysis of the methionine-specific regulons MetJ, MetR  
260 and SahR in Proteobacteria, we identified the core-, taxonomy- and genome-specific members of  
261 regulons and demonstrated their involvement in different aspects of the methionine metabolism.  
262 Other amino acid-specific TF regulons analyzed in the current work are described in more detail in  
263 the following sections.

#### 264 **TrpR, TyrR and other TF regulons for aromatic amino acid metabolism**

265 The aromatic amino acids tryptophan, tyrosine and phenylalanine are synthesized in  
266 Proteobacteria by the common pathway leading from erythrose 4-phosphate through 2-dehydro-3-  
267 deoxy-D-arabinoheptonate-7-phosphate (DAHP), and shikimate to chorismate (Figure 4). After  
268 chorismate, the pathway divides into the three terminal biosynthetic pathways that are specific for  
269 each aromatic amino acid. *E. coli* has three DAHP synthase isoenzymes, AroF, AroG, and AroH, which  
270 are feedback inhibited by tyrosine, phenylalanine and tryptophan, respectively. The biosynthesis of  
271 aromatic amino acids is regulated at both the DNA and RNA levels. The DNA-binding transcription  
272 factors TyrR and TrpR jointly control the expression of genes involved in the aromatic amino acid  
273 metabolism in *E. coli* (Pittard and Yang 2008). At the RNA level, the *trpEDCBA* operon encoding the  
274 tryptophan biosynthesis enzymes and the phenylalanine biosynthesis gene *pheA* are regulated by  
275 translational attenuation in *E. coli* and other  $\gamma$ -proteobacteria (Panina, et al. 2001). The tryptophan-  
276 responsive regulator TrpR in *E. coli* acts as a repressor of the *trpEDCBA* operon, the tryptophan  
277 transporter gene *mtr*, and the regulatory gene *trpR* (Czernik, et al. 1994; Jeeves, et al. 1999). In  
278 addition, TrpR negatively regulates the expression of the shikimate kinase *aroL* and the DAHP  
279 synthase *aroH* that are involved in the chorismate biosynthesis. The tyrosine-responsive regulator  
280 TyrR in *E. coli* negatively controls the tyrosine biosynthesis genes *tyrB*, *aroF-tyrA*, *aroLM*, the  
281 aromatic amino acid transporter *aroP* and the *tyrR* gene itself. In addition, TyrR activates the

282 tyrosine- and tryptophan-specific transporters *tyrP* and *mtr* and the folate biosynthesis gene *folA* in  
283 the presence of tyrosine or phenylalanine (Yang, et al. 2004; Pittard, et al. 2005). The TyrR regulon  
284 was also partially studied in two other Enterobacteria. In *Citrobacter freundii*, it activates the  
285 tyrosine degradation gene *tpl* (Smith and Somerville 1997). In *Enterobacter cloacae*, TyrR activates  
286 the *ipdC* gene involved in the synthesis of indole acetate from tryptophan and represses a  
287 divergently transcribed gene, *akr*, encoding a putative aldo-keto reductase (Coulson and Patten  
288 2015). An ortholog of TyrR in *Pseudomonas putida*, known as PhhR, is responsible for the activation  
289 of genes essential for phenylalanine degradation and phenylalanine homeostasis (Herrera, et al.  
290 2010). In *Pseudomonas aeruginosa*, PhhR directly controls the *phhABC*, *hpd*, and *dhcA* transcriptional  
291 units involved in the phenylalanine and tyrosine catabolism (Palmer, et al. 2010).

292 The comparative genomics approach was applied to analyze regulons controlled by transcription  
293 factors homologous to TrpR and TyrR/PhhR and to predict novel regulons for aromatic amino acid  
294 metabolism (Table S5). The TrpR-family regulons reconstructed in eight lineages of  $\gamma$ -proteobacteria  
295 control genes for the tryptophan biosynthesis, uptake and catabolism (Figure 4). In most of the  
296 analyzed taxonomic groups, TrpR regulates the *trpR* and *trpE* genes that form the conserved regulon  
297 core, whereas other genes from tryptophan biosynthesis pathway and the *mtr* transporter were  
298 classified as taxon-specific members of the regulon. Two other known targets of TrpR in *E. coli*, the  
299 chorismate biosynthesis genes *aroLM* and *aroH*, represent regulatory interactions that are  
300 conserved in a small number of closely-related *Enterobacteriales* genomes but not in other lineages.  
301 New predicted members of the TrpR regulons include various aromatic amino acid biosynthesis  
302 genes such as *aroG* in *Pasteurellales*, *aroF-tyrA* in *Shewanellaceae*, *aroF2* and *aroA* in *Vibrionales*, as  
303 well as the tryptophan degradation genes *tnaAB* and a predicted tryptophan transporter from the  
304 COG0733 family in *Vibrionales*. Interestingly, the TrpR regulon in *Shewanella* spp. does not include  
305 the tryptophan biosynthesis operon, which is regulated by a translational attenuator at the RNA  
306 level (Panina, et al. 2001).

307 The content of reconstructed TyrR (PhhR) regulons is highly variable across the analyzed 6  
308 lineages of  $\gamma$ -proteobacteria (Table S5). The most conserved members of these regulons are the *tyrR*  
309 gene itself, the tyrosine biosynthesis and transport genes *aroF-tyrA* and *tyrP*, as well as the  
310 phenylalanine and tyrosine degradation genes *phhAB*, *hmgABC* and *hpd* (Figure 4). The aromatic  
311 amino acid transporters *mtr* and *aroP*, as well as the chorismate biosynthesis genes *aroLM*, which  
312 were previously known as TyrR-regulated genes in *E. coli*, belong to the TyrR regulons only in  
313 *Enterobacteriales*. The *folA* gene represents another previously known member of the TyrR regulon  
314 in *E. coli*, however we were unable to find conserved TyrR-binding sites upstream of *folA* orthologs in  
315 other *Enterobacteriales*.

316 A novel predicted tyrosine transporter from the COG2814 family was found under TyrR  
317 regulation in seven genomes of *Enterobacteriales*. The reconstructed TyrR regulons in *Vibrionales*  
318 are extended to include a predicted novel tyrosine transporter from the COG0733 family and the  
319 *aroG* gene. The most significant shifts in the regulon content were identified in *Shewanellaceae*,  
320 where TyrR controls the degradation pathways for various amino acids including phenylalanine  
321 (*phhAB*), tyrosine (*hmgCB*), tryptophan (*tdo-kyn*), branched chain amino acids (*ldh*, *brnQ*, *liu*, *ivd*, and  
322 *bkd* operons), proline (*putA*), methionine (*mdeA*), and oligopeptides (various peptidase genes). In  
323 addition, the conserved part of the TyrR regulons in *Shewanellaceae* includes the  
324 tyrosine/phenylalanine biosynthesis genes *aroA* and *tyrB*, as well as the *aceBA* and *acsA* genes from  
325 the central carbon metabolism. Finally, the *tpl* gene encoding an alternative pathway of tyrosine  
326 degradation belongs to the TyrR regulons in *Citrobacter koseri* and two *Pasteurellales*, whereas the

327 indole acetate synthesis gene *ipdC* is regulated by TyrR in some *Enterobacteriales* and  
328 *Shewanellaceae* genomes.

329 The homogentisate pathway of the tyrosine degradation encoded by the *hmgABC* operon in *P.*  
330 *putida* is regulated by the IclR-family repressor HmgR and homogentisate as anirepressor (Arias-  
331 Barrau, et al. 2004). Similar HmgR regulons were reconstructed in four other *Pseudomonas* species,  
332 whereas the *hmgABC* genes in two other *Pseudomonas* spp. belong to the TyrR-family PhrR regulons  
333 (Table S5). In a closely-related bacterium from the *Pseudomonadaceae* family, *Azotobacter*  
334 *vinelandii*, which lack both PhrR and HmgR regulons, we identified a novel LysR-family regulon for  
335 the homogentisate pathway genes, which we termed HmgQ. Orthologous HmgQ regulators in the  
336 *Shewanellaceae* family are predicted to control the *hmgA-hpd* genes, whereas the *hmgCB* genes of  
337 the homogentisate pathway belong to the extended TyrR regulon in *Shewanella* spp.. Another novel  
338 regulator from the MarR family (termed HmgS), was identified in several *Alteromonadales* and  
339 *Pseudoalteromonadales* species, where it is predicted to control the *hmgAB* genes.

340 In conclusion, the transcriptional regulation of aromatic amino acid metabolism is highly  
341 variable among major lineages of  $\gamma$ -proteobacteria (Table S5). The TyrR-family regulators control the  
342 aromatic amino acid biosynthesis, uptake and/or catabolic pathways in most of the analyzed taxa. In  
343 contrast, the reconstructed regulons in the *Shewanellaceae* family predict a global regulatory role of  
344 TyrR for genes that are involved in catabolism of various amino acids and in central carbon  
345 metabolism. The mode of TyrR action on its predicted novel targets in *Shewanella* is to be  
346 determined experimentally. Preliminary comparative analysis of positions of the TyrR-binding sites in  
347 the promoter gene regions suggest that TyrR probably acts as an activator for most of the amino  
348 acid degradation operons in *Shewanella* spp. (data not shown). The homogentisate pathway in  $\gamma$ -  
349 proteobacteria is controlled by either TyrR/PhhR, or by non-orthologous local regulators from the  
350 IclR, LysR, and MarR protein families. We also observed interchangeability between the TyrR and  
351 TrpR regulons: the *aroF-tyrA* genes are controlled by TyrR in most of the analyzed lineages, whereas  
352 in the *Shewanellaceae* family, this operon is predicted to be controlled by TrpR. Overall, the major  
353 biological role of TyrR in *Enterobacteriales* and *Pasteurellales* is the regulation of aromatic amino  
354 acid biosynthesis and transport genes, however in *Pseudomonas* and *Shewanella* it mostly controls  
355 the amino acid degradation pathways, whereas in other *Alteromonadales* species, as well as in  
356 *Vibrionales* and *Aeromonadales*, it is implicated in the control of both biosynthetic and catabolic  
357 pathways.

358

359

### 360 HypR regulon for proline and 4-hydroxyproline utilization

361 L-proline, the only proteinogenic imino acid, is used by many bacteria as a source of energy  
362 and a precursor for other amino acid synthesis. 4-hydroxy-L-proline, which can be synthesized post-  
363 translationally from L-proline, is also a rich source of carbon and nitrogen for many microorganisms.  
364 In *Sinorhizobium meliloti*, the hydroxyproline transport and utilization genes (*hyp*) are negatively  
365 regulated by the GntR-family regulator HypR, with 4-hydroxy-L-proline as an inducer (White, et al.  
366 2012). Orthologs of HypR were identified in 13 taxonomic groups that mostly belong to  $\gamma$ -  
367 proteobacteria but also include three  $\alpha$ -proteobacterial and two  $\beta$ -proteobacterial taxa (Figure S2).  
368 The core of reconstructed HypR regulons includes *hypR*, which is autoregulated in 32 out of 46  
369 studied genomes, and *hypE*, *hypO*, *hypD*, and *hypH* encoding enzymes involved in the conversion of  
370 hydroxyproline into  $\alpha$ -ketoglutarate (Figure 5). Operon organization of the *hyp* genes varies among

371 the studied bacteria. Taxonomy-specific regulon members include an alternative 4-hydroxyproline  
372 epimerase (*hypY*) and two putative enzymes from the TCA cycle, malate dehydrogenase (*hypS*) and  
373 citrate isomerase (*hypX*), that are potentially involved in  $\alpha$ -ketoglutarate utilization (Figure 5). PutA,  
374 the main enzyme of the proline catabolic pathway that provides proline oxidation into 1-pyrroline-5-  
375 carboxylate, is the taxonomy-specific member of the HypR regulons in the *Shewanellaceae* and  
376 *Aeromonas* spp. Ornithine can be converted into proline via ornithine cyclodeaminase (COG2423),  
377 which is predicted to be a part of HypR regulon in *Vibrio parahaemolyticus*, *Paracoccus denitrificans*  
378 and several *Shewanella* spp. Thus, HypR function probably expands onto ornithine degradation.

379 In *S. meliloti*, hydroxyproline is imported into the cell via the ABC-family transporter  
380 HypMNPQ, which is predicted to be a part of HypR regulons only in three other genomes and thus  
381 was classified as a taxonomy-specific regulon member. Two other predicted hydroxyproline  
382 transporters, namely HypT from the MFS family and HypABC from the TRAP family, were identified  
383 as genome-specific members of the HypR regulons. Furthermore, HypR-regulated genes encoding a  
384 putative TonB-dependent outer membrane transporter in several *Alteromonadales* and a COG531-  
385 family permease in *Erwinia amylovora* can be also involved in hydroxyproline/proline transport.

386 The large amounts of proline and hydroxyproline are found in the abundant protein collagen  
387 (Phang, et al. 2015). We identified a number of secreted collagenases (*colA1*, *colA2* and *colA3*) within  
388 the reconstructed HypR regulons in the *Alteromonadales* (mostly in *Shewanella* spp.), suggesting the  
389 HypR regulons evolved in these species to include the upstream metabolic steps in the  
390 proline/hydroxyproline utilization pathway (Figure 5). Moreover, the reconstructed HypR regulons in  
391 the *Alteromonadales* and *Aeromonas* taxa of  $\gamma$ -proteobacteria include various proline (di)peptidases  
392 (*PrdP*, *AmpP*, and *YpdF*) and proline dipeptide/tripeptide permease (*PdtP*), suggesting these species  
393 utilize another upstream source of proline for the catabolic pathway (Figure 5).

394

### 395 **HutC regulon for histidine utilization**

396 Histidine is a well-known source of carbon, nitrogen and energy for many bacteria. The  
397 histidine degradation pathway was studied in *Klebsiella aerogenes* and *Salmonella typhimurium* and  
398 involves four reactions catalyzed by HutH, HutU, HutI and HutG (re-named HutG2 in this work,  
399 belongs to the COG0010 family), whereas in *Pseudomonas* spp. the pathway involves an alternative  
400 HutG enzyme from the COG3741 family, as well as an additional reaction catalyzed by HutF (Figure  
401 6) (Goldberg and Magasanik 1975; Zhang and Rainey 2007). The histidine utilization genes are  
402 regulated by orthologous HutC repressors in the above three  $\gamma$ -proteobacteria. Orthologs of HutC  
403 were identified in 113 genomes from all studied taxa of  $\alpha$ -,  $\beta$ -, and  $\gamma$ -proteobacteria except the  
404 *Pasteurellales* (Figure S2). The core of reconstructed HutC regulons includes all known histidine  
405 catabolic enzymes including both alternative HutG enzymes, as well as the HutD protein, which has  
406 yet unknown function in the pathway. At that the HutC regulons in the *Pseudomonadaceae*,  
407 *Enterobacteriales*, *Burkholderiales*, *Rhizobiales* and *Vibrionales* taxa often include multiple paralogs  
408 of the histidine ammonia-lyase HutH. In addition to the *hut* genes, HutC was predicted to co-regulate  
409 the histidine biosynthesis operon in *Colwellia psychrerythraea* and *Idiomarina loihiensis* (Figure 6).

410 The taxonomy- and genome-specific members of the reconstructed HutC regulons are  
411 represented by a number of known or putative transporters involved in histidine uptake (Figure 6).  
412 These include three known histidine uptake systems: the HisT permease in the *Burkholderiales*,  
413 *Moraxellaceae* and *Pseudomonadaceae*, and two distinct ABC-family transporters, HisJMPQ in  
414 *Burkholderia* and HutXYZ in *Pseudomonadas* and some *Rhizobiales*. A novel histidine transporter

415 from the ABC family (named HisXYZ) was predicted in the *Comamonadaceae*, *Ralstonia* and  
416 *Rhizobiales*. Moreover, the reconstructed regulons include a novel TonB-dependent outer  
417 membrane transporter in the *Caulobacterales* and *Sphingomonadales*, a COG2814-family permease  
418 in *Ralstonia* spp. and a COG3314-family transmembrane protein in *Aeromonas*, *Psychromonas* and  
419 *Marinomonas* spp. that are potentially involved in histidine uptake. Additional putative transporter  
420 from the COG1457 family was identified in the HutC regulons of *Burkholderia*, *Pseudomonas*,  
421 *Klebsiella* and *Acinetobacter* spp., however all these species already possess the HisT permease.  
422 Therefore, there is not enough information to support assignment of histidine specificity to these  
423 novel COG1457-family transporters that are homologous to purine and allantoino transporters.

424

#### 425 **Taxonomy-specific regulon expansion/shrinking**

426 In addition to the above described five amino acid-specific regulons and also the previously  
427 described methionine regulons (Leyn, et al. 2014), we observed many variations in reconstructed  
428 regulons for orthologous TFs in different lineages of Proteobacteria including regulon expansion and  
429 contraction and many cases of recruiting non-orthologous TFs to control equivalent pathways. The  
430 most interesting and novel examples of the observed evolutionary changes in the reconstructed TF  
431 regulons are briefly described below.

432 The FabR repressor, which was previously known to control the fatty acid biosynthesis genes  
433 *fabAB* in *E. coli* and other *Enterobacteriales*, co-regulates the unsaturated fatty acid biosynthesis  
434 genes *desABC* in several lineages of  $\gamma$ -proteobacteria. In addition, the FabR regulon in six *Shewanella*  
435 species is expanded by the *pfaRABCD* operon encoding polyunsaturated fatty acid synthase. The  
436 fatty acid degradation pathway in *Shewanellaceae* and other  $\gamma$ -proteobacteria is regulated by PsrA,  
437 whereas in *Enterobacteriales* the analogous pathway is regulated by FadR. The FadR regulon in  
438 *Shewanellaceae* is contracted and retains only two operons shared with the orthologous regulon in  
439 *Enterobacteriales* and *Vibrionales* (*fadIJ* and *fadL*). The PsrA regulon in *Shewanellaceae* is expanded  
440 by several operons involved in the tricarboxylic acid cycle (*aceBA*, *sdh*, *gltA*). The biological role of  
441 PsrA regulons in two lineages of  $\beta$ -proteobacteria, *Ralstonia* and *Burkholderia*, is shifted to control  
442 the fatty acid biosynthesis genes, whereas the fatty acid degradation genes are predicted to be co-  
443 regulated by a novel regulator TetR-family regulator, termed FadP, in the above two lineages, as well  
444 in *Comamonadaceae*, which lack PsrA or FadR regulons (Kazakov, et al. 2009).

445 HexR in *Enterobacteriales* is a local regulator of glucose-6-phosphate dehydrogenase (*zwf*),  
446 whereas in other lineages of  $\gamma$ -proteobacteria it co-regulates *zwf-pgl* with genes from the Entner-  
447 Doudoroff pathway (*edd*, *eda*), glucokinase (*glk*) and pyruvate kinase (*pykA*). The HexR regulons in  
448 *Shewanellaceae* and *Vibrionales* are significantly expanded to include various other genes from the  
449 central glycolytic and fermentation pathways, glucose transport, mannitol utilization, nucleoside  
450 metabolism, glutamate biosynthesis, and the glycine cleavage system (Leyn, et al. 2011). The  
451 pyruvate-responsive regulator PdhR, which solely control the pyruvate dehydrogenase operon  
452 *aceEF-lpdA* in *Enterobacteriales*, *Vibrionales* and several other lineages, undergoes radical expansion  
453 to include genes involved in the tricarboxylic acid cycle (*sdhCDAB*, *gltA*, *aceAB*, *oadGAB*) and  
454 fermentation (*pflBA*, *focA*, *lldP-dld*) in *Shewanellaceae*.

455 NtrC protein is a regulator of nitrogen assimilation described in *E. coli* and *Rhodobacter*  
456 *capsulatus* (Reitzer 2003; Masepohl and Hallenbeck 2010). Orthologs of the NtrC protein were found  
457 in 19 analyzed taxa. A core part of the regulon contains genes for glutamine synthetase (*glnA*),  
458 ammonium transporter (*amtB*) and nitrogen assimilation regulatory genes (*glnBK* and *ntrB*, *ntrC*). On

459 the other hand, the NtrC regulon demonstrates taxon-specific expansions to other nitrogen  
460 metabolism genes. NtrC-dependent regulation of glutamate dehydrogenase (*gdhA*) is a specific  
461 feature of the *Moraxellaceae*, *Rhodobacterales* and  $\delta$ -proteobacteria. Genes encoding glutamate  
462 synthase (*gltBD*) are regulated by NtrC in the *Moraxellaceae* and *Shewanellaceae*, as well as in some  
463  $\beta$ -,  $\alpha$ - and  $\delta$ -proteobacteria. In a number of taxa, the NtrC regulon is expanded to the genes  
464 encoding hydrogenases that act on carbon-nitrogen bonds. Thus, allophanate hydrolase (*atzF*) and  
465 agmatinase (*speB*) are regulated in the *Rhizobiales* and  $\beta$ -proteobacteria, respectively, whereas  
466 urease (*ureABC*) and urea ABC transporters (*uctABC* and *urtABCDEF*) are regulated in the  
467 *Alteromonadales*, *Oceanospirillales*, *Rhizobiales* and *Rhodobacterales*. In  $\alpha$ - and  $\beta$ -proteobacteria,  
468 the NtrC regulon is expanded to genes involved in nitrogen oxide uptake and reduction, such as  
469 assimilatory reductases of nitrate (*nasAB*) and nitrite (*nasDE* and *nirA*), nitrate-nitrite antiporter  
470 (*narK*) and nitrate ABC transporter (*nrtABC*). Together, the core of the NtrC regulon includes genes  
471 necessary to inclusion of ammonia into organic compounds through glutamine synthesis, whereas  
472 the taxon-specific regulon members are necessary for generation of ammonia via metabolism of  
473 various nitrogen compounds.

474

#### 475 **Non-orthologous TFs for N-acetylglucosamine utilization pathway**

476 Three different TFs were previously found in Proteobacteria to control the N-  
477 acetylglucosamine catabolic pathway, namely NagC, NagQ and NagR (Yang, et al. 2006). All three  
478 regulons have similar cores consisting of two central enzymes from the N-acetylglucosamine  
479 pathway (*nagA* and *nagB*) and a PTS-family transporter that is involved in uptake and  
480 phosphorylation of N-acetylglucosamine. Taxonomic distribution of these three regulatory systems is  
481 not uniform: NagC and NagR were found in  $\gamma$ -proteobacteria, whereas NagQ was identified in  $\alpha$ - and  
482  $\beta$ -proteobacteria, as well as in some lineages of  $\alpha$ - and  $\gamma$ -proteobacteria. Interestingly, *Reinekea* sp. has  
483 two distinct regulators, where the NagQ regulon contains genes involved in the sugar catabolic  
484 pathway (*nagKAB*) and chitin degradation (*cdxA*, *chiA*), whereas NagC controls genes encoding an N-  
485 acetylglucosamine-specific PTS transporter and chemotaxis proteins. Furthermore, in two  
486 *Xanthomonas* spp. we found both NagQ and NagR, where NagQ regulates the N-acetylglucosamine  
487 catabolic and transport genes (*nagAB* and *nagP*), while NagR regulons include the N-  
488 acetylglucosamine kinase and TonB-dependent outer membrane receptors that might be involved in  
489 sugar transport across the outer memberane. Overall, all three N-acetylglucosamine-specific TF  
490 regulons are expanded in many genomes to include various chitin utilization genes. Also, a  
491 significant expansion of the NagC regulon was observed in the *Vibrionales*, where it includes the  
492 central glycolytic (*gapA*, *gapB*, *fbaA*, *pgk*, *eno*) and glycogen biosynthesis (*glgAC*) genes.

493

#### 494 **Two distinct TF regulons for biotin biosynthesis pathway**

495 Two distinct TFs, BirA and BioQ, control the biotin/vitamin B7 biosynthesis pathway in  
496 Proteobacteria. BirA was previously studied in many details in *E. coli* (Beckett 2005). It is a  
497 bifunctional protein that functions both as a transcriptional repressor and a biotin-protein ligase,  
498 which covariantly links biotin to biotin-dependent enzymes. BirA enzymes are ubiquitous in  
499 microorganisms, while the N-terminal DNA-binding domain can be only found in a subset of BirA  
500 proteins from a broad number of Proteobacteria, Firmicutes and several other lineages of Bacteria  
501 and Archaea. Among the studied Proteobacteria, BirA repressors and regulons were found in the  $\gamma$ -  
502 and  $\delta$ -subdivisions. The most conserved part of BirA regulons consists of the biotin biosynthesis

503 genes (*bioABCFD*). The BirA regulons in *Desulfovibrionales* are expanded to include the fatty acid  
504 biosynthesis genes (*fabF*, *fabH*, *acpP*), that are involved in the same pathway with the biotin-  
505 dependent acetyl-CoA carboxylase. The BirA proteins from  $\beta$ - and  $\alpha$ -subdivisions of Proteobacteria  
506 have lost their DNA-binding domains, and apparently the BirA regulons do not exist in these species.

507 The previous comparative genomics analysis of biotin pathway genes has identified a novel  
508 GntR-family TF in  $\alpha$ -proteobacteria from the *Rhizobiales* and *Rhodobacterales* lineages, termed  
509 BioR, which was predicted to control the biotin metabolism genes (Rodionov and Gelfand 2006). The  
510 reconstructed BioR regulons include the biotin biosynthesis genes (*bioABDF*, *bioCG*, *bioZ*), as well as  
511 a novel ECF-family transporter for biotin (*bioYMN*) (Hebbeln, et al. 2007). The BioR regulon was later  
512 experimentally validated in *Brucella melitensis* and *Paracoccus denitrificans* (Feng, et al. 2013; Feng,  
513 et al. 2015).

514

### 515 **Identification of a novel TF regulon involved in NAD biosynthesis**

516 In the *Enterobacteriales*, the NAD cofactor metabolism genes are controlled by NadR  
517 regulator, which is absent in all other lineages of Proteobacteria. The most conserved part of NadR  
518 regulon is the *nadA-pnuC* operon that encodes a *de novo* NAD biosynthesis enzymes and a ribosyl  
519 nicotinamide transporter. In several enterobacterial genomes, NadR controls additional NAD  
520 biosynthesis and nicotinate/vitamin B3 salvage genes (*nadB*, *pncB*, *niaP*, *nadR*).

521 In  $\alpha$ - proteobacteria and several species of  $\beta$ - and  $\gamma$ -proteobacteria we found a novel TF,  
522 termed NadQ, which presumably controls the NAD biosynthesis genes. Proteins from the NadQ  
523 orthologous group belong to yet uncharacterized protein family (COG4111) that is characterized by a  
524 characteristic C-terminal DNA-binding domain with a helix-turn-helix (HTH) motif, which is  
525 homologous to another regulator of NAD metabolism, NrtR (Rodionov, et al. 2008). However, the N-  
526 terminal effector binding domain of NadQ is unique as it is not similar to the ADP ribose-binding  
527 domain of NrtR. Palindromic DNA binding motifs for NadQ identified in seven lineages of  
528 Proteobacteria are characterized by the common consensus sequence ttATRCTCnnnGAGYATAa,  
529 where R and Y stand for purines or pyrimidines, respectively. The *nadQ* genes are often clustered on  
530 the chromosome with the *de novo* NAD biosynthesis genes (*nadABC*). Thus, the core of  
531 reconstructed NadQ regulons in proteobacteria includes these central NAD biosynthesis genes. In  
532 the *Rhodobacterales* and *Caulobacterales*, the NadQ regulon is expanded to include the lower NAD  
533 biosynthesis pathway genes (*nadE* and *nadD*). Effector molecule for the novel NadQ regulator is to  
534 be determined experimentally but the regulon content suggests that it can be either NAD itself or  
535 one of pathway intermediates.

### 536 **Conclusions**

537 We used the comparative genomics approach for reconstruction of regulatory networks for amino  
538 acid and other central metabolic pathways that are controlled by specific groups of TFs. The results  
539 of this study demonstrate considerable variability of the TF regulons for the central metabolic  
540 pathways in Gram-negative bacteria from the phylum Proteobacteria. The core members of the  
541 characterized TF regulons are involved in arginine biosynthesis (ArgR), biotin biosynthesis (BirA),  
542 fatty acid biosynthesis (FabR) and degradation (FadR, FadP, PsrA), glycolate, lactate and pyruvate  
543 utilization (GlcC, LldR, PdhR), central carbohydrate metabolism (HexR), histidine and  
544 hydroxyproline/proline utilization (HutC, HypR), branched-chain amino acid degradation (LiuR, LiuQ),  
545 methionine metabolism (MetJ, MetR, SahR), nitrogen assimilation (NtrC), deoxyribonucleotide

546 biosynthesis (NrdR), N-acetylglucosamine utilization (NagC, NagQ, NagR), pyrimidine degradation  
547 (RutR), tyrosine and phenylalanine metabolism (TyrR) and tryptophan biosynthesis (TrpR). Large-  
548 scale phylogenomic and comparative genomics analyses of these TFs reveal numerous examples of  
549 various evolutionary processes for regulators and their regulons both at the levels of a taxonomic  
550 group/class of bacteria and an individual genome. These predicted evolutionary processes can be  
551 classified into three distinct types: (i) “regulon expansion” in certain taxa compared to other lineages  
552 that can be ranged from additions of several regulons members to large-scale shifts in the regulated  
553 metabolic pathways (e.g., PdhR, TyrR and TrpR regulons in *Shewanella* spp.); (ii) “fuzzy regulons”  
554 when a regulon contains a small conserved core and a large periphery of taxon- and genome-specific  
555 genes (e.g. ArgR, HexR and NtrC regulons); (iii) “regulon loss or acquisition” when entire regulon  
556 (including a TF and all its TFBSs and target genes) is absent or present only in specific genomes  
557 within a taxonomic group of bacteria (e.g. GlcC and HypR that are present in individual species of  
558 *Enterobacteria* or NagR that was found in all but one *Shewanella* spp.). The most conserved  
559 regulatory interactions were identified within TF regulons that are involved in the control of certain  
560 essential biosynthetic pathways (e.g. BirA, NrdR, and FabR). Overall, this study provides new insights  
561 into the evolutionary mechanisms that shape transcriptional regulatory networks in Bacteria.

562

---

## 563 ABBREVIATIONS

564 TF, Transcription factor; TFBS, transcription factor binding site; PWM, positional weight matrix;  
565 CRON, cluster of co-regulated orthologous operons.

567

## 568 ACKNOWLEDGEMENTS

569 This work was supported by the Russian Foundation for Basic Research (14-04-00870) and by the  
570 Russian Academy of Sciences via the program “Molecular and Cellular Biology”. Additional funding  
571 was provided by the Genomic Science Program (GSP), Office of Biological and Environmental  
572 Research (OBER), U.S. Department of Energy (DOE), and is a contribution of the Pacific Northwest  
573 National Laboratory (PNNL) Foundational Scientific Focus Area. Regulon reconstruction in sulfate-  
574 reducing δ-proteobacteria, data accumulation and visualization in the RegPrecise database, and  
575 project maintenance in the RegPredict web server by ENIGMA - Ecosystems and Networks  
576 Integrated with Genes and Molecular Assemblies (<http://enigma.lbl.gov>), a Scientific Focus Area  
577 Program at Lawrence Berkeley National Laboratory, is based upon work supported by the U.S.  
578 Department of Energy, Office of Science, Office of Biological & Environmental Research under  
579 contract number DE-AC02-05CH11231.

728 <sup>1</sup>Initially, we studied 21 TFs that are present in *E. coli* and/or *Shewanella* spp. and that are  
729 conserved in five or more taxonomic groups of Proteobacteria. Additionally, we studied TFs  
730 that represent non-orthologous replacements of the initial set of TFs in some taxonomic  
731 groups are marked by asterisk.

732 <sup>2</sup>Number of genomes and taxonomic groups (in parenthesis) of Proteobacteria that contain  
733 the studied TF regulon. The detailed distribution of regulons and regulogs is provided in  
734 Figure S2.

735 <sup>3</sup>Total number of candidate TF-binding sites (TFBSs) and TF-regulated genes (target genes) in  
736 all studied genomes.

737 <sup>4</sup>Average number of candidate TFBSS per genome.

**Figure S1. Bioinformatics workflow used for reconstruction of TF regulons.**

For regulon reconstruction we started from collections of known TFs in *Escherichia coli* and *Shewanella* species and identification of their orthologs. Collections of TFs were obtained from RegulonDB (Gama-Castro, et al. 2016) for *E. coli* and the RegPrecise (Novichkov et al., 2013) for *Shewanella* spp. For subsequent reconstruction steps we used genomes from MicrobesOnline (Dehal, et al. 2010) database because the RegPredict platform for reconstruction of transcription regulation is linked with genomes in MicrobesOnline. In each taxonomic group, from 4 to 16 representative genomes were selected based on the MicrobesOnline species tree. Closely related strains were eliminated from our analysis to

avoid skews in the consistency check approach and to simplify the simultaneous analysis in the RegPredict web server. At that we preferably selected most well studied genome representative in each set of closely-related genomes. Next we searched for orthologous TFs in the selected genomes using the bidirectional best hits approach and protein BLAST server at NCBI (Altschul, et al. 1997).

For regulon reconstruction in each group of genomes possessing TF orthologs we used standard comparative genomics approach (Rodionov 2007) that consists of the next steps:

1. Obtain training set of potential TFBS;
2. Build positional weight matrix (PWM);
3. Whole-genomic search for additional TFBSs and regulon members;
4. False positive filtering;
5. PWM refinement and continue from step 2.

For collection of training sets we used two strategies. (i) For studied known regulons we collected upstream regions of known to be regulated genes with attention for more precise information about location of TFBSs (as electrophoretic mobility shift assay or DNase footprinting assay). (ii) For novel TF regulons, we used genomic context analysis where we predicted regulation of neighborhood genes by their conservative co-localization in one locus mapped to phylogenetic tree of TF. Another approach is functional analysis based on assumption that genes from one metabolic pathway or one process should be regulated simultaneously. Based on this approach we taken upstreams of genes from one process. Association of TF with regulation was made by conservative co-localization of TF gene with genes from this pathway.

Collected upstream regions were used to identify a common DNA motif using the Discover Profiles tool in the RegPredict platform (Novichkov et al., 2010). We searched for DNA motifs either palindromic or tandem repeat symmetry. Sequences of identified DNA motif sites were used to build PWM. The constructed PWMs were further used to search for additional potential TFBSs across upstreams of all genes in genomes using the RegPredict server. Typically we searched the regions beginning 400 nt upstream to and ending 50 nt downstream to the translational start of each gene. Typical threshold for site search procedure was selected as 10% less of the lowest site score from the training set.

The whole genomic searches in RegPredict result in construction of a set of CRONs (Clusters of co-Regulated Orthologous operoNs). Each CRONs in RegPredict was built by the following algorithm: 1) PWM found potential TFBSs above threshold; 2) operon predicted by taking gene with potential TFBS as the first gene of operon and prolong operon to all genes with the same direction and intergenic distance less than 200 nt; 3) identification of orthologs and paralogs for each gene in this operon based on Orthologous Groups in MicrobesOnline database; 4) steps 2 and 3 repeated until convergence. Automatic construction of CRONs and manual curation of the obtained CRONs in the RegPredict server allowed us to filter out false positive site predictions by utilizing the consistency check approach. The consistency check approach is based on the assumption that true sites are conserved in evolution. It should be noted that the cases of operon gene content rearrangement are also taken into consideration in the course of CRON analysis and curation. On next step, the identified true positive TFBSs were added to refine PWM and further repeat the genomic site searches.

At the final step of the manual regulon annotation, gene functions are assigned using the existing gene annotations in Genbank and SEED databases (Overbeek, et al. 2005), annotations of homologous proteins in SwissProt / UniProt database (UniProt 2015) and analysis of Pfam domains (Finn, et al. 2016). All reconstructed regulons were finally deposited in the latest release of the RegPecise database (<http://regprecise.lbl.gov>) (Novichkov, et al. 2013).

**Figure S2. Taxonomic distribution of studied TF regulogs and regulons in 21 taxonomic groups of Proteobacteria**

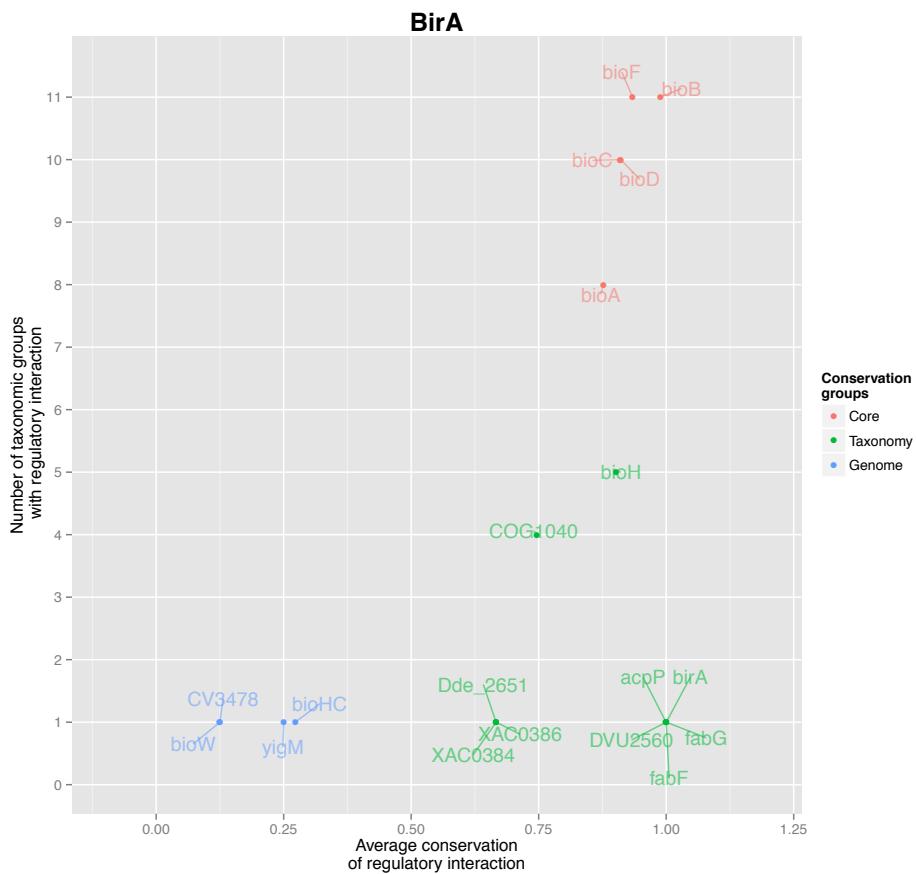

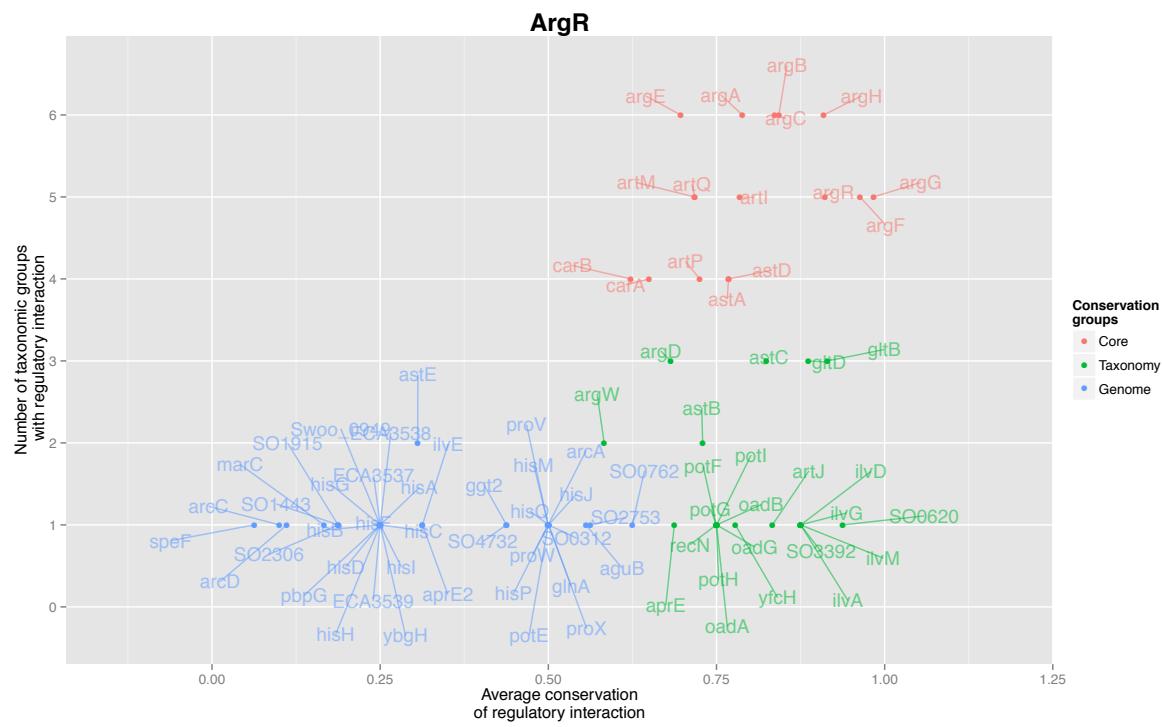

21 TFs are present in *E. coli* and/or *Shewanella* spp. and are conserved in five or more taxonomic groups of Proteobacteria.

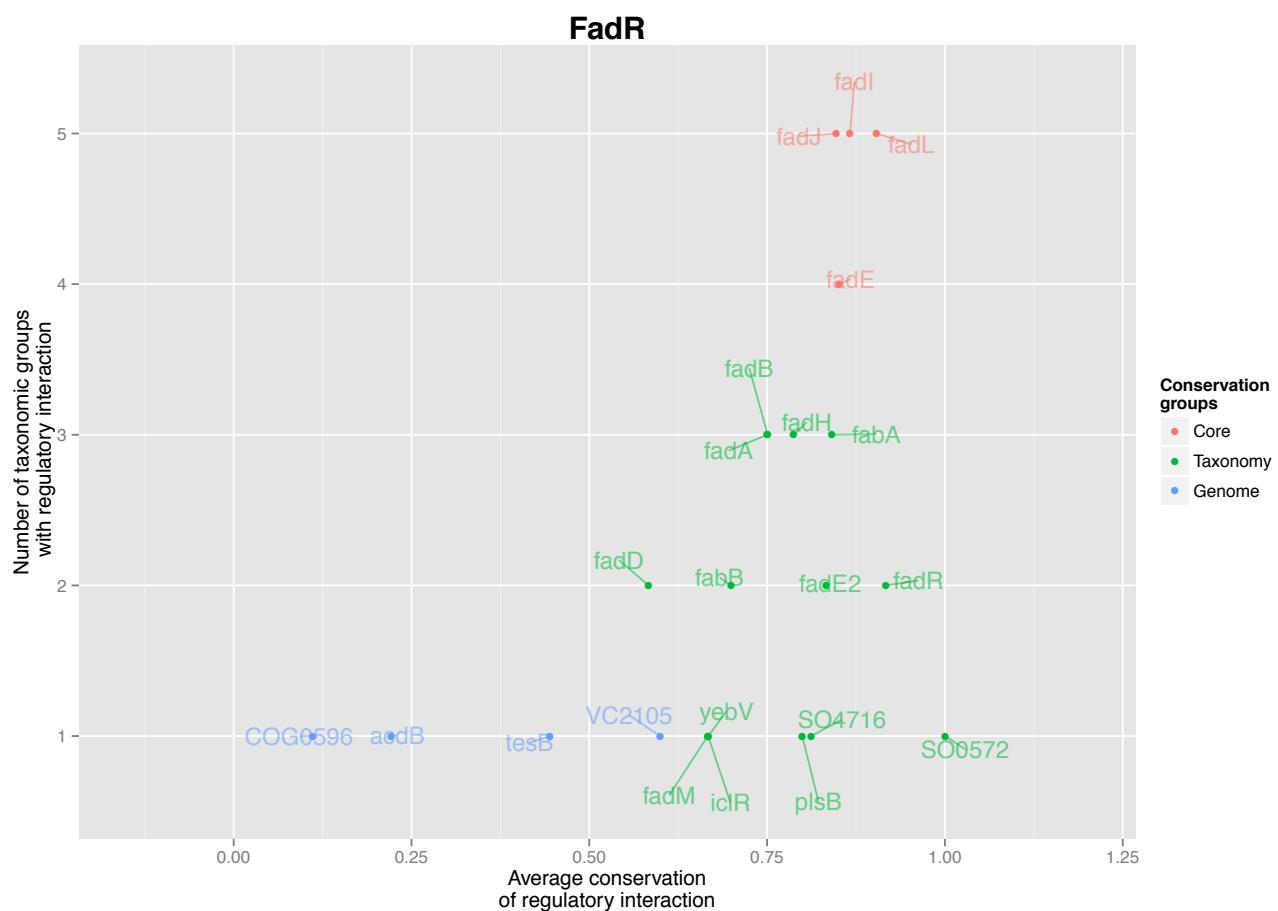

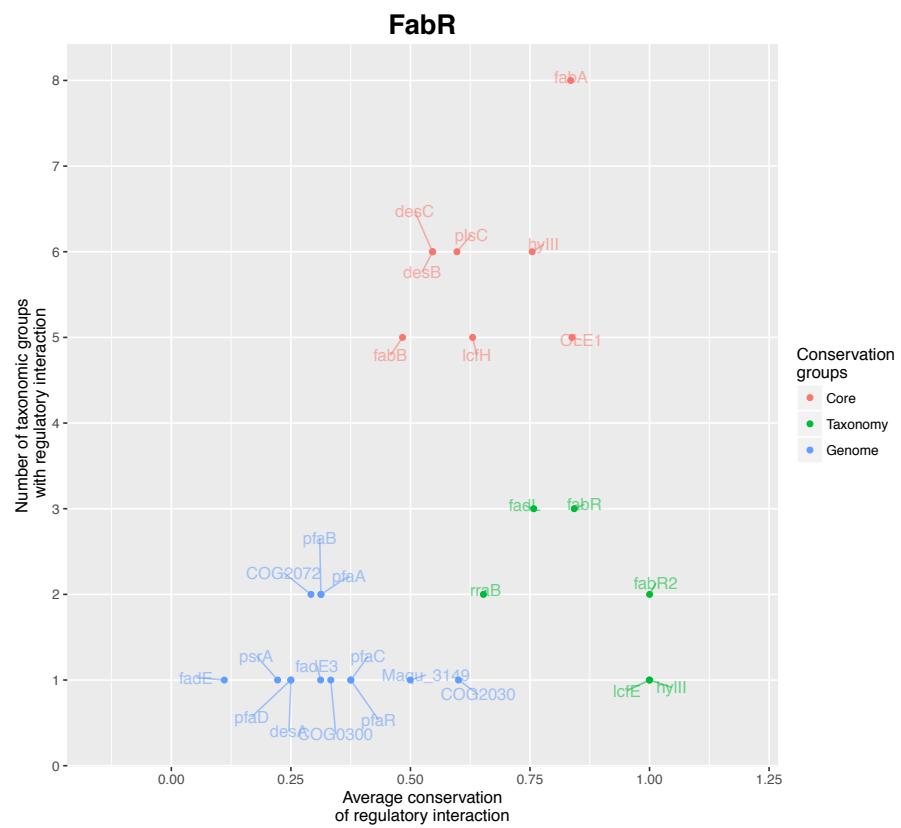

12 TFs that represent non-orthologous replacements of the initial set of TFs in some taxonomic groups are marked by asterisk (\*).

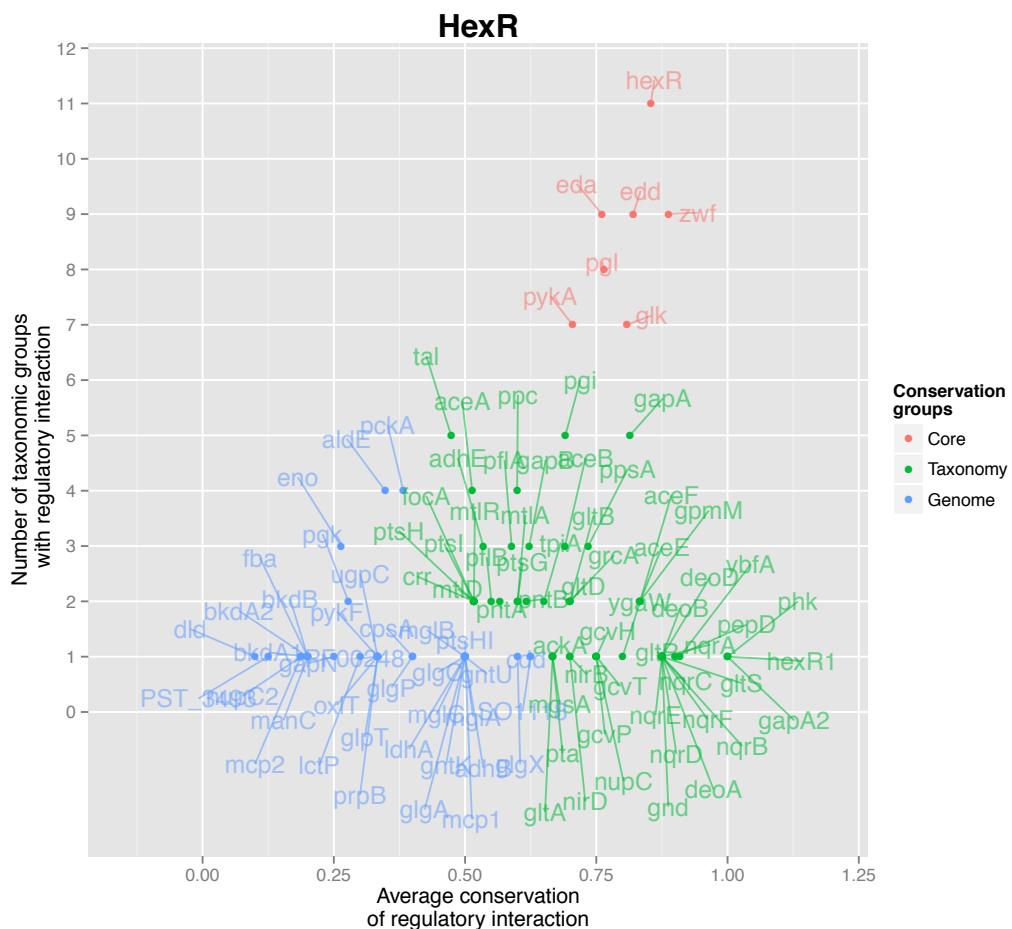

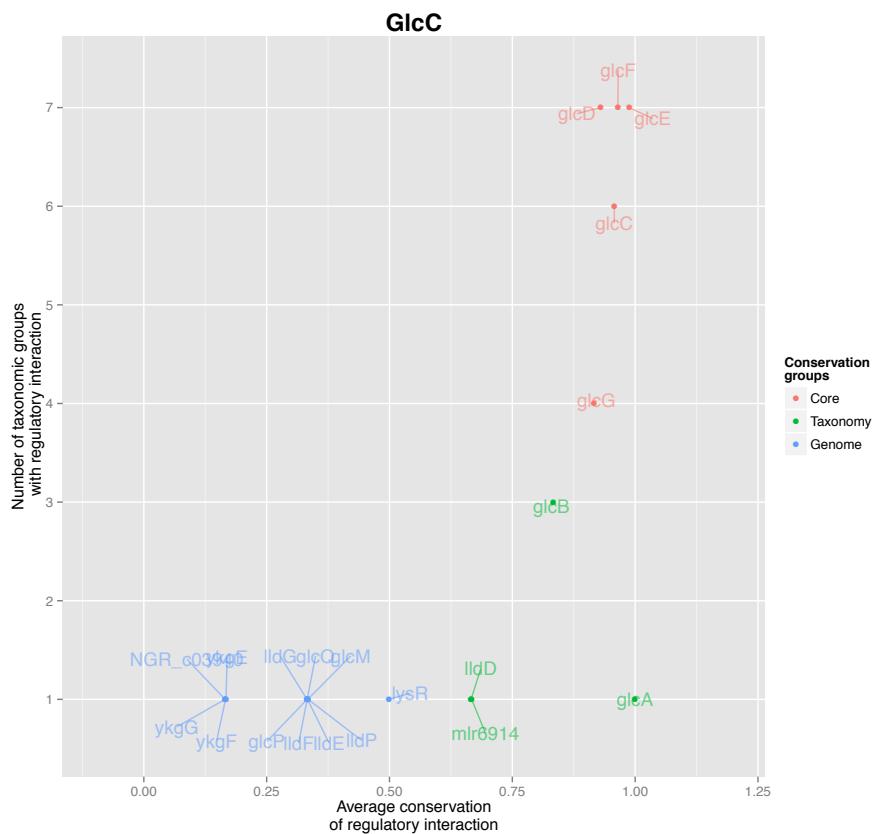

Each cell in represents a TF regulog; each number corresponds to the number of TF regulons per regulog.

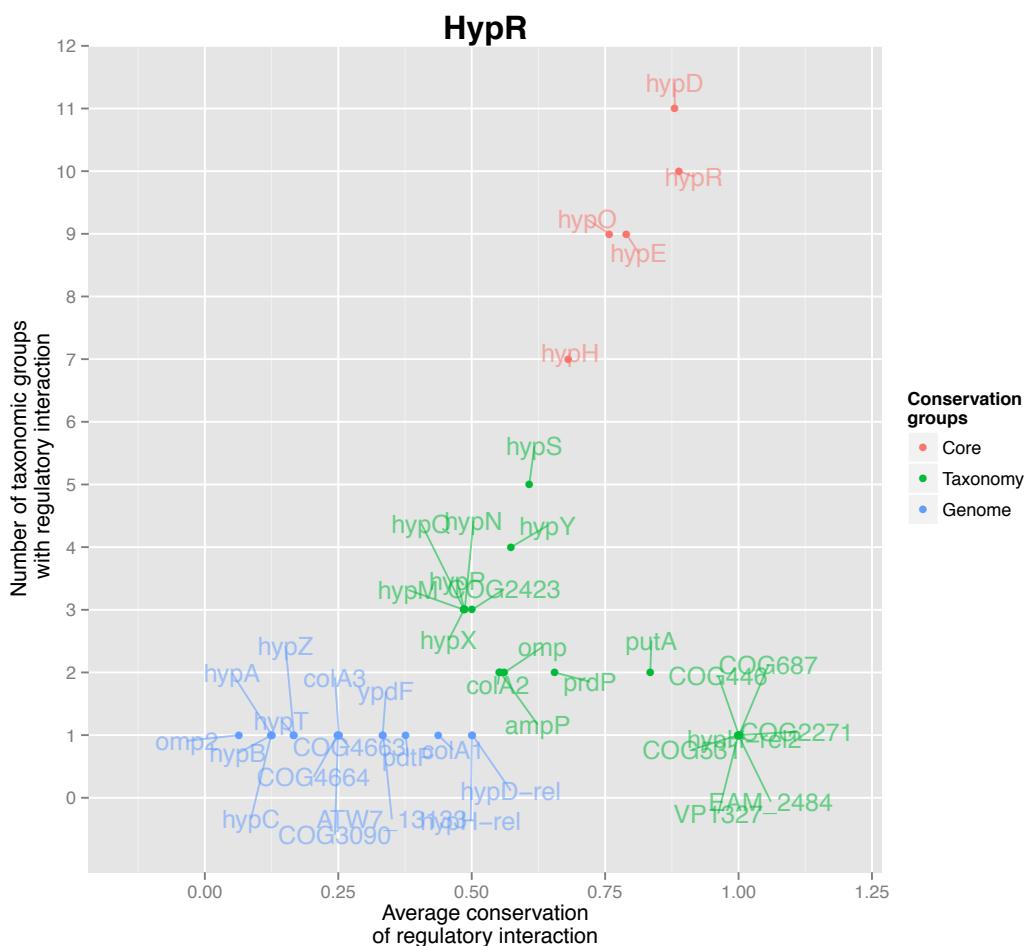

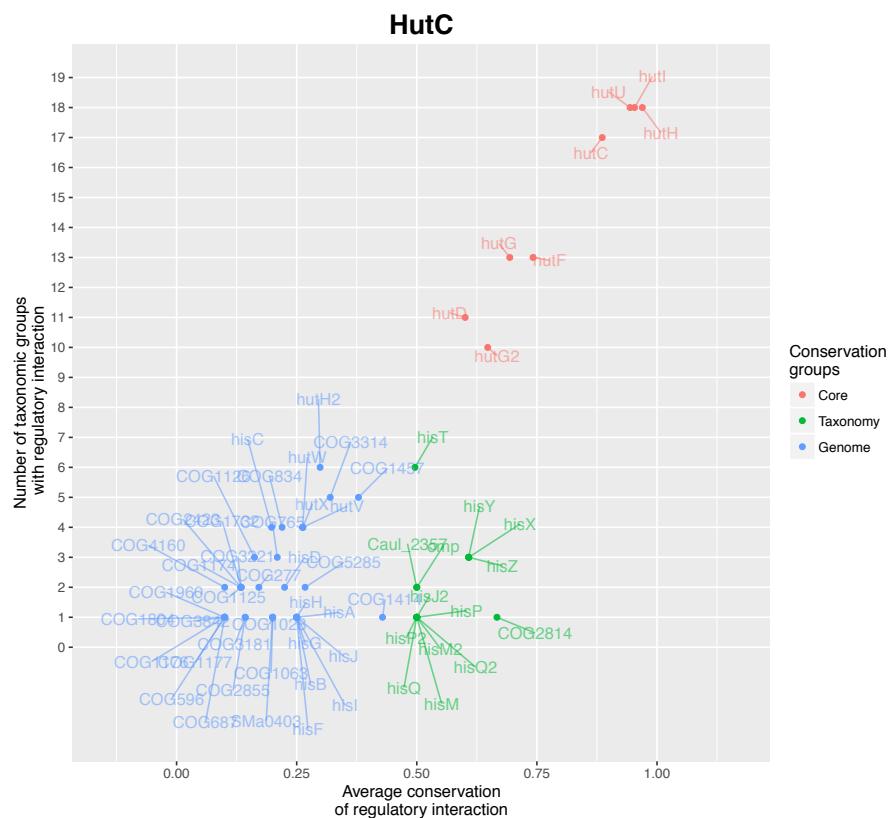

Numbers in red font highlight TFs/taxonomic groups that have multiple regulogs represented by paralogous TFs.

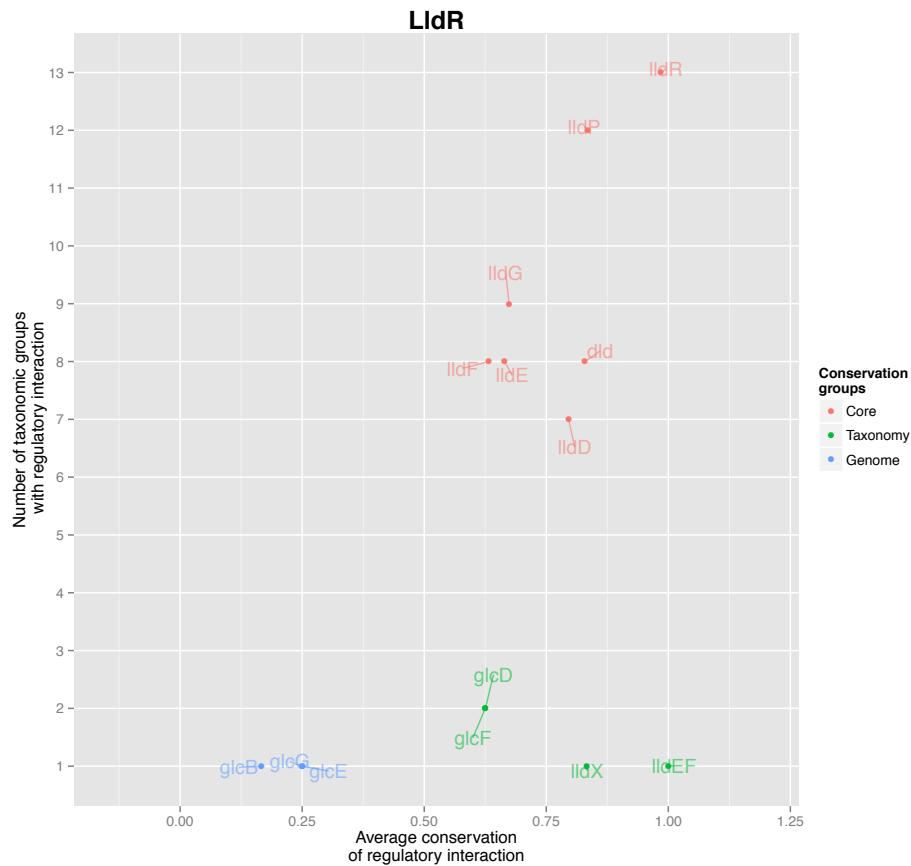

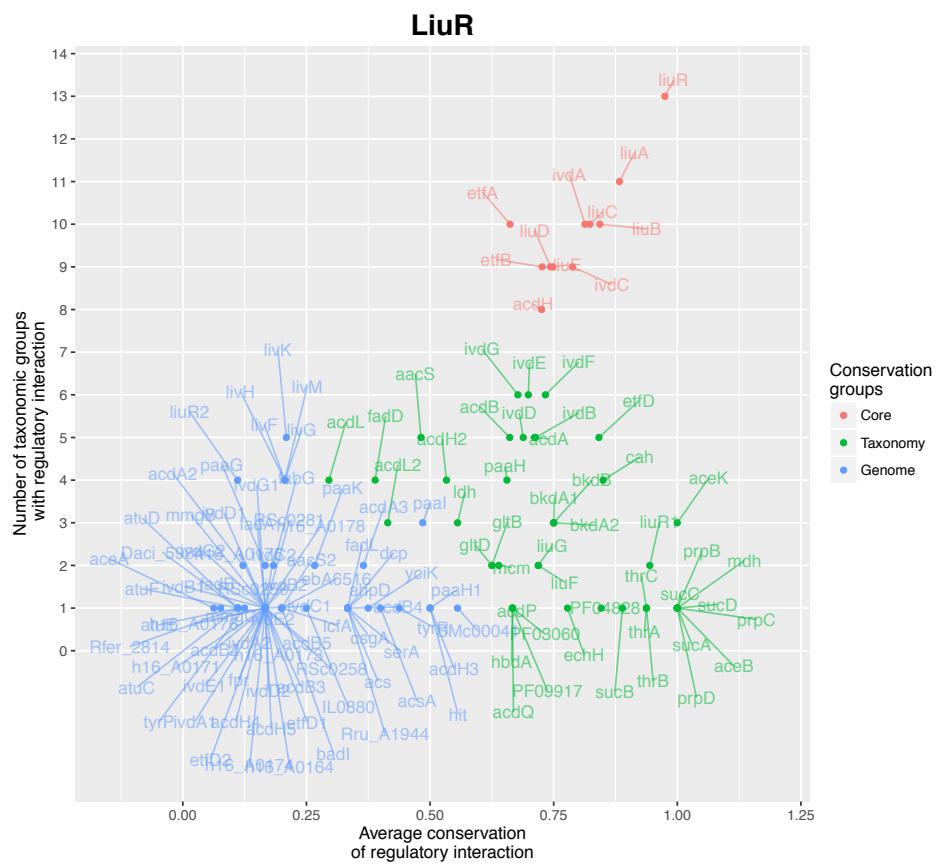

**Figure S3.** Conservation of regulatory interactions in the reconstructed regulons. Core, Taxonomy-specific and Genome-specific groups are highlighted with red, green and blue color respectively. Regulon member names are connected with respective dots by dashes. Functional belonging of regulon members is listed in table S3.

**Table S3. Reconstructed regulatory interactions and functional annotations for the analyzed TF regulons of Proteobacteria.**

Regulon	Target gene	RI <sup>1</sup>	Taxa <sup>2</sup>	Functional role	Metabolic pathway / Biological process
ArgR	argH	57	6	Argininosuccinate lyase (EC 4.3.2.1)	Arginine biosynthesis
ArgR	argB	54	6	Acetylglutamate kinase (EC 2.7.2.8)	Arginine biosynthesis
ArgR	argC	53	6	N-acetyl-gamma-glutamyl-phosphate reductase (EC 1.2.1.38)	Arginine biosynthesis
ArgR	argG	52	5	Argininosuccinate synthase (EC 6.3.4.5)	Arginine biosynthesis
ArgR	argF	52	5	Ornithine carbamoyltransferase (EC 2.1.3.3)	Arginine biosynthesis
ArgR	argA	51	6	N-acetylglutamate synthase (EC 2.3.1.1)	Arginine biosynthesis
ArgR	argR	48	5	Arginine biosynthesis transcription regulator ArgR, ArgR family	Arginine biosynthesis
ArgR	argE	42	6	Acetylornithine deacetylase (EC 3.5.1.16)	Arginine biosynthesis
ArgR	artI	41	5	Arginine ABC transporter, substrate-binding protein	Arginine transport
ArgR	artQ	39	5	Arginine ABC transporter, permease protein 1	Arginine transport
ArgR	artM	39	5	Arginine ABC transporter, permease protein 2	Arginine transport
ArgR	astD	37	4	Succinylglutamic semialdehyde dehydrogenase (EC 1.2.1.71)	Arginine degradation
ArgR	astA	37	4	Arginine N-succinyltransferase (EC 2.3.1.109)	Arginine degradation
ArgR				Acetylornithine aminotransferase (EC 2.6.1.11) / N-succinyl-L,L-diaminopimelate aminotransferase (EC 2.6.1.17) / Succinylornithine transaminase (EC 2.6.1.81)	Arginine degradation
ArgR	astC	31	3		
ArgR	astB	21	2	Succinylarginine dihydrolase (EC 3.5.3.23)	Arginine degradation
ArgR	artP	28	4	Arginine ABC transporter, ATP-binding protein	Arginine transport
ArgR	carA	25	4	Carbamoyl-phosphate synthase small chain (EC 6.3.5.5)	Arginine and pyrimidine biosynthesis
ArgR	carB	24	4	Carbamoyl-phosphate synthase large chain (EC 6.3.5.5)	Arginine and pyrimidine biosynthesis
ArgR	argD	22	3	Acetylornithine aminotransferase (EC 2.6.1.11)	Arginine biosynthesis
ArgR	gltB	34	3	Glutamate synthase [NADPH] large chain (EC 1.4.1.13)	Glutamate biosynthesis
ArgR	gltD	33	3	Glutamate synthase [NADPH] small chain (EC 1.4.1.13)	Glutamate biosynthesis
ArgR	argW	17	2	Predicted arginine uptake transporter, COG3314 family	Arginine transport
ArgR	SO0620	15	1	Conserved hypothetical protein	
ArgR	ilvM	14	1	Acetolactate synthase small subunit (EC 2.2.1.6)	Branched-chain amino acid biosynthesis
ArgR	SO3392	14	1	NADH-dependent flavin oxidoreductase, Oye family	
ArgR	ilvG	14	1	Acetolactate synthase large subunit (EC 2.2.1.6)	Branched-chain amino acid biosynthesis
ArgR	ilvD	14	1	Dihydroxy-acid dehydratase (EC 4.2.1.9)	Branched-chain amino acid biosynthesis
ArgR	ilvA	14	1	Threonine dehydratase biosynthetic (EC 4.3.1.19)	Branched-chain amino acid biosynthesis
ArgR	artJ	10	1	arginine ABC transporter, substrate-binding protein	Arginine transport
ArgR	yfcH	7	1	Conserved hypothetical protein	
ArgR	omp	14	1	TonB-dependent outer membrane transporter	Arginine transport ?
ArgR	oadA	12	1	Oxaloacetate decarboxylase, alpha chain (EC 4.1.1.3)	Pyruvate metabolism
ArgR	oadB	12	1	Oxaloacetate decarboxylase, beta chain (EC 4.1.1.3)	Pyruvate metabolism
ArgR	oadG	12	1	Oxaloacetate decarboxylase gamma chain (EC 4.1.1.3)	Pyruvate metabolism
ArgR	potF	12	1	Putrescine ABC transporter, substrate-binding protein (TC 3.A.1.11.2)	Putrescine transport
ArgR	potG	12	1	Putrescine ABC transporter, ATP-binding protein (TC 3.A.1.11.2)	Putrescine transport
ArgR	potH	12	1	Putrescine ABC transporter, permease protein 1 (TC 3.A.1.11.2)	Putrescine transport
ArgR	potI	12	1	Putrescine ABC transporter, permease protein 2 (TC 3.A.1.11.2)	Putrescine transport
ArgR	recN	12	1	DNA repair protein RecN	DNA repair
ArgR	aprE	11	1	Alkaline serine protease	
ArgR	SO0762	10	1	Isochorismate hydrolase (EC 3.3.2.1)	
ArgR	astE	7	2	succinylglutamate desuccinylase	Arginine degradation
ArgR	SO2753	9	1	Prolyl endopeptidase (EC 3.4.21.26)	
ArgR	arcA	5	1	Arginine deiminase (EC 3.5.3.6)	Arginine degradation
ArgR	arcB	1	1	Ornithine carbamoyltransferase (EC 2.1.3.3), catabolic	Arginine degradation
ArgR	arcC	1	1	Carbamate kinase (EC 2.7.2.2)	Arginine degradation

<b>ArgR</b>	arcD	1	1	Arginine/ornithine antiporter	Arginine degradation
<b>ArgR</b>	hisJ	6	1	histidine ABC transporter, substrate-binding protein	Histidine transport
<b>ArgR</b>	hisM	6	1	histidine ABC transporter, inner membrane permease	Histidine transport
<b>ArgR</b>	hisP	6	1	histidine ABC transporter, ATP-binding protein	Histidine transport
<b>ArgR</b>	hisQ	6	1	histidine ABC transporter, permease protein	Histidine transport
<b>ArgR</b>	potE	8	1	Putrescine/ornithine antiporter	Putrescine transport
<b>ArgR</b>	proV	3	1	Glycine betaine/L-proline ABC transporter, ATP-binding protein	Proline transport
<b>ArgR</b>	proW	3	1	Glycine betaine/L-proline ABC transporter, permease protein	Proline transport
<b>ArgR</b>	proX	3	1	Glycine betaine/L-proline ABC transporter, substrate-binding protein	Proline transport
<b>ArgR</b>	SO0312	8	1	Predicted outer membrane porin	
<b>ArgR</b>	ggt2	7	1	Gamma-glutamyltranspeptidase (EC 2.3.2.2)	Glutathione metabolism
<b>ArgR</b>	SO4732	7	1	Conserved hypothetical protein	
<b>ArgR</b>	mcp	6	1	Methyl-accepting chemotaxis protein	
<b>ArgR</b>	aprE2	5	1	Cold-active alkaline serine protease (EC 3.4.21.62)	
<b>ArgR</b>	ilvE	5	1	Branched-chain amino acid aminotransferase (EC 2.6.1.42)	Branched-chain amino acid biosynthesis
<b>ArgR</b>	ECA3537	3	1	amino acid-binding protein	
<b>ArgR</b>	ECA3538	3	1	polar amino acid ABC transporter, inner membrane subunit	
<b>ArgR</b>	ECA3539	3	1	amino acid ABC transporter, ATP-binding protein	
				Phosphoribosylformimino-5-aminoimidazole carboxamide ribotide isomerase (EC 5.3.1.16)	
<b>ArgR</b>	hisA	4	1	Histidinol-phosphatase (EC 3.1.3.15) / Imidazoleglycerol-phosphate dehydratase (EC 4.2.1.19)	Histidine biosynthesis
<b>ArgR</b>	hisB	4	1	Histidinol-phosphate aminotransferase (EC 2.6.1.9)	Histidine biosynthesis
<b>ArgR</b>	hisC	4	1	Histidinol dehydrogenase (EC 1.1.1.23)	Histidine biosynthesis
<b>ArgR</b>	hisD	4	1	Imidazole glycerol phosphate synthase cyclase subunit (EC 4.1.3.-)	Histidine biosynthesis
<b>ArgR</b>	hisF	4	1	ATP phosphoribosyltransferase (EC 2.4.2.17)	Histidine biosynthesis
<b>ArgR</b>	hisG	4	1	Imidazole glycerol phosphate synthase amidotransferase subunit (EC 2.4.2.-)	Histidine biosynthesis
				Phosphoribosyl-AMP cyclohydrolase (EC 3.5.4.19) / Phosphoribosyl-ATP pyrophosphatase (EC 3.6.1.31)	
<b>ArgR</b>	hisI	4	1		Histidine biosynthesis
<b>ArgR</b>	pbpG	4	1	D-alanyl-D-alanine endopeptidase	
<b>ArgR</b>	Swoo_0949	4	1	Peptidase U32

<b>NagC</b>	chi	6	2	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagC</b>	nagD	8	1	Phosphatase NagD predicted to act in N-acetylglucosamine utilization subsystem	N-acetylglucosamine utilization
				PTS system, N-acetylglucosamine-specific IIB component (EC 2.7.1.69) / PTS system, N-	
<b>NagC</b>	nagE1	6	1	acetylglucosamine-specific IIC component (EC 2.7.1.69)	N-acetylglucosamine utilization
<b>NagC</b>	gapA	5	1	NAD-dependent glyceraldehyde-3-phosphate dehydrogenase (EC 1.2.1.12)	Glycolysis
<b>NagC</b>	chbR	6	1	Chitobiose-specific regulator ChbR, AraC family	Transcription regulation
<b>NagC</b>	chbB	6	1	PTS system, chitobiose-specific IIB component (EC 2.7.1.69)	Chitobiose utilization
<b>NagC</b>	gdhA	1	1	NADP-specific glutamate dehydrogenase (EC 1.4.1.4)	Glutamate degradation
<b>NagC</b>	rpmJ1	1	1	ribosomal protein L36	

<b>NagC</b>	chbA	6	1	N,N'-diacetylchitobiose-specific PTS system, EIIA component	Chitobiose utilization
<b>NagC</b>	exbD	1	1	Biopolymer transport protein ExbD/TolR	
<b>NagC</b>	tonB	1	1	Periplasmic binding protein TonB	
<b>NagC</b>	chbC	6	1	PTS system, chitobiose-specific IIC component (EC 2.7.1.69)	Chitobiose utilization
<b>NagC</b>	exbB	1	1	Biopolymer transport protein ExbB	
<b>NagC</b>	chbG	6	1	Cellobiose phosphotransferase system YdjC-like protein	
<b>NagC</b>	chbF	5	1	Chitobiose-specific 6-phospho-beta-glucosidase ChbF (EC 3.2.1.86)	Chitobiose utilization
<b>NagC</b>	ybfM	4	1	N-acetylglucosamine-regulated outer membrane porin	Chitobiose utilization
<b>NagC</b>	cbp	4	1	Chitin binding protein	Chitin degradation
<b>NagC</b>	gigA	3	1	Glycogen synthase, ADP-glucose transglucosylase (EC 2.4.1.21)	Glycogen metabolism
<b>NagC</b>	grcA	3	1	autonomous glycal radical cofactor GrcA	
<b>NagC</b>	chiP	3	1	Outer membrane chitoporin	Chitobiose transport
<b>NagC</b>	chiD	3	1	Chitodextrinase precursor (EC 3.2.1.14)	Chitin degradation
<b>NagC</b>	gigC	3	1	Glucose-1-phosphate adenyltransferase (EC 2.7.7.27)	Glycogen metabolism
<b>NagC</b>	gapB	3	1	NADPH-dependent glyceraldehyde-3-phosphate dehydrogenase (EC 1.2.1.13)	Glycolysis
<b>NagC</b>	ompC	3	1	Predicted OmpC-like chitoporin	Chitobiose utilization
<b>NagC</b>	adh	2	1	Alcohol dehydrogenase (EC 1.1.1.1); Acetaldehyde dehydrogenase (EC 1.2.1.10)	
<b>NagC</b>	gitA	2	1	Citrate synthase (sil) (EC 2.3.3.1)	Tricarboxylic acid cycle
<b>NagC</b>	chiS	2	1	Chitin catabolic cascade sensor histidine kinase ChiS	Transcription regulation
<b>NagC</b>	epd	2	1	D-erythrose-4-phosphate dehydrogenase (EC 1.2.1.72)	
<b>NagC</b>	galP	2	1	D-galactose transporter	Galactose transport
<b>NagC</b>	chi1	1	1	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagC</b>	VP1029	1	1	Hypothetical protein	
<b>NagC</b>	ompU	1	1	Outer membrane protein OmpU	
<b>NagC</b>	VC1591	1	1	Oxidoreductase, short-chain dehydrogenase/reductase family	
<b>NagC</b>	aldC	1	1	Alpha-acetolactate decarboxylase (EC 4.1.1.5)	
<b>NagC</b>	budB	1	1	Acetolactate synthase, catabolic (EC 2.2.1.6)	
<b>NagC</b>	alsR	1	1	Transcriptional regulator of alpha-acetolactate operon alsR	Transcription regulation
<b>NagC</b>	nanM	1	1	N-acetylneurameric acid-induced hypothetical transmembrane protein	N-acetylneurameric acid transport
<b>NagC</b>	fimB	1	1	type 1 fimbriae regulatory protein FimB	
<b>NagC</b>	nanC	1	1	N-acetylneurameric acid outer membrane channel protein NanC	N-acetylneurameric acid transport
<b>NagQ</b>	nagQ	33	10	Predicted transcriptional regulator of N-Acetylglucosamine utilization, GntR family	Transcription regulation
<b>NagQ</b>	nagA	30	10	N-acetylglucosamine-6-phosphate deacetylase (EC 3.5.1.25)	N-acetylglucosamine utilization
<b>NagQ</b>	nagB2	26	9	Glucosamine-6-phosphate deaminase [isomerizing], alternative (EC 3.5.99.6) PTS system, N-acetylglucosamine-specific IIB component (EC 2.7.1.69) / PTS system, N-	N-acetylglucosamine utilization
<b>NagQ</b>	nagE	15	6	acetylglucosamine-specific IIC component (EC 2.7.1.69)	N-acetylglucosamine utilization
<b>NagQ</b>				PTS system, glucose-specific IIA component (EC 2.7.1.69) / Phosphocarrier protein of PTS system / Phosphoenolpyruvate-protein phosphotransferase of PTS system (EC 2.7.3.9)	Sugar transport
<b>NagQ</b>	ptsl	15	5		
<b>NagQ</b>	nagK	13	3	N-acetylglucosamine kinase of eukaryotic type (EC 2.7.1.59)	N-acetylglucosamine utilization
<b>NagQ</b>	murQ	8	3	N-acetylmuramic acid 6-phosphate etherase (EC 4.2.-)	N-acetylmuramic acid utilization
<b>NagQ</b>	nagT	11	3	N-Acetyl-D-glucosamine ABC transport system, sugar-binding protein	N-acetylglucosamine utilization
<b>NagQ</b>	nagV	10	3	N-Acetyl-D-glucosamine ABC transport system, permease protein 2	N-acetylglucosamine utilization
<b>NagQ</b>	nagU	10	3	N-Acetyl-D-glucosamine ABC transport system, permease protein 1	N-acetylglucosamine utilization
<b>NagQ</b>	nagW	10	3	N-Acetyl-D-glucosamine ABC transport system, ATP-binding component	N-acetylglucosamine utilization
<b>NagQ</b>	hex	3	2	Beta-hexosaminidase (EC 3.2.1.52)	N-acetylglucosamine utilization
<b>NagQ</b>	chiA	2	2	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagQ</b>	cdxA	2	2	Chitodextrinase precursor (EC 3.2.1.14)	Chitin degradation
<b>NagQ</b>	omp_nag	4	1	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagQ</b>	nagD	6	2	Hypothetical oxidoreductase related to N-acetylglucosamine utilization	
<b>NagQ</b>	nagZ	1	1	Beta N-acetyl-glucosaminidase (EC 3.2.1.52)	Chitin degradation

<b>NagQ</b>	nagB	3	1	Glucosamine-6-phosphate deaminase (EC 3.5.99.6)	N-acetylglucosamine utilization
<b>NagQ</b>	nagR	2	1	Transcriptional regulator of N-acetylglucosamine utilization, LacI family	Transcription regulation
<b>NagQ</b>	wecA	1	1	Undecaprenyl-phosphate N-acetylglucosaminy 1-phosphate transferase (EC 2.7.8.-)	
<b>NagQ</b>	hex2	1	1	N-Acetyl-D-glucosamine ABC transport system ATP-binding protein	Chitin degradation
<b>NagQ</b>	cga	1	1	Glucoamylase (EC 3.2.1.3)	
<b>NagQ</b>	ybfM	1	1	N-acetylglucosamine-regulated outer membrane porin	Chitobiose utilization
<b>NagQ</b>	cbp21	1	1	Chitin binding protein	Chitin degradation
<b>NagQ</b>	chiC	1	1	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagQ</b>	chi	1	1	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagQ</b>	nagP	2	1	N-acetylglucosamine transporter, NagP	N-acetylmuramic acid utilization
<b>NagQ</b>	omp1	1	1	Outer membrane protein (porin)	Chitobiose utilization
<b>NagQ</b>	CC0542	1	1	Predicted periplasmic phosphohydrolase	
<b>NagQ</b>	MED297_05914	1	1	Hypothetical protein	
<b>NagQ</b>	nagX	1	1	N-acetylglucosamine related transporter, NagX	N-acetylmuramic acid utilization
<b>NagQ</b>	anaG	1	1	Alpha-N-acetylglucosaminidase (EC 3.2.1.50)	Alpha-N-acetylglucosaminidase
<b>NagQ</b>	mIr4776	1	1	Hypothetical protein	
<b>NagQ</b>	nagM	1	1	Predicted N-Acetylglucosamine ABC transporter, inner membrane subunit	N-acetylmuramic acid utilization
<b>NagQ</b>	nagO	1	1	Predicted N-Acetylglucosamine ABC transporter, periplasmic sugar-binding protein	N-acetylmuramic acid utilization
<b>NagQ</b>	nagN	1	1	Predicted N-Acetylglucosamine ABC transporter, permease protein	N-acetylmuramic acid utilization
<b>NagQ</b>	nagK2	1	1	N-acetylglucosamine kinase (EC 2.7.1.59), ROK family	N-acetylglucosamine utilization
<b>NagQ</b>	nagD1	1	1	Probable oxidoreductase	
<b>NagQ</b>	nagL	1	1	Predicted N-Acetylglucosamine ABC transporter, ATP-binding protein	N-acetylmuramic acid utilization
<b>NagR</b>	omp_nag	24	3	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagR</b>	trpX	24	3	Tryptophan halogenase	
<b>NagR</b>	nagA	23	4	N-acetylglucosamine-6-phosphate deacetylase (EC 3.5.1.25) PTS system, N-acetylglucosamine-specific IIB component (EC 2.7.1.69) / PTS system, N-acetylglucosamine-specific IIC component (EC 2.7.1.69)	N-acetylglucosamine utilization
<b>NagR</b>	nagP	23	4	N-acetylglucosamine kinase of eukaryotic type (EC 2.7.1.59)	N-acetylglucosamine utilization
<b>NagR</b>	nagK	21	3	N-acetylglucosamine related transporter, NagX	N-acetylglucosamine utilization
<b>NagR</b>	nagX	19	3	N-acetylglucosamine related transporter, NagX	N-acetylglucosamine utilization
<b>NagR</b>	hex	18	4	Beta-hexosaminidase (EC 3.2.1.52)	Chitobiose utilization
<b>NagR</b>	nagB2	14	4	Glucosamine-6-phosphate deaminase [isomerizing], alternative (EC 3.5.99.6)	N-acetylglucosamine utilization
<b>NagR</b>	nagK2	6	1	Predicted N-acetylglucosamine kinase, glucokinase-like (EC 2.7.1.59)	N-acetylglucosamine utilization
<b>NagR</b>	nagR	8	3	Transcriptional regulator of N-acetylglucosamine utilization, LacI family	Transcription regulation
<b>NagR</b>	nagB	9	3	Glucosamine-6-phosphate deaminase (EC 3.5.99.6)	N-acetylglucosamine utilization
<b>NagR</b>	chiA	10	3	Chitinase (EC 3.2.1.14)	Chitin degradation
<b>NagR</b>	nixC	3	1	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagR</b>	naxA	3	1	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagR</b>	cbp	7	2	Chitin and N-acetylglucosamine-binding protein A	Chitin degradation
<b>NagR</b>	pckA	2	1	Phosphoenolpyruvate carboxykinase [ATP] (EC 4.1.1.49)	Gluconeogenesis
<b>NagR</b>	chiD	2	1	Chitodextrinase (EC 3.2.1.14)	Chitin degradation
<b>NagR</b>	pgi2	2	1	Glucose-6-phosphate isomerase (EC 5.3.1.9)	Glycolysis
<b>NagR</b>	sapC	10	1	Peptide transport system permease protein sapC (TC 3.A.1.5.5)	
<b>NagR</b>	mcp_nag	8	1	N-acetylglucosamine regulated methyl-accepting chemotaxis protein	Chemotaxis
<b>NagR</b>	nixD	2	1	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagR</b>	nixB	2	1	N-acetylglucosamine-regulated TonB-dependent outer membrane receptor	Chitobiose utilization
<b>NagR</b>	pilM	7	1	homolog of type IV pilus assembly protein PilM	
<b>NagR</b>	duf81	6	1	protein of unknown function DUF81	
<b>NagR</b>	nagS2	1	1	Putative sulfatase (EC 3.1.6.-)	
<b>NagR</b>	SO0851	5	1	preplin-type cleavage/methylation-like protein	

<b>NagR</b>	CPS_2383	1	1	Putative surface protein

<b>RutR</b>	amiC	1	1	Predicted amidase	
<b>SahR</b>	sahR	61	9	Predicted regulator of methionine metabolism, ArsR family	Transcription regulation
<b>SahR</b>	ahcY	50	7	Adenosylhomocysteinase (EC 3.3.1.1)	Methionine metabolism
<b>SahR</b>	metF	43	7	5,10-methylenetetrahydrofolate reductase (EC 1.5.1.20)	Methionine biosynthesis
<b>SahR</b>	metK	41	7	S-adenosylmethionine synthetase (EC 2.5.1.6)	Methionine metabolism
<b>SahR</b>	metH	32	6	5-methyltetrahydrofolate--homocysteine methyltransferase (EC 2.1.1.13)	Methionine biosynthesis
<b>SahR</b>	meth2	14	4	5-methyltetrahydrofolate--homocysteine methyltransferase (EC 2.1.1.13)	Methionine biosynthesis
<b>SahR</b>	metE	8	4	5-methyltetrahydropteroylglutamate--homocysteine methyltransferase (EC 2.1.1.14)	Methionine biosynthesis
<b>SahR</b>	bhmT	4	2	Betaine--homocysteine S-methyltransferase (EC 2.1.1.5)	Methionine biosynthesis
<b>SahR</b>	panC	5	1	Pantoate--beta-alanine ligase (EC 6.3.2.1)	Alanine metabolism

<b>SahR</b>	metB	1	1	Cystathionine gamma-synthase (EC 2.5.1.48)	Methionine biosynthesis
<b>SahR</b>	metX2	1	1	Homoserine O-acetyltransferase (EC 2.3.1.31)	Methionine biosynthesis
<b>SahR</b>	hom	1	1	Homoserine dehydrogenase (EC 1.1.1.3)	Methionine biosynthesis
<b>SahR</b>	metE2	1	1	methionine synthase	Methionine biosynthesis
<b>SahR</b>	DUF1852	1	1	Protein of unknown function DUF1852	
<b>SahR</b>	ddl	1	1	D-alanine--D-alanine ligase B (EC 6.3.2.4)	Alanine metabolism
<b>SahR</b>	Caul_3406	1	1	PIN domain protein	
<b>SahR</b>	metT	1	1	Methionine transporter MetT	Methionine transport
<b>SamR</b>	metE	1	1	5-methyltetrahydropteroylglutamate--homocysteine methyltransferase (EC 2.1.1.14)	Methionine biosynthesis
<b>SamR</b>	metF2	4	1	5,10-methylenetetrahydrofolate reductase (EC 1.5.1.20)	Methionine biosynthesis
<b>SamR</b>	metX2	4	1	Homoserine O-acetyltransferase (EC 2.3.1.31)	Methionine biosynthesis
<b>SamR</b>	metB	4	1	Cystathionine gamma-synthase (EC 2.5.1.48)	Methionine biosynthesis
<b>SamR</b>	hom	3	1	Homoserine dehydrogenase (EC 1.1.1.3)	Methionine biosynthesis
<b>SamR</b>	metK	4	1	S-adenosylmethionine synthetase (EC 2.5.1.6)	SAM biosynthesis
<b>SamR</b>	samR	4	1	Transcriptional regulator of methionine metabolism, ArsR family	Transcription regulation
<b>SamR</b>	metH1	3	1	5-methyltetrahydrofolate--homocysteine methyltransferase (EC 2.1.1.13)	Methionine biosynthesis
<b>SamR</b>	metH2	3	1	5-methyltetrahydrofolate--homocysteine methyltransferase (EC 2.1.1.13)	Methionine biosynthesis
<b>TrpR</b>	trpE	36	6	Anthraniate synthase, aminase component (EC 4.1.3.27)	Tryptophan biosynthesis
<b>TrpR</b>	trpR	37	6	Trp operon repressor	Transcription regulation
<b>TrpR</b>	trpG	12	4	Anthraniate synthase, amidotransferase component (EC 4.1.3.27)	Tryptophan biosynthesis
<b>TrpR</b>	trpB	30	4	Tryptophan synthase beta chain (EC 4.2.1.20)	Tryptophan biosynthesis
<b>TrpR</b>	trpC	27	3	Indole-3-glycerol phosphate synthase (EC 4.1.1.48)	Tryptophan biosynthesis
<b>TrpR</b>	trpA	29	3	Tryptophan synthase alpha chain (EC 4.2.1.20)	Tryptophan biosynthesis
<b>TrpR</b>	mtr	17	3	Tryptophan-specific transport protein	Tryptophan transport
<b>TrpR</b>	trpD	24	2	Anthraniate phosphoribosyltransferase (EC 2.4.2.18)	Tryptophan biosynthesis
<b>TrpR</b>	trpD_a	10	1	Anthraniate synthase, amidotransferase component (EC 4.1.3.27)	Tryptophan biosynthesis
<b>TrpR</b>	trpD_b	10	1	Anthraniate phosphoribosyltransferase (EC 2.4.2.18)	Tryptophan biosynthesis
<b>TrpR</b>	tyrA	16	1	Chorismate mutase I (EC 5.4.99.5) / Prephenate dehydrogenase [EC:5.4.99.5 1.3.1.12]	Tyrosine & Phenylalanine biosynthesis
<b>TrpR</b>	COG1541	1	1	Coenzyme F390 synthetase	
<b>TrpR</b>	aroF	16	1	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (EC 2.5.1.54)	Aromatic amino acid biosynthesis
<b>TrpR</b>	SSF55729	1	1	Acyl-CoA N-acetyltransferase	
<b>TrpR</b>	COG0733(Trp)	8	1	Predicted tryptophan transporter, SNF family	Tryptophan transport
<b>TrpR</b>	aroG	6	1	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (EC 2.5.1.54)	Aromatic amino acid biosynthesis
<b>TrpR</b>	aroH	6	1	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (EC 2.5.1.54)	Aromatic amino acid biosynthesis
<b>TrpR</b>	aroM	4	1	AroM family protein	Aromatic amino acid biosynthesis
<b>TrpR</b>	aroL	4	1	Shikimate kinase III (EC 2.7.1.71)	Aromatic amino acid biosynthesis
<b>TrpR</b>	yaiA	4	1	putative cytoplasmic protein	
<b>TrpR</b>	aroA	3	1	5-Enolpyruvylshikimate-3-phosphate synthase (EC 2.5.1.19)	Aromatic amino acid biosynthesis
<b>TrpR</b>	COG4221	2	1	Short-chain alcohol dehydrogenase of unknown specificity	
<b>TrpR</b>	HI1388	2	1	Anthraniate synthase, amidotransferase component (EC 4.1.3.27)	Tryptophan biosynthesis
<b>TrpR</b>	tnaB	2	1	Tryptophan-specific transport protein	Tryptophan transport
<b>TrpR</b>	aroF2	2	1	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (EC 2.5.1.54)	Aromatic amino acid biosynthesis
<b>TrpR</b>	HAPS_1139	1	1	ABC transporter, inner-membrane component	
<b>TrpR</b>	HAPS_0395	1	1	ABC transporter, substrate binding component	
<b>TrpR</b>	HAPS_1138	1	1	ABC transporter, ATP-binding protein	
<b>TrpR</b>	tnaA	1	1	Tryptophanase (EC 4.1.99.1)	Tryptophan utilization
<b>TrpR</b>	trpB2	1	1	Tryptophan synthase beta chain like (EC 4.2.1.20)	Tryptophan utilization
<b>TyrR</b>	phhA	41	5	Phenylalanine-4-hydroxylase (EC 1.14.16.1)	Phenylalanine degradation
<b>TyrR</b>	phhB	38	5	Pterin-4-alpha-carbinolamine dehydratase (EC 4.2.1.96)	Phenylalanine degradation

TyrR	tyrA	39	5	Chorismate mutase I (EC 5.4.99.5) / Prephenate dehydrogenase [EC:5.4.99.5 1.3.1.12]	Tyrosine & Phenylalanine biosynthesis
TyrR	tyrR	45	6	Transcriptional regulator of aromatic amino acid biosynthesis	Transcription regulation
TyrR	aroF	35	5	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (EC 2.5.1.54)	Aromatic amino acid biosynthesis
TyrR	COG2814	7	1	Predicted tyrosine transporter, COG2814 family	Tyrosine transport
TyrR	emrD	9	1	multidrug resistance protein D	
TyrR	pepD	9	1	Aminoacyl-histidine dipeptidase (Peptidase D) (EC 3.4.13.3) Proline dehydrogenase (EC 1.5.99.8) (Proline oxidase) / Delta-1-pyrroline-5-carboxylate dehydrogenase (EC 1.5.1.12)	
TyrR	putA	9	1	Proline degradation	
TyrR	kyn	8	1	kynureninase (tryptophan degradation)	Tryptophan degradation
TyrR	aroM	6	1	AroM family protein	Aromatic amino acid biosynthesis
TyrR	SO1117	8	1	peptidase M17, leucyl aminopeptidase	
TyrR	tdo	8	1	tryptophan 2,3-dioxygenase	Tryptophan degradation
TyrR	mtr	5	1	Tryptophan-specific transport protein	Tryptophan transport
TyrR	yaiA	5	1	hypothetical protein	
TyrR	aroG	5	2	2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase I alpha (EC 2.5.1.54)	Aromatic amino acid biosynthesis
TyrR	COG1284	4	1	Hypothetical protein	
TyrR	Sfri_3409	6	1	Hypothetical protein	
TyrR	aprE	6	1	Alkaline serine protease	
TyrR	Sfri_3410	6	1	transcriptional regulator, XRE family protein	
TyrR	ompF	4	1	outer membrane porin F	
TyrR	ipdC	7	2	Indole-3-pyruvate decarboxylase (EC 4.1.1.74)	Tryptophan degradation
TyrR	prlC	4	1	Oligopeptidase A (EC 3.4.24.70)	
TyrR	pep1	3	1	Alkaline serine exoprotease A precursor (EC 3.4.21.-)	
TyrR	aprE2	3	1	Cold-active alkaline serine protease (EC 3.4.21.62)	
TyrR	omp2	3	1	putative TonB-dependent outer membrane receptor	
TyrR	tpl	3	2	Tyrosine phenol-lyase (EC 4.1.99.2)	Tyrosine degradation
TyrR	folA	1	1	Dihydrofolate reductase (EC 1.5.1.3)	Tetrahydrofolate biosynthesis
TyrR	pep2	1	1	peptidase M4 thermolysin	
TyrR	omp1	1	1	TonB-dependent receptor	
TyrR	pep4	1	1	prolyl oligopeptidase family protein	
TyrR	tyrP	32	5	Tyrosine-specific transport protein	Tyrosine transporter
TyrR	hmgB	29	5	Maleylacetoacetate isomerase (EC 5.2.1.2)	Tyrosine degradation
TyrR	hmgC	29	5	Fumarylacetoacetate (EC 3.7.1.2)	Tyrosine degradation
TyrR	hpd	14	4	4-hydroxyphenylpyruvate dioxygenase (EC 1.13.11.27)	Tyrosine degradation
TyrR	hmgA	13	4	Homogentisate 1,2-dioxygenase (EC 1.13.11.5)	Tyrosine degradation
TyrR	aceA	12	1	Isocitrate lyase (EC 4.1.3.1)	Tricarboxylic acid cycle
TyrR	aceB	16	1	Malate synthase (EC 2.3.3.9)	Tricarboxylic acid cycle
TyrR	acsA	8	1	Acetoacetyl-CoA synthetase (EC 6.2.1.16)	Acetyl-coenzyme A synthetase
TyrR	aroA	14	1	5-Enolpyruvylshikimate-3-phosphate synthase (EC 2.5.1.19)	Aromatic amino acid biosynthesis
TyrR	aroL	10	1	Shikimate kinase III (EC 2.7.1.71)	Aromatic amino acid biosynthesis
TyrR	aroP	11	1	Aromatic amino acid transport protein AroP	Aromatic amino acid transport
TyrR	bkdA1	16	1	Branched-chain alpha-keto acid dehydrogenase, E1 component, alpha subunit (EC 1.2.4.4)	Branched_chain amino acid degradation
TyrR	bkdA2	16	1	Branched-chain alpha-keto acid dehydrogenase, E1 component, beta subunit (EC 1.2.4.4) Dihydrolipoamide acyltransferase component of branched-chain alpha-keto acid dehydrogenase complex (EC 2.3.1.168)	Branched_chain amino acid degradation
TyrR	bkdB	16	1		Branched_chain amino acid degradation
TyrR	brnQ	16	1	Branched-chain amino acid transport system carrier protein	Branched_chain amino acid transport
TyrR	COG0733(Tyr)	13	2	Predicted tyrosine transporter, SNF family	
TyrR	tyrR2	2	1	Tyrosine and phenylalanine degradation transcriptional activator, TyrR family	Transcription regulation
TyrR	ivdA	16	1	3-ketoacyl-CoA thiolase [isoleucine degradation] (EC 2.3.1.16)	Branched_chain amino acid degradation

TyrR	ivdB	16	1	Methylmalonate-semialdehyde dehydrogenase (EC 1.2.1.27)	Branched_chain amino acid degradation
TyrR	ivdC	16	1	Branched-chain acyl-CoA dehydrogenase (EC 1.3.99.12) Enoyl-CoA hydratase [valine degradation] (EC 4.2.1.17) / Enoyl-CoA hydratase [isoleucine degradation] (EC 4.2.1.17)	Branched_chain amino acid degradation
TyrR	ivdD	16	1	3-hydroxyisobutyryl-CoA hydrolase (EC 3.1.2.4)	Branched_chain amino acid degradation
TyrR	ivdE	16	1	3-hydroxyisobutyrate dehydrogenase (EC 1.1.1.31)	Branched_chain amino acid degradation
TyrR	ivdF	16	1	3-hydroxyacyl-CoA dehydrogenase [isoleucine degradation] (EC 1.1.1.35)	Branched_chain amino acid degradation
TyrR	ivdG	16	1	Leucine dehydrogenase (EC 1.4.1.9)	Branched_chain amino acid degradation
TyrR	ldh	16	1	Isovaleryl-CoA dehydrogenase (EC 1.3.99.10)	Branched_chain amino acid degradation
TyrR	liuA	14	1	Methylcrotonyl-CoA carboxylase carboxyl transferase subunit (EC 6.4.1.4)	Branched_chain amino acid degradation
TyrR	liuB	14	1	Methylglutaconyl-CoA hydratase (EC 4.2.1.18)	Branched_chain amino acid degradation
TyrR	liuC	14	1	Methylcrotonyl-CoA carboxylase biotin-containing subunit (EC 6.4.1.4)	Branched_chain amino acid degradation
TyrR	liuD	16	1	Hydroxymethylglutaryl-CoA lyase (EC 4.1.3.4)	Branched_chain amino acid degradation
TyrR	liuE	14	1	Succinyl-CoA:3-ketoacid-coenzyme A transferase subunit A (EC 2.8.3.5)	Branched_chain amino acid degradation
TyrR	liuF	13	1	Succinyl-CoA:3-ketoacid-coenzyme A transferase subunit B (EC 2.8.3.5)	Branched_chain amino acid degradation
TyrR	liuG	13	1	Predicted transcriptional regulator LiuR of leucine degradation pathway, MerR family	Transcription regulation
TyrR	mdeA	14	2	Methionine gamma-lyase (EC 4.4.1.11)	Methionine degradation
TyrR	pep3	14	1	peptidase, M13 family	
TyrR	phhC	5	1	Aromatic-amino-acid aminotransferase (EC 2.6.1.57)	Phenylalanine degradation
TyrR	phhR	7	1	Phenylalanine degradation transcriptional activator, TyrR family	Transcription regulation
TyrR	tyrB	16	1	Tyrosine aminotransferase (EC 2.6.1.42)	Tyrosine biosynthesis / Tyrosine degradation

<sup>1</sup> Number of regulatory interactions

<sup>2</sup> Number of taxa with regulation

**Table S4. Metabolic and gene content of reconstructed TF regulons in Proteobacteria classified by conservation of regulatory interactions.**

TF name	TF regulon members	Assigned metabolic pathway or process <sup>1</sup>	Major function	TF effector
<b>ArgR</b>			<b>Arginine metabolism</b>	<b>Arginine</b>
	<b>Core</b>			
	argH, argB, argC, argG, argF, argA, argE	Arginine biosynthesis		
	argR	Transcription regulation		
	artI, artQ, artM, artP	Arginine transport		
	astD, astA	Arginine degradation		
	carA, carB	Arginine and pyrimidine biosynthesis		
	<b>Taxonomy-specific</b>			
	argD	Arginine biosynthesis		
	argW, artJ, omp	Arginine transport		
	gltB, gltD	Glutamate biosynthesis		
	ilvM, ilvG, ilvD, ilvA	Branched-chain amino acid biosynthesis		
	potF, potG, potH, potI	Putrescine transport		
	recN	DNA repair		
	oadA, oadB, oadG	Pyruvate metabolism		
	astC, astB	Arginine degradation		
	<b>Genome-specific</b>			
	ilvE	Branched-chain amino acid biosynthesis		
	hisJ, hisM, hisP, hisQ	Histidine transport		
	arcA, arcB, arcC, arcD, astE	Arginine degradation		
	hisA, hisB, hisC, hisD, hisF, hisG, hisH, hisI	Histidine biosynthesis		
	proV, proW, proX	Proline transport		
	speF, potE	Putrescine metabolism		
<b>BioR</b>	<b>All target genes</b>		<b>Biotin biosynthesis</b>	<b>Unknown</b>
	bioY, bioM, bioN	Biotin transport		
	bioB, bioF, bioD, bioA, bioZ, bioG, bioC	Biotin biosynthesis		
	bioR	Transcription regulation		
<b>BirA</b>	<b>Core</b>		<b>Biotin biosynthesis</b>	<b>Biotin</b>
	bioB, bioF, bioD, bioC, bioA	Biotin biosynthesis		
	<b>Taxonomy-specific</b>			
	bioH	Biotin biosynthesis

	fabA, fabB, lcfH	Fatty acid biosynthesis		
	plsC	Glycerolipid metabolism		
	hyIII	Fatty acid metabolism		
	<b>Taxonomy-specific</b>			
	desB, desC	Unsaturated fatty acid biosynthesis		
	fadL, lcfE	Fatty acid biosynthesis		
	fabR, fabR2	Transcription regulation		
	<b>Genome-specific</b>			
	pfaA, pfaB, pfaC, pfaD	Unsaturated fatty acid biosynthesis		
	pfaR, psrA	Transcription regulation		
	fadE	Fatty acid degradation		

FadP	Core		Fatty acid degradation	Unknown
	fadA, fadB, acdA, acdB, acdH, echH, acdP, acdQ, fadD	Fatty acid degradation		
	etfA, etfB, etfD	Electron transfer chain for fatty acid degradation		
	pncA	Nicotinate biosynthesis		
	fadP	Transcription regulation		
	<b>Taxonomy-specific and Genome-specific</b>			
	acsA	Acetyl-coenzyme A synthetase		
	BPSL1236	Glycolysis		
	liuR	Transcription regulation		
	paal, paaG4, paaH1, bktB, alkK	Fatty acid degradation		
FadR	Core		Fatty acid degradation	Palmitoyl-CoA; Oleoyl-CoA
	fadL, fadI, fadJ, fadE	Fatty acid degradation		
	<b>Taxonomy-specific</b>			
	fabA, fabB	Fatty acid biosynthesis		
	plsB	Glycerolipid metabolism		
	fadA, fadD, fadH, fadB, fadM, SO0572	Fatty acid degradation		
	fadR, iclR	Transcription regulation		
	<b>Genome-specific</b>			
	acdB, tesB	Fatty acid degradation		
GlcC	Core		Glycolate utilization	Glycolate
	glcE, glcF, glcD, glcG	Glycolate utilization		
	glcC	Transcription regulation		
	<b>Taxonomy-specific</b>			
	glcB	Tricarboxylic acid cycle		
	glcA	Glycolate transport		
	lldD	Lactate utilization		
	<b>Genome-specific</b>			
	glcQ, glcM, glcP	Glycolate transport		
	lldG, lldE, lldF, ykgE, ykgF, ykgG, lldP	Lactate utilization		
	lysR	Transcription regulation		
HexR	Core		Central carbohydrate metabolism	2-keto-3-deoxy-6-phosphogluconate
	glk, pykA	Glycolysis		
	edd, eda	Entner-Doudoroff pathway		
	zwf, pgl	Pentose phosphate pathway		
	hexR	Transcription regulation		
	<b>Taxonomy-specific</b>			
	tal, phk, gnd	Pentose phosphate pathway		
	nqrD, nqrC, nqrF, nqrA, nqrE, nqrB	Electron transport chain		
	adhE, pflA, pflB, ackA, pta, focA	Fermentation		
	ppsA	Gluconeogenesis		
	ptsl, ptsH, ptsG, crr	Glucose transport		
	gltD, gltB	Glutamate biosynthesis		
	gcvT, gcvP, gcvH	Glycine cleavage system		
	gapA, pgi, ppc, tpiA, gapB, gpmM	Glycolysis		
	mtlA, mtlD	Mannitol utilization		
	pntB, pntA	NAD metabolism		
	nirB, nirD	Nitrogen metabolism		
	deoD, deoA, deoB, nupC	Nucleoside metabolism		
	mtlR, gltR, gltS	Transcription regulation		

aceB, aceA	Tricarboxylic acid cycle		
<b>Genome-specific</b>			
bkdA2, bkdB, bkdA1	Branched-chain amino acid degradation		
adhB, ldhA	Fermentation		
mglA, mglB, mglC	Galactose transport		
gntU, gntK	Gluconate utilization		
pckA	Gluconeogenesis		
ptsHI	Glucose transport		
glpT	Glycerol-3-phosphate transport		
glgX, glgA, glgC, glgP	Glycogen utilization		
gapN, eno, pgk, fba, aldE	Glycolysis		
lctP, dld	L-lactate utilization		
manC	Mannose utilization		
cdd	Nucleoside metabolism		
<b>HmgQ</b>	<b>All target genes</b>	<b>Tyrosine degradation</b>	<b>Unknown</b>
hmgA, hmgB, hmgC, hpd, gloA	Tyrosine degradation		
hmgQ	Transcription regulation		
<b>HmgR</b>	<b>All target genes</b>	<b>Tyrosine degradation</b>	<b>Homogentisate</b>
hmgA, hmgB, hmgC, hpd	Tyrosine degradation		
COG2814	Tyrosine transport		
hmgR	Transcription regulation		
<b>HmgS</b>	<b>All target genes</b>	<b>Tyrosine degradation</b>	<b>Unknown</b>
hmgA, hmgB	Tyrosine degradation		
hmgS	Transcription regulation		
<b>HutC</b>	<b>Core</b>	<b>Histidine utilization</b>	<b>Urocanate</b>
hutU, hutH, hutI, hutD, hutF, hutG, hutG2	Histidine degradation		
hutC	Transcription regulation		
<b>Taxonomy-specific</b>			
histT, hisX, hisY, hisZ, hisP, hisQ, hisM, hisJ, COG2814, omp	Histidine transport		
<b>Genome-specific</b>			
hutV, hutW, hutX, COG3314	Histidine transport		
hutH2	Histidine degradation		
hisA, hisB, hisC, hisD, hisF, hisG, hisH, hisI	Histidine biosynthesis		
<b>HypR</b>	<b>Core</b>	<b>Proline and 4-hydroxyproline utilization</b>	<b>Proline; 4-hydroxyproline</b>
hypD, hypE, hypH, hypO	Hydroxyproline/proline degradation		
hypR	Transcription regulation		
<b>Taxonomy-specific</b>			
hypY, hypH'-2	Hydroxyproline/proline degradation		
putA, prdP, ampP	Proline degradation		
hypP, hypM, hypN, hypQ	Hydroxyproline transport		
COG531, omp	Hydroxyproline/proline transport		
hypX, hypS	TCA cycle		
colA2	Collagen degradation		
<b>Genome-specific</b>			
pdtP	Proline transport		
hypA, hypB, hypC, hypT	Hydroxyproline transport		

hypD', hypH'  
colA1, ypdF, colA3

Hydroxyproline/proline degradation  
Collagen degradation

<b>LiuQ</b>	<b>Core</b>	<b>Branched-chain amino acid degradation</b>	<b>Unknown</b>

The presence or absence of gene orthologs is shown by '+/-' signs. Colored '+' signs (red, purple, green, blue) indicate that the gene belongs to TyrR(PhhR), HmgR, HmgQ, HmgS regulons, respectively.

Last column shows the list of all corresponding operons from reconstructed regulons. Additional member of *TyrR* regulons that are not involved in aromatic amino acid metabolism are not included.

Color code for genes in the table:

Color code for genes in the table:

Tyr (Phhr) regulator gene
Chorismate biosynthesis genes
Tyr biosynthesis pathway genes
Tyr transporter genes
Tyr degradation genes
