Keywords: Late Iron Age, La Tène culture, NW Hungary; Celtic settlement; iron blommery, iron ore, iron slag, smelting, slag-pit furnace, tuyere

In the vicinity of Ménfőcsanak, near the city of Győr, on top of a levee on the southern side of the Marcal River lies a complex of La Tène sites including a large cemetery and cluster of settlements (Pl. 1). The first burials were found in 1967. The ten burials recovered during this short period of rescue excavation made Ménfőcsanak a key La Tène site in the Carpathian Basin (Uzsoki 1969a; 1969b; 1987). Excavations started on a larger scale in 1993 in and around the area of the previously known cemetery. Two and a half hectares were investigated and 277 burials unearthed, making this the largest excavated Celtic burial ground in the Carpathian Basin (EGRY 2007, 32–33). According to preliminary reports the cemetery dates to the LT B1-C period (VADAY 2006, 609; EGRY 2007, 33).

While Ménfőcsanak became an important archaeological site in terms of burials in the history of the Celtic ‘migrations’ in the fourth century BC, the Late Iron Age settlement to the east of the cemetery has not yet received the attention it merits. The completion of the processing of material from excavation prior to the construction of *National Highway 83* (which took place in 1993) and the *Bevásárlóközpont* excavation (in 1995, 2006) has provided an opportunity briefly to summarize the settlement features and archaeological assemblages (TANKÓ–EGRY 2009; TANKÓ 2012a).

Another large-scale excavation was the Celtic settlement investigated between 2009 and 2011. During this from an area of 277.165 m² nearly eleven thousand structures has been documented (Pl. 1/1–2). More than 90% of the archaeological finds were dated to the Late Iron Age and Roman Imperial Period. The remains of these two periods were observed the most intensely (ILON 2012a, 104–105; ILON 2012b, 237–238; MERKL–ILON 2012, 53).

The Late Iron Age settlement site is located on the gentle slope of the *Szeles-dűlő* hill rising above a bend in the Marcal River to the north of Ménfőcsanak, and is surrounded by the marshy meadows of the Pándzsa stream. According to current data it is apparent that the Celtic settlement of Ménfőcsanak was established in the LT B1 phase, in the second half of the 4th century BC. It was abandoned during the LT B2/C1 transition period or LT C1 period at the latest, in the second half of the 3rd century BC (TANKÓ 2012a, 256–257).

Based on the uncovered structures and artifacts, Ménfőcsanak was primarily an agrarian settlement (TANKÓ 2012a, fig. 3). However, can be observed in the case of recently published Celtic villages in north-east Hungary (SZABÓ–CZAJLIK 2004; SZABÓ ET AL. 2008), much information suggests that industrial activity – mainly metalwork – was conducted on primarily agricultural land at Ménfőcsanak too. The most obvious signs of this are the iron ore (Pl. 2/6) and/or furnace slag (Pl. 2/8, 10),¹ even though no

1 We would like to thank to A. Vaday for allowing us to analyse the findings.

in situ bloomery furnace was found. Analyzing the fragments of slags on the site it can be determined that the iron processing was carried out in the southern part of the settlement, near the structure 93/31, 93/492, and 95/49. The finds which can be connected primarily to ironwork were found in sunken buildings or in their vicinity in this part of the settlement. The largest volume of iron ore (two pieces) and bloomery slags (52 pieces) were in the filling of the building no. 93/31 (TANKÓ 2004). Some of these fragments of slags and ores were analyzed by X-ray diffraction (Fig. 1).²

Fig. 1. Analysis of iron ore and slags from structure no. 93/31

The two iron ores were particularly interesting (Fig. 1/95.1.626 and 95.1.644; Pl. 2/6). Both of them had high (40–50%) iron content (Fe). The good quality iron ore had a high content of manganese oxide (MnO), with a significantly lower content of titanium oxide (TiO₂), vanadium oxide (V₂O₅) and chrome oxide (Cr₂O₃). During the blooming process these components of ore had improved the quality of the iron and would probably have increased the impact strength and wear resistance however, this may have been at the expense of its tensile strength. The high volume of silicium oxide probably had no effect on iron quality (more than 1 m% in iron can cause difficulties in machining), because most of it was removed from iron ore as slag during the smelting process. The iron ore contained in small amounts calcium oxide (CaO), magnesium oxide (MgO) and alum earth (Al₂O₃).

This raises the question what was the source of this iron ore? There are several ore deposits at the western, south-eastern and eastern edge of the Small Hungarian Plain. Ferrous minerals are known in the Burgenland and Transdanubian mountains (GÖMÖRI-KISHÁZI 1985, fig. 1). According to the present state of research only in Burgenland and the western part of Hungary – from Oberpullendorf to Vasvár – has it been possible to prove iron ore mining taken place in the Iron Age (SCHMID 1977, 11–23; MEYER 1977, 25–48; BIELEININ 1977, 49–62; KAUS 1977, 63–70; CZAJLIK 2012, 55–56). R. Pleiner in many works dealing with the theme of early iron smelting and smithing in Carpathian Basin, localized a mining and primary processing center in the Burgenland based on east Austrian iron ore deposits (PLEINER-PRINC 1984, Tab. 5–7; PLEINER 1994, fig. 1). After analyzing iron ores and slag samples, which was found in western Hungarian La Tène Iron Age settlements, it seems that the processing of ferrous minerals was not limited to only the Burgenland, but the using of bloomery technology is also detectable further afield – for example Sopron-Krautacker (GÖMÖRI-KISHÁZI 1985, 337, fig. 7) or Velemzentvid (CZAJLIK 2000, 70–71).

Ménfőcsanak is located roughly 100 km east from the processing center mentioned by Pleiner. However, it is not surprising. According to Pleiner, the small-scale production of early ironmakers was in any case not dependent upon the rich and large ore bodies which become important late; only instead, very small deposits of bog ore or weathered limonite and haematite outcrops in the vicinity of

2 The analysis was conducted by Kohászati Múzeum and Metalcontrol Kft in Miskolc.

the settlement could have been used (PLEINER 2000, 90); it cannot be excluded to have been the case at Ménfőcsanak.

Beside iron ore, the large amount of slags is also important evidence for the use of a bloomery smelter in Ménfőcsanak. According to the slag typology of SPERL (1980), residual furnace slag with embedded charcoal and unreduced ore pieces, Sperl type B1 (Pl. 2/8, 10), slagged wall, Sperl type B2 (Pl. 2/12) and last slag flow from the outlet channel, Sperl type C1 were found at the site. Analyzing slags confirmed that slag deposit on sandstone (Fig. 1/95.1.2014, Pl. 2/11) and the residual furnace slag (Fig. 1/95.1.636, Pl. 2/8) have detectable iron content (Fe). The analysis of ferrous slag composition has been made at La Tène period settlements at Ordacsehi and Sajópetri a few years ago (CZAJLIK–MOLNÁR 2007; TÖRÖK *ET AL.* 2013).

It is not a long distance in space or in time between Ordacsehi and Ménfőcsanak Celtic villages. It is necessary to compare the data because of Ordacsehi's relative proximity to Ménfőcsanak besides their similarities in settlement structures. There are ten samples of slags at Ordacsehi, but only two at Ménfőcsanak. In this situation and the relatively small sample size the resultant indicative values it is necessary in the future to have a larger sample to get a better picture about different types of furnace. The slags from Ménfőcsanak contain manganese oxide (MnO), but it is relatively low as is the case at Ordacsehi. However, significant differences can be detected in connection with the proportion of phosphorus (P_2O_5). This component has a significantly higher proportion than the sample in Ordacsehi (TÖRÖK *ET AL.* 2013, 25, 1. táblázat). As J. Piaskowski has mentioned, the phosphorus could come from slag-forming gangue during the reductive smelting process. 0.4–0.7% rates of phosphorus are not rare in this situation (PIASKOWSKI 1965, 84). The high rate (7–10%) of alumina (Al_2O_3) is also noticeable in the Ménfőcsanak slags. The alumina content rarely exceeds 6%, but higher values have also been described, for example from Mšec in the Czech Republic (PLEINER–PRINC 1984, 159). Alumina comes principally from the ore gangue or furnace lining, while it also comes from fuel ash (PLEINER 2000, 252). The samples examined from both sites are acid slags in which there is more silica and silicates (SiO_2) than lime (CaO) and magnesia (MgO).

There could be several reasons for the high rate of silicates and lime. The iron ore might be contained it, but these components could be enriched from the additional slag-forming gangue (limestone, sandstone, clay, etc.) during the smelting process. Recently conducted research has shown that, on the surface of metallurgical slags contact with the soil particles may produce a thin silicate oxide layer. This may have different results in examination (McDONNEL 1991, 25).

Low levels of sulfur (S), sodium (Na_2O) and potassium (K_2O) can be found only in slags. These components are missing from iron ore, thus it can derive from the fuel ash. Components (mainly MnO , TiO_2 és MgO) of examined slags in Ménfőcsanak are related with the early medieval slags from Hidegség (GÖMÖRI 1995 194, Abb. 8). The similarity between Late Iron Age and early medieval slags requires further investigation.

In structure no. 93/31 there were two fragments of stone, which have slag flow deposit on their surface (Pl. 2/11). Analyses were made both for the slag (Fig. 1/95.1.2014 material) and the limestone (Fig. 1/95.1.2014 crust). The fragments of limestone contain quartz (SiO_2) in smaller part (17%) and calcium carbonate ($CaCO_3$) in greater part (82%). The carbonate rocks (e.g. limestone) are used in iron metallurgy today as slag-forming gangue, but this method of slag-making was known already known in the La Tène settlement of Sajópetri (SZABÓ–CZAJLIK 2004, 131; CZAJLIK–MOLNÁR 2007, 265). In the case of Ménfőcsanak – according to the polished side of sandstone – this was not a slag-forming gangue but more likely was used for the construction of furnace.

Based on this information, it was certain that good quality ore with a high percentage of iron (Fe) was available at Ménfőcsanak. This contained some of components (Mn , Ti , Cr , V) which improve the quality of steel. Most of the harmful substances (P, Si, Ca) left as slag from the ore during the smelting process, while some other elements (S, Na, K) was left as slag-forming gangue or fuel ash.

There is not any direct data to reconstruct the blooming furnace, since it was not possible to investigate the furnace *in situ* in Ménfőcsanak. However – like as was previously mentioned – Sperl B1 type residual furnace slag with embedded charcoal and unreduced ore pieces (Pl. 2/8, 10), Sperl B2 type slagged wall (Pl. 2/11) and Sperl C1 type last slag flow from the outlet channel were found in the structures of Celtic settlement; this, according to Sperl's theory (SPERL 1980, 14–18, 64–65), refers

to use of a smelting furnace. The curved rim-crafted, highly burned fragment of a pottery structure with indications of the flow deposit of slag might be a part of a furnace. Some stone fragments also refer to the use of furnace. The highly burned sandstone with slag deposition may be associated with iron smelting. Many examples are known that inside the furnace may be lined with sandstone in order to maintain the heat inside effectively (KRASA 1933, fig. 5; GARNER 2011, fig. 16–17). Bloomery furnaces lined with clay – sometimes having stone lining at their basis – are known in the eastern Celtic world.

Domed furnaces were widely used in the Late Iron Age from Bavaria to the Burgenland (PLEINER–PRINC 1984, 133–135, Abb. 1). This ‘Burgenland type’ furnace (BIELENIN 1994) has not yet been discovered east from the eponymous region, but based on available data we cannot exclude that the domed furnace was used in Ménfőcsanak. Another type of furnace – widely used from the Czech Republic to south Poland and eastern Austria (PLEINER 2000, 149–162) – is the slag-pit furnace (Pl. 2). It has great variability of form and constructions but usually it is easy to identify by its slag pit. Although its existence cannot be denied there is a yet no information about it having been in use in Ménfőcsanak.

A new find probably having been in use in connection with metallurgical activity was uncovered in 2011 in the north-eastern area of the La Tène settlement.³ The archaeological structure has two different numbers in the documentation, because the limits of the excavation could not be identified in the soil, thus these two structures are considered one context based on the location of the finds. The structure 8539/8654 was a shallow pit from which pottery and animal bones were unearthed (Pl. 3). Two pots standing on their mouths were found at one end of the pit. Between them three other pots, were broken and were lying on the bottom of the pit together with some other sherds, animal bones and a clay funnel-shaped vessel. The animal remains were identified as bones of hares, sheep and goats. Beside the hand-made, graphite tempered, bi-conical shape pots and conical shape bowl, there was a wheel-thrown, black colored, reductive fired cooking pot found (Pl. 4/2). There is no doubt that this last was the product of the La Tène culture and it is known many parallels from early and middle La Tène period in Transdanubia (Uzsoki 1987, pl. XIX, 1; HORVÁTH 1987, pl. XVIII, 9; TANKÓ 2012b, 103, fig. 3). The dating of the hand-made pot with fingernail-impressed motifs under rim (Pl. 4/1) is more complicated. This type of pot is dated to the early La Tène period by KAPPEL (1969, 58–65) from end of Ha D to beginning of LT B is proved by many sites from east Austria and western Hungary too, like Sopron–Krautacker (JEREM 1986, Taf. 3) or Inzersdorf (RAMSL 1998, 21).

The most interesting find of this unusual context is the ‘clay funnel’ (Pl. 5). It is made of strongly tempered graphite clay; the surface is covered with graphite powder. It has a diameter of 190 mm, and 130 mm length. In the middle of the funnel-shape object there is a slightly oval hole with 35–40 mm diameter. It has cracks on it and slightly chipped on its rim. There was no opportunity to get a direct conclusion for the function of this object from this context. Because of its heavy weight and robust design the using as passage or avenue for a fluid or flowing substance in a pot cannot be imagined.

This find is unique and it is so far without analogies in La Tène material culture. However – considering its size and shape – it is very reminiscent of modern industrial tuyeres as used in present-day metallurgy. The tuyere is a nozzle into which the outlet tube of a blowing device is inserted, to permit a blast of air to be delivered to the interior of a smelting furnace. Its roles were to protect the bellows tube from the effect of the hot furnace charge and to dampen down the vibrations from the bellows to the furnace wall. Tuyeres were mostly made of specially prepared clays. Clay tuyeres usually used dry, so during smelting, the inner tips became fired and because of this these tips survive more frequently, than the rest of tuyere (PLEINER 2000, 197). The origin of clay tuyeres dates back to the Bronze Age, before the introduction of iron technology. Various types of tuyere were used for non-ferrous metallurgical operations (TYLECOTE 1987, 115–123). In iron production, tuyeres were used both in smelting furnace and in forging hearts (PLEINER 2000, 197–198). The shapes of tuyeres vary greatly. The earliest Iron Age finds are connected to the Late La Tène and Roman period. In this time the clay tuyeres were typical (PLEINER 2000, 208–212; GARNER 2011, 64). Conical tuyeres (Pl. 6) have only been found at two Roman Age site, both in Vaud, Switzerland (PELET 1973, 31–32, fig. 2–3; PLEINER 2000, fig. 56/1). They are similar to the find from Ménfőcsanak in form and size. They are 105 mm long (Ménfőcsanak: 130 mm) with a 30–40 mm bore

³ I would like to thank to G. Ilon for allowing the publishing of the findings from structure 8539/8645.

(Ménfőcsanak: 35–40 mm). At Mšec in western Bohemia, in a Middle La Tène context a fragment of a thick, trumpet-shaped tuyere was found in a layer of slag and debris (PLEINER-PRINC 1984, 145, fig. 8C, 10, 8). A similar conical-shaped tuyere was found in Siegen-Niederschelden which could be dated to LT B-C (GARNER 2011, 40, fig. 46).

The fragments in Mšec and Siegen are clear evidence of the use of the conical-shaped tuyeres in the La Tène Iron Age. Based on this fact, it is highly probable that the ‘clay funnel’ – which was found in structure of 8539/8645 – in Ménfőcsanak is a tuyere for metallurgy. However, it was probably not used, although patches either major or secondary combustion heat traces can be observed on surface.

The tuyere of Ménfőcsanak is particularly interesting in its circumstances. Whole pots – two of which were standing in an unusual way – upside down – were beside sherds, animal bones and the mentioned industrial artefact. It is very difficult to understand the purpose of deposition and context of this find, but a similar pit was recently uncovered at Sajópetri. A whetstone and iron tools (shears, axe, iron knife and staple) were placed on a grind stone, which was found in a pit in the central part of the site no. 46A (SZABÓ ET AL. 2004, 26, fig. 3, 5). These depots are sometimes interpreted as a victim of construction, however often there is no available data for the interpretation. Finally, it is also questionable whether the carefully hidden artifacts are possibly indicative of an emergency situation or not (GUICHARD-PAQUELOT 2003, 16–21). However, the votive character of Sajópetri finds could scarcely be doubted. On the one hand there are no signs of disaster in the settlement. On the other hand, the composition of the dépôt for agricultural production (a whetstone and grinding stone), livestock (shears), the tree and the building work (axe, staple) refers to both. The aim of ritual deposition could be the fertility and perhaps the flourishing settlement or to ensure security (SZABÓ 2005, 102; SZABÓ 2007, 225–227). Based on Szabó’s interpretation of Sajópetri we cannot deny the possibility of a ritual purpose in Ménfőcsanak.

In summary, it can be stated even though a furnace was not uncovered many traces were found pointing to the on-site processing of iron smelting. The iron ore, the different types of slags, perhaps the fragments of furnace wall with flow slag and the conical tuyere confirm Celtic metallurgy in the early La Tène period at Ménfőcsanak.

List of figures

Fig. 1. Analysis of iron ore and slags form structure no. 93/31

List of plates

- Pl. 1. Győr–Ménfőcsanak. 1. Site plan with the location of the La Tène cemetery and settlement; 2. Distribution of iron ore and slags in the territory of southern part of the La Tène settlement.
- Pl. 2. Reconstruction of the slag-pit furnace with the metallurgical finds in Ménfőcsanak. A. Before smelting: 1. shaft; 2. virgin soil; 3. tuyere; 4. bellow; 5. charcoal; 6. iron ore, staw or brush wood. B. After smelting: 8. furnace slag with ore residues and charcoal; 9. iron sponge; 10. slag bloc in the pit; 11. charcoal and ash (after PLEINER 1980; 2000).
- Pl. 3. Ménfőcsanak, structure no. 8539/8645.
- Pl. 4. Ménfőcsanak, pottery from structure no. 8539/8645.
- Pl. 5. Ménfőcsanak, tuyere from the structure no. 8539/8645.
- Pl. 6. Conical and disc-shape tuyeres (after PLEINER 2000). 1. Bellaires (PELET 1973), 2. Ballyourney (TYLECOTE 1986, without scale), 3. Bradown (CLEERE 1963).
