ABSTRACT

We use fluctuating magnetic helicity to investigate the polarisation properties of Alfvénic fluctuations at ion-kinetic scales in the solar wind as a function of β_p , the ratio of proton thermal pressure to magnetic pressure, and θ_{vB} , the angle between the proton flow and local mean magnetic field, \mathbf{B}_0 . Using almost 15 years of *Wind* observations, we separate the contributions to helicity from fluctuations with wave-vectors, \mathbf{k} , quasi-parallel and oblique to \mathbf{B}_0 , finding that the helicity of Alfvénic fluctuations is consistent with predictions from linear Vlasov theory. This result suggests that the non-linear turbulent fluctuations at these scales share at least some polarisation properties with Alfvén waves. We also investigate the dependence of proton temperature in the β_p - θ_{vB} plane to probe for possible signatures of turbulent dissipation, finding that it correlates with θ_{vB} . The proton temperature parallel to \mathbf{B}_0 is higher in the parameter space where we measure the helicity of right-handed Alfvénic fluctuations, and the temperature perpendicular to \mathbf{B}_0 is higher where we measure left-handed fluctuations. This finding is inconsistent with the general assumption that by sampling different θ_{vB} in the solar wind we can analyse the dependence of the turbulence distribution on θ_{kB} , the angle between \mathbf{k} and \mathbf{B}_0 . After ruling out both instrumental and expansion effects, we conclude that our results provide new evidence for the importance of local kinetic processes that depend on θ_{vB} in determining proton temperature in the solar wind.

1. INTRODUCTION

The solar wind is a variable flow of plasma that escapes from the solar corona out into the heliosphere. In-situ measurements of the solar wind provide insights into the fundamental physical processes occurring in expanding astrophysical plasmas. Fluctuations in the solar wind plasma and electromagnetic fields exist over many orders of magnitude in scale, linking both microscopic and macroscopic processes (see Matteini et al. 2012; Alexandrova et al. 2013, and references therein). The couplings between large-scale dynamics and small-scale kinetic processes are central to our understanding of energy transport and heating in these plasmas (Verscharen et al. 2019). There are still many open questions in regards to wave dissipation and plasma heating in collisionless plasmas. Understanding these mechanisms in the collisionless solar wind plasma is a major outstanding problem in the field of heliophysics research.

In solar wind originating from open field lines in the corona, fluctuations are predominantly Alfvénic (Coleman 1968; Belcher et al. 1969; Belcher & Davis Jr. 1971), with only a small compressional component (Howes et al. 2012; Klein et al. 2012; Chen 2016; Šafránková et al. 2019). At scales $10^5 \lesssim L \lesssim 10^8$ m, called the inertial range, non-linear interactions between fluctuations lead to a turbulent cascade of energy towards smaller scales (Tu & Marsch 1995; Bruno & Carbone 2013). This range is characterised by fluctuations with increasing anisotropy toward smaller scales, $k_{\perp} \gg k_{\parallel}$,

where k_{\parallel} and k_{\perp} are components of the wave-vector, **k**, in the direction parallel and perpendicular to the local mean magnetic field, **B**₀, respectively (Horbury et al. 2008; MacBride et al. 2010; Wicks et al. 2010; Chen et al. 2011, 2012). At scales close to the proton inertial length, d_p , and proton gyro-radius, ρ_p , typically $L \sim 10^5$ m at 1 au, the properties of the fluctuations change due to Hall (Galtier 2006; Galtier & Buchlin 2007) and finite-Larmor-radius (Howes et al. 2006; Schekochihin et al. 2009; Boldyrev & Perez 2012) effects. The non-linear turbulent fluctuations at these ion-kinetic scales exhibit some properties that are consistent with those of kinetic Alfvén waves (KAWs; Leamon et al. 1999; Bale et al. 2005; Howes et al. 2008; Sahraoui et al. 2010; Woodham et al. 2019).

Solar wind proton velocity distribution functions (VDFs) typically deviate from local thermal equilibrium due to a low rate of collisional relaxation (Kasper et al. 2008; Marsch 2012; Maruca et al. 2013; Kasper et al. 2017). The coupling of small-scale electromagnetic fluctuations and the kinetic features of the proton VDFs can lead to energy transfer between fluctuating fields and the particles. Collisionless damping of these fluctuations can lead to dissipation of turbulence via wave-particle interactions such as Landau (Leamon et al. 1999; Howes et al. 2008) and cyclotron (Marsch et al. 1982, 2003; Isenberg & Vasquez 2019) resonance, or other processes such as stochastic heating (Chandran et al. 2010, 2013) and reconnection-based mechanisms (Sundkvist et al. 2007; Perri et al. 2012). These mechanisms are dependent on the modes present and the background plasma conditions, i.e.,

a function of the ratio of proton thermal pressure to magnetic pressure, $\beta_p = n_p k_B T_p/(B_0^2/2\mu_0)$, where n_p is the proton density, and T_p is the proton temperature. Each mechanism leads to distinct fine structure in proton VDFs, increasing the effective collision rate. These processes ultimately lead to plasma heating, and therefore, changes in the macroscopic properties of the plasma (e.g., Marsch 2006).

In addition to damping of turbulent fluctuations, non- 156 Maxwellian features of solar wind VDFs such as tempera- 157 ture anisotropies relative to ${\bf B}_0$, beam populations, and rela- 158 tive drifts between plasma species provide sources of free en- 159 ergy for instabilities at ion-kinetic scales (Kasper et al. 2002a, 160 2008, 2013; Hellinger et al. 2006; Bale et al. 2009; Maruca 161 et al. 2012; Bourouaine et al. 2013; Gary et al. 2015; Alter- 162 man et al. 2018). These modes grow until the free energy 163 source is removed, acting to limit departure from an isotropic 164 Maxwellian. Ion-scale kinetic instabilities are prevalent in 165 collisionally young solar wind (Klein et al. 2018, 2019), al- 166 though the interaction between instabilities and the back- 167 ground turbulence is still poorly understood (e.g., Klein & 168 Howes 2015). As the solar wind flows out into the helio- 169 sphere, instabilities, local heating, heat flux, and collisions all 170 alter the macroscopic thermodynamics of the plasma through 171 coupling between small-scale local processes and large-scale 172 dynamics. These processes lead to a deviation from Chew- 173 Goldberger-Low theory (CGL; Chew et al. 1956) for double 174 adiabatic expansion (Matteini et al. 2007).

Alfvénic fluctuations in the solar wind are characterised by 176 magnetic field fluctuations, $\delta \mathbf{B}$, with a quasi-constant field magnitude, $|\mathbf{B}|$. Since the fluctuations have large amplitudes, ¹⁷⁷ $\delta {\bf B}/{\bf B}_0 \sim 1$, the magnetic field vector traces out a sphere of $_{178}$ constant radius (Barnes 1981), leading to fluctuations in the 179 angle, θ_{RB} , between the local field, $\mathbf{B} = \mathbf{B}_0 + \delta \mathbf{B}$, and the radial direction. These fluctuations correlate with proton motion 181 and therefore, the solar wind bulk velocity, \mathbf{v}_{sw} , also exhibits 182 a dependence on θ_{RB} (Matteini et al. 2014, 2015). If these 183 fluctuations play a role in plasma heating, we also expect a 184 correlation between them and the proton temperature. Recent 185 studies have shown that the proton temperature anisotropy at 1 au exhibits a dependence on θ_{RB} (D'Amicis et al. 2019a) that ₁₈₇ is not present closer to the Sun (Horbury et al. 2018), suggesting ongoing dynamical processes related to these fluctuations 189 in the solar wind. In fact, larger wave power in transverse 190 Alfvénic fluctuations is also correlated with proton temperature anisotropy (Bourouaine et al. 2010), consistent with an 192 increase in fluctuations in θ_{RB} .

Single-spacecraft observations have an inherent spatiotemporal ambiguity that complicates investigation of the coupling between Alfvénic fluctuations and the plasma bulk pa- 193 rameters. These measurements are restricted to the sampling 194 of a time series defined by the trajectory of the spacecraft with 195 respect to the flow velocity, \mathbf{v}_{sw} . This limitation means that we 196 can only resolve the component of k along the sampling direc- 197 tion, i.e., predominantly the radial direction. Previous studies (e.g., Horbury et al. 2008; Wicks et al. 2010; He et al. 2011; Podesta & Gary 2011b) assume that the underlying distribution of turbulence in the solar wind is independent of θ_{vB} , the angle between \mathbf{v}_{sw} and \mathbf{B}_0 . Based on this assumption, these 198 studies use measurements of the solar wind plasma at differ- 199 ent θ_{vB} to probe the turbulence as a function of θ_{kB} , the angle 200 between **k** and \mathbf{B}_0 . However, if there is indeed a dependence ²⁰¹ of the plasma bulk parameters (including the temperature and 202 temperature anisotropies as observed) on $\theta_{RB} \simeq \theta_{\nu B}$, then this 203

assumption may not be valid.

In this paper, we investigate whether the solar wind proton temperature anisotropy depends on the polarisation properties of small-scale Alfvénic fluctuations, and hence θ_{vB} , in the context of turbulent dissipation. In Section 2, we discuss the linear theory and polarisation properties of Alfvén waves. In Sections 3 and 4, we describe our analysis methods, using single-spacecraft measurements to measure the polarisation properties of Alfvénic fluctuations at ion-kinetic scales in the solar wind. We present our main results in Section 5, testing how the dissipation of turbulence at these scales affects the macroscopic bulk properties of the solar wind. We show that Alfvénic fluctuations present at ion-kinetic scales in the solar wind share at least some polarisation properties with Alfvén waves from linear Vlasov theory. By also investigating the statistical distribution of proton temperature in the β_p - θ_{vB} plane, we find that there is a clear dependence in this reduced parameter space that also correlates with the magnetic helicity of Alfvénic fluctuations. We discuss the implications of our results in Section 6, namely that we cannot sample different θ_{vB} to analyse the dependence of the turbulence on θ_{kB} without considering other plasma properties. In Section 7, we consider both instrumental and expansion effects, showing that they do not account for the observed temperature distribution. Finally, in Section 8, we conclude that our results provide new evidence for the importance of local kinetic processes that depend on θ_{vB} in determining proton temperature in the solar wind.

2. POLARISATION PROPERTIES OF ALFVÉN WAVES

In collisionless space plasmas such as the solar wind, the linearised Vlasov equation describes linear waves and instabilities. Non-trivial solutions exist only when the complex frequency, $\omega = \omega_r + i\gamma$, solves the hot-plasma dispersion relation (Stix 1992). Here, ω_r is the wave frequency and γ is the wave growth ($\gamma > 0$) or damping ($\gamma < 0$) rate. One such solution is the Alfvén wave, which is ubiquitous in space plasmas. At $k_{\parallel}d_p \ll 1$ and $k_{\perp}\rho_p \ll 1$, this wave is incompressible and propagates along ${\bf B}_0$ at the Alfvén speed, v_A , resulting in transverse perturbations to the field (Alfvén 1942). The fluctuations in velocity, $\delta {\bf v}$, and the magnetic field, $\delta {\bf b}$, exhibit a characteristic (anti-)correlation, $\delta {\bf v} = \mp \delta {\bf b}$, for propagation (parallel) anti-parallel to ${\bf B}_0$. Here, ${\bf b}$ is the magnetic field in Alfvén units, ${\bf b} = {\bf B}/\sqrt{\mu_0\rho}$, where ρ is the plasma mass density. The Alfvén wave has the dispersion relation:

$$\omega_r(k) = k v_A \cos \theta_{kB}. \tag{1}$$

Approaching ion-kinetic scales, $k_{\parallel}d_p \simeq 1$ or $k_{\perp}\rho_p \simeq 1$, the dispersion relation splits into two branches: the Alfvén ion-cyclotron (AIC) wave for small θ_{kB} (Gary & Borovsky 2004) and the KAW for large θ_{kB} (Gary & Nishimura 2004).

We define the polarisation of a wave as:

$$P = -\frac{i\delta E_y}{\delta E_x} \frac{\omega_r}{|\omega_r|},\tag{2}$$

where δE_x and δE_y are components of the Fourier amplitudes of the fluctuating electric field transverse to $\mathbf{B}_0 = B_0 \hat{\mathbf{z}}$ (Stix 1992; Gary 1993). Therefore, P gives the sense and degree of rotation in time of a fluctuating electric field vector at a fixed point in space, viewed in the direction parallel to \mathbf{B}_0 . A circularly polarised wave has $P = \pm 1$, where +1 (-1) designates right-handed (left-handed) polarisation. In this definition, a

right-hand polarised wave has electric field vectors that rotate in the same sense as the gyration of an electron, and a left-hand polarised wave, the same sense as ions. For more general elliptical polarisation, we take the real part, Re(P).

Magnetic helicity is a measure of the degree and sense of spatial rotation of the magnetic field (Woltjer 1958a,b). It is an invariant of ideal magnetohydrodynamics (MHD) and defined as a volume integral over all space:

$$H_m \equiv \int_V \mathbf{A} \cdot \mathbf{B} d^3 \mathbf{r},\tag{3}$$

where **A** is the magnetic vector potential defined by **B** = $\nabla \times$ **A**. Matthaeus et al. (1982) propose the fluctuating magnetic helicity, $H'_m(\mathbf{k})$, as a diagnostic of solar wind fluctuations, which in spectral form (i.e., in Fourier space) is defined as:

$$H'_{m}(\mathbf{k}) \equiv \delta \mathbf{A}(\mathbf{k}) \cdot \delta \mathbf{B}^{*}(\mathbf{k}), \tag{4}$$

where $\delta \mathbf{A}$ is the fluctuating vector potential, and the asterisk indicates the complex conjugate of the Fourier coefficients (Matthaeus & Goldstein 1982b). This definition removes contributions to the helicity arising from \mathbf{B}_0 . By assuming the Coulomb gauge, $\nabla \cdot \mathbf{A} = 0$, the fluctuating magnetic helicity can be written:

$$H_m'(\mathbf{k}) = i \frac{\delta B_y \delta B_z^* - \delta B_y^* \delta B_z}{k_x},$$
 (5)

where the components of $\delta \mathbf{B}(\mathbf{k})$ are Fourier coefficients of a wave mode with \mathbf{k} . This result is invariant under cyclic permutations of the three components x,y,z (See Equation 2 in Howes & Quataert 2010). We define the normalised fluctuating magnetic helicity density as:

$$\sigma_m(\mathbf{k}) \equiv \frac{kH'_m(\mathbf{k})}{|\delta \mathbf{B}(\mathbf{k})|^2},\tag{6}$$

where $|\delta {\bf B}({\bf k})|^2 = \delta B_x^* \delta B_x + \delta B_y^* \delta B_y + \delta B_z^* \delta B_z$. Here, $\sigma_m({\bf k})$ is 256 dimensionless and takes values in the interval [-1,1], where 257 $\sigma_m = -1$ indicates fluctuations with purely left-handed helicity, 258 and $\sigma_m = +1$ purely right-handed helicity. A value of $\sigma_m = 0$ 259 indicates no overall coherence, i.e., there are either no fluctuations with coherent handedness or there is equal power in 261 both left-handed and right-handed components so that the net 262 value is zero.

Gary (1986) first explored the dependence of Re(P) for ²⁶⁴ small-scale Alfvén waves on different parameters by numerically solving the full electromagnetic dispersion relation, ²⁶⁵ showing that it changes sign depending on both θ_{kB} and ²⁶⁷ β_p . In the cold-plasma limit ($\beta_p \ll 1$), the Alfvén wave has ²⁶⁸ Re(P) < 0 for all θ_{kB} . However, from linear Vlasov theory, at ²⁶⁹ $\beta_p \simeq 10^{-2}$, the wave has Re(P) < 0 for $0^\circ \le \theta_{kB} \lesssim 80^\circ$, but ²⁷⁰ has Re(P) > 0 for $\theta_{kB} \gtrsim 80^\circ$. As β_p increases, the wave has ²⁷¹ Re(P) > 0 for an increasing range of oblique angles so that at ²⁷² $\beta_p \simeq 10$, the transition occurs at about 40°. This result reveals ²⁷³ that the changing polarisation properties on both θ_{kB} and β_p ²⁷⁴ will affect possible wave-particle interactions, and hence tur- ²⁷⁵ bulence damping mechanisms that can occur in a plasma. For ²⁷⁶ example, left-handed AIC waves can cyclotron resonate with ²⁷⁷ ions, leading to heating perpendicular to \mathbf{B}_0 . On the other hand, right-handed KAWs are compressive at small scales, giving rise to density fluctuations and a non-zero component

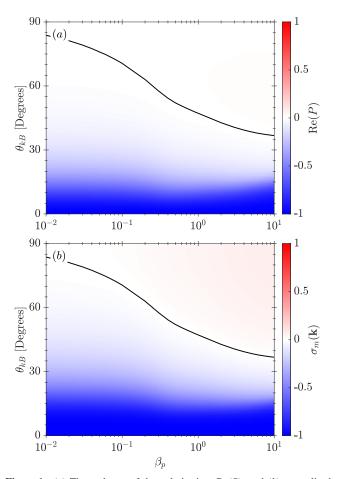

Figure 1. (a) The real part of the polarisation, Re(P), and (b) normalised fluctuating magnetic helicity density, $\sigma_m(\mathbf{k})$, of Alfvén waves with $kd_p = 0.05$ as a function of β_p and θ_{kB} , calculated using the NHDS code (see main text). The black lines indicate the isocontours Re(P) = 0 and $\sigma_m(\mathbf{k})$ = 0.

of the wave electric field, $E_{\parallel} \neq 0$. Hence, KAWs can Landau resonate with both electrons and ions, leading to heating parallel to \mathbf{B}_0 .

We plot both Re(P) and $\sigma_m(\mathbf{k})$ for Alfvénic fluctuations across the β_p - θ_{kB} plane in Figure 1. The black lines are isocontours of Re(P) = 0 and $\sigma_m(\mathbf{k}) = 0$, respectively. We note that for waves with $\theta_{kB} \simeq 0$, there is no difference between the values of Re(P) and $\sigma_m(\mathbf{k})$. To calculate these lines, we solve the linear Vlasov equation using the New Hampshire Dispersion relation Solver (NHDS; Verscharen et al. 2013; Verscharen & Chandran 2018). Here, $\mathbf{k} = k_{\perp} \hat{\mathbf{x}} + k_{\parallel} \hat{\mathbf{z}}$, and we assume a plasma consisting of protons and electrons with isotropic Maxwellian distributions, equal density and temperature, and no drifting components. We set $kd_p = 0.05$, where the angle θ_{kB} defines $k_{\perp} = k \sin \theta_{kB}$ and $k_{\parallel} = k \cos \theta_{kB}$. Therefore, $k_{\parallel}d_p$ and $k_{\perp}\rho_p$ change throughout the β_p - θ_{kB} plane,² while the normalised scale of the waves remains constant. We also set $v_A/c = 10^{-4}$, which is typical for solar wind conditions where $v_A \simeq 50$ km/s (Klein et al. 2019). While our assumption of an isotropic proton-electron plasma is not truly representative of the more complex ion VDFs typically observed in the solar wind, protons remain the most important ion component for solar wind interaction with Alfvénic fluctuations. Therefore, we expect that the polarisation properties of Alfvénic

¹ The black lines in Figure 1 are constant over the range: $kd_p = [0.01, 1]$.

² The scales d_p and ρ_p are related by: $\rho_p = d_p \sqrt{\beta_p}$.

fluctuations in the solar wind are adequately described by the 320 theoretical description provided in Figure 1. 321

3. REDUCED SPECTRA FROM SPACECRAFT MEASUREMENTS

In the solar wind, the polarisation properties of fluctuations 324 are typically determined using the fluctuating magnetic helic- 325 ity. However, from a single-spacecraft time series of magnetic 326 field measurements, it is only possible to determine a reduced 327 form of the helicity (Batchelor 1970; Montgomery & Turner 328 1981; Matthaeus et al. 1982):

$$H_m^{\prime r}(\omega_{sc}) = \frac{2\operatorname{Im}\left\{\mathcal{P}_{TN}^r(\omega_{sc})\right\}}{k_r},\tag{7}$$

where ω_{sc} is the frequency of the fluctuations in the spacecraft frame, $k_r = k \cos \theta_{kv}$ is the component of the wave-vector along the flow direction of the solar wind plasma, \mathbf{v}_{sw} , and θ_{kv} is the angle between \mathbf{k} and \mathbf{v}_{sw} . Here,

$$\mathcal{P}_{ii}^{r}(\omega_{sc}) = \delta B_{i}^{*}(\omega_{sc}) \cdot \delta B_{i}(\omega_{sc}) \tag{8}$$

is the reduced power spectral tensor, where the $\delta B_i(\omega_{sc})$ are the complex Fourier coefficients of the time series of **B** in radial-tangential-normal (RTN) coordinates.³ In this coordinate system, the solar wind flow is approximately radial, $\mathbf{v}_{sw} \simeq v_{sw} \hat{\mathbf{R}}$. The reduced tensor is an integral of the true spectral tensor, $\mathcal{P}_{ij}(\mathbf{k})$ (Fredricks & Coroniti 1976; Forman et al. 2011; Wicks et al. 2012):

$$\mathcal{P}_{ij}^{r}(\omega_{sc}) = \int \mathcal{P}_{ij}(\mathbf{k}) \, \delta \left[\omega_{sc} - \left(\mathbf{k} \cdot \mathbf{v}_{sw} + \omega_{pl} \right) \right] \, d^{3}\mathbf{k}. \tag{9}$$

Taylor's hypothesis (Taylor 1938) assumes that the fluctuations in the solar wind evolve slowly as they are advected past the spacecraft so that the plasma-frame frequency, ω_{pl} , satisfies $|\omega_{pl}| \ll |\mathbf{k} \cdot \mathbf{v}_{sw}|$ (Matthaeus & Goldstein 1982b; Perri & Balogh 2010). Therefore, the Doppler shift of the fluctuations into the spacecraft frame becomes:

$$\omega_{sc} = \omega_{pl} + \mathbf{k} \cdot \mathbf{v}_{sw} \simeq \mathbf{k} \cdot \mathbf{v}_{sw} \equiv k_r v_{sw}, \tag{10}$$

so that the ω_{pl} term drops from Equation 9. Then, a time series of magnetic field measurements under these assumptions 343 represents a spatial cut through the plasma and we can write 344 \mathcal{P}_{ij}^{r} and H_{m}^{rr} as functions k_{r} using Equation 10. However, it is 345 not possible to determine the full wave-vector, \mathbf{k} , or θ_{kB} , from 346 single-spacecraft measurements. Since $v_{A} \ll v_{sw}$, Taylor's hypothesis is usually well-satisfied for Alfvén waves in the solar 348 wind with the dispersion relation given by Equation 1, as well as for the small-wavelength extensions of the Alfvén branch 349 under the parameters considered here (see Howes et al. 2014; 350 Klein et al. 2014a).

Based on the definition in Equation 6, the normalised re- 352 duced fluctuating magnetic helicity density is then defined as: 353

$$\sigma_m^r(k_r) \equiv \frac{k_r H_m^{\prime r}(k_r)}{\left|\delta \mathbf{B}(k_r)\right|^2} = \frac{2\operatorname{Im}\left\{\mathcal{P}_{TN}^r(k_r)\right\}}{\operatorname{Tr}\left\{\mathcal{P}^r(k_r)\right\}},\tag{11}$$

where Tr{} denotes the trace. Previous studies (e.g., Horbury et al. 2008; Wicks et al. 2010; He et al. 2011; Podesta & Gary 2011b) use θ_{vB} as a measure of a specific θ_{kB} in

the solar wind. For example, measurements of $\sigma_m^r(k_r)$ separated as a function of θ_{vB} show a broad right-handed signature at oblique angles and a narrow left-handed signature at quasi-parallel angles (He et al. 2011, 2012a,b; Podesta & Gary 2011b; Klein et al. 2014b; Bruno & Telloni 2015; Telloni et al. 2015). These signatures are associated with KAW-like fluctuations from the turbulent cascade and ion-kinetic instabilities, respectively (Telloni & Bruno 2016; Woodham et al. 2019).

By defining the field-aligned coordinate system,

$$\hat{\mathbf{z}} = \frac{\mathbf{B}_0}{|\mathbf{B}_0|}; \, \hat{\mathbf{y}} = -\frac{\mathbf{v}_{sw} \times \mathbf{B}_0}{|\mathbf{v}_{sw} \times \mathbf{B}_0|}; \, \hat{\mathbf{x}} = \hat{\mathbf{y}} \times \hat{\mathbf{z}}, \tag{12}$$

so that \mathbf{v}_{sw} lies in the x-z plane with angle θ_{vB} from the $\hat{\mathbf{z}}$ direction (Wicks et al. 2012; Woodham et al. 2019), we can decompose $\sigma_m^r(k_r)$ into the components:

$$\sigma_{ij}(k_l) = \frac{2\operatorname{Im}\left\{\mathcal{P}_{ij}^r(k_l)\right\}}{\operatorname{Tr}\left\{\mathcal{P}^r(k_l)\right\}},\tag{13}$$

where the indices i, j, l = x, y, z. We derive the following relationship between the components, $\sigma_{ij}(k_l)$, and $\sigma_m^r(k_r)$ (see Appendix):

$$\sigma_{xy}(k_z) = \sigma_m^r(k_r) \frac{k_z}{k_r},\tag{14}$$

$$\sigma_{xz}(k_y) = -\sigma_m^r(k_r) \frac{k_y}{k_r},\tag{15}$$

and

$$\sigma_{yz}(k_x) = \sigma_m^r(k_r) \frac{k_x}{k_r}.$$
 (16)

For fluctuations with $k_z\gg k_x$, i.e., **k** quasi-parallel to ${\bf B}_0$, $\sigma_{xy}(k_z)$ is the dominant contribution to $\sigma_m^r(k_r)$. Similarly, $\sigma_{yz}(k_x)$ dominates for modes with $k_x\gg k_z$, i.e., **k** at oblique angles, $\theta_{kB}\gtrsim 60^\circ$. As the solar wind velocity is confined to the x-z plane, we have no information about k_y from single-spacecraft measurements and $\sigma_{xz}(k_y)$ is not useful in a practical sense. From Section 2, we expect that AIC waves generated by kinetic instabilities have $k_z\gg k_x$. The anisotropic Alfvénic turbulent cascade leads to the generation of nearly perpendicular wave-vectors with $k_x\gg k_z$. Therefore, we can separate the helicity signatures of the two kinetic scale branches of the Alfvén wave using our decomposition technique.

4. DATA ANALYSIS

We analyse magnetic field data from the MFI fluxgate magnetometer (Lepping et al. 1995; Koval & Szabo 2013) and proton data from the SWE Faraday cup (Ogilvie et al. 1995; Kasper et al. 2006) instruments on-board the *Wind* spacecraft from Jun 2004 to Oct 2018. For each proton measurement, we define a local mean field, \mathbf{B}_0 , averaged over the SWE integration time (\sim 92 s). We estimate the normalised cross-helicity (Matthaeus & Goldstein 1982a) for each \sim 92 s interval,

$$\sigma_c = \frac{2(\delta \mathbf{v} \cdot \delta \mathbf{b})}{|\delta \mathbf{v}|^2 + |\delta \mathbf{b}|^2},\tag{17}$$

where $\delta \mathbf{b} = \mathbf{b} - \langle \mathbf{b} \rangle_{1h}$ and $\delta \mathbf{v} = \mathbf{v}_{sw} - \langle \mathbf{v}_{sw} \rangle_{1h}$. Here, the mean is over a one hour window centred on the instantaneous values and we assume that $\mathbf{v}_{sw} \simeq \mathbf{v}_p$, where \mathbf{v}_p is the proton bulk

³ In the RTN coordinate system, $\hat{\mathbf{R}}$ is the unit vector from the Sun towards 358 the spacecraft, $\hat{\mathbf{T}}$ is the cross-product of the solar rotation axis and $\hat{\mathbf{R}}$, and $\hat{\mathbf{N}}$ 359 completes the right-handed triad.

velocity. An averaging interval of one hour gives σ_c for fluctuations in the inertial range. The cross-helicity, $\sigma_c \in [-1,1]$, is a measure of the (anti-)correlation between velocity and magnetic field fluctuations, and therefore, Alfvénicity (e.g., D'Amicis & Bruno 2015; D'Amicis et al. 2019b; Stansby et al. 2019; Perrone et al. 2020). A value $|\sigma_c| = 1$ indicates purely unbalanced Alfvénic fluctuations propagating in one direction, whereas $\sigma_c = 0$ indicates either balanced (equal power in opposite directions) or a lack of Alfvénic fluctuations. In case of $\sigma_c = 0$, we expect no coherent value of $|\sigma_m| > 0$ at ion-kinetic scales.

Similarly to Woodham et al. (2019), we account for heliospheric sector structure in the magnetic field measurements by calculating σ_c averaged over a running window of 12 hours. For solar wind fluctuations dominantly propagating anti-sunward, the sign of σ_c depends only on the direction of **B**₀. Therefore, if $\langle \sigma_c \rangle > 0$, we reverse the signs of the B_R and B_T components for each \sim 92 s measurement so that sunward fields are rotated anti-sunward. This procedure removes the inversion of the sign of magnetic helicity due to the direction of the large-scale magnetic field with respect to the Sun. We transform the 11 Hz magnetic field data associated with each proton measurement into field-aligned coordinates (Equation 12) using \mathbf{B}_0 averaged over ~ 92 s. We then compute the continuous wavelet transform (Torrence & Compo 1998) using a Morlet wavelet to calculate the magnetic helicity spectra, σ_{xy} and σ_{yz} , as functions of $f_{sc} = \omega_{sc}/2\pi$ using Equation 13. We average the spectra over \sim 92 s, corresponding to the SWE measurement cadence, to ensure that the fluc- 421 tuations contributing to the helicity spectra persist for at least 422 several proton gyro-periods, $2\pi/\Omega_p$, giving a clear coherent 423 helicity signature at ion-kinetic scales.

We estimate the amplitudes of σ_{xy} and σ_{yz} at ion-kinetic ⁴²⁵ scales by fitting a Gaussian function to the coherent peak ⁴²⁶ in each spectrum at frequencies close to the Taylor-shifted ⁴²⁷ frequencies, v_{sw}/d_p and v_{sw}/ρ_p (see Woodham et al. 2018). ⁴²⁸ We neglect any peak at $f > f_{\rm noise}$, where $f_{\rm noise}$ is the frequency above which instrumental noise of the MFI magnetometer becomes significant. ⁵ We also reject a spectrum if ⁴³¹ the angular deviation in **B** exceeds 15° during the ~92 s measurement period to ensure that we measure the anisotropy of ⁴³² fluctuations at ion-kinetic scales with sufficient accuracy (see ⁴³⁴ also Section 7.1). We designate the amplitude of the peak ⁴³⁵ in each σ_{xy} spectrum as $\sigma_{\parallel} \equiv \max_{k_z} \sigma_{xy}(k_z)$ to diagnose the ⁴³⁶ helicity of the modes with **k** quasi-parallel to **B**₀, and σ_{yz} as ⁴³⁷ $\sigma_{\perp} \equiv \max_{k_x} \sigma_{yz}(k_x)$ to diagnose the helicity of the modes with ⁴³⁸ **k** oblique to **B**₀ (see Section 3 and Appendix).

In our analysis, we include only measurements of Alfvénic 440 solar wind, $|\sigma_c| \geq 0.8$, and low collisionality, $N_c < 1$, which 441 contain the strongest Alfvénic fluctuations with a non-zero magnetic helicity. Here, N_c is the Coulomb number (Maruca et al. 2013; Kasper et al. 2017), which estimates the number 443 of collisional timescales for protons. We calculate N_c using 444 the proton-proton collision frequency, neglecting collisions 445 between protons and other ions. We bin the data in $\log_{10}(\beta_p)$ 446 and θ_{vB} using bins of width $\Delta \log_{10}(\beta_p) = 0.05$ and $\Delta \theta_{vB} = 5^{\circ}$. 447 We restrict our analysis to $0.01 \leq \beta_p \leq 10$ and include the full 448 range of $\theta_{vB} = [0^{\circ}, 180^{\circ}]$ to account for any dependence on he-449 liospheric sector structure. In Figure 2, we plot the probability 450 density distribution of the data,

452

453

454

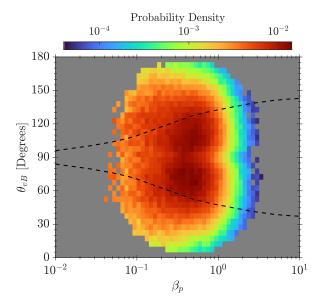

Figure 2. Probability density distribution of solar wind data in the β_P - θ_{vB} plane, calculated using Equation 18. The dashed black lines indicate the isocontours of $\tilde{\sigma}_m(\theta_{vB}) = 0$ mirrored about the line $\theta_{vB} = 90^\circ$ (see main text).

$$\tilde{p} = \frac{n}{N\Delta\beta_p\Delta\theta_{vB}},\tag{18}$$

in the β_p - θ_{vB} plane, where n is the number of data points in each bin and N is the total number of data points. We overplot the isocontour of $\sigma_m(\mathbf{k}) = 0$ from Figure 1(*b*) by replacing θ_{kB} with θ_{vB} , i.e., $\tilde{\sigma}_m(\theta_{vB}) = 0$. If we assume the turbulence is independent of θ_{vB} , then any dependence on θ_{vB} exclusively reflects a dependence on θ_{kB} (see Horbury et al. 2008; Wicks et al. 2010; He et al. 2011; Podesta & Gary 2011b). We mirror the $\tilde{\sigma}_m(\theta_{vB}) = 0$ curve around the line $\theta_{vB} = 90^\circ$ to account for heliospheric sector structure. The distribution of data in Figure 2 shows two peaks at $\theta_{\nu B} \sim 70^{\circ}$ and $\theta_{\nu B} \sim 110^{\circ}$ around $\beta_p \sim 0.5$. There are fewer data points at quasi-parallel angles, showing that the majority of data are associated with oblique angles. Naïvely, one would expect the distribution to follow the large-scale Parker spiral, peaking at angles $\sim 45^\circ$ and $\sim 135^{\circ}$. However, we note that θ_{vB} is calculated at ~ 92 s timescales, over with the local mean field \mathbf{B}_0 has already been deflected from the Parker spiral by Alfvénic fluctuations present at larger scales. There is also a clear β_p dependence in Figure 2, with the majority of the data lying in the range $0.1 \lesssim \beta_p \lesssim 1$, which is typical for quiescent solar wind (Wilson III et al. 2018).

5. RESULTS

In Figure 3, we plot the median values of σ_{\parallel} and σ_{\perp} for each bin in the β_p - θ_{vB} plane. We neglect any bins with fewer than 20 data points to improve statistical reliability. From Figure 1, we expect to measure KAW-like fluctuations with $\sigma_{\perp} > 0$ in the area of the β_p - θ_{vB} plane enclosed by the two dashed lines at quasi-perpendicular angles, and AIC wave-like fluctuations with $\sigma_{\parallel} < 0$ at quasi-parallel angles. Figure 3 is consistent with this expectation; we see a strong negative helicity signal at $0^{\circ} \leq \theta_{vB} \leq 30^{\circ}$ and $150^{\circ} \leq \theta_{vB} \leq 180^{\circ}$, with a minimum of $\sigma_{\parallel} \simeq -0.8$ approaching $\theta_{vB} \simeq 0^{\circ}$, as well as a weaker positive signal of $\sigma_{\perp} \simeq 0.4$ at angles $60^{\circ} \leq \theta_{vB} \leq 120^{\circ}$. Both σ_{\parallel} and σ_{\perp} are symmetrically distributed about the line $\theta_{vB} = 90^{\circ}$ since we remove the ambiguity in the sign

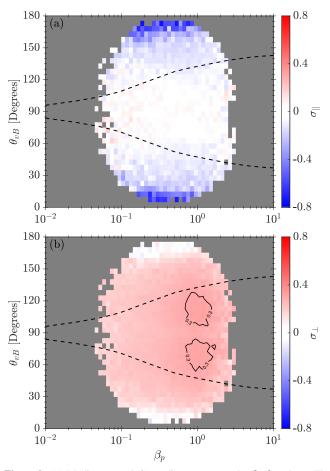

Figure 3. (a) Median σ_{\parallel} and (b) median σ_{\perp} across the β_p - θ_{vB} plane. The 515 dashed black lines indicate the isocontours of $\tilde{\sigma}_m(\theta_{vB})=0$ mirrored about the 516 line $\theta_{vB}=90^\circ$. We also include contours of constant $\sigma_{\perp}=0.3$ in Panel (b) as 517 solid black lines.

of the helicity due to the direction of \mathbf{B}_0 . The distribution of σ_{\parallel} is consistent with the presence of quasi-parallel propagating AIC waves from kinetic instabilities in the solar wind (Woodham et al. 2019; Zhao et al. 2018, 2019a). Elsewhere in Figure 3(a), the median value of σ_{\parallel} is zero, showing that a coherent signal of parallel-propagating fluctuations at ion-kinetic scales in the solar wind is not measured at oblique angles.

In Figure 3(b), there are two peaks in the median σ_{\perp} close to $\beta_p \sim 1$, located at $\theta_{vB} \sim 70^\circ$ and $\theta_{vB} \sim 110^\circ$. Despite these peaks, the signal is spread across the parameter space, except at quasi-parallel angles where $\sigma_{\perp} \simeq 0$. We interpret this spread using Taylor's hypothesis. Due to the $\mathbf{k} \cdot \mathbf{v}_{sw}$ term in the δ -function in Equation 9, a $\cos \theta_{kv}$ factor modifies the contribution of all modes to the reduced spectrum measured in the direction of \mathbf{v}_{sw} . If $\theta_{kv} = 0^{\circ}$, then $\cos \theta_{kv} = 1$, and the waves are measured at their actual k. However, oblique modes measured at a fixed ω_{sc} correspond to a higher k in the plasma frame. Since the turbulent spectrum decreases in amplitude with increasing k, the reduced spectrum is most sensitive to 537 the smallest k in the sampling direction. For parallel prop- 538 agating fluctuations such as AIC waves, $\theta_{vB} \simeq \theta_{kv}$, but for a 539 broader k-distribution of obliquely propagating fluctuations, 540 multiple fluctuations with different k and therefore, different 541 θ_{kB} , contribute to a single $\theta_{\nu B}$ bin. The signal at $\theta_{\nu B} \lesssim 30^{\circ}$ 542 is then likely due to fluctuations with $\theta_{kB} \gtrsim 60^{\circ}$, since they 543 contribute to σ_{\perp} , i.e., have a significant k_{\perp} component.

As the polarisation properties of small-scale Alfvénic fluctuations are consistent with predictions from linear theory, it is reasonable to expect that T_p is also correlated in the β_p - θ_{vB} plane. This expectation follows because different Alfvénic fluctuations are associated with different dissipation mechanisms, leading to distinct heating signatures. On the other hand, if the properties of the turbulence are truly independent of θ_{vB} , then we expect the dissipation mechanisms, and therefore, proton heating to be independent of θ_{vB} . To test this hypothesis, we plot the median values of $T_{p,\perp}/\langle T_{p,\perp}\rangle$ and $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$ for each bin in the β_p - θ_{vB} plane in Figure 4. Here, $\langle T_{p,\perp/\parallel} \rangle$ is the average value of $T_{p,\perp/\parallel}$ over all angles for each bin in $\log_{10}(\beta_p)$. This column normalisation removes the systematic proportionality of T_p with β_p . The colour of each bin in the θ_{vB} - β_p plane, therefore, shows as a function of $\theta_{\nu B}$ whether the proton temperature is equal to, larger than, or smaller than the average for a specific β_p .

Figure 4 shows a clear dependence of the median columnnormalised $T_{p,\perp}$ and $T_{p,\parallel}$ on both $\theta_{\nu B}$ and β_p . In general, we see higher $T_{p,\perp}/\langle T_{p,\perp}\rangle$ at quasi-parallel angles where σ_{\parallel} is largest in Figure 3(a), associated with AIC waves driven by kinetic instabilities (Kasper et al. 2002b; Matteini et al. 2007; Bale et al. 2009; Maruca et al. 2012; Woodham et al. 2019). We also see higher $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$ at oblique angles where σ_{\perp} is largest in Figure 3(b), associated with KAW-like fluctuations (Leamon et al. 1999; Bale et al. 2005; Howes et al. 2008; Sahraoui et al. 2010). However, there are also enhancements in $T_{p,\perp}/\langle T_{p,\perp}\rangle$ where $\sigma_{\perp} \simeq 0.3$, as indicated by the contours of constant σ_{\perp} from Figure 3(b). Despite enhancements in both the column-normalised $T_{p,\perp}$ and $T_{p,\parallel}$ in this region of parameter space, the proton temperature remains anisotropic with $T_{p,\perp}/T_{p,\parallel} < 1$. We note that a lack of helicity signature does not imply that waves are not present. Therefore, if the enhancements in proton temperature are associated with different dissipation mechanisms, we do not expect a perfect correlation with σ_{\parallel} and σ_{\perp} in the $\theta_{\nu B}$ - β_p plane.

Hellinger & Trávníček (2014) recommend to exercise caution when bin-averaging solar wind data in a reduced parameter space. While conditional statistics have been employed in several studies (e.g., Bale et al. 2009; Maruca et al. 2011; Osman et al. 2012), this non-trivial procedure may give spurious results as a consequence of superposition of multiple correlations in the solar wind and should be interpreted cautiously. We find no evidence that the correlations shown in Figure 4 are caused by or related to other underlying correlations in the solar wind multi-dimensional parameter space. In particular, we rule out the known correlation between v_{sw} and T_p (Matthaeus et al. 2006; Perrone et al. 2019) by separating our results as a function of solar wind speed, finding that Figure 4 is largely unchanged (not shown). This is consistent with the fact that the β_p - θ_{vB} parameter space we investigate is determined by the properties of Alfvénic fluctuations, which exist in both fast and slow wind (e.g., D'Amicis et al. 2019b).

6. DISCUSSION

It is well-known that Alfvénic turbulence is anisotropic, its properties dependent on the angle, θ_{kB} . For a single spacecraft sampling in time, the common assumption of ergodicity means that we measure a statistically similar distribution of turbulent fluctuations. Hence, by sampling along different directions relative to a changing θ_{vB} , we measure different components of the same distribution, e.g., the spectrum of magnetic fluctuations parallel and perpendicular to

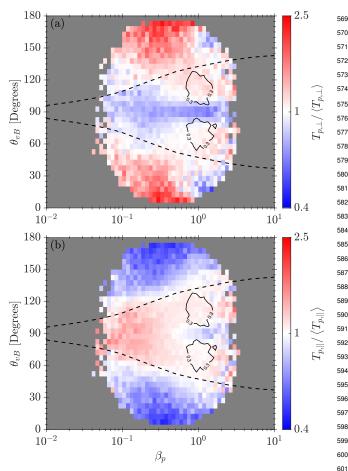

Figure 4. (a) Median proton perpendicular temperature, $T_{p,\perp}/\left\langle T_{p,\perp}\right\rangle$ and (b) median proton parallel temperature, $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$, across β_p - $\theta_{\nu B}$ space. In $_{603}$ both panels, we column-normalise the data by the median temperature in each β_p bin, $\langle T_{p,\perp/\parallel} \rangle$, to remove the systematic dependency of β_p on temperature. The dashed black lines indicate the isocontours of $\tilde{\sigma}_m(\theta_{vB}) = 0$ mirrored about the line $\theta_{vB} = 90^{\circ}$. We also include contours of constant $\sigma_{\perp} = 0.3$ from Figure 606 3(b) as black lines.

 ${\bf B}_0$. The same is true for magnetic helicity, where the left- or right-handedness is determined only by the sampling direction. Certain fluctuations may still exist and we do not measure them since we do not sample close enough to the \mathbf{k} of these modes for them to make a significant contribution to the $\mathbf{k} \cdot \mathbf{v}_{sw}$ term in Equation 9. Therefore, if turbulent dissipation is ongoing, we expect the resultant heating to exhibit the same 615 distribution as the fluctuations at ion-kinetic scales. This is 616 because the polarisation properties of solar wind fluctuations 617 affect what dissipation mechanisms can occur.

We initially hypothesised that the proton temperature would not exhibit a systematic dependence on either θ_{vB} or $\sigma_{\parallel,\perp}$. However, we show a clear dependence of $T_{p,\perp/\parallel}/\langle T_{p,\perp/\parallel}\rangle$ on $_{621}$ θ_{vB} in Figure 4 that also correlates with the magnetic helic- ₆₂₂ ity signatures of different Alfvénic fluctuations at ion-kinetic 623 scales. This result suggests that the properties of the turbulence also change with $\theta_{\nu B}$. In other words, differences in the 625 spectra of magnetic fluctuations with changing $\theta_{\nu B}$ are due to $_{626}$ both single-spacecraft sampling effects and differences in the underlying distribution of turbulent fluctuations. If this interpretation is correct, studies that sample many angles θ_{vB} as the solar wind flows past a single spacecraft to build up a picture of the turbulence in the plasma, i.e., to sample different θ_{kB} , need to be interpreted very carefully (e.g., Horbury et al. 2008;

Wicks et al. 2010; He et al. 2011; Podesta & Gary 2011b). In this study, we measure θ_{vB} at \sim 92 s timescales, which suppresses large-scale correlations such as the Parker-spiral. Instead, we show correlations between small-scale fluctuations with respect to a local mean field and the macroscopic proton temperature. Therefore, it is fair to assume that the dependence of $T_{p,\perp}/\langle T_{p,\perp}\rangle$ and $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$ on $\theta_{\nu B}$ and β_p reflects the differences in the localised dissipation and heating processes at ion-kinetic scales in the solar wind.

A large enough $T_{p,\perp}/T_{p,\parallel}$ can drive AIC waves unstable in the solar wind (Kasper et al. 2002b; Matteini et al. 2007; Bale et al. 2009; Maruca et al. 2012). The driving of these waves is enhanced by the frequent presence of an α -particle proton differential flow or proton beam in the solar wind (Podesta & Gary 2011a,b; Wicks et al. 2016; Woodham et al. 2019; Zhao et al. 2019b, 2020a). The enhancement in $T_{p,\perp}/\langle T_{p,\perp}\rangle$ at quasi-parallel angles in Figure 4(a) is likely responsible for the driving of these modes and correlates with the peak in σ_{\parallel} at these angles in Figure 3(a), where we measure the strongest signal. While we are unable to observe AIC waves at oblique angles using a single spacecraft, we also measure KAW-like fluctuations at these angles using σ_{\perp} in Figure 3(*b*). The peaks in σ_{\perp} correlate with the observed enhancement in $T_{p,\perp}/\langle T_{p,\perp}\rangle$, and therefore, are consistent with the dissipation of these fluctuations leading to perpendicular heating. A common dissipation mechanism proposed for KAW-like fluctuations is Landau damping (e.g., Howes 2008; Schekochihin et al. 2009); however, this leads to heating parallel to \mathbf{B}_0 . Instead, perpendicular heating may arise from processes such as stochastic heating (Chandran et al. 2010, 2013) or even cyclotron resonance (Isenberg & Vasquez 2019), although more work is needed to confirm this.

We note that several studies (Markovskii & Vasquez 2013, 2016; Markovskii et al. 2016; Vasquez et al. 2018) show that non-linear fluctuations confined to the plane perpendicular to \mathbf{B}_0 can produce the observed right-handed helicity signature in σ_{\perp} in the same way as linear KAWs (e.g., Howes & Quataert 2010; He et al. 2012b). In this study, we refer to KAW-like fluctuations as non-linear turbulent fluctuations with polarisation properties that are consistent with linear KAWs, rather than linear modes. This interpretation does not preclude the possibility of resonant damping (Li et al. 2016, 2019; Klein et al. 2017a, 2020; Howes et al. 2018; Chen et al. 2019) or stochastic heating (e.g., Cerri et al. 2021) discussed above, however, additional processes cannot be ruled out. For example, kinetic simulations show perpendicular heating of ions by turbulent processes that may be unrelated to wave damping or stochastic heating, although, the exact heating mechanism is still unclear (e.g., Parashar et al. 2009; Servidio et al. 2012; Vasquez 2015; Yang et al. 2017).

The variation of $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$ in the β_p - θ_{vB} plane in Figure 4(b) is more difficult to interpret. This result could also be a signature of proton Landau damping of KAW-like fluctuations, although, this process is typically stronger at $\beta_p \gtrsim 1$ (Gary & Nishimura 2004; Kawazura et al. 2019). While we measure fluctuations that can consistently explain the enhancement in $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$, other fluctuations may be present that we do not measure. Direct evidence of energy transfer between the fluctuations and protons is needed to confirm this result, for example, using the field-particle correlation method (Klein & Howes 2016; Howes et al. 2017; Klein 2017; Klein et al. 2017b; Chen et al. 2019; Li et al. 2019). This evidence will require higher-resolution data than provided by Wind. We

note that caution must be given when interpreting these results, since several other effects may also explain the temperature dependence seen in the β_P - θ_{VB} plane. For example, instrumental effects and the role of solar wind expansion may result in similar temperature profiles. We now discuss these two effects in turn, showing that they cannot fully replicate our results presented in this paper.

7. ANALYSIS CAVEATS

7.1. Instrumentation & Measurement Uncertainties

The SWE Faraday cups on-board Wind measure a reduced VDF that is a function of the average direction of \mathbf{B}_0 over the measurement interval (Kasper 2002). As the spacecraft spins every 3 s in the ecliptic plane, the Faraday cups measure the current due to ions in several angular windows. The Faraday cups repeat this process using a different voltage (energy) window for each spacecraft rotation, building up a full spectrum every \sim 92 s. By fitting a bi-Maxwellian to the reduced proton VDF, the proton thermal speeds, $w_{p,\parallel}$ and $w_{p,\perp}$, are obtained and converted to temperatures via $T_{p,\perp/\parallel} = m_p w_{p,\perp/\parallel}^2 / 2k_B$, where m_p is the proton mass. Due to the orientation of the cups on the spacecraft body, the direction of \mathbf{B}_0 with respect to the axis of the cups as they integrate over the proton VDF can cause inherent uncertainty in $w_{p,\parallel}$ and $w_{p,\perp}$. For example, if \mathbf{B}_0 is radial, then measurements of $w_{p,\parallel}$ have a smaller uncertainty compared to when the field is perpendicular to the cup, i.e., \mathbf{B}_0 is orientated out of the ecliptic plane by a significant angle, $\theta_{vB} \gtrsim 60^{\circ}$ (Kasper et al. 2006). In Figure 5, we plot the percentage uncertainty in $w_{p,\parallel}$ and $w_{p,\perp}$,

$$U(w_{p,\perp/\parallel}) = \frac{\Delta w_{p,\perp/\parallel}}{w_{p,\perp/\parallel}} \times 100\%,$$
 (19)

in the β_p - θ_{vB} plane, where $\Delta w_{p,\perp/\parallel}$ is the uncertainty in $w_{p,\perp/\parallel}$, derived from the non-linear fitting of the distribution functions. We note that these uncertainties are not equivalent to Gaussian measurement errors; however, they provide a qualitative aid to understand systematic instrumental issues in the Faraday cup data.

We see that $w_{p,\perp}$ has a larger uncertainty (\sim 40%) at quasiparallel angles in Figure 5(a), which is almost independent of β_p . While the median $T_{p,\perp}/\langle T_{p,\perp}\rangle$ in Figure 4(a) is larger at these angles, it exhibits a clear dependence on β_p . Therefore, increased uncertainty in the temperature measurements alone 693 cannot completely account for the observed enhancement in 694 $T_{p,\perp}/\langle T_{p,\perp}\rangle$ at these angles in the β_p - θ_{vB} plane. At quasiperpendicular angles, the uncertainty in $w_{p,\perp}$ is less than 10%, suggesting that the enhancements in $T_{p,\perp}/\langle T_{p,\perp}\rangle$ in Figure 4(a) at $\beta_p \simeq 1$ and $40^\circ \lesssim \theta_{vB} \lesssim 140^\circ$ are unlikely to result from instrumental uncertainties. From Figure 5(b), the unsequence of the sequence of t certainty in $w_{p,\parallel}$ is largest at $\theta_{\nu B} \simeq 90^{\circ}$, although there is a larger spread to $70^{\circ} \lesssim \theta_{\nu B} \lesssim 110^{\circ}$ at $\beta_p \gtrsim 0.3$. By comparation ing with Figure 4(*b*), the enhancement in $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$ over the $\frac{1}{702}$ entire β_p range does not coincide exactly with the regions of $_{703}$ β_p - θ_{vB} space where these measurements have increased uncertainty. We also expect that any increased uncertainty in 705 the $w_{p,\parallel}$ measurements would lead to increased noise that destroys any coherent median signal in this space, weakening 707 the enhancement seen in Figure 4(b). Therefore, we conclude $_{708}$ that the increased uncertainty in $w_{p,\parallel}$ at oblique angles is not $v_{p,\parallel}$ the sole cause of the observed enhancement in $T_{p,\parallel}/\langle T_{p,\parallel}\rangle$.

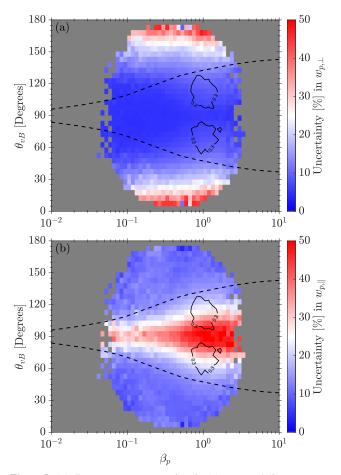

Figure 5. Median percentage uncertainty in (a) $w_{p,\perp}$ and (b) $w_{p,\parallel}$, across β_p - θ_{vB} space. The dashed black lines indicate the isocontours of $\overline{\sigma}_m(\theta_{vB}) = 0$ mirrored about the line $\theta_{vB} = 90^\circ$. We also include contours of constant $\sigma_\perp = 0.3$ from Figure 3(b) as black lines.

Another source of uncertainty from the SWE measurements arises from the changing magnetic field direction over the course of the \sim 92 s measurement interval (Maruca & Kasper 2013). We quantify the angular fluctuations in **B** using:

$$\psi_B = \sum_{i=1}^{N} \arccos\left(\hat{\mathbf{B}}_i \cdot \hat{\mathbf{B}}_{92}\right) / N, \tag{20}$$

where N is the number of spacecraft rotations in a single measurement, \mathbf{B}_{92} is the average magnetic field direction over the whole measurement interval, and $\hat{\mathbf{B}}_i$ is the magnetic field unit vector averaged over each 3 s rotation. A large ψ_B can lead to the blurring of anisotropies in the proton thermal speeds. In other words, the fluctuations in **B** over the integration time result in a broadening of the reduced VDFs, increasing uncertainty in these measurements (e.g., see Verscharen & Marsch 2011). To reduce this blurring effect, we remove SWE measurements with angular deviations $\psi_B > 15^{\circ}$. Maruca (2012) provides an alternative dataset of proton moments from SWE measurements to account for large deviations in the instantaneous magnetic field, using an average \mathbf{B}_0 over each voltage window scan (i.e., one rotation of the spacecraft, \sim 3 s) to calculate $w_{p,\perp}$ and $w_{p,\parallel}$. Maruca & Kasper (2013) show that the Kasper (2002) dataset often underestimates the temperature anisotropy of proton VDFs. Our comparison with this alternative dataset (not shown here) reveals that both $T_{p,\perp}/\langle T_{p,\perp}\rangle$

and $T_{p,\parallel}/\left\langle T_{p,\parallel}\right\rangle$ show a similar, albeit slightly reduced, dependence on both β_p and θ_{vB} . This result suggests that the temperature dependence we see in the β_p - θ_{vB} plane is unlikely caused by the blurring of proton temperature anisotropy measurements.

7.2. CGL Spherical Expansion

Another possible source of proton temperature dependence on θ_{vB} is the expansion of the solar wind as it flows out into the heliosphere. The double adiabatic closure presented by Chew et al. (1956) predicts the evolution of $T_{p,\perp}$ and $T_{p,\parallel}$ assuming no collisions, negligible heat flux, and no local heating:

$$\frac{d}{dt}\left(\frac{T_{p,\perp}}{B}\right) = 0 \quad \text{and} \quad \frac{d}{dt}\left(\frac{T_{p,\parallel}B^2}{n_p^2}\right) = 0, \quad (21)$$

where d/dt is the convective derivative. Under the assumption of steady-state spherical expansion, which is purely transverse to the radial direction with a constant radial velocity, $\mathbf{v}_{sw} = v_{sw} \hat{\mathbf{R}}$, the continuity equation gives $n_p \propto 1/r^2$, where r^{753} is the radial distance from the Sun. We assume that the radial evolution of the magnetic field in the equatorial plane follows the Parker spiral (Parker 1958),

$$B \propto \frac{\sqrt{\cos^2 \phi_0 + r^2 \sin^2 \phi_0}}{r^2},$$
 (22) 759

which gives a radial dependence of $B \propto 1/r^2$ when $\phi_0 = 0^\circ$ and $B \propto 1/r$ when $\phi_0 = 90^\circ$. The angle, ϕ_0 , is the foot-point longitude of the field at the solar wind source surface, given by:

$$\phi_0 = \arctan\left(\frac{r_0\Omega_{\odot}}{v_{\rm sw}}\right),$$
 (23)

where $\Omega_{\odot}=2.85\times 10^{-6}$ rad/s is the constant solar angular rotation rate and $r_0\simeq 20R_{\odot}$ (Owens & Forsyth 2013). Therefore, a value of v_{sw} sets the value of ϕ_0 at a given radius, 70. Then, $\phi=\tan^{-1}(B_{\phi}/B_r)$ is the azimuthal angle of **B** in the equatorial plane at a distance, r, from the Sun. The two angles are related by $\tan\phi=R\tan\phi_0$, where $R=r/r_0$. From Equations 21, 22, and the radial dependence of n_p , we obtain:

$$\frac{T_{p,\perp}}{T_{0,\perp}} = \frac{\sqrt{\cos^2(\phi_0) + R^2 \sin^2(\phi_0)}}{R^2},$$
 (24)

and

$$\frac{T_{p,\parallel}}{T_{0,\parallel}} = \frac{1}{\cos^2(\phi_0) + R^2 \sin^2(\phi_0)},\tag{25}$$

where $T_{0,\perp}$ and $T_{0,\parallel}$ are the perpendicular and parallel proton 786 temperatures at r_0 , respectively. We use Equations 24 and 25 787 to investigate the dependence of proton temperature on ϕ at 788 $r=215R_{\odot}\simeq 1$ au. Since the solar wind velocity is radial, the 789 angle ϕ is approximately equal to $\theta_{\nu B}$. We set $T_{0,\perp}=10$ and 790 $T_{0,\parallel}=1$, giving $T_{0,\parallel}=1$ for $T_{0,\parallel}=1$ giving $T_{0,\parallel}=1$ bution of angles $T_{0,\parallel}=1$ 0 using Equation 23 by selecting a range of 792 wind speeds: $T_{0,\parallel}=1$ 0 with T_{0

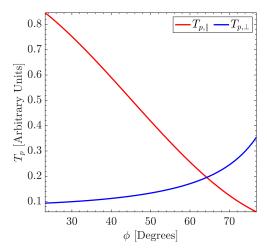

Figure 6. The temperature profiles $T_{p,\parallel}$ and $T_{p,\perp}$ as functions of ϕ at $r \simeq 1$ au for CGL spherical expansion given by Equations 24 and 25.

clearly the variation in $T_{p,\perp}$. We see that $T_{p,\parallel}$ remains similar to the value set close to the Sun (small ϕ), and decreases rapidly with increasing ϕ , approaching zero at $\phi \gtrsim 70^\circ$. On the other hand, $T_{p,\perp}$ is largest at $\phi \gtrsim 60^\circ$ and approaches 0.1 for $\phi \lesssim 30^\circ$. This dependence of $T_{p,\perp}$ and $T_{p,\parallel}$ is opposite to what we observe in Figure 4, which in general shows larger $T_{p,\parallel}$ at $\theta_{vB} \simeq 90^\circ$ and larger $T_{p,\perp}$ at $\theta_{vB} \simeq 0^\circ$. Therefore, spherical expansion alone cannot explain our results.

8. CONCLUSIONS

We use magnetic helicity to investigate the polarisation properties of Alfvénic fluctuations with finite radial wavenumber, k_r , at ion-kinetic scales in the solar wind. Using almost 15 years of *Wind* observations, we separate the contributions to helicity from fluctuations with wave-vectors quasiparallel and oblique to \mathbf{B}_0 , finding that the helicity of Alfvénic fluctuations is consistent with predictions from linear Vlasov theory. In particular, the peak in magnetic helicity at ion-kinetic scales and its variation with β_p and θ_{vB} shown in Figure 3 are in agreement with the dispersion relation of linear Alfvén waves (Gary 1986), when modified by Taylor's hypothesis. This result suggests that the non-linear turbulent fluctuations at these scales share at least some polarisation properties with Alfvén waves.

We also investigate the dependence of local kinetic heating processes due to turbulent dissipation on θ_{vB} . In Figure 4, we find that both $T_{p,\perp}$ and $T_{p,\parallel}$, when normalised to their average value in each β_p -bin, show a clear dependence on θ_{vB} . The temperature parallel to \mathbf{B}_0 is generally higher in the parameter-space where we measure a coherent helicity signature associated with KAW-like fluctuations, and perpendicular temperature higher in the parameter-space where we measure a signature expected from AIC waves. We also see small enhancements in the perpendicular temperature where we measure the strongest helicity signal of KAW-like fluctuations. However, we re-iterate the important fact that the lack of a wave signal is not the same as a lack of presence of waves.

Our results suggest that the properties of turbulent fluctuations at ion-kinetic scales in the solar wind depends on the angle $\theta_{\nu B}$. This finding is inconsistent with the general assumption that sampling different $\theta_{\nu B}$ allows us to sample different parts of the same ensemble of fluctuations that is otherwise unaltered in its statistical properties. Therefore, studies that sample different $\theta_{\nu B}$ in order to sample different $\theta_{k B}$ need to be

interpreted very carefully. Instead, if we assume that the dissipation mechanisms and proton heating depend on θ_{vB} , the enhancements in proton temperature in Figure 4 are consistent with the role of wave-particle interactions in determining proton temperature in the solar wind. For example, whenever we measure the helicity of AIC waves or KAW fluctuations, then we also measure enhancements in proton temperature. However, the inverse is not necessarily true. We suggest that heating mechanisms associated with KAWs lead to both parallel (Howes 2008; Schekochihin et al. 2009) and perpendicular (Chandran et al. 2010, 2013; Isenberg & Vasquez 2019) heating. We rule out both instrumental and large-scale expansion effects, finding that neither of them alone can explain the observed temperature profile in the β_p - θ_{vB} plane.

In summary, our observations suggest that the properties of Alfvénic fluctuations at ion-kinetic scales determine the level of proton heating from turbulent dissipation. This interpretation is consistent with recent studies showing that larger magnetic helicity signatures at ion-kinetic scales are associated with larger proton temperatures and steeper spectral exponents (Pine et al. 2020; Zhao et al. 2020b, 2021). Our findings, therefore, provide new evidence for the importance of local kinetic processes in determining proton temperature in the solar wind. We emphasise that our conclusions do not invoke causality, just correlation. For example, we cannot rule out a lack of cooling rather than heating. However, while the 855 adiabatic expansion of the solar wind causes the temperature 856 to vary with θ_{vB} , this cannot explain the observed temperature 857 profiles in the β_p - θ_{vB} plane. Further work is ongoing in order 858 to confirm these results and develop a theory for the processes 859 associated with the polarisation properties of Alfvénic fluctu- 860 ations that lead to the observed temperature profiles.

LDW thanks B. Alterman, L. Matteini, D. Stansby, and J. Stawarz for useful comments and discussions. LDW is also grateful to B. Maruca for sharing his processed SWE dataset for validation testing. APPENDIX

DECOMPOSITION OF FLUCTUATING MAGNETIC HELICITY

Here we present a mathematical derivation that decomposes $\sigma_m^r(k_r)$ into the different contributions, $\sigma_{ij}(k_l)$, calculated using Equation 13 (see also Wicks et al. 2012). In Figure 7, we plot the median value of the peak in $\sigma_m^r(k_r)$ across the β_p - $\theta_{\nu B}$ plane, showing two helicity signatures of opposite handedness. This technique allows us to separate the helicity signatures of different fluctuations at ion-kinetic scales in the solar wind, as we show in Figure 3.

We consider a spacecraft that samples a single mode with wave-vector:

$$\mathbf{k} = k_{\perp} \cos \alpha \,\hat{\mathbf{x}} + k_{\perp} \sin \alpha \,\hat{\mathbf{y}} + k_{\parallel} \,\hat{\mathbf{z}},\tag{A1}$$

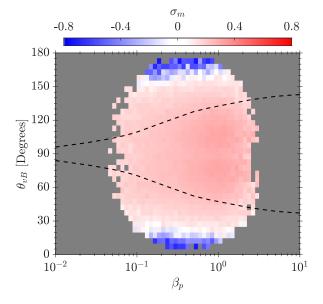

Figure 7. Median value of the peak in $\sigma_m^r(k_r)$ across the β_p - θ_{vB} plane. The dashed black lines indicate the isocontours of $\tilde{\sigma}_m(\theta_{vB}) = 0$ mirrored about the line $\theta_{vB} = 90^\circ$.

where α is the azimuthal angle of **k** in the *x-y* plane. The full signal from turbulence corresponds to a superposition of the signals from each of the modes, so considering a single mode is sufficient to understand how the components $\sigma_{ij}(k_l)$ are related to $\sigma_m^r(k_r)$. Without loss of generality, we take the solar wind velocity to be in the *x-z* plane,

$$\mathbf{v}_{sw} = v_{sw} \sin \theta_{vB} \,\hat{\mathbf{x}} + v_{sw} \cos \theta_{vB} \,\hat{\mathbf{z}}, \tag{A2}$$

and the local mean magnetic field to be $\mathbf{B}_0 = B_0 \hat{\mathbf{z}}$. We use the relation $2 \operatorname{Im} \{a^*b\} \equiv i(ab^* - a^*b)$ to rewrite $H_m^{\prime\prime\prime}(k_r)$ in RTN coordinates from Equation 7 into the form:

$$H_m^{\prime r}(k_r) = i \frac{\delta B_T \delta B_N^* - \delta B_T^* \delta B_N}{k_r}.$$
 (A3)

The normalised reduced fluctuating magnetic helicity, $\sigma_m^r(k_r)$, is then given by Equation 11. We define the relation between the RTN and the field-aligned (Equation 12) coordinate systems using the unit vector along the sampling direction, $\hat{\mathbf{v}}_{sw} = \mathbf{v}_{sw}/|\mathbf{v}_{sw}|$:

$$\hat{\mathbf{R}} = \hat{\mathbf{v}}_{sw} = \sin \theta_{vB} \hat{\mathbf{x}} + \cos \theta_{vB} \hat{\mathbf{z}};$$

$$\hat{\mathbf{T}} = \hat{\mathbf{B}}_{0} \times \hat{\mathbf{v}}_{sw} / |\hat{\mathbf{B}}_{0} \times \hat{\mathbf{v}}_{sw}| = \hat{\mathbf{y}};$$

$$\hat{\mathbf{N}} = \hat{\mathbf{R}} \times \hat{\mathbf{T}} = -\cos \theta_{vB} \hat{\mathbf{x}} + \sin \theta_{vB} \hat{\mathbf{z}}.$$
(A4)

By substituting for the RTN unit vectors in terms of $\hat{\mathbf{x}}$, $\hat{\mathbf{y}}$, and $\hat{\mathbf{z}}$ and simplifying, we obtain:

$$\sigma_{m}^{r}(k_{r}) = \frac{1}{|\delta \mathbf{B}(k_{r})|^{2}} \left\{ \left[\frac{i(\delta B_{x} \delta B_{y}^{*} - \delta B_{x}^{*} \delta B_{y})}{k_{z}} \right] k_{z} \cos \theta_{vB} \right.$$

$$+ \left[\frac{i(\delta B_{x} \delta B_{z}^{*} - \delta B_{x}^{*} \delta B_{z})}{k_{y}} \right] k_{y} \sin \theta_{vB} \sin \alpha$$

$$+ \left[\frac{i(\delta B_{y} \delta B_{z}^{*} - \delta B_{y}^{*} \delta B_{z})}{k_{x}} \right] k_{x} \sin \theta_{vB} \cos \alpha \right\}.$$
(A5)

By defining the non-reduced fluctuating magnetic helicity (see also, Equation 5) as:

$$H'_{m}(\mathbf{k}) = i \frac{\delta B_{x} \delta B_{y}^{*} - \delta B_{x}^{*} \delta B_{y}}{k_{z}}$$

$$\equiv i \frac{\delta B_{y} \delta B_{z}^{*} - \delta B_{y}^{*} \delta B_{z}}{k_{x}} \equiv i \frac{\delta B_{z} \delta B_{x}^{*} - \delta B_{z}^{*} \delta B_{x}}{k_{y}},$$
(A6)

we can manipulate Equation A5 into the form,

$$\sigma_m^r(k_r) = \frac{H_m'(\mathbf{k})}{|\delta \mathbf{B}(k_r)|^2} \{ k_z \cos \theta_{\nu B} - k_y \sin \theta_{\nu B} \sin \alpha + k_x \sin \theta_{\nu B} \cos \alpha \},$$

$$\equiv \sigma_{xy}(k_z)\cos\theta_{\nu B} + \sigma_{xz}(k_y)\sin\theta_{\nu B}\sin\alpha + \sigma_{\nu z}(k_x)\sin\theta_{\nu B}\cos\alpha, \tag{A7}$$

where we define the different contributions, $\sigma_{ij}(k_l)$, using Equation 13. We equate each of the terms between the two forms in Equation A7 to obtain the following direct relations between $\sigma_m^r(k_r)$ and $\sigma_{xy}(k_z)$, $\sigma_{xz}(k_y)$ and $\sigma_{yz}(k_x)$:

$$\sigma_{xy}(k_z) = \frac{H'_m(\mathbf{k})}{|\delta \mathbf{B}(k_r)|^2} k_z = \sigma_m^r(k_r) \frac{k_z}{k_r},\tag{A8}$$

$$\sigma_{xz}(k_y) = -\frac{H'_m(\mathbf{k})}{|\delta \mathbf{B}(k_r)|^2} k_y = -\sigma_m^r(k_r) \frac{k_y}{k_r},\tag{A9}$$

878 and,

884

885

886

887

891

892

874

875

876

877

$$\sigma_{yz}(k_x) = \frac{H_m'(\mathbf{k})}{|\delta \mathbf{B}(k_r)|^2} k_x = \sigma_m^r(k_r) \frac{k_x}{k_r},\tag{A10}$$

which are the same as Equations 14, 15, and 16.

To highlight the separation of different fluctuations in the solar wind using this technique, we show in Figure 8(a) a time 911 series of magnetic helicity spectra, σ_m^r , measured by *Wind* on 912 01/07/2012. We plot the spectra as functions of frequency in 913 the spacecraft frame, $f_{sc} = \omega_{sc}/2\pi$ (see Equation 10). In panels (b)-(d), we also plot σ_{ij} , showing the decomposition of 916 opposite handedness at $f_{sc} \simeq 1$ Hz in panel (a) are completely separated into the components σ_{xy} and σ_{yz} in panels 919 (b) and (c). In panel (d), we see only small enhancements close to 0.33 Hz, which corresponds to the spin frequency of 922 the spacecraft. Besides this spacecraft artefact, there is no coherent helicity signature in σ_{xz} , as expected.
