# Synthetic, Spectroscopic and Structural Studies on Carbametallaboranes containing Aromatic and Fused Aromatic Ring Systems 

Zoë G. Lewis

Thesis Presented for the Degree of
Doctor of Philosophy
University of Edinburgh
1991

## Declaration

Except where specific reference is made to other sources, the work presented in this thesis is the original work of the author. It has not been submitted, in whole or in part, for any other degree. Certain of the results have been accepted for publication.

For my parents

## Acknowledgements

First and foremost, I would like to thank my supervisor, Dr. Alan Welch, without whose advice, encouragement and boundless enthusiasm this work would not have been achieved.

Thanks are also due to Dr. David Reed for his help in recording and interpreting n.m.r. spectra.

I am also grateful to John Millar and Heather Grant, who obtained numerous other n.m.r. spectra, and to Elaine $M^{c}$ Dougall, who performed the elemental analyses.

I have very much appreciated the constant encouragement and advice from all those who have worked in laboratories 290-293 over the years. In particular I would like to thank Kenny Shaw and Stuart Macgregor for their help and support, especially in the final weeks of writing this thesis.

Finally, thanks are due to the University of Edinburgh for the use of their facilities, and to the Department of Education for Northern Ireland for financial support.

## Abstract

Chapter I consists of a brief overview of carbaborane chemistry related to this work, including concepts of cluster bonding and slip distortions in carbametallaboranes derived from $\left[7,8 \text {-nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$. This is followed by an introduction to the transition metal chemistry of fused aromatic ligands, with specific reference to the similar bonding capabilities of these and carbaborane species. The Chapter culminates in a discussion of the structure of the first reported fused aromatic carbametallaborane, namely $3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $-\mathrm{cos}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ (1), including a rationalisation of the observed cisoid molecular conformation.

Chapter 2 is divided into two sections, $A$ and $B$. Section $A$ presents the syntheses and structures of three indenyl carbametallaboranes, where one or two aryl or alkyl functions have been introduced at the cage carbon atoms, i.e. 1-Ph-3-( $\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}$ )-3,1,2-closo- $\mathrm{C}_{8} \mathrm{~B}_{9} \mathrm{H}_{10}$ (2), 1- $\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{B}_{9} \mathrm{H}_{10}$ (3) and 1,2-( $\left.\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (4). In the mono-substituted species, 2 and 3, the indenyl ligand adopts a conformation analogous to that in 1, i.e. the indenyl ring junction carbon atoms are cisoid with respect to the cage carbon atoms. In 4 the presence of two ether substituents has resulted in the adoption of the "next best" staggered conformation. A series of EHMO calculations performed on idealized models of $1-4$ predict theoretical energy minimum conformations which are in broad agreement with those observed crystallographically. Section $B$ describes the synthesis and structural determination of the first reported fluorenyl carbametallaborane complex, 3-( $\left.\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)-3,1,2$-closo- $\mathrm{Cx}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ (5). The molecular conformation has been rationalised in terms of the trans influence of the facial cage boron atoms, and is in full accord with that predicted by the results of EHMO calculations on an idealised model of 5 .

Chapter 3 documents the synthesis of the previously unreported species " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ ", and its reactions with a series of dithallium carbaboranes. The structure of the novel indenyl rhodium carbaborane compound $3-\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)-8-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-3,1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ (6a) is discussed. Subsequently the structures of further species incorporating a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{6}\right)\right\}$ fragment, i.e. $7-\mathrm{R}-10-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \quad[\mathrm{R}=\mathrm{H}$ (6b), $\mathrm{R}=$ $\mathrm{CH}_{2} \mathrm{OCH}_{3}$ (7)], $9-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}^{2}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right]-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11} \quad$ (6c) and 7-Ph-9/11-\{( $\left.\left.\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ (8b), together with the initially targeted closo carbarhodaboranes, $1-\mathrm{R}^{1}-2-\mathrm{R}^{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)$-3,1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}, \quad\left[\mathrm{R}^{1}=\mathrm{Ph}, \mathrm{R}^{2}=\mathrm{H}(8 \mathbf{a}), \mathrm{R}^{1}=\mathrm{R}^{2}=\right.$ $\mathrm{CH}_{2} \mathrm{OCH}_{3}$ (9)] have been deduced from analysis of spectral data. The indenyl rhodium dichloride precursor has retrospectively been assigned to have a complex polymeric composition.

Chapter 4 contains structural information on diphenylcarbaborane and some transtion metal derivatives. The parent carbaborane, $1,2-\mathrm{Ph}_{2}-1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ (10) crystallises with two independent molecules per asymmetric unit, and the cage carbon-carbon bond length in each is longer than that observed in orthocarbaborane, which has been attributed to repulsions between adjacent phenyl $\pi$-systems. Moreover, the variation in degree of twist in the aromatic functions of molecules $A$ and $\mathbf{B}$ has been correlated with the inter cage carbon carbon distances. The synthesis and structural determination of $7,8-\mathrm{Ph}_{2}$-10-endo- $\mathrm{Ph}_{3} \mathrm{PHg}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (11), in which the phenyl substituents are substantially more twisted than in 10 , is discussed. This twist has been attributed to the relatively short cage carbon-carbon bond length (1.58 $\AA$ ) Finally a structural determination of 1,2- $\mathrm{Ph}_{2}-3-\mathrm{Cp}^{*}-3,1,2-$ pseudo-closo-Rh( $\mathrm{B}_{9} \mathrm{H}_{9}$ (13), has shown substantial distortion in the twelve vertex polyhedron, with the cage carbon atoms $2.50 \AA$ apart. This has been attributed to repulsions between adjacent ortho hydrogen atoms on the phenyl
substituents, which are substantially twisted to accommodate the bulky $\mathrm{Cp}^{*}$ ligand.

Chapter 5 gives details of the experimental procedures leading to the results discussed in the main body of the work, and comprises three sections, $A B$ and $C$. Section A describes synthetic methods, and includes spectral and microanalytical data, Section $B$ covers crystallographic techniques and Section $C$ discusses molecular orbital calculations.

## Abbreviations

| AO | atomic orbital |
| :---: | :---: |
| BNCT | Boron-Neutron Capture Therapy |

## Chapter 1

## Introduction

## Introduction

In 1965, M. Frederick Hawthorne and co-workers reported a carbaborane analogue of ferrocene; $\left[\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)_{2}\right]^{2-}$, which was the first example of a carbametallaborane complex. ${ }^{1}$ The precedent for the synthesis of this compound was the observation of similar frontier molecular orbitals (MO's) in the five-membered ring systems of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$, (I), (the dicarbollyl ligand), and $\left[\mathrm{C}_{5} \mathrm{H}_{5}\right]^{-}\left(\mathrm{Cp}^{-}\right)$, (II), (the cyclopentadienyl ligand)..$^{2,3}$ Subsequently a vast new area of boron chemistry has evolved, involving the syntheses and characterisation of an enormous number of carbametallaboranes of varying size and atom composition.

II

Whilst $\mathrm{Cp}^{-}$and $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ form many structurally analogous metal complexes, some dicarbollyl complexes exhibit notable distortions compared with Cp analogues, in that the metal atom is not centrally positioned above the ligand face, but is "shifted" laterally across it. 4,5 These effects may be attributed to the lower symmetry of the bonding $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagon, due to its heterogeneous nature, and are more fully discussed later. ${ }^{6-8}$

Slip distortions are of course not unique to carbametallaboranes, but are also observed in metal complexes of fused aromatic ligands, such as indenyl ( $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{-}$), (III), ${ }^{9,10}$ fluorenyl $\left(\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]^{-}\right),(\text {IV })^{11,12}$ and naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right),(\mathrm{V}) .{ }^{13}$

III

IV

V
The indenyl and fluorenyl ligands both contain five-membered ring systems analogous to that in Cp , and can therefore also be described as formal analogues of the dicarbollyl ligand. Given the said tendency of both fused aromatic and dicarbollyl ligands to form distorted metal complexes, the incorporation of both ligands in one molecule is of potential interest.

This introductory chapter starts with a brief overview of carbaborane and carbametallaborane chemistry most pertinent to the work contained in this thesis, including the concepts of cluster bonding and slip distortions in carbametallaboranes. This is followed by an introduction to the chemistry of fused aromatic ligands, with particular emphasis on indenyl transition metal complexes, which have been studied in some detail. The two areas are, as it were, fused, with a discussion of the structure of the first known indenyl carbametallaborane, ${ }^{14}$ including rationalisation of the preferred solid-state conformation, which forms the basis of the on-going work.

## Carbaboranes and Carbametallaboranes

## Introduction

Carbaboranes and carbametallaboranes are essentially derivatives of boron hydride precursors, and exhibit very similar cage geometries to their polyboron analogues. Much initial interest in carbaborane chemistry arose from the greater stability exhibited-by many of these cluster species compared with structurally analogous airand moisture-sensitive boron hydrides, particularly among the smaller and more open-faced polyhedra. Most known carbaboranes contain five to twelve cage atoms, usually with one or two carbon atoms per molecule, although clusters with a larger number of carbon atoms are also known.

As time and space available here preclude full coverage of the wide spectrum of carbaborane chemistry, the following pages concentrate upon the chemistry of carbaboranes and carbametallaboranes derived from ortho-carbaborane (1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ ), (VI), which is of most relevance to this work.

## Icosahedral Closo-Carbaboranes

Ortho-carbaborane, together with its isomers meta- and para-carbaborane, (1,7and 1,12-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ respectively) is exceptional in its ease of preparation and high stability. The 1,2 - isomer is the most readily available, and its chemistry has been particularly extensively studied.

The most convenient synthesis of ortho-carbaborane, and indeed a whole range of carbon-substituted derivatives, is the reaction of decaborane, $\mathrm{B}_{10} \mathrm{H}_{14}$, (VII), with the appropriate alkyne in the presence of a Lewis base ${ }^{15}$ (eg SMe $\left.{ }_{2}, \mathrm{MeCN}\right)$ involving the following typical reaction scheme:

$$
\text { nido }-\mathrm{B}_{10} \mathrm{H}_{14}+2 \mathrm{SMe}_{2}--->\text { arachno- }\left(\mathrm{SMe}_{2}\right)_{2} \mathrm{~B}_{10} \mathrm{H}_{12}+\mathrm{H}_{2}
$$

$$
\text { arachno- }\left(\mathrm{SMe}_{2}\right)_{2} \mathrm{~B}_{10} \mathrm{H}_{12}+\mathrm{R}^{1} \mathrm{C}=\mathrm{CR}^{2}-\cdots>1,2-\mathrm{R}^{1} \mathrm{R}^{2}-1,2 \text {-closo- } \mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}
$$

From kinetic studies it is suggested that the rate determining step involves the attack of alkyne on, e.g., the monosulphide, $\mathrm{Me}_{2} \mathrm{SB}_{10} \mathrm{H}_{12} \cdot{ }^{16}$

This method of synthesis has yielded numerous twelve-vertex closo-carbaboranes incorporating a wide variety of cage substituent $\mathrm{R}^{1}$ and $\mathrm{R}^{2} .{ }^{17}$ The nature of the substituent is often of importance in dictating the ultimate stereochemistry of subsequent reaction products.

The structure of ortho-carbaborane has been determined by electron diffraction methods, ${ }^{18}$ and the cage is found to be a slightly distorted icosahedron, reflecting shorter distances between and to the two carbon atoms. In addition to this structural determination, a number of $X$-ray crystal structures of mono- and di-substituted
derivatives of ortho-carbaborane have been studied. 19.20 Molecular parameters for these compounds are similar to those in the unsubstituted carbaborane. Typical C-C distances are in the range $1.63-1.70 \AA$, B-C distances in the range $1.66-1.77 \AA$ and $\mathrm{B}-\mathrm{B}$ distances are between 1.70 and $1.89 \AA$.

## Selective Cage Degradation

The reaction of $1,2-\mathrm{R}_{2}-1,2$-closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ with strong bases, such as the alkoxide ion, affords $\left[7,8-\mathrm{R}_{2}-7,8 \text {-nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{-21,22}$ The boron atom removed is the one in closest proximity to the carbon atoms, i.e. $\mathrm{B}(3)$ or $\mathrm{B}(6)$. Similarly, the 1,7 -closo species produces $\left[7,9-\mathrm{R}_{2}-7,9 \text {-nido- } \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{-}$. The reaction scheme is the following:

$$
\text { closo }-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}+\mathrm{RO}+2 \mathrm{ROH} \cdots--->\left[\text { nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}+\mathrm{B}(\mathrm{OR})_{3}+\mathrm{H}_{2}
$$

Deprotonation of the monoanionic species, using sodium hydride, or prolonged reflux with a considerable excess of alkoxide, yields $\left[\mathrm{R}_{2} \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]^{2-}$, the so-called dicarbollyl ligand, named after the Spanish word "olla" , which is a type of water jug shaped like an eleven-vertex nido icosahedron. Reactions of this ligand have been of major importance in the development of carbametallaborane chemistry.

## Synthesis of Carbametallaboranes

The construction of polyhedral cages containing metal, boron and carbon atoms has been achieved by a variety of methods, the most common of which involve the reaction of an existing carbaborane cage framework with a metal reagent.

The use of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ was historically the first route employed for syntheses of carbametallaboranes, with Hawthorne reporting the structure of $\left[\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)_{2}\right]^{2-}$ in 1965. ${ }^{1}$ The dicarbollyl dianion used in this, and numerous further reactions by the Hawthorne group, was formed by deprotonation of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$. A typical reaction is the following:

$$
\left.\left[7,8-\text { nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}+\mathrm{NaH} \rightarrow--->\text { nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}+\mathrm{H}_{2}
$$

$$
\begin{gathered}

In 1972 F.G.A. Stone and co-workers reported the preparation and synthetic utility of the thallium complexes $\mathrm{Tl}_{2}\left[\mathrm{R}_{2} \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right],{ }^{23}$ which precipitate upon addition of thallium (I) acetate to an aqueous solution of $\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$or its alkyl derivatives, and more recently an improved synthesis of dithallium carbaboranes has been reported. ${ }^{24}$ The nature of bonding of thallium to the cage is discussed later in this Chapter. Reaction with halogeno-derivatives of the transition metals, eg $\mathrm{FeCl}_{2}$, $\mathrm{CoCl}_{2}$ and $\mathrm{Pt}\left(1,5-\mathrm{C}_{8} \mathrm{H}_{12}\right) \mathrm{Cl}_{2}$ leads to the formation in high yield of corresponding 3,1,2- $\mathrm{MC}_{2} \mathrm{~B}_{9}$ derivatives.

## Bonding Description of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$

The attempts to synthesise dicarbollyl analogues of metallocenes were based on the observation that cyclopentadienyl and dicarbollyl anions both possess $6 \pi$-electrons which occupy similar frontier orbitals associated with their open pentagonal faces.

The MO scheme for $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ has been derived from the bonding description of the isostructural borane, $\left[\mathrm{B}_{11} \mathrm{H}_{11}\right]^{4-}(\mathrm{VIII}) .{ }^{3}$

Extended Hückel molecular orbital (EHMO) calculations on this species have confirmed that it has 24 bonding MO's, in agreement with simple electron counting rules. There are five MO's available for metal complexation, which are localized predominantly on the open $B_{5}$ face and are directed towards the vacant apex position of this face. These comprise three bonding orbitals ( $a_{1}$, which is strongly bonding, and two degenerate, $\mathrm{e}_{1}$, which are more weakly bonding), and two antibonding orbitals ( $e_{2}$ ). Exact orbital degeneracy will be removed in the case of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$, but the essential pattern of orbital composition and relative energy will not substantially change. This orbital scheme is represented in Figure 1.1,25 along with a similar orbital scheme for $\left[\mathrm{C}_{5} \mathrm{H}_{5}\right]^{-}, 26$ which shows the resemblence in the frontier MO's of the two ligands.

The structure of the ferrocene analogue, $\left[\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)_{2} \mathrm{Fe}\right]^{2-}$ can be described in terms of valence bond theory, in a similar way to that of $\mathrm{Cp}_{2} \mathrm{Fe} .{ }^{27,28}$ Each [ $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ ligand can be assumed to donate three pairs of electrons to $\mathrm{Fe}^{I I}$, which accommodates the six pairs in $\mathrm{d}^{2} \mathrm{sp}^{3}$ hybrid orbitals, while its $\mathrm{d}^{6}$ electrons pair up in the remaining, non-bonding, 3d orbitals, thus satisfying the 18 -electron rule.

Figure $1.1 \pi$-MO's of $\left[\mathrm{C}_{5} \mathrm{H}_{5}\right]$ and $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$

However, the structure of carbametallaboranes may also be rationalized in terms of cluster bonding, where the metal fragment is incorporated as a vertex in the polyhedron. Closo- $\mathrm{MC}_{2} \mathrm{~B}_{9}$ icosahedra are essentially isostructural with the "parent" closo- $\mathrm{C}_{2} \mathrm{~B}_{10}$ carbaborane, ${ }^{18}$ as well as $\mathrm{B}_{12} \mathrm{H}_{12}{ }^{2-.}$. ${ }^{29}$ Indeed there are clear structural relationships in isoelectronic borane and heteroborane polyhedra of all sizes. The nature of bonding in these boron cage structures, for many years a chemical puzzle, is now reasonably well understood, and the subject is addressed in the following section.

## Structure and Bonding in Polyhedral Clusters

Earlier this century the term "electron deficient" was applied to boron cage compounds, as there are fewer electrons than would normally be required for a "classical structure", where ordinary electron-pair bonds exist between each pair of bonded atoms. Obviously some kind of multi-centre bonding is involved, with extensive delocalisation of electrons within the polyhedron. In fact, the notion of "electron deficient" boranes is a very misleading one, as most species have closed-shell electronic structures, and indeed many, particularly carbaboranes and carbametallaboranes, compare favourably with hydrocarbons, in terms of thermal and chemical stability.

There are three ways in which bonding in boron hydride cages may be understood:
1)Localized valence-bond structures incorporating two- and three-centre electron-pair bonds, ${ }^{30}$
2)Quantitative molecular orbital treatments of individual cluster systems, and
3)Consideration of the total number of skeletal electrons involved in the polyhedral framework. ${ }^{31.32}$

Localized valence-bond arguments were developed largely by William Lipscomb and co-workers. ${ }^{30}$ Although useful for describing smaller and more open-cage boron hydrides, the method becomes complicated for large, closed polyhedral systems. Detailed molecular orbital calculations have been carried out on a number of boranes and carbaboranes, but inclusion of metal atoms in the polyhedral cluster increases the complexity of the calculations.

The last approach has been found to be the most widely applicable, particularly following the advent of a general set of rules devised by Kenneth Wade in 1971, 31, which recognize the relationship between the cage geometry and the number of electrons involved in the skeletal framework.
which recognize the relationship between the cage geometry and the number of electrons involved in the skeletal framework.

Briefly, there are four main classes of polyhedral cage, namely closo, nido, arachno, hypho, names derived from Greek or Latin words describing the extent of "opening out" of the cage. Closo cages are closed polyhedra consisting entirely of triangulated faces. Removal of one vertex from a closed cage structure yields a nido cage, which has the same basic shape as the parent compound, but with one open face. Removal of one more vertex from this face results in the corresponding arachno structure, and loss of a third vertex from the open face of the arachno cage gives a hypho derivative, which has the same cage geometry as its parent closo borane, but with three vertices missing. The point to note is that if removal of a vertex does not change the polyskeletal electron count, the overall cage geometry remains the same.

The general rules predicting cage geometry from the number of electron-pairs involved in skeletal bonding are summarized below:

| Number of Cage <br> Atoms | Number of Skeletal <br> Electron Pairs | Assigned Cage <br> Geometry |
| :---: | :---: | :---: |
| n | $\mathrm{n}+1$ | closo |
| n | $\mathrm{n}+2$ | nido |
| n | $\mathrm{n}+3$ | arachno |
| n | $\mathrm{n}+4$ | hypho |

For example, the rules can be seen to rationalize the structure of $\left[\text { nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{\text {, }}$, (DX), which has been determined crystallographically. ${ }^{33}$

This species contains BH and CH units, as well as an endo-hydrogen atom associated with one of the boron atoms on the open face. For main group elements in general the number of electrons (e) available for skeletal bonding is $v+x-2$, where $v$ is the number of valence shell electrons of the neutral atom, and $x$ the number of electrons supplied by the exo-polyhedral atom(s). Each boron and carbon atom form a localized bond with its associated exo-polyhedral hydrogen atom ( $x=1$ ). This leaves each of the BH units (where $\mathrm{v}=3$ ) three orbitals and two electrons, and the CH units (where $v=4$ ) three orbitals and three electrons, to bind together and generate molecular orbitals extending within and over the polyhedral surface.

The total polyhedral electron count, for an eleven-vertex cage, is therefore calculated as follows:

Skeletal Electron Source
$2 \mathrm{X}\{\mathrm{CH}\}$ $8 \mathrm{X}\{\mathrm{BH}\}$
$1 \mathrm{X}\left\{\mathrm{BH}_{2}\right\}$ -ve charge

Number of Electrons
6
16
3
1

$$
\Rightarrow 26
$$

$$
=>2 n+4
$$

$$
\Rightarrow n+2 \text { S.E.P's }
$$

$\mathrm{n}+2$ S.E.P's (skeletal electron pairs) corresponds to a nido cage geometry.

Although transition metals have a total of nine valence orbitalsy they, like boron and carbon atoms, contribute only three orbitals to cluster bonding, leaving six remaining atomic orbitals for bonding to external ligands, and for storing "non-bonding" pairs. Since these orbitals are usually filled (to satisfy the 18 -electron rule), electron donation from the transition metal fragment to the cage is given by $e=v+x-12$ ( $v$ is the number of valence electrons of the neutral metal, i.e. no assumptions are made concerning metal oxidation state). Thus the total electron count for $\mathrm{CpCoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$, which has a closed polyhedral structure, ${ }^{14}$ is the following:

## Skeletal Electron Source

$1 \mathrm{X}\{\mathrm{CpCo}\}$
$2 \mathrm{X}\{\mathrm{CH}\}$
9 X (BH)
Number of Electrons

$$
\begin{gathered}
2 \\
6 \\
18 \\
\Rightarrow \\
\Rightarrow 26 \\
\Rightarrow>n+2 \\
\Rightarrow>+1 \text { S.E.P.'s }
\end{gathered}
$$

$\mathrm{n}+1$ skeletal electron pairs corresponds to a closo cage geometry.
N.B. The CpCo moiety is isolobal with a BH unit.
"Slipped" Carbametallaboranes

Although electron counting formalisms conveniently describe the geometries of many cluster species, there are some anomolous structures which cannot be reasoned purely in these terms. Examples of these occur among a number of carbametallaboranes of the type $1,2-\mathrm{R}_{2}-3-\mathrm{L}-3,1,2-\mathrm{MC}_{2} \mathrm{R}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, where the metal is not centrally positioned above the carbaborane face, (X).

X

The slip distortions observed can be defined in terms of displacement ( $\Delta^{\mathrm{P}}$ ) of the metal atom from its more usual position above the centroid of the open pentagonal face of the ligand towards the unique facial boron atom. ${ }^{7}$ Formally this is the distance from the perpendicular of the reference plane to the metal atom, the perpendicular passing through the centroid of the lower pentagonal belt $\mathrm{B}(5,6,11,12,9)$. This lower belt is usually used as a reference since Wallbridge and co-workers ${ }^{34,35}$ recognized that in slipped carbametallaboranes there is an increase in non-planarity of the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face bound to the metal. This is expressed in terms of "fold" angles $\theta^{p}$ and $\phi^{p}$, folding occurring along the $\mathrm{B}(4) \cdots \cdot \mathrm{B}(7)$ axis. Both "slip" and "fold" parameters are illustrated below:

$\left[\mathrm{M}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)_{2}\right]^{\mathrm{n}-}$ species

Slip distortions are exhibited by bis-dicarbollyl complexes in which the metal atom has eight or more d electrons, e.g. $\mathrm{Ni}^{\text {II }}, \mathrm{Pd}^{\text {II }}, \mathrm{Cu}^{\text {II }}, \mathrm{Au}^{\text {II }}(\mathrm{n}=2)$; $\mathrm{Cu}^{\text {III }}, \mathrm{Au}^{\text {III }}(\mathrm{n}=1) \mathbf{4}^{4,5,6}$ The two cages are shifted laterally across the metal atom by an average of $c a .0 .5 \AA$, in contrast with more symmetric conformations found in complexes of $d^{3}-d^{7}$ metals.

The simple explanation is that the metal atom slips to avoid an undesirable ( $>18 \mathrm{e}^{-}$) configuration. More detailed explanation lies in results of MO calculations, which suggest that slippage of the metal atom away from a central position over each cage face results in the stabilization of the occupied and formally antibonding molecular orbitals. ${ }^{36}$
$\mathrm{L}_{2} \mathrm{MC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ species

Similar slip distortions are observed for complexes of heavier and late transition metals, e.g. $\mathrm{Pt}^{\mathrm{II}}, \mathrm{Pd}^{\mathrm{II}}, \mathrm{L}=\mathrm{PR}_{3} .^{7,8}$ For example, in $\left(\mathrm{Et}_{3} \mathrm{P}\right)_{2} \mathrm{Pt}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right) \Delta^{\mathrm{p}}=0.42 \AA$ and $\theta^{\mathrm{p}}$ and $\phi^{\mathrm{p}}$ are 4.7 and $4.4^{\circ}$ respectively. ${ }^{7}$

Explanation of this has also been derived from analysis of the results of molecular orbital calculations, with optimum overlap of metal and ligand orbitals occurring for lateral distortion of the angular $\mathrm{ML}_{2}$ fragment towards the unique facial boron atom. ${ }^{7}$

## Pseudo $\sigma$-Bonded Carbametallaboranes

An extreme distortion is found in a small number of carbametallaboranes of the type $\left(\mathrm{LMC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)^{0,-1}$, where the metal atom is attached to the carbaborane moiety essentially by a $\sigma$-bond with the unique facial boron atom, $\mathrm{B}(10)$, with weaker interactions to the other two $[B(9,11)]$. This form of distortion occurs for $\mathrm{d}^{10}$ metal atoms, e.g. $\mathrm{Hg}{ }^{\mathrm{II} 37}$ and $\mathrm{Au}^{\mathrm{I}},{ }^{25}$ where $\mathrm{L}=\mathrm{PR}_{3}$, and the metal fragments can be regarded
as one-orbital donors to the ligand (formally isolobal with a hydrogen atom), adopting an endo position over the open face ( $c f\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-33}$ ).

This is presumably because $\mathrm{Au}^{\mathrm{I}}$ and $\mathrm{Hg}^{I I}$ prefer linear co-ordination (vs. tetrahedral), as their 6px and 6py atomic orbitals are too high lying to form valence orbitals along with the $\mathrm{s}-\mathrm{pz}$ hybrid. In contrast Cu has four $\mathrm{sp}^{3}$ hybrid orbitals available for bonding, as the copper 4 px and 4 py orbitals lie at relatively lower energies. ${ }^{38}$ Thus $\left[\mathrm{PPh}_{3} \mathrm{CuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$has a closo-cage structure, with the metal $\eta^{5}$-bonded to the cage. ${ }^{39}$

The $\left[3,1,2-\mathrm{TlC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{\text {- }}$ ion represents a very extreme case of this type of distortion. $\mathrm{Tl}^{\mathrm{I}}$ has a fully saturated $\mathrm{d}^{10} \mathrm{~s}^{2}$ configuration, and the Tl - cage distances are very long, suggesting a situation close to an ion-pair formation, $[\mathrm{TI}]^{+}\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-.37}$ The weak thallium cage bonding is consistent with the facile displacement of thallium by other metals, which offers a convenient route for syntheses of new carbametallaboranes (see earlier). ${ }^{23}$

In summary, the vast majority of $\mathrm{MC}_{2} \mathrm{~B}_{9}$ carbametallaboranes have closo structures which may be rationalized by Wade's rules. However, a number of "slipped" carbametallaboranes are also known. In these cases the formal oxidation state and electron configuration of the metal must be considered, together with the formal coordination geometry of the metal fragment.

## Atom Numbering

At this stage it is perhaps appropriate to clarify the numbering schemes used to define atoms in carbaborane cages.

In the nido cage system, $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$, the number sequence starts with the apex boron atom (that which is furthest from the open $\mathrm{C}_{2} \mathrm{~B}_{3}$ face), with successive pentagonal rings numbered in a clock-wise direction; to go from number $6->7$ one
connectivity is crossed. Heteroatoms take the lowest numbers possible, and for two or more different heteroatom types rules of precedence have been established. Thus the two carbon atoms, which lie in the "top" pentagonal belt, are numbered 7 and 8 (see diagram of $I$ below).

I

VI

In closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$, where there is no geometrically unique apex, one of the carbon atoms is assigned the number one position, and successive five-membered rings numbered in accordance with the above rules, the second carbon atom numbered 2 (see diagram of VI above).

In the case of carbametallaboranes, the cage numbering scheme depends on the position of the metal above the cage. In closed $\mathrm{MC}_{2} \mathrm{~B}_{9}$ species, where the metal has essentially replaced a BH vertex, the metal is numbered third, after the two carbon atoms (i.e. one of the carbon atoms retains the principal apical position), e.g. 3-Cp-3,1,2-closo- $\mathrm{FeC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$. However, in slipped pseudo $\sigma$-bonded $\mathrm{MC}_{2} \mathrm{~B}_{9}$ species the metal atom is best not considered as a formal vertex, and regarded merely as a substituent, e.g. 10 -endo- $\mathrm{HgPPh}_{3}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$.

## Transition Metal Complexes of Fused Aromatic Ligands

## Indenyl Metal Complexes

## Introduction

The indenyl ligand, $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{-}$, essentially comprises a five- and a six-membered ring fused together via two so-called ring-junction carbon atoms. With transition metals it readily forms complexes which are analogous to those of the cyclopentadienyl ligand.

Initial interest in indenyl transition metal complexes stemmed from recognition of their enhanced reactivity relative to cyclopentadienyl analogues. For instance they act as more efficient catalysts in inter-molecular hydroacylation reactions, ${ }^{40}$ cyclo-trimerisation of alkynes to benzenes, ${ }^{41}$ and cyclo-co-trimerisation of alkynes and nitriles to pyridines. ${ }^{42}$ In addition $\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{ML}_{\mathrm{n}}$ complexes show enhanced reactivity in both $\mathrm{S}_{\mathrm{N}}{ }^{143}$ and $\mathrm{S}_{\mathrm{N}} 2^{43-45}$ ligand substitution reactions. All these processes are presumed to proceed via slippage ( $\eta^{5} \rightarrow \eta^{3}$ ) at some stage in the mechanism, which is well known to be more facile in indenyl complexes, than in analogous cyclopentadienyl complexes.

## Syntheses

Syntheses of indenyl metal complexes is achieved using routes similar to those employed in synthesising Cp analogues. The $\mathrm{CH}_{2}$ group in indene is easily deprotonated, e.g. with $\mathrm{Bu}^{\mathrm{Li}}$, and the resulting lithium indenide may then be reacted with the appropriate metal halide, as in the following example:

$$
2 \mathrm{Li}\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]+\mathrm{FeCl}_{2} \cdots-->\mathrm{Fe}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}+2 \mathrm{LiCl}
$$

In most structurally characterized metal complexes the indenyl ligand is essentially $\eta^{5}$-bonded, via its five-membered ring. However, significant slip distortions from $\eta^{5}$ toward $\eta^{3}$, usually toward $C(2)$, exist in all cases, and can be explained in terms of recovery of some resonance energy as $\mathrm{p} \pi$ atomic orbitals of the ring junction carbon atoms are more delocalized over the indenyl $\pi$-system, as illustrated in the diagram below, which also shows a common numbering scheme used throughout this work.

"Slip" and "fold" distortions have been calculated for a number of indenyl metal complexes. The slip can be defined in two ways; firstly as $\Delta^{\mathrm{h}}, 9$ which is calculated according to Mingos' definition for analogous distortions in carbametallaboranes, where the slip distortion is the distance between the normal to a reference plane and the metal, the normal passing through the centroid of the five-membered ring; or secondly, as $\Delta \mathrm{M}-\mathrm{C},{ }^{10}$ which is the difference between the average of the metal-carbon distances $\mathrm{C}(1), \mathrm{C}(2), \mathrm{C}(3)$ and $\mathrm{C}(4), \mathrm{C}(9)$. Associated with the slip is a folding of the $\mathrm{C}_{5}$ ring, along the $\mathrm{C}(1) \cdots \mathrm{C}(3)$ axis, the fold angle, $\Omega$, [or HA (hinge-angle)] being defined as the dihedral angle between the planes of the three-carbon and four-carbon fragment of the five-membered ring.

$\Delta^{\mathrm{h}}$ values for a selection of complexes are in the range 0.125 $\left.\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{CrNO}(\mathrm{CO})_{2}\right)\right]^{46}$ to $0.298 \AA \quad\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{3} \mathrm{UCl}\right]^{47}$, (corresponding $\Delta \mathrm{M}-\mathrm{C}$ values 0.11 to $0.19 \AA$ respectively), with fold angles typically quite small, ranging from $\left.3.5^{\circ}\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{Zr}\left(\mathrm{CH}_{3}\right)_{2}\right)\right]^{48}$ to $8.9^{\circ}\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Rh}(\operatorname{cod})\right] .{ }^{49}$

## $\eta^{3}$-Bonded Indenyl Complexes

A number of structures incorporating a formally $\eta^{3}$-bonded indenyl ligand are known, including $\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{W}(\mathrm{CO})_{2}, 50 \quad\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Ir}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3},{ }^{51}$ and $\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{V}(\mathrm{CO})_{2} .{ }^{52}$ The tungsten species is one of two products of the reaction between $\mathrm{C}_{9} \mathrm{H}_{8}$ and $\mathrm{W}(\mathrm{CO})_{6}$, the other product being $\left.\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)(\mathrm{CO})_{3} \mathrm{~W}\right]_{2}$. The iridium example is interesting, in that $\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right)$ is only obtained when small phosphine ligands are used, i.e.

$$
\begin{gathered}
\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Ir}(\mathrm{coe})_{2}+\text { excess } \mathrm{L}-\cdots\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Ir}_{2} \\
\text { where } \mathrm{L}=\mathrm{PEt}_{3},\left(\text { cone angle } 145^{\circ}\right)
\end{gathered}
$$

but:

$$
\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) I(\mathrm{coe})_{2}+3 \mathrm{~L} \cdots\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{IrL}_{3}
$$

where $\mathrm{L}=\mathrm{PMe}_{3}, \mathrm{PPhMe}_{3}$ (cone angles 118 and $122^{\circ}$ respectively)

The third mentioned species is the product of the reaction between $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{~V}$ and CO, demonstrating relatively facile slippage to accommodate incoming ligands.

In all cases of $\eta^{3}$-bonding the metal atom is substantially slipped away from $\mathbf{C}(4)$ and $C(9)$, with $\triangle M-C$ values of $0.783,0.853$ and $0.559 \AA$ for the tungsten, iridium and vanadium species respectively. Corresponding fold angles ( $\Omega$ ), are also much greater than $\eta^{5}$-bonded indenyl ligands, with values of 26,28 and $21^{\circ}$ respectively.

## Conformation

The resonance energy gained in the distortion to an allyl-ene-type five-membered ring in indenyl complexes has the effect of stabilising various conformations of the ring relative to the other ligands on the metal. Such conformations can usually be predicted by using simple trans influence arguments; the preferred conformation of the indenyl relative to the $\mathrm{ML}_{\mathrm{x}}$ fragment is such that the ligands with the greatest trans influence are trans to the six-membered ring. Thus in $\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Ir}\left\{\mathrm{P}_{\left.\left.\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\} \mathrm{H}\right] \mathrm{BF}_{4}{ }^{9} \text { the hydride is trans to the ring-junction carbon atoms }}\right.\right.$ of the indenyl ring, and in $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{MoCO}_{2}\left(\eta^{3}-\mathrm{C}_{4} \mathrm{H}_{7}\right)^{9}$ the two carbonyl ligands, which have greater trans influence than the allyl ligand, share the side trans to the ring-junction carbon atoms.

The driving force for these conformations is presumably that the weaker metal-ring-junction carbon atom bonds (which result from the $\mathrm{p} \pi$ orbitals on these atoms being only partially released from involvement with the metal) are compensated by the stronger metal-ligand bonds to the functions diagonally opposite.

It is interesting to note the change in conformation which accompanies a progressive increase in slippage in a series of bis-indenyl metal complexes, $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{M},\left(\mathrm{M}=\mathrm{Fe}^{I I}, \mathrm{Co}^{I I}, \mathrm{Ni}^{\mathrm{II}}\right),{ }^{10}$ ( which are $\mathrm{d}^{6}, \mathrm{~d}^{7}$, and $\mathrm{d}^{8}$ species respectively), as broad parallels may be drawn between these species and bis-dicarbollyl metal analogues. An additional parameter has been used to describe the relative rotational orientation of the two indenyl ring systems. ${ }^{10}$ This is the rotation angle, RA, the angle
between planes including the metal, $\mathrm{C}(2)$, and the mid-point of the ring junction carbon atoms for each indenyl ligand. A rotation angle of $0^{\circ}$ indicates a completely eclipsed geometry, whilst an angle of $180^{\circ}$ corresponds to a fully staggered arrangement, as sketched below:

$\mathbf{R A}=0^{\circ}$

$R A=180^{\circ}$

Indenyl conformation, together with slip and fold parameters for these three species are summarised in Table 1.1.

Table 1.1 Comparison of Slip and Fold Parameters and Rotation Angles for a Series of $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{M}$ Complexes

| Compound | $\Delta_{m-c}(\AA)$ | $\Omega\left({ }^{\circ}\right)$ | $R$ |
| :---: | :---: | :---: | :---: |
| $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{Fe}$ | $\left.{ }^{\circ}\right)$ |  |  |
| $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{Co}$ | 0.05 | 2.6 | 13.0 |
| $\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{Ni}$ | 0.11 | 7.3 | 10.7 |
|  | 0.42 | 13.7 | 175.0 |

The iron complex has an 18 -electron count at the metal, and consequently no major distortion is expected (or indeed observed). An "extra" electron in the cobalt analogue results in slightly greater distortion, although the ligand is still essentially $\eta^{5}$-bonded. In both these complexes the indenyl six-membered rings lie $c i s$ to each other. However, the bis-indenyl nickel complex exhibits quite distinct distortion, with slip and fold parameters somewhere in between those expected for formally $\eta^{5}$ and $\eta^{3}$-bonding modes. In addition, the six-membered ring systems are now trans to
each other. This can be compared with the (allyl) ${ }_{2} \mathrm{Ni}$ system, where a trans configuration is favoured. ${ }^{53}$

Analogous complexes of cyclopentadienyl species $\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{M},\left(\mathrm{M}=\mathrm{Fe}^{54}, \mathrm{Co}^{55}\right.$, $\mathrm{Ni}^{56}$ ) all exhibit nearly perfect five-fold symmetry in the solid-state. Addition of electrons to the doubly degenerate M -ring anti-bonding level results in a gradual increase in $\mathrm{M}-\mathrm{C}$ bond lengths (from $2.046 \AA$ in $\mathrm{Cp}_{2} \mathrm{Fe}$ to $2.185 \AA$ in $\mathrm{Cp}_{2} \mathrm{Ni}$ ), but not a side-ways slip.

Distortions in the indenyl complexes are obviously fundamentally different, and may be attributed to the fact that the "unused" $\mathrm{p} \pi$ orbitals and electrons can be stabilized by entering into the indenyl $\pi$ system, which is not the case for Cp analogues.

The slippage, and related conformational change of ligands in bis-indenyl complexes can be compared with the $\mathrm{Ni}^{\mathrm{IV}}, 57 \mathrm{Ni}{ }^{[I I}, 58 \mathrm{Ni}^{15,59}$ bis-dicarbollyl analogues, where a somewhat similar pattern is observed. In the $\mathrm{Ni}^{\mathrm{IV}}$ complex the cage carbon atoms are cisoid to each other and the metal is essentially symmetrically bonded to both $\mathrm{C}_{2} \mathrm{~B}_{3}$ ligand faces. The $\mathrm{d}^{8} \mathrm{Ni}^{\mathrm{II}}$ bis-dicarbollyl complex has a large lateral slip distortion (ca. $0.4 \AA$ ), and the carbon atoms are transoid with respect to each other. The $\mathrm{Ni}^{I I I}$ bis-dicarbollyl species represents an intermediate non-slipped, transoid conformation. The reasons for slip distortions in bis-dicarbollyl complexes of $\mathrm{d}^{8}$ and $d^{9}$ metals, which have been discussed earlier, are based on optimum overlap of metal and ligand orbitals.

## Fluorenyl Metal Complexes

The fluorenyl ligand, $\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]^{-}$, comprises a five-membered ring and two six-membered rings fused via two pairs of ring-junction carbon atoms, $\mathrm{C}(1), \mathrm{C}(2)$ and
$C(4), C(5)$, given the carbon numbering scheme indicated below:

Considering the propensity of cyclopentadienyl and indenyl ions to form metal complexes, a surprisingly small number of fluorenyl analogues are known.

Those that have been reported are typically synthesised by the reaction of alkali metal fluorenide with the appropriate metal halide, e.g.

$$
2 \mathrm{Li}\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]+\mathrm{ZrCl}_{4}--->\left(\eta^{3}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{Zr}\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)+2 \mathrm{LiCl}
$$

Structurally characterized fluorenyl complexes include
$\left(\eta^{3}-\mathrm{C}_{13} \mathrm{H}_{9}\right)\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{ZrCl}_{2},{ }^{11}$

$$
\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{Cr}(\mathrm{CO})_{2} \mathrm{NO}^{12} \quad \text { and }
$$

$\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\eta^{6}-\mathrm{C}_{13} \mathrm{H}_{9}\right),{ }^{60}$ which show three possible bonding modes of the fluorenyl ligand.

Slip distortions similar to those found in indenyl metal complexes are found in $\eta^{5}$ and $\eta^{3}$-fluorenyl systems. For instance in bis-fluorenyl zirconium dichloride $\Delta^{h}$ values for the formally $\eta^{5}$ - and $\eta^{3}$-bonded ligands are 0.244 and $0.474 \AA$ respectively. In fact, this complex was the first example of trihapto bonding in a planar $\pi$-system.

The first reported fluorenyl containing iron complex has an unprecedented "zwitterionic" structure. $\mathrm{FeCp}\left(\eta^{6}-\mathrm{C}_{13} \mathrm{H}_{9}\right)$ is formed on deprotonation of $\left[\mathrm{FeCp}\left(\eta^{6}-\mathrm{C}_{13} \mathrm{H}_{10}\right)\right]^{+}$, where migration of metal coordination from the six- to the
five-membered ring does not occur, as might be expected. This contrasts the facile migration in protonation-deprotonation reactions of $\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \cdot{ }^{61}$

$$
\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}+\mathrm{H}^{+} \rightleftharpoons=\Longrightarrow \quad\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\eta^{6}-\mathrm{C}_{9} \mathrm{H}_{8}\right)\right]^{+}
$$

The stability of the unusual zwitterionic fluorenyl structure may be explained in terms of retention of benzenoid character in the six-membered ring.

## Transition Metal Complexes of Naphthalene

A number of transition metal complexes containing $\pi$-bound naphthalene ligands are known. Structural data available for naphthalene complexes illustrate the presence of slip distortions similar to those observed in indenyl complexes. In this case resonance stabilization is facilitated by $\eta^{6}->\eta^{4}$ ring slippage, as illustrated below:

For instance in the recently reported structure of $\mathrm{Ru}\left(\eta^{6}-\mathrm{C}_{10} \mathrm{H}_{8}\right)\left(\eta^{4}-\operatorname{cod}\right),{ }^{13}$ the ring-junction carbon atoms $\mathrm{C}(5)$ and $\mathrm{C}(10)$ are significantly (ca. $0.1 \AA$ ) further from the metal than carbons $\mathrm{C}(1)$ to $\mathrm{C}(4)$, with $\Delta=0.07 \AA$. Also apparent is a non-planarity associated with the bonded ring, with an angle of $8.4^{\circ}$ between the planes defined by $C(1)$ to $C(4)$ and $C(1), C(4), C(5), C(10)$.

Distortions of a similar type and magnitude have also been observed for
$\mathrm{Fe}\left(\mathrm{Et}_{2} \mathrm{C}_{2} \mathrm{~B}_{4} \mathrm{H}_{4}\right)\left(\eta^{6}-\mathrm{C}_{10} \mathrm{H}_{8}\right) \cdot{ }^{64}$
Some $\eta^{4}$-bonded compounds are also known, e.g. $\operatorname{Ru}\left(\eta^{6}-\mathrm{C}_{6} \mathrm{Me}_{6}\right)\left(\eta^{4}-\mathrm{C}_{10} \mathrm{H}_{8}\right),{ }^{65}$ and this slippage has occurred with correspondingly large deviation from planarity of the naphthalene ring, with a deformation angle of $41.5^{\circ}$.

Finally, an icosahedral naphthalene containing carbametallaborane, $1-\left(\eta^{6}-\mathrm{C}_{10} \mathrm{H}_{8}\right)-2,4-\mathrm{Me}_{2}-1,2,4-\mathrm{FeC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9},{ }^{24}$ has been reported, although no structural parameters are available for this complex. Presumably the naphthalene ligand is $\eta^{6}$-bonded to iron (giving an 18 -electron configuration), but the fact that the naphthalene ligand is relatively easily displaced, e.g. by CO , can be attributed to relatively facile $\eta^{6}->\eta^{4}$ slippage of the bonded six-membered ring system. Thus naphthalene carbametallaboranes might act as useful precursors in the syntheses of potentially interesting molecules. For instance the naphthalene ligand may be displaced by other, non-fused aromatic species, such as amino-acids containing aromatic side-chains (phenylalanine, tyrosine), of possible relevance in the field of Boron-Neutron Capture Therapy (BNCT).

## Indenyl Carbametallaboranes

Whilst numerous cyclopentadienyl carbametallaboranes have been synthesised and characterised, ${ }^{66}$ only one indenyl analogue had been synthesised previous to this work. ${ }^{14}$ This is the cobalt species $3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ (1), which formed in modest yields upon the reaction of $\mathrm{Li}\left[\mathrm{C}_{9}\left[\mathrm{H}_{7}\right], \mathrm{Co}(\mathrm{acac})_{3}\right.$ and $\mathrm{Tl}_{2}\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$
in thf. The synthesis of indenyl carbametallaboranes is of interest for two reasons:

1) To study selective slip distortions - indenyl metal fragment across carbaborane ligand $v s$ carbaborane metal fragment across indenyl ligand, and
2) To study the conformation of metal-bonded ligands with respect to each other.

Both points are considered in the structure of 1 , which was determined crystallographically, as illustrated in Figure 1.2 below. This shows that the metal atom is essentially symmetrically located above the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face ( $\Delta^{\mathrm{P}}=0.028$ ), forming the twelfth vertex in the closo polyhedron.

Figure 1.2 Perspective and Plan Views of 1

The $C_{2} B_{3}$ face is slightly folded, with $\theta^{P}$ and $\phi^{\mathrm{P}}$ values of 0.49 and $2.35^{\circ}$ respectively. These modest slip and fold distortions are fully expected for a $d^{6}$ metal centre.

Although also formally $\eta^{5}$-bonded, the indenyl ligand is slightly slipped across the metal atom, such that the metal- $\mathrm{C}(34,39)$ distance is longer than the average distance to $\mathrm{C}(31-33)$, with $\Delta^{\mathrm{h}}=0.089 \AA$.

The conformation of the indenyl ligand with respect to polyhedral carbon atoms is cisoid. The hydrocarbon ligand is staggered with respect to the carbaborane face, which is easily explained by the fact that the exo-hydrogen atoms on the cage are elevated at an angle of ca. $26^{\circ}$ above the upper pentagonal belt. An eclipsed arrangement would increase steric interaction between exo-hydrogen atoms and the hydröcarbon ring H atoms, which is clearly unfavourable.

The cisoid conformation can be explained in the same terms as those used to discuss the observed conformation in other transition metal complexes containing the indenyl ligand. ${ }^{9}$ That is that the presence of ligands of greatest trans influence opposite the ring-junction atoms can compensate for relatively weak bonding to metal of the latter, by virtue of partial delocalisation of their $\mathrm{p} \pi$ atomic orbitals into the indenyl six-membered ring $\pi$-system. The trans influence of the facial boron atoms of $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ is greater than that of the carbon atoms, as the frontier orbitals of the nido-carbaborane ligand are localized on the boron atoms. ${ }^{25}$ Thus the observed cisoid conformation is readily understood.

## Scope of the Work Presented

The studies presented in this thesis primarily investigate the conformations adopted by carbametallaboranes derived from dicarbollyl ligands in which bulky alkyl or aryl substituents have been introduced at the cage carbon atoms. Initially, this work centred upon species containing fused aromatic systems, with the attempted syntheses of a number of cobalt and rhodium analogues of the previously reported indenyl carbacobaltaborane, 1.

During the course of these studies, the more general transistion metal chemistry of the nido cage derivative of diphenylcarbaborane, $1,2-\mathrm{Ph}_{2}-1,2-$ closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$, developed into an area of unprecedented interest, and this forms the subject of the later work.

In an industrial context, some substantial research has been directed towards a family of carbarhodaboranes incorporating bulky cage substituents, which are potentially effective catalysts in, for example, alkene hydrogenation and isomerisation. ${ }^{67}$ Thus the work discussed herein may be of some significance in these, and related, studies.

## Chapter 2

## Fused Aromatic Carbacobaltaboranes

## Section A : Indenyl Carbacobaltaboranes

## Introduction

The synthesis and structural characterisation of an indenyl carbametallaborane, namely $3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ (1), was first reported in 1986. ${ }^{14}$ The conformation observed in the solid state structure, in which the ring junction carbon atoms of the indenyl ligand are cisoid with respect to the cage carbon atoms, has been shown to be electronically preferred by the results of molecular orbital calculations, as already outlined in Chapter 1.

This Chapter details the resulting molecular conformations in a series of analogous indenyl carbacobaltaboranes, where bulky alkyl or aryl functions have been introduced at the cage carbon atoms. In such cases electronic preferences may come into competition with steric effects introduced by these cage substituents. Two monosubstituted derivatives, and one disubstituted derivative, have been synthesisied and spectroscopically and structurally characterised. In addition the observed orientation of the indenyl ligand with respect to the cage has in each case been compared with the theoretically calculated minimum energy conformation.

## Synthesis of 2

Compound 2 was formed during the reaction of $\mathrm{Tl}_{2}\left[7-\mathrm{Ph}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ with $\mathrm{LiC}_{9} \mathrm{H}_{7}$ and $\mathrm{Co}(\mathrm{acac})_{3}$ in thf, and was isolated as an orange solid by preparative thin layer chromatography (tlc), as described in Chapter 5.

Microanalysis figures were consistent with the proposed formulation of the compound.

## N.m.r. Studies

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ n.m.r. spectrum shows 8 signals, with 2 boron nuclei resonating coincidently, consistent with the low symmetry of the monosubstituted cage. As anticipated, all boron atoms exhibit coupling to an exo -polyhedral hydrogen atom in the proton coupled spectrum, with ${ }^{1} \mathrm{~J}_{\mathrm{BH}}$ in the region of $120-150 \mathrm{~Hz}$.

The ${ }^{1} \mathrm{H}$ spectrum cannot be so readily interpreted. At 298 K the spectrum contains resonances due to $\mathrm{H}(2)$ ( 2.51 p.p.m.) and 7 indenyl protons, but only 3 phenyl protons. In view of this inconsistency the high frequency region of the spectrum was monitored as a function of decreasing temperature, and proton resonances were assigned by a series of selective decoupling experiments.

All proton resonances except those of $H(12), H(13), H(15)$ and $H(16)$ can be assigned at $298 \mathrm{~K} . \mathrm{H}(13)$ and $\mathrm{H}(15)$ were distinguished as a result of decoupling $\mathrm{H}(16)$ at 185 K , with the signal due to $\mathrm{H}(15)$ collapsing from an apparent triplet to a doublet. There is one coincidence at 185 K , at $c a .7 .3$ p.p.m., involving $\mathrm{H}(13)$ and $\mathrm{H}(14)$. A complete list of ${ }^{1} \mathrm{H}$ assignments at 298 K and 185 K is given in Table 2.1. (For atom labelling see Figure 2.3)

Table 2.1 Chemical Shifts (p.p.m.) and Assignments in the High Frequency Region of the ${ }^{1} \mathrm{H}$ Spectra of 2, at 298 K and 185 K

| H Atom | $\delta(298 \mathrm{~K})$ | $\delta(185 \mathrm{~K})$ |
| :---: | :---: | :---: |
| $\mathrm{H}(31)$ | 6.30 | 6.40 |
| $\mathrm{H}(32)$ | 5.79 | 5.85 |
| $\mathrm{H}(33)$ | 5.26 | 5.23 |
| $\mathrm{H}(35)$ | 6.04 | 5.66 |
| $\mathrm{H}(36)$ | 7.28 | 7.26 |
| $\mathrm{H}(37)$ | 7.46 | 7.44 |
| $\mathrm{H}(38)$ | 7.50 | 7.55 |
| $\mathrm{H}(13)$ | $7.3-7.4$ | $c a .7 .3$ |
| $\mathrm{H}(14)$ | $7.3-7.4$ | $c a .7 .3$ |
| $\mathrm{H}(5)$ | - | 7.40 |
| $\mathrm{H}(12)$ | - | 6.34 |
| $\mathrm{H}(16)$ |  | 7.68 |

The decoupling experiments also bring to notice a number of fine couplings. So called zig-zag coupling occurs between $\mathrm{H}(33)$ and $\mathrm{H}(38)$, and $\mathrm{H}(31)$ and $\mathrm{H}(35)$, with ${ }^{5} \mathrm{~J}_{\mathrm{HH}}$ in the region of 1 Hz . W-coupling is also present between $\mathrm{H}(31)$ and $\mathrm{H}(33)$, with a similar coupling constant.

The high frequency region of the spectrum has been monitored as a function of decreasing temperature, and the results of these experiments are presented in Figure 2.1. Although $\mathrm{H}(12)$ and $\mathrm{H}(16)$ are not observed at 298 K , broad signals due to them begin to appear at 264 K , and by 223 K each has been resolved into a doublet. In addition, the signal due to $\mathrm{H}(13)$ and $\mathrm{H}(15)$ broadens at 264 K and is resolved into 2 distinct resonances at lower temperatures. It must also be noted that resonances due to $\mathrm{H}(12)$ and $\mathrm{H}(35)$, marked * and ${ }^{\dagger}$ respectively on Figure 2.1, move progressively to lower frequency as the temperature is lowered.

Figure 2.1 Variable Temperature N.M.R. Experiment on the High Frequency Region of the Proton Spectrum of 2
$298 K$

The n:m.r. studies are consistent with restricted rotation of the phenyl substituent about the $\mathrm{C}(1)-\mathrm{C}(11)$ axis on progressive cooling of the solution. Let us first consider the movement of resonances due to $\mathrm{H}(12)$ and $\mathrm{H}(35)$ to lower frequency at lower temperatures. It will be useful to refer to Figure 2.3 for their positions in the crystallographically determined structure, presumably the preferred conformation in the solid state (see later in this section). If this is indeed also the preferred conformation in solution as the temperature decreases, the rotation of the phenyl ring will become increasingly restricted by the presence of the indenyl ligand, lying cisoid with respect to the cage carbon atoms. Hence $\mathrm{H}(12)$ and $\mathrm{H}(35)$ will experience magnetic anisotropy of the $\mathrm{C}(34)-\mathrm{C}(39)$ and $\mathrm{C}(11)-\mathrm{C}(16)$ ring systems respectively, which explains the upfield progression of their resonances as the system is cooled.

Further evidence for restricted rotation of the pendent phenyl group lies in the fact that the ortho and meta hydrogen atoms of the ring undergo coalescence as the solution is cooled. If the phenyl group is rotating rapidly, both $\mathrm{H}(12)$ and $\mathrm{H}(16)$ (ortho hydrogen atoms) and $\mathrm{H}(13)$ and $\mathrm{H}(15)$ (meta hydrogen atoms) will be chemically equivalent to each other, and only one signal for each pair will be observed. However, should rotation be restricted, they will cease to be chemically equivalent, and each hydrogen will exhibit independent signals.

The ortho hydrogen atoms, $\mathrm{H}(12)$ and $\mathrm{H}(16)$ initially appear at 264 K , as two bröad signals which are resolved into two doublets at 223 K . 298 K is presumably close to coalescence temperature, as the two broad resonances have become one, which is now so broad that it is not observed above the base line. A single resolved resonance can presumably be expected for the two hydrogen atoms upon further warming of the system, as the phenyl substituent is able to rotate freely, these two then becoming chemically equivalent. Similarly, the single resonance for $\mathrm{H}(13)$ and $\mathrm{H}(15)$ at 298 K is resolved into two distinct resonances at 223 K , coalescence for the 2 meta hydrogen atoms occurring at $c a .264 \mathrm{~K}$.

## Structural Study on 2

## Introduction

An accurate, low temperature X-ray crystal diffraction experiment was carried out in order to investigate the effect of cage substitution on the molecular conformation. Diffraction quality crystals were grown by slow diffusion of $n$-hexane into a methylene chloride solution of the compound at $-30^{\circ} \mathrm{C}$. Details of crystallographic procedures and crystal data may be found in Section B of Chapter 5.

## Discussion

Perspective and plan views of 2 are shown in Figure 2.2 and Figure 2.3 respectively, with the appropriate molecular numbering scheme. All H atoms have the same number as the B or C atom to which they are bound. Table 2.2 gives final atomic co-ordinates for refined atoms, Table 2.3 bond distances and selected interbond angles, and Table 2.4 lists anisotropic thermal parameters.

It is immediately obvious from Figure 2.3 that the indenyl six membered ring is cisoid with respect to the cage carbon atoms, and hence substitution of a hydrogen atom by a phenyl group at $\mathbf{C}(1)$ does not significantly change the conformation from that observed for 1.

Figure 2.2 Perspective View of 1-Ph-3-( $\left.\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-$ closo $-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, (2)

A number of geometrical calculations were carried out, all related to the lower, more planar, pentagonal belt of the icosahedral cage of $2[B(5), B(6), B(11), B(12)$, $B(9)$ ]. The phenyl substituent subtends an elevation angle at $C(1)$ of $21.6^{\circ}$, resulting in a distance of only $2.82 \AA$ between $H(35)$ and the best (least-squares) plane through the $\mathrm{C}(11)-\mathrm{C}(16)$ ring. Given that the sum of the van der Waals radius for a hydrogen atom $(1.2 \AA)$ and the thickness of a benzene ring $(1.675 \AA)$ is close to this value, it is to be expected that significant ring current effects are experienced by $\mathrm{H}(35)$ in low temperature n.m.r. studies. In addition the phenyl group is twisted by ca. $9.0^{\circ}$ about the $C(1)-C(11)$ bond, such that $C(16)$ is more elevated than $C(12)$. This phenomenon may be explained in terms of a reduction of close non-bonded contacts between $\mathrm{H}(16) \cdots \mathrm{H}(4)$ and $\mathrm{H}(12) \cdots \mathrm{H}(2)$. In the observed structure these values are 2.12(4) and $2.23(3) \AA$ respectively, close to the sum of the van der Waals radii of 2 hydrogen atoms ( $2.4 \AA$ ).

The best plane through the indenyl ligand makes a dihedral angle of $c a .7 .4^{\circ}$ with the lower $\mathrm{B}_{5}$ belt. However, this angle comprises both a sideways "twist" of $c a .5 .1^{\circ}$, where $\mathrm{C}(35)$ is more elevated than $\mathrm{C}(38)$, and an upward "tilt" of $c a .4 .7^{\circ}$, with $\mathrm{C}(36)$ lying at a higher elevation than $\mathbf{C}(34)$. These values may be attributed to the presence of the phenyl substituent on $\mathrm{C}(1)$, equivalent "twist" and "tilt" angles in the unsubstituted compound (1) being significantly smaller (ca. 3.7 and $0.6^{\circ}$ respectively.) Therefore, although the presence of the pendent phenyl group has not forced the indenyl ligand to adopt an entirely different conformation with respect to the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face, it has necessitated the adoption of a subtly different molecular structure.

The top face of the carbaborane cage is envelope folded across the $B(4) \cdots B(7)$ vector, such that $B(4)$ and $B(7)$ lie at higher elevation than $B(8), C(1)$ and $C(2)$, resulting in $\phi^{\mathrm{P}}$ and $\theta^{\mathrm{P}}$ values of 0.42 and $1.73^{\circ}$ respectively. As expected there is no substantial slip of the $d^{6}$ metal atom across this face ( $\Delta^{\mathrm{P}}=0.035 \AA$ ). However, a more
substantial slip is observed w.r.t the indenyl ligand, with the cobalt atom slipped away from the ring-junction carbon atoms towards $C(32)\left(\Delta^{h}=0.118 \AA\right)$. The slip parameter is slightly higher than that observed in 1, reflecting the already mentioned side-ways twist and upward tilt of the indenyl ligand. The five-membered ring is slightly folded about the $\mathrm{C}(31) \cdots \mathrm{C}(33)$ vector $\left(\Omega=3.53^{\circ}\right)$. Definitions for the angles $\phi^{\mathrm{p}}$ and $\theta^{\mathrm{p}, 34}$ together with the slip parameters $\Delta^{\mathrm{p} .7}, \Delta^{\mathrm{h}, 9}$ are given in Chapter 1.

In addition to these parameters, the direction of the slip distortion may be formally defined by $\sigma^{9}$, which is the angle between the slip vector, $S$ (a vector connecting the projection of the metal atom onto the plane through the indenyl five-membered ring and the ring centroid), and a reference vector, $\mathbf{R}$ [where $\mathbf{R}$ is the vector from the ring centroid to the unique atom $C(2)]$.

$\sigma$ is assigned a positive value when $\mathbf{S}$ points towards $\mathbf{C}(31)$ (or is anticlockwise w.r.t. $\mathbf{R}$ when seen from above). In $\mathbf{2}$ the value of $\sigma$ is $+15.1^{\circ}$, which is close to the value observed in the structure of $\mathbf{1}\left(+16.6^{\circ}\right)$.

Although the slippage of the metal away from $\mathrm{C}(34)$ and $\mathrm{C}(39)$ presumably allows for greater electron delocalisation over the indenyl six-membered ring, the latter still exhibits distinct non-aromatic character, with two carbon-carbon distances $[\mathrm{C}(35)-\mathrm{C}(36)$ and $\mathrm{C}(37)-\mathrm{C}(38)]$ significantly shorter than the others, giving a butadiene-like carbon atom sequence. The bond distances are essentially the same as those observed in the indenyl six-membered ring of $\mathbf{1}$.

## Synthesis

Compound 3 , the monoether derivative of 1 , was formed similarly to 1 and 2 , by stirring, in this case, $\mathrm{Tl}_{2}\left[7-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ with $\mathrm{LiC}_{9} \mathrm{H}_{7}$ and $\mathrm{Co}(\mathrm{acac})_{3}$ in thf, the pure species being again isolated in fairly modest yield by preparative tlc. Full details may be found in Section A of Chapter 5.

## N.m.r. Studies

The ${ }^{11} \mathrm{~B}$ n.m.r. spectrum shows nine signals of equal integral, all boron atoms showing the expected coupling to exo-polyhedral hydrogen atoms in the proton coupled spectrum. These results are fully consistent with the proposed compound, where all boron nuclei are chemically inequivalent.

The ${ }^{1} \mathrm{H}$ spectrum exhibits the expected signals for the indenyl hydrogen atoms in the high frequency region, and for $\mathrm{H}(2)$, at $\delta 2.52$ p.p.m. The $\mathrm{CH}_{2}$ group of the pendent ether function gives rise to a so-called $A B$ pattern, as its hydrogen atoms can never be magnetically equivalent, but are nearly so, and two independent doublet resonances are observed. The methyl hydrogen atoms give the expected singlet resonance at $\delta 3.53$ p.p.m.

## Structural Study on 3

## Introduction

Brick red crystals suitable for diffraction were grown by slow diffusion of hexane into a dichloromethane solution at $-30^{\circ} \mathrm{C}$. Details of the crystallographic procedures and crystal data for the structure are detailed in Chapter 5, Section B.

## Discussion

Perspective and plan views of 3 are shown in Figure 2.4 and Figure 2.5 respectively, together with the appropriate numbering scheme. All indenyl and cage hydrogen atoms have the same number as the B or C atom to which they are bound.

Table 2.5 lists final atomic co-ordinates for all atoms, Table 2.6 bond distances and selected interbond angles, and Table 2.7 anisotropic thermal parameters for all non hydrogen atoms.

Figure 2.5 gives a clear view of the conformation of the indenyl ligand with respect to the metal-bonded carbaborane face. As in 2 , the presence of one substituent, in this case an ether function, has not caused a significant change in conformation; the ring junction carbon atoms are still cisoid with respect to the cage carbon atoms.

A notable feature, best represented in Figure 2.4, is the unexpected position of the ether oxygen atom, which lies above the metal-bonded $\mathrm{C}_{2} \mathrm{~B}_{3}$ face, with a significant twist at $\mathrm{C}(11)$. The torsion angle $\mathrm{C}(1)-\mathrm{C}(11)-\mathrm{O}(1)-\mathrm{C}(12)$ has a value of $94.27^{\circ}$, compared with near $180^{\circ}$ torsions for the ether functions in the diether derivative, 4 (see later). The former may be traced to an intramolecular interligand hydrogen bond, $\mathrm{O}(1) \cdots \cdot \mathrm{H}(33)$, the distance between the two atoms being $2.544(22) \AA$. This value is within the range of typical hydrogen bond distances, between 2.4 and $2.9 \AA .{ }^{26}$ Moreover, the angles $\mathrm{H}(33) \cdots \cdot \mathrm{O}(1)-\mathrm{C}(11)$ and $\mathrm{H}(33) \cdots \mathrm{O}(1)-\mathrm{C}(12)$ are 112.7(5) and $122.7(5)^{\circ}$ respectively.

Figure 2.4 Perspective View of $1-\mathrm{CH}_{2} \mathrm{OCH}_{3}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-$ closo- $6 \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, (3)

Figure 2.5 Plan View of $1-\mathrm{CH}_{2} \mathrm{OCH}_{3}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $6 \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}(3)(\mathrm{B}(5)$, $B(6), B(9), B(10), B(11)$ and $B(12)$ removed for clarity)

Table 2.5 Co-ordinates of Refined Atoms and Equivalent Isotropic Thermal
Parameters $\left(\AA^{2}\right)$ for $1-\mathrm{CH}_{2} \mathrm{OCH}_{3}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-\operatorname{closo}-\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right.$, (3)

The indenyl ligand is "twisted" sideways by $6.5^{\circ}$ in the same direction as in 2, i.e. such that $\mathrm{C}(35)$ is more elevated than $\mathrm{C}(38)$. It is also "tilted" upwards [ $\mathrm{C}(36)$ more elevated than $\mathrm{C}(34)$ ] by an angle of $5.4^{\circ}$, making an overall dihedral angle of $c a .8 .1^{\circ}$ with the reference $B_{5}$ lower belt. As in 2, these values may be attributed to the presence of a substituent on the cage, in this case a monoether function.

The $C_{2} B_{3}$ face is envelope folded, with $\phi^{p}$ and $\theta^{p}$ values of $0.46^{\circ}$ and $2.36^{\circ}$ respectively. Once again there is no substantial slip of the cobalt atom across the face of the cage. The five-membered ring of the indenyl ligand is also slightly folded, with a fold angle, $\Omega$, of $3.71^{\circ}$, and $\Delta^{\mathrm{h}}(0.114 \AA)$ is again greater than in the unsubstituted species, 1 . The latter may be traced to the increased twist and tilt of the indenyl ligand to accommodate the cage substituent. Indeed the slightly increased twisting of the indenyl ligand in this complex compared with that in $2\left(6.5^{\circ} v s .5 .1^{\circ}\right)$ may contribute to the relatively greater value of $\sigma,+25.7^{\circ}$. Finally, bond distances in the indenyl six-membered ring show the same pattern and are in the same range as in the previous species.

1,2-( $\left.\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-$ closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, (4)

## Synthesis

The disubstituted analogue of 3 was synthesised by the reaction of $\mathrm{Tl}_{2}\left[7,8-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ with $\mathrm{LiC}_{9} \mathrm{H}_{7}$ and $\mathrm{Co}(\mathrm{acac})_{3}$ in thf, and isolated as a brick red solid by preparative tlc. Details of the procedure may be found in Chapter 5, Section A.

## N.m.r. Studies

The ${ }^{11} B$ spectrum exhibits six resonances in the ratio 1:1:2:2:2:1, with all boron nuclei showing coupling to an exo-polyhedral hydrogen atoms in the proton coupled spectrum. This is in full accord with there being a mirror plane of symmetry through the molceule, implying either a static, symmetric structure or (more likely) rapid rotation of the indenyl ligand about the $\mathrm{Co}(3)-\mathrm{B}(10)$ axis on the n.m.r time scale.

Such free rotation appears to continue, even on substantial cooling, as the spectrum remains essentially unchanged at $-90^{\circ} \mathrm{C}$.

The ${ }^{1} \mathrm{H}$ n.m.r. spectrum shows the expected signals for indenyl hydrogen atoms in the high frequency region. The methylene hydrogen atoms of the pendent ether groups give rise to an AB pattern, similar to that observed for 3 , the two inner methylene hydrogen atoms, $\mathrm{H}(211)$ and $\mathrm{H}(212)$ (see positions in Figure 2.7) being magnetically equivalent, and the two outer hydrogen atoms, $\mathrm{H}(221)$ and $\mathrm{H}(222)$, also being equivalent. A single resonance is observed for hydrogen atoms of both methyl groups, at $\delta 3.34$ p.p.m.

## Structural Study on 4

## Introduction

Large crystals suitable for diffraction were grown by slow diffusion of hexane into a dichloromethane solution of 4 at $-30^{\circ}$. Full details of the crystallographic procedures and crystal data for the structure can be found in Chapter 5.

## Discussion

Perspective and plan views of 4 are shown in Figure 2.6 and Figure 2.7 respectively, which also show the appropriate numbering scheme. All indenyl and
cage hydrogen atoms have the same number as the B or C atom to which they are bonded. Table 2.8 lists final atomic co-ordinates for all atoms, Table 2.9 bond distances and selected interbond angles, and Table 2.10 gives anisotropic thermal parameters for all non-hydrogen atoms.

Figure 2.7 gives a clear view of the molecular conformation. The indenyl ligand is rotated by $c a .72^{\circ}$ from its position in 1-3, since the ring junction carbon atoms now lie above $\mathrm{B}(7)$. This presumably arises as a result of the steric crowding which would ensue between the upwardly directed ether functions and the indenyl six-membered ring if the the molecule were to adopt a cisoid conformation. It is interesting to note that in the recently reported compound $\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Fe}\left(\mathrm{Et}_{2} \mathrm{C}_{2} \mathrm{~B}_{4} \mathrm{H}_{4}\right) \mathrm{Ni}\left(\eta-\mathrm{C}_{5} \mathrm{Me}_{5}\right)$, the indenyl-cage conformation appears to be $\mathrm{cis}^{68}$ (unfortunately no atomic co-ordinates were published by which to check this proposition). In this case the ethyl substituents on the eight membered carbadimetallaborane are not substantially inclined toward the indenyl ligand, whilst in $4 \mathrm{C}(11)$ and $\mathrm{C}(12)$ are at angles of 22.66 and $23.51^{\circ}$ from $\mathrm{C}(1)$ and $\mathrm{C}(2)$ respectively. Thus the associated methylene hydrogen atoms, $\mathrm{H}(111)$, $H(112), H(211)$ and $H(212)$ are particularly elevated with respect to the cage. It is also worth noting that, in contrast to the monoether derivative, there is no substantial twist in either pendent ether group. Torsion angles $\mathrm{C}(1)-\mathrm{C}(11)-\mathrm{O}(11)-\mathrm{C}(111)$ and $\mathrm{C}(2)-\mathrm{C}(21)-\mathrm{O}(21)-\mathrm{C}(211)$ are 175.92 and $174.10^{\circ}$ respectively.

The indenyl ligand is twisted by $6.7^{\circ}$, such that $\mathrm{C}(35)$ is more elevated than $\mathrm{C}(38)$, which may be traced to a close contact between $\mathrm{H}(211)$ and $\mathrm{H}(35)$ [2.53(3) $\AA$ ]. Similarly, close proximity of $\mathrm{H}(112)$ and $\mathrm{H}(32)$, which are $2.51 \AA$ apart, may explain why the ligand is not "tilted" to the same extent as in 2 and 3 , the angle of tilt being only $1.4^{\circ}$ [where $\mathbf{C}(36)$ is slightly more elevated than $\mathbf{C}(34)$ ].

Figure 2.7 Plan View. of 1,2-( $\left.\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (4) $(B(5), B(6), B(9), B(10), B(11)$ and $B(12)$ removed for clarity)

The $\mathrm{C}_{2} \mathrm{~B}_{3}$ face is folded into an envelope, with values of $\phi^{\mathrm{P}}$ and $\theta^{\mathrm{P}} 1.23$ and $2.37 \AA$ respectively. As in 1-3 the five-membered ring of the indenyl ligand is folded about $C(31) \cdots C(33)$ and $\Omega=4.15^{\circ}$. Notably $\Delta^{h}(0.082 \AA)$ is slightly lower than in the three previous examples and the value of $\sigma\left(+34.9^{\circ}\right)$ indicates that the slip vector $S$ is now almost exactly between $C(31)$ and $C(32)$. These values reflect a subtle change in the Co-indenyl five-membered ring distances with the $\mathrm{Co}-\mathrm{C}(39)$ bond length now essentially intermediate between $\mathrm{Co}-\mathrm{C}(34)$ and $\mathrm{Co}-\mathrm{C}(33)$.

These differences (albeit small) may be explained by the change in conformation of the indenyl ligand w.r.t. the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face, enforced by the presence of two ether functions on the carbaborane ligand face. The cisoid conformation, where the stronger bonds from the facial boron atoms to the metal are trans to the ring junction carbon atoms of the indenyl ligand, presumably allows for increased delocalisation of their $\mathrm{p} \pi$ atomic orbitals, and weaker bonding to the metal, relative to $\mathrm{C}(31)-(33) \operatorname{In} 4$, $\mathbf{C}(39)$ is no longer trans to two boron atoms, which may allow slightly less delocalisation of the $\mathrm{p} \pi$ atomic orbitals and more interaction with the metal orbitals, resulting in less slippage of the cobalt atom across the five-membered ring away from $\mathbf{C}(39)$. In addition the longer $\mathrm{Co}-\mathrm{C}(33)$ distance may be compensated by there being two boron atoms trans to $\mathrm{C}(33)$. However, the change in molecular conformation in this species relative to 1,2 and 3 has not had a noticable effect on the bond distances in the indenyl six-membered ring, which are of similar pattern and values to those in the latter three complexes.

## EHMO Calculations

## Introduction

In order to compare observed with theoretically predicted molecular conformations, a series of extended Hückel molecular orbital (EHMO) calculations were performed on idealised models of 1-4.

The change in the sum of 1 -electron energies for each of the four compounds was monitored as a function of rigid rotation of the $\mathrm{C}_{9} \mathrm{H}_{7}$ ligand about the $\mathrm{Co} \cdots \cdots(10)$ axis. Plots of the relative energy vs $\alpha$, the dihedral angle between the perpendicular bisectors of the aromatic and carbaborane ligands, show theoretical maximum and minimum energy conformations for each model compound.

Details of model parameters and a general methodology for these, and later calculations, are contained in Chapter 5, Section C.

## Results and Discussion

Figure 2.8 and Figure 2.9 represent potential energy curves for idealised models of 1 and 2, labelled I and II, whilst Figure 2.10 and Figure 2.11 show similar curves for

$$
1-\mathrm{CH}_{3}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-\text { closo }-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \quad \text { (III) and }
$$ $1,2-\left(\mathrm{CH}_{3}\right)_{2}-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (IV), which are models for 3 and 4. Figure 2.12 presents the relative energy plots on a common scale.

Figure 2.8 Relative Energy Plot for I, an Idealised Model of 1

Figure 2.9 Relative Energy Plot for III, an Idealised Model of 2

For I, the theoretical minimum occurs at $\alpha=36^{\circ}$, which is in good agreement with the observed conformation. ${ }^{14}$ Note that local maxima and minima of the curve shown in Figure 2.8 correspond to eclipsed and staggered forms respectively. This is not unprecedented, as significant repulsions between the indenyl hydrogen atoms and those of the $\mathrm{C}_{2} \mathrm{~B}_{3}$ metallabonded face will occur when they are lying directly over each other. The theoretical barrier to rotation is in the region of 0.26 eV . As the indenyl ligand rotates freely about the $\mathrm{Co} \cdots \cdots \mathrm{B}(10)$ axis, even at low temperatures, it is impossible to obtain a comparative experimental value for this barrier.

The relative energy plot for the model compound II shows a local minimum energy conformation approximating to that observed in the structure of 2. Generally, local maxima and minima correspond to eclipsed and staggered conformations, but there is one exception; the maximum energy confomation occurs when $\alpha=324^{\circ}$, where carbon atoms are cis-staggered with respect to each other, with $\mathrm{C}(1)$ lying underneath the $\mathrm{C}(34)-\mathrm{C}(39)$ bond. This is in fact not so surprising, as at this point there will be maximum steric interaction between the six-membered ring and the substituent phenyl group. Indeed, the calculated barrier to rotation for the model compound is very large, $c a .10 \mathrm{eV}$, which is quite consistent with the observation that the low temperature n.m.r. spectrum of 2 shows restricted rotation of the indenyl ligand about the $\mathrm{Co} \cdots \cdots \mathrm{B}(10)$ axis.

Figure 2.10 Relative Energy Plot for III, an Idealised Model of 3

Figure 2.11 Relative Energy Plot for IV, an Idealised Model of 4

Figure 2.12 Relative Energy Plots for I - IV on a Common Scale

A similar, though naturally smaller barrier to rotation (of $c a .2 .12 \mathrm{eV}$ ) is calculated for model III, which represents the monoether derivative. Once again local minima correspond to staggered conformations of the ring junction carbon/cage atoms, except once more when $\alpha=324^{\circ}$, and the indenyl ligand is closest to the cage substituent. The conformation of the indenyl ligand in the crystal structure corresponds to a local energy minimum for the model.

The plot for IV, modelling the diether derivative, clearly shows that the cisoid conformation observed in 1-3 is unfavoured, with the first local minimum energy for the system occurring at $\alpha=108^{\circ}$, close to the conformation observed in 4 . It is notable that the maximum energy for IV occurs at the cis eclipsed conformation ( $\alpha=0,360^{\circ}$ ). At this point both ether functions come into closest contact with the indenyl six-membered ring. The calculated barrier to rotation is $c a .3 .7 \mathrm{eV}$ (roughly twice that for 3).

In conclusion theoretically calculated energy minimum conformations for models of the indenyl carbacobaltaborane series are in good agreement with those observed in the crystal structures. In addition, barriers to rotation have been calculated for I to IV, with the greatest barrier predicted to occur in the monophenyl derivative. Although this barrier is almost certainly overestimated for the real molecule, 2, (since a simple rigid rotor model is used in the calculations), it is nevertheless significant that the solution fluctionality of 2 may be arrested by cooling, whilst that of $\mathbf{4}$ has not been.

## Section B : Fluorenyl Carbametallaborane Chemistry

## Introduction

The fluorenide anion, $\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]^{-}$, is formed on the treatment of fluorene with bases of appropriate strength. Given that it is to the indenide anion as indenide is to cyclopentadienide, i.e. it comprises two pseudo-aromatic six-carbon rings fused to the $\mathrm{C}_{5}$ unit, it has also been considered a likely candidate to form metal complexes. Following the characterisation of ferrocene ${ }^{27,28}$, numerous organometallic complexes incorporating the cyclopentadienyl ligand were synthesised. It is somewhat surprising, therefore, that only a few fluorenyl analogues have been reported, of which there is a brief resume in Chapter 1.

Having successfully characterised a number of indenyl carbacobaltaboranes, it seemed appropriate to attempt the synthesis of at least one fluorenyl analogue. Obviously the same question arises for fluorenyl carbametallaboranes as for indenyl complexes, namely which of the various possible conformations the aromatic ligand will adopt in the solid state. The work detailed in this section includes the synthesis and structural determination of the first fluorenyl carbametallaborane, 3- $\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$, together with the results of EHMO calculations on an idealised model, which predicts a molecular conformation in full accord with that observed in the crystal structure.

## 3-( $\left.\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)$-3,1,2-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}, 5$

## Synthesis

The fluorenyl carbacobaltaborane compound 5 was synthesised by an analogous route to that previously described for the related indenyl species. Lithium fluorenide was added drop-wise to a cold suspension of $\mathrm{Co}(\mathrm{acac})_{3}$ and $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ in thf , and subsequent work-up of the reaction mixture afforded the target compound. Full details are contained in Chapter 5, Section A. Although obtained in too low a yield for n.m.r. spectroscopic analysis, the compound formed crystals suitable for diffraction, and the following structural study was carried out.

## Structural Study on 5

## Introduction

A crystal structure determination of the fluorenyl carbacobaltaborane complex was carried out in order to fully characterise the compound, and to identify the preferred conformation of the fused aromatic ligand with respect to the metalla-bonded carbaborane face. Crystals of 5 were obtained by slow diffusion of $n$-hexane into a methylene chloride solution of the compound at $-30^{\circ}$. Details of the crystal data, data collection and solution and refinement of the structure may be found in Chapter 5, Section B.

Figure 2.13 shows a perspective view of a single molecule with the appropriate numbering scheme, hydrogen atoms having the same number as the carbon or boron atom to which they are bound. Figure 2.14 shows a plan view, with all but the five atoms of the upper $C_{2} B_{3}$ face of the carbaborane ligand removed for clarity.

Table 2.11 lists refined atom co-ordinates, Table 2.12 interbond distances and selected angles, and Table 2.13 anisotropic thermal parameters.

Both plan and perspective views show that the fluorenyl ligand is clearly $\eta^{5}$-bonded to cobalt, although the metal atom is substantially slipped across the $\mathrm{C}_{5}$ ring, towards $C(33)$. In contrast to the indenyl analogues, where $C(34)$ and $C(39)$ are always substantially further from the metal than $\mathbf{C}(31)-(33), C(31)$ and $C(39)$ are furthest away from the cobalt atom [2.142(10) and $2.160(10) \AA$ respectively], C(32) and $\mathrm{C}(34)$ are at intermediate distances $[2.098(10)$ and $2.118(10) \AA$ respectively], with the shortest M-C distance being that between Co and C(33) [2.026(10) $\AA$ ] The slip distortion, $\Delta^{\mathrm{h}}$, has a value of $0.095 \AA$, with $\sigma$ [in this case the angle between the slip vector $S$ and a reference vector from the ring centroid to $\mathrm{C}(33)]$ ) being $+11.85^{\circ}$ (i.e. $S$ is positionally anti-clockwise w.r.t. $R$ when viewed from above, as in Figure 2.13).

Slippage towards the more electron rich $C(33)$ is observed in other formally $\eta^{5}$ fluorenyl metal complexes, namely $\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{Cr}(\mathrm{CO})_{2} \mathrm{NO}^{12}\left(\Delta^{\text {h }}=0.011 \AA\right)$ and $\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)\left(\eta^{3}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{ZrCl}_{2}{ }^{11}$ ( $\Delta^{\mathrm{h}}$ for the $\eta^{5}$-bonded ligand $=0.244 \AA$ ). Although the latter value in particular seems quite large, the ligand is still described as being formally $\eta^{5}$-bonded, with $\Delta^{h}$ for the $\eta^{3}$-fluorenyl ligand having the much greater value of $0.474 \AA$.

Figure 2.13 Perspective View of 3-( $\left.\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)-3,1,2$-closo $-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$, (5)

The $\mathrm{C}_{5}$ ring in 5 is also folded towards $\mathrm{Co}(3)$ in an envelope conformation, by $6.87^{\circ}$ across the $\mathrm{C}(32) \cdots \mathrm{C}(34)$ vector. Although all fluorenyl carbon atoms are not entirely co-planar, as a whole the ligand is tilted such that $\mathrm{C}(37)$ is $c a .0 .25 \AA$ closer to the lower $\mathrm{B}_{5}$ belt than $\mathrm{C}(313)$.

As expected there is no substantial slippage of the metal atom across the $\mathrm{C}_{2} \mathrm{~B}_{3}$ carbaborane face, the actual value of $\Delta^{\mathrm{P}}$, the slip parameter, being zero to within experimental error. The $\mathrm{C}_{2} \mathrm{~B}_{3}$ face is, however, envelope folded about the $\mathrm{B}(4) \ldots \mathrm{B}(7)$ vector, with fold angles $\theta^{\mathrm{P}}=2.69^{\circ}$ and $\phi^{\mathrm{P}}=1.37^{\circ}$.

As previously stated, an important feature of the structure of 5 is the conformation of the fluorenyl ligand relative to the metal-bonded carbaborane face. For indenyl carbametallaboranes it has been shown that, in the absence of more than one bulky substituent, the indenyl ligand preferentially lies such that its six-membered ring is cisoid with respect to the cage carbons. In this orientation the relatively weak metal- $\mathrm{C}_{\text {ring-junction }}$ bonding can be compensated by relatively strong metal-boron bonding, the frontier molecular orbitals of the carbaborane ligand being localised on the facial boron atoms. Extending this argument to 5 , in which there are now two pairs of ring-junction carbon atoms in the carbocyclic ligand, of the three possible staggered conformations shown in Figure 2.15 the observed conformation is intuitively expected to be A , which involves one pair of bridge-carbon atoms, C (34) and $\mathrm{C}(39)$ lying trans to two boron atoms, with the other pair, $\mathrm{C}(31)$ and $\mathrm{C}(32)$ trans to one boron atom and one carbon atom. In B C(31) and C(32) are trans to 2 carbon atoms, and in $\mathbf{C}$ both sets of bridge-carbon atoms are trans to one carbon and one boron atom.

A series of EHMO calculations were performed on an idealized model of 5 in order to compare the crystallographically observed conformation with that predicted theoretically. As for the related indenyl carbacobaltaboranes, the change in the sum
of 1 -electron energies was monitored as a function of rigid rotation of, in this case, the $\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]^{-}$ligand about the $\mathrm{Co}(3) \cdots \cdot \mathrm{B}(10)$ vector.

Figure 2.16 presents the results of the calculations in the form of an energy curve. The theoretical minimum energy conformation of the system occurs at $\alpha=144^{\circ}$, which corresponds to the conformation observed in the crystal structure $[\alpha=0$ corresponds to a cis-stagjered conformation, in which $C(94)$ and $C(99)$ lie directly above the cage atom $B(7)$ ]. As for the corresponding model of the indenyl carbacobaltaborane, 1, local maxima correspond to eclipsed forms, and local minima to the staggered conformations $A, B$ and $C$, as depicted in Figure 2.15. The calculated barrier to rotation is 0.27 eV .

In addition, it is worth noting the cobalt ring-junction carbon distances in relation to calculated atom-atom overlap populations. As $\mathrm{C}(34)$ and $\mathrm{C}(39)$ are both trans to two boron atoms, and metal-boron bonding is expected to be somewhat stronger than metal-cage carbon bonding, correspondingly weaker interactions between $\operatorname{Co}(3)$ and $C(34,39)$ can be expected than between $\mathrm{Co}(3)$ and $\mathrm{C}(31,32)$, which are both trans to one carbon and one boron atom. Although measured errors in the observed distances are too large to render the differences statistically significant,-it is nevertheless worth noting that $\mathrm{Co}(3)-\mathrm{C}(39)$ is indeed $0.018(13) \AA$ longer than $\mathrm{Co}(3)-\mathrm{C}(31)$, and $\mathrm{Co}(3)-\mathrm{C}(34)$ is $0.020(14) \AA$ longer than $\mathrm{Co}(3)-\mathrm{C}(32)$. Moreover, the relative distances are in accord with calculated atom-atom overlap populations, shown in Figure 2.15, diagram $\mathbf{A}$.

C

Figure 2.16 Relative Energy Plot for an Idealised Model of 5

Finally, the observed conformation of 5 can be compared with that of another fluorenyl complex, $\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right) \mathrm{Cr}(\mathrm{CO})_{2} \mathrm{NO}^{12}$, where more than one orientation of the carbocyclic ligand is possible. In the latter compound the metal is bonded on one side by the fluorenyl group, and on the other by one nitrosyl and two carbonyl ligands. The crystallographically determined conformation is one in which the more electron withdrawing nitrosyl group is trans to the relatively electron rich carbon, $\mathrm{C}(1)$ [equivalent to $\mathrm{C}(33)$ in 5]. The weaker junction carbon-metal bonds are trans to those between the neutral carbonyl ligands and chromium.

This is fully comparable to the situation occurring in the fluorenyl carbacobaltaborane, where the more electronegative cage carbon atoms are trans to relatively electron rich $\mathrm{C}(33)$, and the facial boron atoms, more strongly bound to the metal, are trans to the ring junction carbons of the aromatic ligand.

## Conclusions

Three indenyl carbacobaltaborane complexes, incorporating carbaborane ligands in which bulky alkyl or aryl functions have been introduced at the cage carbon atoms, have been synthesised and spectroscopically and structurally characterised. In the case of the two monosubstituted derivatives, 2 and 3, the observed conformation of the indenyl six-membered ring w.r.t. the cage carbon atoms is cisoid, which is also the conformation observed in the previously reported unsubstituted species, 1. However, the presence of two ether functions in 4 has resulted in the adoption of the "next best" staggered conformation. A series of EHMO calculations performed on idealised models of the four complexes 1-4 have predicted theoretical minimum energy conformations which are close to those observed in the crystal structure determinations.

In addition, an analogous fluorenyl carbacobaltaborane has been synthesised and structurally characterised. The conformation of the fused aromatic ligand w.r.t. the cage carbon atoms has been readily explained in terms of relative bond strengths between the cobalt atom and the metalla-bonded ligand atoms, such that relatively strong $\mathrm{Co}-\mathrm{B}(4,7,8)$ bonds are trans to the weaker fluorenyl-Co bonds. This observed conformation is in full accord with that predicted from a series of EHMO calculations performed on an idealised model of the compound.

## Chapter 3

## Indenyl Rhodium Carbaborane Complexes

## Introduction

The indenyl carbacobaltaboranes described in the previous Chapter generally form in quite modest yields, as do metallaboranes and carbametallaboranes incorporating $\{\mathrm{CpCo}\}^{69}$ and $\left\{\mathrm{Cp}^{*} \mathrm{Co}\right\}^{70}$ moieties $\left(\mathrm{Cp}^{*}=\left(\mathrm{CH}_{3}\right)_{5} \mathrm{C}_{5}\right)$. This may well be attributed to the somewhat arbitrary route employed in the synthesis of these compounds, involving the reaction of $\mathrm{CoCl}_{2}$ or $\mathrm{Co}(\mathrm{acac})_{3}$ with the appropriate cyclopentadienide and carbaborane anions.

In contrast, some metallaboranes and carbametallaboranes incorporating a \{CpRh\}/\{Cp**h moiety have been reported in relatively good yields, from reactions involving the metal halide complexes $\left[\mathrm{CpRhX} \mathrm{X}_{2}\right]_{\mathrm{n}}{ }^{71}$ (where $\mathrm{X}=\mathrm{I}$ and n is greater than 2) and $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2} \cdot{ }^{72,73}$ In such reactions the cyclopentadienyl metal dichloride precursor introduces an already intact ligand-metal fragment to the borane or carbaborane anion, thus reducing the likelihood of numerous side-reactions, and resulting in higher yields of target products compared with cobalt analogues. Potentially higher yield syntheses of a number of analogous indenyl metalla- and carbametallaboranes were thus envisaged, starting with the hitherto unknown indenyl analogue of $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$ and the non-methylated amorphous species $[\mathrm{CpRhCl}]_{2}$

This Chapter details the reactions of the previously unreported species " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with a number of carbaborane anions of the type $\left[\mathrm{R}_{1} \mathrm{R}_{2} \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]^{2-}$, resulting in the formation of a variety of carbarhodaboranes of novel structure. It begins with a brief introduction to the syntheses and reaction chemistry of $[\mathrm{CpRhX}]_{n}$ and $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$, forming the precedent for the attempted synthesis of an indenyl
analogue. The syntheses and characterisation of a number of indenyl rhodium carbaborane complexes are then discussed, followed by a general consideration of the nature of the reactions involved.

## Chemistry of $\left[\mathbf{C p R h} X_{2}\right]_{n}$ and $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$

The synthesis of $\left[\mathrm{CpRhBr}_{2}\right]_{\mathrm{n}}$ from the reaction of $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Rh}\left(\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{Ph}\right)$ with bromine, was reported in $1963 .{ }^{74}$ Five years later, a synthetic route to the chloride was reported, which involves a multi-step reaction starting with $\mathrm{RhCl}_{2}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)_{2}$ and TICp. ${ }^{75}$ A more convenient synthesis of the latter was detailed by Maitlis and co-workers, from the reaction of $\mathrm{RhCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ with freshly cracked cyclopentadiene in refluxing methanol. ${ }^{76}$ This was published together with the synthesis and characterisation of $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$, the first known complex containing a $\left\{\mathrm{Cp}^{*} \mathrm{Rh}\right\}$ moiety. The latter was, in fact, prepared serendipitously, during the reaction of $\mathrm{RhCl}_{3} .3 \mathrm{H}_{2} \mathrm{O}$ with hexamethyl (Dewar) benzene, (hexamethylbicyco[2.2.0]hexa-2,5-diene).

The structure of the pentamethylated derivative, which is soluble in organic solvents, has been determined crystallographically, ${ }^{77}$ and is represented in Figure 3.1. The $\mathrm{Rh}_{2} \mathrm{Cl}_{2}$ bridge is planar, and the long $\mathrm{Rh}-\mathrm{Rh}$ distance of $3.719 \AA$ indicates the absence of a Rh -Rh bond. The structure of the unsubstituted Cp analogue is less well defined. The fact that it is insoluble in all organic solvents is suggestive of polymeric character. The infrared spectrum indicates that the metal is bonded to both terminal and bridging chloride ions, with polymer formation possibly occurring via chloride bridges.

The chemistry of $\left[\mathrm{Cp}{ }^{*} \mathrm{MCl}_{2}\right]_{2}(\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ has been well documented, as these compounds and their derivatives have been found to catalyse the hydrogenation of alkenes and arenes. ${ }^{78}$ The dimeric complexes undergo a variety of reactions; in addition to metathetical replacement by other halides and pseudo-halides, the chloride bridge is split on reaction with donor ligands (e.g. phosphines) ${ }^{76}$ to yield monomeric species. Such reactions have extended into the field of boron chemistry, with the arachno borane anion, $\left[\mathrm{B}_{9} \mathrm{H}_{14}\right]^{-}$, and the nido carbaborane anion $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$(in the presence of base), readily yielding the nido species $\mathrm{Cp}^{*} \mathrm{RhB}_{9} \mathrm{H}_{13}{ }^{72}$ and the closo species $\mathrm{Cp}^{*} \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}{ }^{73}$ in $96 \%$ and $34 \%$ yields respectively, upon reaction with $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$ at room temperature.

The chemistry of $\left[\mathrm{CpRhCl}_{2}\right]_{2}$ has not been as intensively investigated as its dimeric $\mathrm{CP}^{*}$ analogue. However, it also undergoes halide bridge splitting reactions with donor ligands to give monomeric compounds. In addition, the iodo analogue, $\left[\mathrm{CpRhI}_{2}\right]_{\mathrm{n}}$, was reacted with $\mathrm{Tl}_{2}\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$, affording $\mathrm{CpRhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ in $30 \%$ yield. ${ }^{71}$

Given the fact that many indenyl analogues of Cp and $\mathrm{Cp}^{*}$ metal complexes are
known, it was reasonable to assume that the synthesis of an indenyl rhodium dichloride dimer/polymer, a potentially useful synthetic precursor, would be relatively facile.

## Synthesis and Characterisation of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ "

The synthesis of indenyl rhodium dichloride was attempted using an analogous route to that which afforded the polymeric species, $\left.[\mathrm{CpRhCl}]_{2}\right]_{\mathrm{n}}{ }^{76} \mathrm{Thus}, \mathrm{RhCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ and freshly distilled indene were reacted together in refluxing methanol for fifteen hours, during which time a light brown solid precipitated. Microanalysis figures were consistent for the formulation $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}$. The low solubility of the product in organic solvents such as methylene chloride, chloroform and acetonitrile was indicative of some polymeric character. The infrared spectrum of the solid contained absorptions at 330,240 , and $230 \mathrm{~cm}^{-1}$, corresponding to both terminal and bridging $\mathrm{Rh}-\mathrm{Cl}$ stretches respectively.

The n.m.r. spectrum of that part of the product soluble in methylene chloride suggests a complex structure, which will be discussed in more detail following a summary of a number of reactions of indenyl rhodium dichloride with dithallium carbaboranes. For these reactions the formulation " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " was adopted to formally describe the new complex, and a ratio of one mole of carbaborane to one mole of rhodium was used.

Reaction of " $\left.\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathbf{R h C l}\right]_{2}\right]_{2}$ " with $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$

The reaction of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ in methylene chloride afforded three major products, $\mathbf{6 a}, \mathbf{6 b}$ and $\mathbf{6 c}$, in relatively small yields (all $<10 \%$ ), which were isolated by preparative tlc. Full experimental details may be found in Chapter 5, Section A.

## Elucidation of the Structure of $\mathbf{6 a}$

This species, chromatographically the most mobile band, was isolated as a yellow microcrystalline solid. Microanalysis figures for the solid were consistent with the expected closo-carbarhodaborane, $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$. However, subsequent spectral and $X$-ray structural analysis showed this initial supposition to be incorrect.

## Analysis of N.m.r. Spectra

The proton spectrum, shown in Figure 3.2, exhibits some unexpected features. Considering first the aromatic region, which has been expanded for detailed analysis, it appears that more than one indenyl moiety is present in the compound. The expected resonance pattern for a metal-bonded $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{-}$ligand is observed, with a multiplet, corresponding to $\mathrm{H}(5-8)$ (see numbering scheme below), a doublet, $\mathrm{H}(1,3)$ and a triplet, $\mathrm{H}(2)$, (all of which are marked with a * on Figure 3.2).

In addition a lower field multiplet is observed, corresponding to four protons, together with a singlet of integral 2 H . These resonances, (marked by a $\dagger$ on Figure 3.2), may be attributed to an $\eta^{5}$-bonded $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moiety, where substitution of the hydrogen atom $\mathrm{H}(2)$ has occurred, resulting in the downfield shift of resonances due to $\mathrm{H}(5-8)$ and the signal corresponding to $\mathrm{H}(1)$ and $\mathrm{H}(3)$ being a singlet.

In the lower frequency region of the spectrum, there are two resonances, at $\delta 3.80$ and 3.71 p.p.m. (both of integral 2 H ), corresponding to the carbon-bound exo-polyhedral hydrogen atoms; this suggests two $\mathrm{C}_{2} \mathrm{~B}_{9}$ cages, of different nature.

Figure $3.2{ }^{1}$ H N.M.R. Spectrum of $\mathbf{6 a}$

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum of 6 a corroborates this evidence, as it exhibits twelve resonances in the ratio $1: 1: 1: 1: 2: 2: 2: 2: 2: 2: 1: 1$, which integrate for a total of eighteen boron atoms. Two carbaborane cages are thus present in the complex, both having apparent mirror symmetry. The proton-coupled spectrum shows that one boron atom (that which has the highest frequency resonance, 9.19p.p.m.) does not have an associated exo-polyhedral hydrogen atom. Thus substitution has presumably occurred on one of the cages, and, given the evidence from the proton spectrum, it is reasonable to assume that the "missing" exo- H atom has been replaced by the $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ indenyl moiety, with the formation of a B-C bond. From comparison of this spectrum with that of the the previously assigned related carbarhodaborane, $\mathrm{Cp}{ }^{*} \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}{ }^{73}$ the substituted boron atom is the unique facial boron atom, $\mathrm{B}(8)$, which renders the cage a plane of symmetry. $\mathrm{A}^{11} \mathrm{~B}-{ }^{11} \mathrm{~B}$ COSY experiment was carried out, and the spectrum is presented in Figure 3.3. Table 3.1 lists the associated resonance assignments for both the substituted and unsubstituted cages in 6a, together with those made for $\mathrm{Cp}^{*} \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$.

On the strength of this n.m.r. data, two possible structures, A and B, illustrated in Figure 3.4, may be postulated. Structure A comprises two neutral indenyl-rhodium-carbaborane moieties fused via a B-C bond, whereas structure B is best described as a zwitterionic species, and involves the linking of positively charged bis-indenyl rhodium and negatively charged bis-dicarbollyl rhodium fragments. These two structures are not distinguishable from the n.m.r. data alone.

## Structural Study on 6a

In order to unequivocally establish the nature of $\mathbf{6 a}$, a crystal structure determination was carried out on a very small crystal of the compound, grown by slow diffusion of hexane into a thf solution of 6 a at $-30^{\circ} \mathrm{C}$.

Discussion

A perspective view of a single molecule of 6a is presented in Figure 3.5, with appropriate atomic numbering. The compound is clearly shown to be the zwitterionic structure, B , formally $3-\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)-8-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$. In the substituted cage, the carbon atoms were assigned by a combination of their lower thermal parameters (when refined as boron atoms), and the fact that the n.m.r spectrum suggests both cages have a plane of symmetry. In the unsubstituted cage only $\mathrm{C}(1 \mathrm{P})$ could be distinguished from lower thermal parameters, with $\mathrm{B}(2 \mathrm{P})$ and $\mathrm{B}(4 \mathrm{P})$ [both adjacent to $\mathrm{C}(1 \mathrm{P})$ ] assigned part occupancies of $5.5 \mathrm{e}[(\mathrm{B}+\mathrm{C}) / 2]$. The data collected was not sufficiently accurate to enable location of the cage hydrogen atoms. Table 3.2 gives final atomic co-ordinates for refined atoms, and anisotropic thermal parameters for the two rhodium atoms, and Table 3.3 lists selected bond distances and interbond angles.

A number of observations can been made, even though the accuracy of the crystallographic determination is limited. Regarding the bis-indenyl rhodium fragment, the $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}$ and $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moieties are both clearly $\eta^{5}$-bonded to $\mathrm{Rh}(2)$. The large errors in $\mathrm{Rh}(2)-\mathrm{C}$ distances render the calculation of slip distortions somewhat meaningless. However, the average rhodium- $C(14,19)[2.18(6) \AA$ ] and $C(24,29)$ [2.23(6) $\AA$ ] distances are greater than the average distances from $\mathrm{Rh}(2)$ to $\mathrm{C}(11-13)$ [2.13(7) $\AA$ ] and $C(21-23)$ [2.12(5) $\AA$ ], which is a common feature in indenyl metal complexes, and has been discussed previously in some detail in Chapters 1 and 2.

The two indenyl ligands are essentially in a cis-eclipsed conformation, with the rotation angle of $8^{\circ}$ between them (the rotation angle, RA, is defined in Chapter 1 ). This is comparable with the previously discussed bis-indenyl species, $\mathrm{Fe}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}$, incorporating a $d^{6}$ metal, and the $d^{7} C^{I I}$ analogue. The perpendicular distance between the planes through the two indenyl moieties is $3.5 \AA$, the latter being virtually parallel to each other (the angle of elevation of $\mathbf{C}(11)-(19)$ to $\mathbf{C}(21)-(29)$ is $3.1^{\circ}$ ). The pivotal indenyl carbon atom, $C(12)$, subtends an elevation angle of $12.2^{\circ}$ at $B(8)$, which is slightly lower than that generally observed for cage substituents. However, the plane through the $\mathrm{C}(11)$-(19) indenyl ring system makes an angle of $18.2^{\circ}$ with the reference plane in the substituted carbaborane cage [i.e. the lower pentagonal belt comprising $\mathrm{B}(5), \mathrm{B}(6), \mathrm{B}(11), \mathrm{B}(12), \mathrm{B}(9)]$.

Both carbaborane ligands are symmetrically disposed over $\mathrm{Rh}(3)$, with a perpendicular distance of $3.6 \AA$ between the two $C_{2} B_{3}$ planes (i.e. almost the same as in the bis-indenyl moiety). The carbon atoms are cisoid with respect to each other, with the term cisoid implying a staggered conformation. The fact that the carbaborane ligands are staggered with respect to each other, whilst the indenyl ligands are essentially eclipsed, may be explained by the elevated position of the exo-polyhedral atoms relative to the ligand face, whereas all atoms in the the indenyl ligand lie approximately in the same plane. Notably, the non-slipped cisoid conformation in this carbarhodaborane is in full accord with that observed in other $d^{6}$ metal bis-dicarbollyl species, and has been shown to be the most electronically favourable by the results of molecular orbital calculations.

## 3-( $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)-8-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, (6a)

In conclusion, alchough the quality of the data was such that a more detailed discussion of the structure of $6 a$ is not undertaken here, the definitive nature of a mos $\varepsilon$ unusual and interesting species has been established. The same molecule incorporates both a bis-dicarbollyl and a bis-indenyl metal fragment, fused together by a B-C bond, with the carbaborane and organic ligands each exhibiting very similar complexation of a metal atom. Thus 6 a may be viewed as a novel example of the already well established analogy between dicarbollyl and cyclopentadienyl ligands. Moreover, the establishment of the nature of the compound has been of great significance in structural assignments of related complexes to be discussed in this Chapter.

## Characterisation of 6b

Compound $\mathbf{6 b}$, the middle tlc band of the three which were isolated from this reaction, was afforded as an apricot solid, and recrystallisation, from diffusion of hexane into a methylene chloride solution of the product, yielded a microcrystalline material. Microanalysis figures for the latter were consistent with a molecular composition involving two indenyl ligands and one $\mathrm{C}_{2} \mathrm{~B}_{9}$ cage per rhodium atom.

## Analysis of N.m.r. Spectra

Figure 3.6 shows the ${ }^{1} \mathrm{H}$ spectrum of compound $\mathbf{6 b}$. The aromatic region of the proton spectrum, which has been expanded, contains resonances consistent with the presence of a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ moiety, similar to that observed in 6 a . The resonances corresponding to $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}^{*}$ and $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}^{\dagger}$ moieties are marked on the spectrum (note that the triplet due to $\mathrm{H}(2)^{*}$ of the former nearly overlaps with the singlet due to $\mathrm{H}(1)^{\dagger}$ and $\mathrm{H}(3)^{\dagger}$ of the latter moiety). It seems plausible that substitution may again have taken place on a cage by a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ fragmènt.

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (Figure 3.7) exhibits six signals, of relative integral 2:2:1:2:1:1, in the range $\delta-9 \rightarrow-40$ p.p.m., corresponding to a $C_{2} B_{9}$ cage with a mirror plane. Upon inspection of the proton coupled spectrum, one boron atom indeed does not have an associated exo-polyhedral H atom (which has presumably been substituted by the bis-indenylrhodium fragment), as the signal at $\delta-26.40$ p.p.m. remains a singlet, whilst the remaining eight boron resonances exhibit doublet coupling, with $\mathrm{J}_{\mathrm{BH}}$ in the range $125-150 \mathrm{~Hz}$. However, the resonance at $\delta \mathbf{- 2 6 . 4 0}$ p.p.m. does show distinct broadening, which has been attributed to a smaller unresolved coupling to an endo-hydrogen atom.

In fact, the ${ }^{11} \mathrm{~B}$ resonances observed for $\mathbf{6 b}$ occur at similar frequencies to those in the previously characterised species, nido $-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}{ }^{33}$, for which individual boron resonances have been assigned from an ${ }^{11} \mathrm{~B}-{ }^{11} \mathrm{~B}$ COSY experiment. ${ }^{11} \mathrm{~B}$ chemical shifts for both compounds are listed in Table 3.4. Given the presence of an endo-hydrogen atom on the open face of the cage, and the overall shift of the boron resonances to lower frequencies, relative to those observed in 6a, one can assume that a rhodium atom is not $\eta^{5}$ bonded to the open $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagon. From chemical shift assignments for individual boron atoms, the substituted boron atom, which resonates at $\delta-26.40$ p.p.m., is the unique facial atom $\mathrm{B}(10)$ (note that substitution has occurred at the same position in the cage as in 6 a, the change in number merely reflecting the transition from a closo to a nido polyhedron).

The presence of the endo- H atom is confirmed by the presence of a characteristic broad quartet at $\delta-1.54$ in the ${ }^{1} \mathrm{H}$ n.m.r. spectrum. Significant enhancement of this signal is observed upon irradiation at the frequency corresponding to the $B(10)$ resonance, and a much weaker enhancement is observed on irradiation at the frequency of the $\mathrm{B}(9,11)$ resonance at $\delta-9.60$ p.p.m., to which $\mathrm{H}\left(10_{\text {endo }}\right)$ is weakly bound. A single resonance is observed for both cage CH hydrogen atoms at $\delta 2.10$.

Figure $3.6{ }^{\mathbf{1}} \mathrm{H}$ N.M.R. Spectrum of $\mathbf{6 b}$

Figure $3.7{ }^{11} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}-\left({ }^{1} \mathrm{H}\right\}$ N.M.R. Spectra of $\mathbf{6 b}$

Table 3.4 Assigned ${ }^{11} \mathrm{~B}$ resonances for $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$and $\mathbf{6 b}$

|  | $\left[\mathrm{C}_{2} \mathrm{~B}_{\mathbf{2}} \mathrm{H}_{12}\right]^{-}$ | $\mathbf{6 b}$ |
| :---: | :---: | :---: |
| Position | -10.38 | $\delta$ |
| 9,11 | -16.46 | -9.60 |
| 5,6 | -16.46 | -13.77 |
| 3 | -21.29 | -17.81 |
| 2,4 | -32.54 | -20.79 |
| 10 | -37.17 | -26.39 |
| 1 |  | -37.08 |

The n.m.r. data are therefore consistent with the structure illustrated in Figure 3.8, formally $10-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ in which the $\left\{\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right\}$ fragment in compound 6a has effectively been removed from the open face of the carbaborane ligand, with an endo-hydrogen atom $\sigma$-bonded to $B(10)$. The microanalysis figures for the recrystallised solid are consistent with this formulation, but incorporating half a molecule of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent per molecule of $\mathbf{6 b}$.

Figure 3.8 Proposed Structure of 6b

## Characterisation of $\mathbf{6 c}$

Compound 6c, the slowest moving of the three bands, was isolated as an orange solid, and recrystallised similarly to $\mathbf{6 b}$, also forming as a microcrystalline material. Microanalysis figures for this solid were virtually identical with those of $\mathbf{6 b}$, suggesting a very similar formulation.

## Analysis of N.m.r. Spectra

As in the proton spectrum of $\mathbf{6 b}$, resonances due to both $\eta^{5}$-bonded $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}$ and $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moieties are observed (see Figure 3.9). However, in this case two singlets ( $\delta$ $6.07,5.97$ p.p.m.) and two doublets ( $\delta 6.01,6.00$ p.p.m) are observed, indicating that protons $\mathrm{H}(1,3)^{*}$ and $\mathrm{H}(1,3)^{\dagger}$ are no longer in equivalent magnetic environments. In addition, two broader singlets are observed at $\delta 2.45$ and 2.10 p.p.m., corresponding to non-equivalent cage CH atoms.

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (shown together with the ${ }^{11} \mathrm{~B}$ spectrum in Figure 3.10) exhibits nine signals of equal integral, corresponding to nine unique boron nuclei. The resonances are in a similar frequency range ( $\delta-5->-35$ p.p.m.) to those in the spectrum of $6 \mathbf{b}$, suggesting that the cage contains an open $C_{2} B_{3}$ face which is not bonded to a metal atom. The proton coupled spectrum shows that the boron atom which resonates at $\delta-4.14$ p.p.m. does not have an associated exo-polyhedral hydrogen atom. This resonance corresponds to $\mathrm{B}(9)$ [or $\mathrm{B}(11)$ ], on the open pentagonal belt of the $\mathrm{C}_{2} \mathrm{~B}_{9}$ cage. The signal at $\delta-29.45[\mathrm{~B}(10)]$ appears as a doublet of doublets in the proton coupled spectrum, as, in addition to coupling to an exo- H atom, it exhibits a smaller coupling to an endo-H atom.

Figure $3.9{ }^{1} \mathrm{H}$ N.M.R. Spectrum of $\mathbf{6 c}$

## 융 7 7

The presence of the endo-hydrogen atom is confirmed by the characteristic low frequency signal ( $\delta-2.60$ p.p.m.) in the proton spectrum, which is enhanced significantly upon irradiation at the frequency corresponding to the ${ }^{11} \mathrm{~B}$ resonance at $\delta$ -29.45 (the expected weak association of the endo- H with $\mathrm{B}(9)$ and $\mathrm{B}(11)$ is not observed in the ${ }^{1} \mathrm{H}-\left\{{ }^{11} \mathrm{~B}\right.$ selective $\}$ spectrum, presumably due to a poor signal to noise ratio).

The proposed structure of $\mathbf{6 c}$ is illustrated in Figure 3.11, with the now familiar $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ fragment $\sigma$-bonded to the $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ cage, in this case at $\mathrm{B}(9)$. This structure is consistent with the asymmetry suggested in the ${ }^{11}$ B n.m.r. spectrum, as the cage no longer has a mirror plane. It also explains why the indenyl hydrogen atoms, $\mathrm{H}(21,23)$ and $\mathrm{H}(11,13)$ (as labelled in Figure 3.11) are not equivalent, as they are no longer in identical environments. Similarly, the two cage CH atoms are now in different magnetic environments, and have different chemical shift values.

Figure 3.11 Proposed Structure of $\mathbf{6 c}$

## Reaction of "[(C $\left.\left.\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with $\mathrm{Tl}_{2}\left[7-\mathrm{CH}_{2} \mathrm{OCH}_{3}-\mathbf{7 , 8}-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$

The indenyl rhodium dichloride "dimer" was stirred together with $\mathrm{Tl}_{2}\left[7-\mathrm{CH}_{2} \mathrm{OCH}_{3}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ in methylene chloride, to yield, in small amounts, one chromatographically isolable product, 7, as detailed in Section A of Chapter 5.

## Characterisation of 7

Compound 7 was isolated as an orange solid, which formed microcrystals after slow diffusion of hexane into a methylene chloride solution of the product. Microanalysis of the latter suggested a formulation analogous to those of $\mathbf{6 b}$ and $\mathbf{6 c}$.

## Analysis of N.m.r. Spectra

The aromatic region of the proton spectrum (obtained as a $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution) suggests the presence, once again, of a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ fragment, with multiplets at $\delta 7.23,7.18\left[\mathrm{H}(25-28)\right.$ of the $\mathrm{C}_{9} \mathrm{H}_{7}$ moiety $]$ and $6.66,6.58$ p.p.m. $[\mathrm{H}(15-18)$ in the $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right.$ \} moiety], two doublets at $\delta 6.01$ and 6.00 p.p.m $[\mathrm{H}(21,23)]$, and a singlet at $\delta$ 5.92 p.p.m. $[\mathrm{H}(11,13)]$. However, the expected signal corresponding to $\mathrm{H}(22)$ of the $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}$ moiety is not observed. The spectrum was thus re-run in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}$, (see Figure 3.12 for an expansion of the aromatic region) which contained all the resonances consistent with the bis-indenyl rhodium fragment.

Figure 3.12 Expansion of the Aromatic Region of the ${ }^{1} \mathrm{H}$ N.M.R. Spectrum of 7 (in $\left.\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}\right)$

A doublet of doublets was observed at $\delta 5.93$ p.p.m., which collapsed to a singlet upon irradiation at the frequency corresponding to the resonance due to $\mathrm{H}(21,23)$ at $\delta$ 6.24 p.p.m., and so the former signal may be attributed to $\mathrm{H}(22)$ of the $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)$ ligand.

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (shown together with the ${ }^{11} \mathrm{~B}$ spectrum in Figure 3.13) exhibits resonances corresponding to nine unique boron atoms, one of which, on inspection of the proton coupled spectrum, can be seen to have no associated exo-hydrogen atom. This boron atom, assigned $B(10)$ from its chemical shift value ( $\delta$ -26.36 p.p.m.), does however show a smaller coupling to an endo-hydrogen atom ( $\mathrm{J}_{\mathrm{BH}} \mathrm{ca} .30 \mathrm{~Hz}$ ). A characteristic low frequency signal is observed in the proton spectrum, at $\delta-1.40$ p.p.m., significant enhancement of which is observed upon irradiation at the frequency corresponding to the $\mathrm{B}(10)$ resonance. A much weaker enhancement occurs on irradiation at frequencies corresponding to resonances at $\delta$ -5.92 and -10.02 p.p.m., due to weaker interaction between the endo- H atom and $\mathrm{B}(9)$ and $\mathrm{B}(11)$.

The n.m.r. evidence strongly suggests a structure of similar nature to $\mathbf{6 b}$, formally 7- $\mathrm{CH}_{2} \mathrm{OCH}_{3}-10-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-7,8$-nido $-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, illustrated in Figure 3.14, where substitution of a hydrogen atom by a bis-indenyl rhodium cationic fragment has occurred on the nido- $\mathrm{C}_{2} \mathrm{~B}_{9}$ species $\left[7-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)-7,8 \text {-nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$at the facial boron atom, $\mathrm{B}(10)$.

Figure $3.13{ }^{11} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ N.M.R. Spectra of 7

Reaction between " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " and $\mathrm{TI}_{2}\left[7-\mathrm{Ph}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$
" $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " was stirred together with $\mathrm{Tl}_{2}\left[7-\mathrm{Ph}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ in methylene chloride, the reaction yielding two isolable products, $8 \mathbf{a}$ and $\mathbf{8 b}$, though once again in only poor yields, after work-up involving preparative tlc (see Chapter 5, Section A, for experimental details).

## Characterisation of 8a

Compound 8a, the more mobile of the two bands, was isolated as an olive solid, and then dissolved in methylene chloride. After slow evaporation of the solution,
small amber crystals formed. A unit cell and spacegroup determination of a typical crystal showed it to be the originally targeted closo-carbaborane species, 1-Ph-3- $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, by analogy with the previously characterised cobalt species, 2. This fact, coupled with its weak diffraction, did not justify data collection. Full details of the crystal data obtained are given in Chapter 5, Section 2.

## Characterisation of $\mathbf{8 b}$

Compound 8b was isolated as an orange solid, which formed microcrystals after slow diffusion of hexane into a methylene chloride solution of the product.

## Analysis of N.m.r. Spectra

The ${ }^{1} \mathrm{H}$ spectrum of $\mathbf{8 b}$ is shown in Figure 3.15, and immediately suggests the presence of $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ cationic moiety, with resonances corresponding to $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}^{*}$ and $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}^{\dagger}$, marked as before. The spectrum bears strong resemblance to the proton spectrum of $\mathbf{6 c}$, in that $\mathrm{H}(11), \mathrm{H}(13)$ and $\mathrm{H}(21), \mathrm{H}(23)$ are not magnetically equivalent. Two singlets are observed at $\delta 6.15$ and 5.96 p.p.m. (corresponding to the former), and two doublets at $\delta 5.99$ and 5.95 p.p.m. (corresponding to the latter indenyl hydrogen atoms).

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (not illustrated) exhibits eight resonances, with two nearly coincident signals. As expected, one resonance does not show coupling to an exo-polyhedral hydrogen atom, that at $\delta-4.29$ p.p.m. (i.e. the highest frequency resonance), assigned to $B(9)$ or $B(11)$.

Figure $3.15{ }^{1} \mathrm{H}$ N.M.R. Spectrum of $\mathbf{8 b}$

The resonance at $\boldsymbol{\delta}-28.39$ p.p.m., corresponding to $\mathrm{B}(10)$, appears as a doublet of doublets in the proton coupled spectrum, the extra doublet coupling ( $\mathrm{J}_{\mathrm{BH}} \mathrm{ca} .30 \mathrm{~Hz}$ ) associated with an endo-hydrogen atom. The latter is observed in the proton spectrum, with a low frequency broad quartet at $\delta-2.30$ p.p.m., which is of equal intergral to the single cage CH atom at $\delta 2.79$ p.p.m.

The postulated structure for 8b, formally 7-Ph-9/11-\{( $\left.\left.\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-7,8$-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, is illustrated in Figure 3.16, and shows substitution by the $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ moiety at either $\mathrm{B}(11)$, which is adjacent to the phenyl-substituted carbon, or $\mathrm{B}(9)$. With the information available $\mathrm{B}(9)$ and $\mathrm{B}(11)$ cannot be distinguished, and so there is some doubt about the exact structural assignment.

Figure 3.16 Proposed Structure of 8b

with substitution at $B(9)$

## Reaction of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with $\mathrm{Tl}_{2}\left[7,8-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2} \mathbf{- 7}, 8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$

" $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " and $\mathrm{Tl}_{2}\left[7,8-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ were stirred together in methylene chloride for fifteen hours, with subsequent work-up involving preparative tlc affording only one isolable product, 9 , in very low yield. This was obtained as a yellow solid, which formed dark yellow microcrystals on slow diffusion of hexane into a methylene chloride solution. The full experimental procedures are detailed in Chapter 5, Section A.

## Characterisation of 9

## Analysis of N.m.r. Spectra

The ${ }^{11}$ B- $\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (seen together with the proton coupled spectrum in Figure 3.17) shows six signals of relative intensity $1: 1: 2: 2: 2: 1$, with frequencies in the range $\delta 10->-20$ p.p.m, suggestive of a closo- $\mathrm{MC}_{2} \mathrm{~B}_{9}$ cage. In contrast to the previous spectra, all nine boron atoms have an associated exo-polyhedral hydrogen atom, as seen in the ${ }^{11} \mathrm{~B}$ spectrum.

Accordingly, the proton spectrum exhibits just one $\eta^{5}$-bonded $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]$ ligand, with signals in the ratio 4:2:1 corresponding to $\mathrm{H}(35-38), \mathrm{H}(31,33)$ and $\mathrm{H}(32)$.

The structure is thus presumably the rhodium analogue of the indenyl cobalt species, 4, i.e. $1,2-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$.

Figure $3.17{ }^{11} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}-\left({ }^{1} \mathrm{H}\right\}$ N.M.R. Spectra of 9

## Reconsideration of the Structure of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ "

Given the variety of products which form as a result of reacting " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with dithallium carbaboranes, the structure of indenyl rhodium dichloride is clearly of a more complex nature than that of its cyclopentadienyl analogues, $[\mathrm{CpRhCl}]_{2}$ and $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$ Although the target compounds, $1,2-\mathrm{R}_{1} \mathrm{R}_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)$-3,1,2-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ have been isolated (where $\mathrm{R}_{1}=\mathrm{H}, \mathrm{R}_{2}$ $=\mathrm{Ph}$, and $\mathrm{R}_{1}=\mathrm{R}_{2}=\mathrm{CH}_{2} \mathrm{OCH}_{3}$ ), these species form in very low yields. Instead, the major products (and even these form in yields less than 10\%) are a series of novel zwitterionic complexes, where a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}$ moiety is $\sigma$-bonded to a $\mathrm{C}_{2} \mathrm{~B}_{9}$ cage, via a C-B bond.

In the light of its reaction chemistry, the structure of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " deserves reconsideration. Although microanalysis consistently confirms an overall stoichiometry of $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}$ (the synthesis has been carried out on a number of separate occasions), and the infrared spectrum of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " suggests that rhodium is bonded both to terminal and bridging chloride ions, it is apparently not as "simple" a polymeric species as its $\left.[\mathrm{CpRhX}]_{2}\right]_{2}$ analogues, wherein polymer formation has been suggested to occur via halide bridges.

The latter amorphous species readily afford monomeric compounds on treatment with donor ligands. For example $[\mathrm{CpRhX}]_{2}(X=\mathrm{Cl})$ reacts with $\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{NC}$, ${ }^{79}$ (CyNC), affording $\mathrm{CyNCRhCpCl}_{2}$, in almost quantitative yield. Similarly, $\left[\mathrm{CpRhX}_{2}\right]_{\mathrm{n}}(\mathrm{X}=\mathrm{I})$, reacts with $\mathrm{Tl}_{2}\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ to give a $30 \%$ yield of 3-Cp-1,2-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11} .{ }^{71}$ The complex reaction products of reactions of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with the latter have already been discussed. In addition the reaction between " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " and CyNC was attempted, also affording a complex number of products, which in this case could not be separated to enable their characterisation. Thus polymer formation in the indenyl species presumably does not
occur by chloride bridging alone.

The fact that a $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moiety is $\sigma$-bonded to a cage boron atom in $\mathbf{6 a}, \mathbf{6 b}, \mathbf{6 c}, \mathbf{7}$ and 8b may imply that $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moieties are also present in the dichloride starting material. This may be envisaged in terms of linking between indenyl ligands, via $\mathrm{C}(2)-\mathrm{C}(2)$ bonds, giving fulvalene-like structures within polymeric chains, as illustrated in Figure 3.18 (the known $\mathrm{Rh}(\mathrm{II})$ fulvalene species, $\mathrm{Rh}_{2}\left({ }^{10}{ }^{10} \mathrm{C}_{10} \mathrm{H}_{8}\right) \mathrm{L}_{4}{ }^{80}$ ( $\mathrm{L}=\mathrm{PPh}_{3}$ ) is shown in Figure 3.19). Indeed, a proton n.m.r. spectrum obtained from a $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ soluble portion of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " exhibits signals which may be attibutable to both $\left\{\mathrm{C}_{9} \mathrm{H}_{7}\right\}$ and $\left\{\mathrm{C}_{9} \mathrm{H}_{6}\right\}$ moieties, with multiplets at $\delta 7.33,7.15$, a doublet at 6.10 , and a multiplet at $c a .6 .02$ p.p.m., corresponding to the former, and a multiplet ( $\delta 6.52$ ) and singlet ( 6.17 p.p.m.) corresponding to the latter (substituted) indenyl moiety. However, it must be stressed that the spectrum contains a number of other (unassignable) signals, and this in any case only represents the methylene chloride soluble portion of the indenyl rhodium dichloride species.

With the available information, it is difficult to arrive at any definite conclusions as to the nature of reaction mechanisms involving a polymer of this type. If " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " does indeed contain fulvalene-like polymeric chains, it is hard to perceive a likely driving force for the formation of B-C bonds, and why the rhodium atom should eventually find itself sandwiched between two indenyl moieties, or, in the case of 6a, between two carbaborane cages. However, all these complexes appear to be high lystable species, and it may be that the formation of structures of this type is thermodynamically (or kinetically) very favourable.

Figure 3.18 Possible Structures for " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ "

Figure 3.19 Structure of $\mathrm{Rh}_{2}\left(\eta^{10}-\mathrm{C}_{10} \mathrm{H}_{8}\right) \mathrm{L}_{4}\left(\mathrm{~L}=\mathrm{PPh}_{3}\right)$

If polymer formation occurs via "inter-indenyl" bonds, one way of obtaining a less polymeric indenyl rhodium dichloride precursor might be to start with methylated indene (e.g. 1,2,3-trimethylindene, or permethylated indene, $\left.\mathrm{C}_{9}\left(\mathrm{CH}_{3}\right)_{7} \mathrm{H}\right)$. Preliminary experiments, involving 1,2,3-trimethylindene, synthesised according to a literature preparation, ${ }^{81}$ have not, however, afforded a single, easily isolable product. This initial experiment was carried out on quite a small scale, and is worth repeating with increased quantities of starting materials. Further reactions involving alternative methylated indenes would also be of interest.

One other possible reason for the formation of the novel zwitterionic species is that " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " contains already intact $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Rh}_{\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)^{+} \text {ions ( } \mathrm{Cl}^{-} \text {counterion), }}$ together with some residual $\mathrm{RhCl}_{3}$ (which would also be consistent with microanalysis figures). The bis-indenyl rhodium fragments may then attack the anionic cage, resulting in the formation of a B-C bond. This theory may be tested quite easily, by a trial reaction of a dithallium carbaborane species with, for example, the chloride salt of $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2} \mathrm{Rh}^{+}$.

## Conclusions

The reaction of freshly distilled indene with $\mathrm{RhCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ affords a product of the empirical formula $\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{RhCl}_{2}$. Subsequent reactions of this species with a series of dithallium carbaborane salts have resulted in the formation of a number of novel indenyl rhodium carbaborane species incorporating a $\left\{\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{Rh}\left(\mathrm{C}_{9} \mathrm{H}_{6}\right)\right\}$ fragment, as well as small amounts of the originally targeted $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}$ indenyl carbarhodaboranes. The initially assigned structure, $\left[\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}\right.$ " , is thus questionable, and, retrospectively, a more complex polymeric composition is postulated.

## Chapter 4

## Transition Metal Derivatives of Diphenylcarbaborane

## Introduction

Prior to the work contained in this Chapter, no transition metal derivatives of diphenylcarbaborane, $1,2-\mathrm{Ph}_{2}-1,2$-closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$, had been reported, although the parent carbaborane has been known for over twenty years. The absence of metal derivatives is to some extent surprising, particularly considering the recently reported application of cage-substituted carbarhodaboranes in homogeneous catalysis, ${ }^{67}$ discussed in more detail towards the end of this Chapter.

For the purposes of this work, the synthesis of a metal derivative of diphenylcarbaborane was first considered in the course of the studies detailed in Chapter 2, in which the conformation of a series of indenyl carbacobaltaboranes is related to the degree of substitution at the cage carbon atoms. However, following a similar reaction procedure to that which afforded 1-4, using the previously unreported dithallium carbaborane, $\mathrm{Tl}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$, the diphenyl-substituted analogue of these species could not be isolated. This was attributed to potentially unfavourable interaction between the phenyl cage substituents and the six-membered ring of the indenyl ligand.

The questions arising from this were (i) to what extent might the presence of two phenyl substituents on the open pentagonal face of $\left[7,8-\mathrm{Ph}_{2}-7,8 \text { - nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]^{2-}$ prevent the formation of other transition metal derivatives of diphenylcarbaborane, and (ii) what possible conformations might the two cage substituents adopt on the incorporation of metal vertices. The syntheses of a series of transition metal derivatives was thus envisaged, involving a variety of metal ligand fragments, starting
with those least likely to have significant interaction with the aryl cage substituents.

However, before considering conformations within metal derivatives of diphenylcarbaborane, a structural determination of the parent closo-carbaborane itself was undertaken, in order to establish the orientation of the phenyl rings, and the effect of their substitution on the overall cage geometry.

## 1,2- $\mathrm{Ph}_{2}-1,2$-closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$, (10)

## Synthesis and Characterisation

Diphenylcarbaborane formed during the reaction between decaborane and diphenylacetylene in the presence of dimethyl sulphide, and was isolated as a white crystalline solid, as described in Chapter 5, Section A. Microanalysis figures were consistent with the expected formulation of 10.

The ${ }^{11} \mathrm{~B}$ n.m.r. spectrum exhibits three resonances in the range $0-10$ p.p.m. with integrals in the ratio $2: 4: 4$, consistent with the anticipated $C_{2 v}$ symmetry of the disubstituted icosahedral cage, assuming two signals (each 2B) are coincident.

## Structural Study on 10

Introduction

Diffraction quality crystals of 10 were grown by the slow cooling of a methanol solution of the compound. Details of the crystallographic procedures and crystal data for the structure may be found in Chapter 5, Section B.

## Discussion

The compound crystallises with two independent molecules, $\mathbf{A}$ and $\mathbf{B}$, per asymmetric unit. The structures of 10A and 10B are shown in Figure 4.1 and Figure 4.2 respectively with the appropriate atomic numbering scheme. All hydrogen atoms are given the same number as the carbon or boron atom to which they are bonded. Table 4.1 lists fractional co-ordinates for the refined atoms of both molcules, Table 4.2 bond distances and selected interbond angles, with respective values for each molecule adjacent for ease of comparison, and Table 4.3 contains anisotropic thermal parameters for all non-hydrogen atoms.

Essentially the structures of the two molecules are very similar, with C-B and B-B distances within each cage having comparable values. However, the cage carbon-carbon distance in $\mathbf{A}$ [1.733(4) $\AA$ ] is significantly longer than that observed in B [1.720(4) $\AA$ ], and in addition, the phenyl ring substituents in the latter structure appear to be twisted relative to the ring systems in the former.

Considering first the $\mathbf{C - C}$ bond distances in both molecules, these are significantly longer than that observed in ortho-carbaborane, $1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ [1.65(5)], and indeed a number of other carbon-substituted 1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10}$ species (e.g. $1,2-\mathrm{Br}_{2}-1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10} \quad[1.63(3)]^{19}$ and $1-\mathrm{Me}-2-$ SiMe $_{3}-1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{2} \mathrm{H}_{10}$ $[1.669(4)]) .^{82}$

However, the long C-C distances observed in diphenylcarbaborane are comparable with those observed in a series of aryl substituted carbaborane species, $\mathrm{R}_{1} \mathrm{R}_{2}-1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$, where $\mathrm{R}_{1}=\mathrm{R}_{2}=\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{O}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{COCH}_{3}$, (a), $\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{O}-\mathrm{C}_{6} \mathrm{H}_{5}$, (b) and $\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{COCH}_{3}$, (c), which have cage C - C distances of 1.735(3), 1.736(4) and 1.747(4) $\AA$ respectively. ${ }^{83}$ The structures of these compounds are of interest as they model some carbaborane-bearing units of polyarylene materials. Notably, when the phenyl group of the last of these three species is replaced by a methylene group, i.e. where $\mathrm{R}_{1}=\mathrm{R}_{2}=\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{COCH}_{3}$, (d), the $\mathrm{C}-\mathrm{C}$ distance is significantly lower [1.68(1) $\AA$ ].

It is interesting to compare the structures of the latter two compounds, $\mathbf{c}$ and d , shown below. In $\mathbf{c}$, as indeed in $\mathbf{a}$ and $\mathbf{b}$, the phenyl groups directly bonded to the cage adopt a similar conformation relative to each other as that observed in the structures of $\mathbf{1 0 A}$ and 10B, In molecule d, however, the six-membered rings are separated from the cage carbon atoms by $\mathrm{CH}_{2}$ groups, rendering the pendent functions greater flexibility. As a result the aromatic rings are orientated in opposite directions to each other, with planes through their $\mathrm{C}_{6}$ rings almost parallel with the cage C - C bond.

c

Thus it would appear that when aromatic substituents are closely situated in space, an elongation of the cage $\mathrm{C}-\mathrm{C}$ distance occurs, whereas when they can lie remote from each other, as in d, the C-C distance is significantly shorter, and close to the bond length observed in ortho-carbaborane. Presumably the long C-C distances observed (in 10A, 10B, a, b and c) reflect repulsions between the $\pi$ systems of the aromatic rings.

In considering the conformation of the phenyl rings substituents in these carbaborane species, the twisting of the six-membered ring systems may be defined in terms of an angle $\theta$, the average deviation away from a $90^{\circ}$ torsion about the $C(1)-C(11)$ and $C(2)-C(12)$ bonds. Essentially the torsion angle is the angle between planes defined by $C(1), C(2), C(21)$ and $C(2), C(21), C(22) / C(26)$ [or $C(2), C(1), C(11)$ and $\mathrm{C}(1), \mathrm{C}(11), \mathrm{C}(12) / \mathrm{C}(16)]$.

In A neither of the phenyl rings is substantially twisted, with the planes through $C(11 A-16 A)$ and $C(21 A-26 A)$ lying only 3 and $1^{\circ}$, respectively, away from what may be termed the "normal" postion $\left(\theta=0^{\circ}\right)$. However, in $B$ the twist in both phenyl rings is substantially greater, with $C(11 B)-C(16 B)$ and $C(21 B)-C(26 B)$ twisted synchronously, by 9 and $7^{\circ}$ respectively (the measured distances between $\mathrm{C}(12 \mathrm{~B})$ and $C(22 B)$ and $C(16 B)$ and $C(26 B)$ having similar values). Recalling that the cage $C-C$ distance in $\mathbf{B}$ is significantly shorter than that in $\mathbf{A}$, there appears to be a correlation between the length of the cage C-C bond, and the degree of twisting exhibited by the phenyl substituents. In an attempt to rationalise this, the following factors are considered.

A combination of the cage $\mathrm{C}-\mathrm{C}$ bond length, and the $\mathrm{C}-\mathrm{C}-\mathrm{C}_{\text {phenyl }}$ bond angles result in variable distances between the pivotal phenyl carbon atoms, $\mathrm{C}(11)$ and $C(21)$. This distance represents the closest contact of the phenyl substituents, and thus is the source of the greatest crowding in the molecule. In A, where the
$C(2)-C(1)-C(11)$ and $C(1)-C(2)-C(21)$ angles are $119.50(26)$ and $119.75(25)^{\circ}$, the $\mathrm{C}(11) \cdots \mathrm{C}(21)$ distance is $3.220(5) \AA$, whereas in B , where $\mathrm{C}(2 \mathrm{~B})-\mathrm{C}(1 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})$ and $\mathrm{C}(1 \mathrm{~B})-\mathrm{C}(2 \mathrm{~B})-\mathrm{C}(21 \mathrm{~B})$ are $118.82(25)$ and $118.49(25)^{\circ}$ respectively, $\mathrm{C}(11 \mathrm{~B}) \cdots \mathrm{C}(21 \mathrm{~B})$ is 3.160 (4). A rough estimate of the degree of crowding of the $\pi$-systems of the two phenyl rings may be made by calculating $\mathbf{x}$, the average length of the normal to the $\mathrm{C}_{\text {cage }}-\mathrm{C}_{\text {phenyl }}$ vector, as sketched below:

Given that half the thickness of the phenyl $\pi$-system is approximately $1.675 \AA$, if the distance $\mathbf{x}$ is close to this value, significant crowding of the two phenyl rings may be expected. The value of $\mathbf{x}$ in $\mathbf{B}(1.80 \AA)$ is shorter than that calculated for $\mathbf{A}(1.85 \AA)$, suggesting potentially greater steric strain in the former. However, the synchronous twisting of the ring systems will reduce the potentially unfavourable overlap of the p-orbitals on each pivotal carbon atom, which may explain why the cage C-C distance, and the resulting value of $\mathbf{x}$, are smaller in $\mathbf{B}$.

A series of EHMO calculations was performed on an idealised model of diphenylcarbaborane, in which the two phenyl substituents were synchronously rotated about $\mathrm{C}(1)-\mathrm{C}(11)$ and $\mathrm{C}(2)-\mathrm{C}(21)$ (labelled $\mathrm{C} 9, \mathrm{C} 91$ and $\mathrm{C} 12, \mathrm{C} 121$ in the
model). The sum of one-electron energies (i.e. the relative energy of the system) was monitored as a function of the increasing degree of twist $(\theta)$ away from a $90^{\circ}$ torsion about $C(1)-C(11)$ and $C(2)-C(21)$. The results are plotted in Figure 4.3.

## Figure 4.3 Energy Plot for the Idealised Model of 10

Although the change in energy is small (well within crystal packing forces), there is none the less a gradual decrease in the overall energy of the system as the phenyl groups twist in the same direction, until the adjacent ortho hydrogen atoms on either ring begin to come into close contact, at $\theta=c a .60^{\circ}$.

Thus far it has been assumed that the increased C-C bond length in diaryl-substituted carbaboranes is a result of the steric repulsions between closely situated aromatic systems. It may also be the case, however, that the phenyl
substituents exert an electronic influence on the carbon-carbon bond. As the above EHMO calculations give a value for the reduced orbital overlap population between atoms (which is a crude measure of the bond strength), the degree of orbital overlap between the cage atoms in the model of diphenylcarbaborane can be compared with values obtained for similar models of 1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ and 1- Ph -1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ (when all phenyl substituents are similarly orientated, with $\theta=0^{\circ}$ ). The respective values of $0.6321,0.4665$ and 0.4525 , imply that, everything else being equal, substitution by phenyl substituents at the cage carbon atoms should in fact strengthen the $\mathrm{C}-\mathrm{C}$ bond, particularly in the case of diphenylcarbaborane.

This suggests that the cage C-C bond distance ( $1.750 \AA$ ) used in the idealised model of the icosahedral cage may, to some extent, be "masking" the steric interaction between the phenyl rings. Thus, in the calculation of orbital overlap, the degree of steric interaction has not been such that the electronic preference for a shorter bond has been countered. Similarly, the energy curve shown in Figure 4.3 may also be somewhat unrealistic, as the long C-C bond length used in the calculations may result in the steric interactions being underestimated. In the real molecules, 10A and 10B, where the cage C-C distances are significantly shorter, a greater variation in the relative energy of the system might be expected as the phenyl rings twist about the $\mathrm{C}(1)-\mathrm{C}(11)$ and $\mathrm{C}(2)-\mathrm{C}(21)$ bonds.

It is worth noting that the reduced overlap population between cage carbon atoms in diphenylcarbaborane slightly decreases (from 0.6321 to 0.6296 ) at $\theta=90^{\circ}$, i.e. when a greater degree of steric interaction occurs in the model.

In conclusion, the introduction of two phenyl functions at the cage carbon atoms has resulted in a significantly longer cage $\mathrm{C}-\mathrm{C}$ bond length in both molecules of $\mathbf{1 0}$ relative to ortho-carbaborane, and this may be attributed to the unfavourable mutual interaction between the $\pi$-systems of the six-membered rings. Moreover, the greater
degree of twisting observed in the phenyl substituents in B, compared to $\mathbf{A}$, is clearly correlated with the shorter distance between the cage carbon atoms in the former.

## 7,8- $\mathrm{Ph}_{2}-10$-endo- $\mathrm{Ph}_{3} \mathrm{PHg}$-7,8-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, (11)

## Introduction

The $\mathrm{d}^{10}$ carbametallaborane species, 10 -endo- $\mathrm{Ph}_{3} \mathrm{PHg}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$, was the first reported example of a pseudo $\sigma$-bonded carbametallaborane. ${ }^{37}$ The mercury atom is co-ordinated almost linearly by triphenylphosphine and the unique boron atom $[\mathrm{B}(10)]$ of the open $\mathrm{C}_{2} \mathrm{~B}_{3}$ face, with additional, though relatively weak, bonding suggested by the other $\mathrm{Hg}-\mathrm{B}$ (facial) distances. Given the substantial slippage of the metal atom away from the carbon atoms in this species, the attempted synthesis of a diphenyl-substituted analogue was considered an appropriate start to a series of transition metal derivatives of diphenylcarbaborane. Compared with other possible moieties, a $\sigma$-bonded linear metal ligand fragment is less likely to interact significantly with the aromatic cage substituents.

## Synthesis and Spectroscopic Analysis

The reaction of $\left[\mathrm{Ph}_{3} \mathrm{PHgCl}_{2}\right]_{2}$ and $\mathrm{Tl}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ in methylene chloride gave a cream coloured solid, a methylene chloride solution of which afforded pale yellow crystals which were subsequently identified as being the target compound, 11.

An ${ }^{11} B$ n.m.r. spectrum of a solution of these crystals exhibits doublet $\left({ }^{1} J_{B H}\right.$ $120-150 \mathrm{~Hz}$ ) signals in the frequency range $-11--29$ p.p.m. of relative integral $5: 2: 1: 1$, consistent with the substituted $C_{2} B_{9}$ cage having a plane of symmetry (assuming three coincident resonances occur at $\delta-11.2$ p.p.m.)

## Structural Study on 11

## Introduction

A crystal structure determination on 11 was carried out in order to confirm the geometry of the cage and establish the orientation of the phenyl cage substituents relative to the $C_{2} B_{3}$ carbaborane face and to the exopolyhedral metal ligand group. Diffraction quality crystals of the compound were obtained by the slow evaporation of a methylene chloride solution. Full details of the crystallographic procedures and crystal data may be found in Chapter 5, Section B.

## Discussion

Figure 4.4 represents a perspective view of a single molecule of 11, which clearly shows the orientation of the phenyl cage substituents, whilst an alternative view is shown in Figure 4.5. Atomic co-ordinates for refined atoms are given in Table 4.4, bond distances and selected interbond angles in Table 4.5, and anisotropic thermal parameters for all non-hydrogen atoms are listed in Table 4.6.

The structure of $\mathbf{1 1}$ is generally analogous to that of the previously determined analogue with a $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ cage. The mercury atom is essentially endo $\sigma$-bonded to $\mathrm{B}(10)$, with a $\mathrm{B}(10)-\mathrm{Hg}$ bond length of $2.178(8) \AA$. The metal atom may also be regarded as being weakly bonded to the other two facial boron atoms, with $\mathrm{Hg}-\mathrm{B}(9)$ and $\mathrm{Hg}-\mathrm{B}(11)$ distances of $2.617(7)$ and $2.535(8) \AA$ respectively. Compared with the unsubstituted species, the metal fragment is slipped slightly further away from the cage carbon atoms, with a shorter $\mathrm{Hg}-\mathrm{B}(10)$, and longer $\mathrm{Hg}-\mathrm{B}(9), \mathrm{Hg}-\mathrm{B}(11)$ distances, respective distances in the former species being 2.20(2), 2.50(2) and 2.53(2) $\AA$.

Figure 4.4 Perspective View of $7,8-\mathrm{Ph}_{2}$-10-endo- $\mathrm{Ph}_{3} \mathrm{PHg}-7,8$-nido $-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (11)

Figure 4.5 Alternative view of 7,8- $\mathrm{Ph}_{2}$-10-endo- $\mathrm{Ph}_{3} \mathrm{PHg}$-7,8-nido- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (11)

Presumably the relatively larger angles $\mathrm{Hg}-\mathrm{B}(10)-\mathrm{B}(11)$ and $\mathrm{Hg}-\mathrm{B}(10)-\mathrm{B}(9)$ [80.4(4) vs 75.9(10) ${ }^{\circ}$ and 77.7 vs $\left.75.5(6)^{\circ}\right]$ in 11 are related to the slight increase in slippage of the latter species. Mercury-carbon(facial) separations of 3.117(6) [C(7)-Hg] and 3.072 [ $\mathrm{C}(8)-\mathrm{Hg}]$ correspond to essentially non-bonding interactions. Consistent with the $\sigma$-bonded description, the hydrogen atom $\mathrm{H}(10)$ is displaced downward from its normal radial position, at an angle of $9.15^{\circ}$, whilst $\mathrm{H}(9)$ and $\mathrm{H}(11)$ subtend angles of 22.10 and $20.52^{\circ}$ respectively (elevation angles defined in Chapter 1).

The distance between the cage carbon atoms is at first sight surprisingly short, when compared with that observed in both independent molecules of $\mathbf{1 0}$, given the anticipated steric repulsions between closely situated aromatic ring systems. However, this distance, coupled with the distortion in C-B and B-B distances within the $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagonal face, relative to those observed in closo- $\mathrm{MC}_{2} \mathrm{~B}_{9}$ carbametallaboranes, are generally comparable with the unsubstituted analogue, and indeed [10-endo-H-7,8-nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-33}$, and the recently reported anionic gold (I) species, $\left[10 \text {-endo }-\mathrm{Ph}_{3} \mathrm{PAu}-7,8 \text {-nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-25}$ Table 4.7 shows comparative distances of the $\mathrm{C}_{2} \mathrm{~B}_{3}$ facial $\mathrm{C}-\mathrm{C}, \mathrm{B}-\mathrm{C}$ and $\mathrm{B}-\mathrm{B}$ distances in 1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$, 10-endo- $\mathrm{Ph}_{3} \mathrm{PHg}-7,8$-nido- $\mathrm{C}_{2}-\mathrm{B}_{9} \mathrm{H}_{11}$ and their diphenyl-substituted analogues, 10 (with average values for molecules $\mathbf{A}$ and $\mathbf{B}$ ), and 11 . In the closo species, the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face is that capped by BH and thus the table shows the change in bond distances on replacing a BH vertex, essentially centrally located above the $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagon, with a $\sigma$-bonded $\mathrm{Ph}_{3} \mathrm{PHg}$ fragment, i.e.:

Table 4.7

| $\mathbf{X}$ | $\mathbf{R}$ | $\mathbf{C - C}(\AA)$ | $\mathbf{B}-\mathbf{C}(\AA)$ | $\mathbf{B - B}(\AA)$ |
| :---: | :---: | :---: | :---: | :---: |
| BH | H | 1.66 | 1.72 | 1.79 |
| BH | Ph | 1.73 | 1.72 | 1.77 |
| $\mathrm{Ph}_{3} \mathrm{PHg}$ | H | 1.54 | 1.61 | 1.86 |
| $\mathrm{Ph}_{3} \mathrm{PHg}$ | Ph | 1.58 | 1.63 | 1.85 |

The origin of the structural change in the slipped carbametallaboranes relative to "true" closo species has been previously considered, on the basis of the results of a charge-iterated EHMO calculation on $\left[7,8 \text {-nido }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-25}$ A sketch diagram of the frontier orbitals so generated is found in Figure 4.6. When a BH vertex occupying a central position above the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face is replaced by a metal ligand fragment, which is slipped towards the unique facial boron atom, $\mathrm{B}(10)$ (using the nido numbering convention), the resulting distortions can be explained as follows:

1) The B-B distances lengthen due to the increased depopulation of $\Psi_{3}$ outweighing the decreased population of $\psi_{1}$, as $\psi_{3}$ is heavily localised on $\mathrm{B}(9), \mathrm{B}(10)$
and $B(11)$,
2) the B-C bonds shorten, as changes in population of all three orbitals act in concert, and
3) the C-C bond shortens, as the decreased population of $\Psi_{1}$ (localised on the carbon atoms) overrides the the effects of changes in populations of $\Psi_{2}$ and $\Psi_{3}$ (which are both localised on the boron atoms).

Figure 4.6 The Occupied $\pi$-Frontier Molecular Orbitals of $\left[7,8 \text {-nido- } \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$

The cage C-C distance in 11 is, however, significantly longer than that observed in the unsubstituted carbamercuraborane, and this may be attributed to the steric repulsions of the phenyl cage substituents, which are obviously brought into very close proximity. The distance between $C(71)$ and $C(81)$ is $3.038 \AA$ and the $C(7)-C(8)-C(81)$ and $C(8)-C(7)-C(71)$ angles have values of 118.17 and $119.02^{\circ}$, giving a value of $\mathbf{x}$ of just $1.73 \AA$ (see earlier for a pictorial definition of $\mathbf{x}$ ). This distance is almost equivalent to the half thickness of a phenyl ring, implying potentially significant interaction between the two $\pi$-systems. The synchronous twisting of the aryl functions, which have torsions of $30^{\circ}[\mathrm{C}(71)-\mathrm{C}(76)]$ and $28^{\circ}$ [C(81)-C(86)] away from the normal position, presumably reduces the overlap of these p-orbitals, and thus relieves the steric strain in the molecule.

The closest contact between the cage-substituted phenyl groups and the triphenylphosphine ligand is that between $\mathrm{H}(85)$ and $\mathrm{H}(16)$ ( $2.40 \AA$ ), with no other significant interactions. This suggests that the twisting of the cage aryl functions has more to do with the steric repulsion within the carbaborane moiety itself, than the presence of the metal ligand fragment above the $C_{2} B_{3}$ face.

In conclusion, the structural study of 11 has shown that the "substitution" of a BH vertex in the closo carbaborane, 10 , by a $\sigma$-bonded mercury triphenylphosphine group has resulted in a distortion in the $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagon. The substantial shortening of the $\mathrm{C}-\mathrm{C}$. bond in 11 has resulted in the increased twist of the two aryl functions, which reduces the unfavourable interaction between adjacent $\pi$-systems.

## Syntheses of 1,2-Ph $\mathbf{2}_{2}$-3-( $\left.\eta-L\right)$-3,1,2-closo- $\mathrm{MC}_{2} \mathrm{~B}_{9}$ species

The first reported example of a transition metal derivative of diphenylcarbaborane described in the previous section incorporates a $\sigma$-bonded linear metal ligand fragment. Subsequently, some attention has been focused on the synthesis of complexes incorporating a conical metal ligand fragment, where the metal would occupy a central position above the open $\mathrm{C}_{2} \mathrm{~B}_{3}$ carbaborane face, thus forming a closed icosahedral carbametallaborane. As 3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}{ }^{84}$ (p-cymene $=\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHC}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}$ ) and 3-Cp*-3,1,2-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}{ }^{73}$ are reported to form in high yields, the syntheses of the diphenyl-substituted analogues of these, $1,2-\mathrm{Ph}_{2}-3$-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ and 1,2- $\mathrm{Ph}_{2}-3-\mathrm{Cp}^{*}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, were undertaken.

1,2- $\mathrm{Ph}_{2}$-3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, (12)

## Synthesis

[ $\left.(p-c y m e n e) \mathrm{RuCl}_{2}\right]_{2}$ and $\mathrm{T}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ were stirred together in methylene chloride for fifteen hours, and following work-up involving preparative tlc the target compound, 12 , was isolated as an orange solid.

## N.m.r. Studies

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ n.m.r. spectrum (shown together with the proton coupled spectrum in Figure 4.7) exhibits six resonances in the ratio 1:2:1:2:2:1, suggesting the molecule has a plane of symmetry. All boron nuclei show coupling to an exo-hydrogen atom ( $\mathrm{J}_{\mathrm{BH}}$ ca. 150 Hz ). Notably the signals are shifted to higher frequency relative to those in the previously assigned spectrum of the related species, 3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ( $\delta-20.1-+30.3$ compared with $-24.0-+4.2$ p.p.m respectively, a point which will be discussed in more detail later in this

Chapter.

The ${ }^{1} \mathrm{H}$ spectrum of 12 is shown in Figure 4.8 and exhibits well resolved signals for the ortho, meta and para hydrogen atoms of the phenyl cage substituents, together with characteristic resonances for an $\eta^{6}$-bonded $p$-cymene ligand, which are marked on the spectrum. The aromatic p-cymene protons, $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{b}}$ (see diagram below), are magnetically inequivalent and give rise to the $A B$ pattern observed at $\delta 5.38$ and 5.13 p.p.m

However, the fact that both $\mathrm{H}^{\mathrm{a}}$ protons and both $\mathrm{H}^{\mathrm{b}}$ protons are themselves equivalent, coupled with the observed molecular symmetry in the ${ }^{11} B$ spectrum, suggests either that the p-cymene ligand is rapidly rotating about the $\operatorname{Ru}(3) \cdots \cdot B(10)$ axis, or that the molecule has an essentially static, symmetric structure, as depicted below:

Given the likely steric interaction between the carbaborane phenyl substituents and the exo-polyhedral aromatic ligand, the latter static representation is perhaps more plausible.

Figure $4.8{ }^{1} \mathrm{H}$ N.M.R. Spectrum of 12

Figure $4.7{ }^{11} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ N.M.R. Spectra of 12

## 1,2- $\mathrm{Ph}_{2}-3-\mathrm{Cp}^{*}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, (13)

## Synthesis

The target complex, 13, was prepared using a similar procedure to that which afforded the related ruthenium species, 12 , specifically the reaction of $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}$ with $\mathrm{Tl}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ in methylene chloride. The compound was isolated as a red solid by preparative tlc. Microanalysis figures were fully consistent with the expected formulation.

## N.m.r. Studies

The ${ }^{1} \mathrm{H}$ spectrum contains resonances in the aromatic region consistent with the two phenyl cage substituents, as well as a single resonance at $\delta 1.29$ p.p.m., corresponding to the methyl protons of the $\mathrm{Cp}^{*}$ ligand.

The ${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}$ n.m.r. spectrum exhibits six resonances in the ratio $1: 1: 2: 2: 2: 1$, with all boron nuclei showing coupling to an exo-hydrogen atom in the proton coupled spectrum. As in the spectrum of $\mathbf{1 2}$ the chemical shift values are at consistently higher frequency than those observed in the spectrum of $3-\mathrm{Cp}^{*}-3,1,2-$ closo $-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$, as indicated in Table 4.8, which also gives the chemical shift values for compound 10 compared with its unsubstituted analogue. ${ }^{85}$ Whilst substitution of the phenyl groups at the cage carbon atoms results in a slight movement to higher frequency of the resonances of $\mathbf{1 0}$, the presence of the substituents in 13 (and indeed 12) appears to have a more significant effect on the pattern of boron resonances.

## Structural Study on 13

## Introduction

In order to determine the orientation of the phenyl rings relative to each other and the cage, in the presence of the $\mathrm{Cp}^{*} \mathrm{Rh}$ fragment, and the overall cage geometry, a structural determination of $\mathbf{1 3}$ was considered to be of potential interest. Diffraction quality crystals were grown by slow diffusion of hexane into a methylene chloride solution at $-30^{\circ} \mathrm{C}$. Details of crystal data collection and structure refinement are contained in Chapter 5, Section B.

## Discussion

Compound 13 crystallises with two independent, though essentially similar, molecules per asymmetric unit, 13A and 13B. Perspective views of these are shown in Figure 4.9 and Figure 4.10 respectively, with both molecules labelled similarly with cage and phenyl hydrogen atoms given the same number as the carbon or boron atom to which they are bound. Figure 4.11 and Figure 4.12 illustrate plan views of molecule A and B respectively, with all but the five metalla-bonded cage atoms removed for clarity, showing the appropriate numbering scheme for the $\mathrm{Cp}{ }^{*}$ ligands. Methyl hydrogen atoms are assigned the number of the carbon atom to which the methyl group is bound, together with the letter $A, B$ and $C$ (molecule $A$ ) or $X, Y, Z$ (molecule B). Table 4.9 gives co-ordinates for refined atoms, Table 4.10 selected bond distances and interbond angles (equivalent values for either molecule adjacent), and Table 4.11 lists anisotropic thermal parameters for appropriate atoms.
$1,2-\mathrm{Ph}_{2}-3-\mathrm{Cp}^{*}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ clearly has a quite distorted geometry compared with that of previously determined closo $\mathrm{MC}_{2} \mathrm{~B}_{9}$ carbametallaboranes, with essentially non-bonding interactions between $\mathrm{C}(1 \mathrm{~A})$ and $\mathrm{C}(2 \mathrm{~A})$ [2.51(3) $\AA$ ] and between $\mathrm{C}(1 \mathrm{~B})$ and $\mathrm{C}(2 \mathrm{~B})[2.50(3) \AA]$. As a result of this deformation, $\mathrm{B}(6)$, in both molecules, is, as it were, pulled out of the plane of atoms $B(5), B(9), B(11)$ and $B(12)$, such that the angle between this plane and that defined by $B(5), B(6)$ and $\mathrm{B}(11)$ is $15.5^{\circ}$ and $22.6^{\circ}$ in molecules $\mathbf{A}$ and $\mathbf{B}$ respectively. This gives rise to relatively short cage $\mathrm{C}-\mathrm{B}$ distances, compared with those in the unsubstituted analogue, e.g. in molecule $\mathrm{A} \mathrm{C}(1 \mathrm{~A})-\mathrm{B}(5 \mathrm{~A})=1.50(3), \mathrm{C}(2 \mathrm{~A})-\mathrm{B}(11 \mathrm{~A})=1.52(2) \AA$ and in molecule $\mathrm{B} C(1 \mathrm{~B})-\mathrm{B}(5 \mathrm{~B})=1.61(3), \mathrm{C}(2 \mathrm{~B})-\mathrm{B}(11 \mathrm{~B})=1.64(3) \AA$. Moreover generally longer $\mathrm{B}-\mathrm{B}$ distances to $\mathrm{B}(6)$ are observed, with $\mathrm{B}(6 \mathrm{~A})-\mathrm{B}(10 \mathrm{~A})=1.82(3) \AA$ and $B(6 B)-B(10 B)=1.93(3) \AA$.

Despite the distorted cage geometry $C(1 A), C(2 A), B(4 A), B(7 A)$ and $B(8 A)$ and $C(1 B), C(2 B), B(4 B), B(7 B)$ and $B(8 B)$ are essentially co-planar, making angles of 4.2 and $1.7^{\circ}$ with their respective lower four atom belt, and $\mathrm{Rh}(3 \mathrm{~A})$ and $\mathrm{Rh}(3 \mathrm{~B})$ are still quite definitely $\eta^{5}$-bonded to the open (albeit distorted) pentagonal rings, with average $\mathrm{Rh}-\mathrm{B} / \mathrm{C}$ distances of 2.16 and $2.18 \AA$ respectively. The $\mathrm{Rh}(3 \mathrm{~A})-\mathrm{B}(6 \mathrm{~A})$ and $\mathrm{Rh}(3 \mathrm{~B})-\mathrm{B}(6 \mathrm{~B})$ distances are 2.92(2) and 2.91(3) $\AA$ respectively, which are shorter than that usually observed in more regular icosahedra, but still too long to be considered bonding interactions.

The very long cage carbon atom separation can be readily understood by considering the orientation of the phenyl cage substituents, which is best represented in Figure 4.12 and Figure 4.13. In molecule $A$ the aromatic rings $C(11 A-16 A)$ and $\mathrm{C}(21 \mathrm{~A}-26 \mathrm{~A})$ are twisted by ca. 78 and $87^{\circ}$ respectively away from the normal position (as defined for 10 and 11), presumably as a result of the presence of the bulky Cp* ligand. It therefore appears that the steric interaction between the two rings has forced the cage carbon atoms apart. In fact, even with the unusually long $\mathrm{C}(1 \mathrm{~A})-\mathrm{C}(2 \mathrm{~A})$ distance, there is an extremely close $\mathrm{H}(12 \mathrm{~A}) \cdots \cdot \mathrm{H}(22 \mathrm{~A})$ contact of $1.71 \AA$ (significantly less than the sum of the van der Waals radii for two hydrogen atoms, $2.2 \AA$ ), suggesting some substantial steric strain in the molecule. Similarly in molecule $B$ the phenyl rings $C(11 B-16 B)$ and $C(21 B-26 B)$ are twisted by 79 and $86^{\circ}$ respectively, with a distance of only $1.85 \AA$ between $\mathrm{H}(12 \mathrm{~B})$ and $\mathrm{H}(22 \mathrm{~B})$.

In both molecules the methyl carbon atoms do not lie in the plane of the $\mathrm{C}_{5}$ pentagon, but are generally elevated above it, although EHMO studies have indicated that, in the absence of steric influences, the optimum conformation for a five-membered cyclic ligand is that in which ring substituents are coplanar with the pentagonal ring. ${ }^{86}$ In molecule $\mathrm{A} \mathrm{C}(311), \mathrm{C}(321)$ and $\mathrm{C}(331)$ are at angles of 7.4, 10.0 and $5.5^{\circ}$ to the $\mathrm{C}_{5}$ plane, these carbon atoms being those nearest the phenyl cage substituents, with $C(341)$ and $C(351)$ marginally below this plane. In molecule $B$
$C(312), C(322)$ and $C(332)$ are also elevated above the $C(31 B-35 B)$ plane, at angles of $5.8,4.2$ and $2.3^{\circ}$ respectively, although in this case $C(342)$ and $C(352)$ also lie above the plane, at angles of 4.8 and $6.3^{\circ}$ respectively. On the whole greater deviation from planarity occurs when the methyl carbon atoms are closer in space to the aromatic rings, and thus these observations may be attributed to steric crowding between the exo-polyhedral ligand and the cage substituents, even though the phenyl rings are substantially less elevated above the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face than is normally expected for cage substitiuents (i.e. $\mathrm{C}(11 \mathrm{~A})$ and $\mathrm{C}(21 \mathrm{~A})$ subtend elevation angles of 17.2 and $14.0^{\circ}$ respectively, and $C(11 B)$ and $C(21 B)$ subtend angles of 14.7 and $20.5^{\circ}$ respectively).

The distortion of this twelve-vertex carbametallaborane can be compared with that observed in the structure of the bimetallic system, $\mathrm{PtW}(\mathrm{CO})_{2}\left(\mathrm{PEt}_{3}\right)_{2}\left\{\eta^{6}-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{8}\left(\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}\right) \mathrm{Me}_{2}\right\},{ }^{87}$ shown in Figure 4.14 below..

Figure 4.14 Structure of $\mathrm{PtW}(\mathrm{CO})_{2}\left(\mathrm{PEt}_{3}\right)_{2}\left(\eta^{6}-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{8}\left(\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}\right) \mathrm{Me}_{2}\right\}$

This species has been formally assigned an iso-closo cage geometry, in which the tungsten atom can be regarded as capping an open six-membered face of the carbaborane moiety. The cage carbon atom separation is $2.88 \AA$ and $B(6)$ has been effectively drawn up towards the open face of the ligand, such that the $\mathrm{W}-\mathrm{B}(6)$ distance is $2.51 \AA$, and the metal atom is essentially ligated by all six atoms $C(1)$, $C(2), B(4), B(7), B(8)$, and $B(6)$. However, there is some variation in bond lengths, with $\mathrm{C}(1)-\mathrm{W}$ and $\mathrm{C}(2)-\mathrm{W}$ being $2.02(2)$ and $2.04(2) \AA$ compared with $\mathrm{W}-\mathrm{B}(4)(2.40 \AA)$ and $W-B(6)$. In addition the angle between $B(5), B(9), B(11)$ and $B(12)$ and $B(5)$, $B(11)$ and $B(6)$ is $24.5^{\circ}$ (slightly greater than that observed in $13 A$ and $13 B$ ), resulting in long $\mathrm{B}(6)-\mathrm{B}(5), \mathrm{B}(11)$ and $\mathrm{B}(10)$ distances of $1.95(3), 1.95(3)$ and 1.93(3) $\AA$ respectively.

The extent of opening of the $\mathrm{M}, \mathrm{C}(1), \mathrm{C}(2), \mathrm{B}(6)$ portion of the cages of 3-Cp ${ }^{*}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}, 13$ and the bimetallic iso-closo species is illustrated in Figure 4.15. The structure of 13 , which has molecular dimensions of intermediate value between iso-closo structure and the more regular closo species, may therefore be described as having a pseudo-closo cage geometry. Although similar distortion away from "true" closo geometry occurs in the latter two species, the reasons for this are quite different. Whilst in $\mathbf{1 3}$ the unusually long cage C - C distance results from the mutual repulsions of the adjacent phenyl substituents, the distortion in the carbawolfraborane is thought to be caused by the $\mathrm{d}^{4}$ metal atom preferring to be sevenco-ordinate.

Figure 4.15 Extent of Cage Opening in Twelve Vertex Polyhedra

3-Cp*-3,1,2-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$

1,2- $\mathrm{Ph}_{2}-3-\mathrm{Cp}^{*}-3,1,2$-pseudo-closo $-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$, (13)

$\mathrm{PtW}(\mathrm{CO})_{2}\left(\mathrm{PEt}_{3}\right)_{2}\left(\eta^{6}-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{8}\left(\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}\right) \mathrm{Me}_{2}\right\}$

Interestingly, the ${ }^{11} \mathrm{~B}$ n.m.r spectrum of the carbawolfraborane has a similar spread of chemical shift values as that observed in the spectrum of 13 , with one particularly high frequency signal at +28.9 p.p.m., attributed to $\mathbf{B}(8)$. Thus the quite substantial shift in the boron resonances of the latter, compared with the unsubstituted analogue (see Table 4.8), may to some extent be linked to the distortion of the polyhedron. This is not unduly surprising, as a change in the electronic distribution within the cage can indeed be expected to accompany a partial "opening" of the cage.

## Suggestions for Further Work

In the light of this unprecedented structure, those of further carbametallaboranes in this series deserve future investigation. Obviously the structure of the (p-cymene)Ru analogue will now be of interest, especially given the similarities in the resonance patterns observed in the ${ }^{11} \mathrm{~B}$ n.m.r. spectra of 12 and 13 . The synthesis of a hexamethylbenzene analogue of $\mathbf{1 2}$ should result in a complex having similar or possibly even greater steric overcrowding than the $\mathrm{Cp}^{*} \mathrm{Rh}$ complex, and this may give rise to further distortion away form a "normal" closo cage geometry towards a twelve vertex iso-closo arrangement.

In addition, it would be of interest to attempt the synthesis of 1-R ${ }^{1}$-2- $\mathrm{R}^{2}-3,3-\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2}-3-\mathrm{H}-3,1,2$-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ (where $\mathrm{R}^{1}=\mathrm{R}^{2}=\mathrm{Ph}$ ) as species of this general type have been shown to be potential catalysts in, for example, alkene hydrogenation and isomerisation. ${ }^{67}$ Successful catalysis requires the (reversible) formation in solution of a catalytically active exo-nido species, which is illustrated overleaf:

exo-nido
closo

Catalytic activity of the system may be improved by increasing the steric bulk of the carbaborane cage substituents, which increases the concentration of the exo-nido species. A diphenyl derivative of this carbarhodaborane may well therefore exhibit some interesting catalytic properties.

## Conclusions

The work contained in this Chapter has shown the somewhat surprising flexibility of twelve-vertex polyhedral systems incorporating two adjacent phenyl substituents. In the parent carbaborane, 10 , the cage carbon carbon distance is longer than that observed in unsubstituted ortho-carbaborane, which may be attributed to a certain degree of repulsion between the $\pi$-systems of the phenyl ring substituents. In the case of the carbamercuraborane, 11, where a $\eta^{5}$-bonded BH vertex has been "replaced" by a pseudo $\sigma$-bonded $\mathrm{Ph}_{3} \mathrm{PHg}$ fragment, the cage carbon atoms are drawn closer together by electronic factors, and the phenyl rings twist synchronously by ca. $30^{\circ}$ away from the normal position observed in 10 A , presumably to alleviate some substantial strain between the phenyl rings.

In the presence of an $\eta^{5}$-bonded $\mathrm{Cp}{ }^{*} \mathrm{Rh}$ moiety above the open face, the twisting of the phenyl rings, by almost $90^{\circ}$, to accommodate the metal ligand fragment, has caused substantial distortion in the cage, with the carbon atoms forced apart, such that they are essentially non-bonding. This has necessitated the term pseudo-closo to describe this novel twelve-vertex carbarhodaborane.

## Chapter 5

## Experimental

As I went along I rehearsed what I meant to do, for I knew how easy it is, in the excitement of doing something for the first time, to forget the proper way to do it, the separate stages and which follows which. More than once I had known perfectly, in theory, how to do a chemistry experiment, but when confronted by the bunsen burner and the tube and all the rest of it, so different in reality from what they had been in thought, I had lost my head and made a mess of it.
L.P.Hartley, from The Go-Between

## Introduction

This Chapter details the experimental procedures leading to the results described in Chapters 2-4. The Chapter comprises three sections:

Section A covers the synthetic methods employed in the preparation of the compounds discussed, including, where available, spectral and microanalytical data.

Section B describes the crystallographic techniques used in determination of the structures of compounds $2,3,4,5,6 \mathrm{a}, 10,11$ and 13 .

Section C describes the general methodology of extended Hückel molecular orbital calculations, and includes tables of atomic co-ordinates of the model compounds studied.

## Section A: Synthetic Methods

## General Techniques

All reactions were carried out under an atmosphere of dry, oxygen-free nitrogen using standard Schlenk techniques, with some subsequent manipulations in air.

Dichloromethane ( $\mathrm{CaH}_{2}$ ), tetrahydrofuran ( Na wire, benzophenone) and n -hexane (Na wire) were dried and distilled immediately prior to use, diethyl ether was dried with Na wire, other solvents were used as received.

Infra-red spectra were recorded as KBr discs or solutions (referenced against the appropriate solvent) on a Perkin-Elmer 598 spectrophotometer.
N.m.r. spectra were recorded at ambient temperature (unless otherwise specified) on Varian VXR-600 ( ${ }^{11} \mathrm{~B},{ }^{11} \mathrm{~B}(\mathrm{COSY}),{ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and $\left.{ }^{1} \mathrm{H}-\left\{{ }^{11} \mathrm{~B}\right\}\right)$, Bruker WH-360 $\left({ }^{11} \mathrm{~B},{ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}\right.$ and $\left.{ }^{1} \mathrm{H}\right)$ and Bruker WP-200 $\left({ }^{11} \mathrm{~B},{ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}\right)$ spectrometers. Techniques for recording ${ }^{1} \mathrm{H}-\left\{{ }^{11} \mathrm{~B}\right.$ selective $\}$ and ${ }^{11} \mathrm{~B}(\mathrm{COSY})$ spectra have been published previously. $88-90$ Chemical shifts are reported relative to external $\operatorname{SiMe}_{4}\left({ }^{1} \mathrm{H}\right)$ and $\mathrm{BF}_{3} \mathrm{OEt}_{2}\left({ }^{11} \mathrm{~B}\right)$, with positive shifts to high frequency.

## Starting Materials

The starting materials $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{24}$, $\mathrm{Tl}_{2}\left[7-\mathrm{Ph}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$, ${ }^{91}$ $\mathrm{Tl}_{2}\left[7-\mathrm{CH}_{2} \mathrm{OCH}_{3}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right],{ }^{92} \mathrm{Tl}_{2}\left[7,8-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right],{ }^{92}$ $\left[\mathrm{PPh}_{3} \mathrm{HgCl}_{2}\right]_{2},{ }^{93}\left[(\mathrm{p} \text {-cymene }) \mathrm{RuCl}_{2}\right]_{2}{ }^{94}$ and $\left[\mathrm{Cp}^{*} \mathrm{RhCl}_{2}\right]_{2}{ }^{75}$ were either prepared by published methods or by methods developed in the author's research group. All other materials used are commercially available and were used as supplied.
$\mathrm{Co}(\mathrm{acac})_{3} \quad(0.52 \mathrm{~g}, \quad 1.46 \mathrm{mmol})$ was dissolved in thf, and $\mathrm{T}_{2}$ [7-Ph-7,8-closo- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] $(0.90 \mathrm{~g}, 1.46 \mathrm{mmol})$ was suspended in the resulting green solution. The mixture was stirred at room temperature and to it was added, dropwise, a freshly prepared solution of $\left.\mathrm{Li}^{[ } \mathrm{C}_{9} \mathrm{H}_{7}\right]$ ( 1.46 mmol ) in thf (from equimolar amounts of BuLi and freshly distilled indene at $0^{\circ} \mathrm{C}$ ). The resultant brown product was stirred overnight and filtered. Volatiles were removed from the filtrate in vacuo, and the resultant solid dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15 \mathrm{ml})$ and filtered. The filtrate was concentrated and chromatographed on silica plates using a hexane/ $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ mixture (1:1) as eluant. Yellow ( $R_{\mathrm{f}} 0.9$, no B-H by i.r. spectroscopy) and orange ( $\boldsymbol{R}_{\mathrm{f}} 0.7$, B-H containing) bands were collected, the latter obtained as a dark red solid from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and subsequently identified as the target compound, 2. Yield 10\%. Calculated (for $\mathrm{C}_{17} \mathrm{H}_{22} \mathrm{~B}_{9} \mathrm{Co}$ ) : \%C 53.4, \%H 5.80; Found : \%C 53.2, \%H 5.72. I.r. $v_{\max } 2540 \mathrm{~cm}^{-1}$ (B-H).
N.m.r. Spectra $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$
${ }^{11} \mathrm{~B}-\left({ }^{1} \mathrm{H}\right\}: \delta \quad 8.25(1 \mathrm{~B}), 2.34(1 \mathrm{~B}), \quad-2.73[2 \mathrm{~B}($ coincident $)], \quad-3.62(1 \mathrm{~B}), \quad-6.32(1 \mathrm{~B})$, $-11.00(1 \mathrm{~B}),-16.74(1 \mathrm{~B})$ and $-17.72(1 \mathrm{~B})$ p.p.m. The ${ }^{1} \mathrm{H}$ n.m.r. chemical shifts have been presented and discussed in Chapter 2.

Synthesis of 1- $\mathrm{CH}_{2} \mathrm{OCH}_{3}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-$ closo $-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}{ }^{3}$

Similarly, $\mathrm{Co}(\mathrm{acac})_{3}, \mathrm{Tl}_{2}\left[7-\mathrm{CH}_{2} \mathrm{OCH}_{3}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right.$ and $\mathrm{Li}\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]$ (1.72mmol of each) were reacted together to afford, after work-up involving preparative tlc, the target compound, 3, as dark red microcrystals. Yield 5\%. I.r. $v_{\max } 2530 \mathrm{~cm}^{-1}$ (B-H).
N.m.r. Spectra $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$
${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}: \delta \quad 8.69(1 \mathrm{~B}), 1.68(1 \mathrm{~B}),-2.65(1 \mathrm{~B}),-3.54(1 \mathrm{~B}),-4.58(1 \mathrm{~B}),-7.00(1 \mathrm{~B})$, $-12.46(1 B),-17.58(1 B)$ and $-19.94(1 B)$ p.p.m.
${ }^{1} \mathrm{H}: \delta 2.52[\mathrm{~s}, 1 \mathrm{H}, \mathrm{H}(2)], 3.53\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{O}-\right), 3.61$ and $3.72\left(\mathrm{AB},{ }^{2} \mathrm{~J}_{\mathrm{HH}} 11 \mathrm{~Hz}, 2 \mathrm{H}\right.$, $-\mathrm{CH}_{2}-\mathrm{O}$ ) , 5.66 [d of d (app. t), ${ }^{3} \mathrm{~J}_{\mathrm{HH}} 3 \mathrm{~Hz}, 3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}(32)$ ], $6.39\left[\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{HH}} 3 \mathrm{~Hz}\right.$, 2 H (coincident), $\mathrm{H}(31,32)$ ], and $7.44-7.61$ [ $\mathrm{m}, 4 \mathrm{H}, \mathrm{H}(35-38)$ ] p.p.m.

## Synthesis of 1,2-( $\left.\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-3-\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-3,1,2-$ closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}, 4$

$\mathrm{Co}(\mathrm{acac})_{3}, \mathrm{Tl}_{2}\left[7,8-\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right]$ and $\mathrm{Li}\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]$ ( 0.86 mmol of each) were reacted together as described for the two previous reactions, except that this reaction was complete after 2.5 hours, and afforded the target compound, 4, after work-up involving preparative tlc. Yield $12 \%$. I.r. $v_{\max } 2540 \mathrm{~cm}^{-1}(\mathrm{~B}-\mathrm{H})$.
N.m.r. Spectra $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$
${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}: \delta 8.93(1 \mathrm{~B}), 1.86(1 \mathrm{~B}),-1.65(2 \mathrm{~B}),-5.12(2 \mathrm{~B}),-14.19(2 \mathrm{~B})$ and $-17.89(1 \mathrm{~B})$ p.p.m.
${ }^{1} \mathrm{H}: \delta 3.17$ and $3.39\left(\mathrm{AB},{ }^{2} \mathrm{~J}_{\mathrm{HH}} 12 \mathrm{~Hz}, 4 \mathrm{H},-\mathrm{CH}_{2}-\mathrm{O}-\right), 3.34\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{CH}_{3}-\mathrm{O}-\right), 5.70[\mathrm{t}$, $\left.{ }^{3} \mathrm{~J}_{\mathrm{HH}} 3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}(32)\right], 6.40\left[\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{HH}} 12 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}(31,32)\right]$ and $7.51-7.58[\mathrm{~m}, 4 \mathrm{H}$, H(35-38)] p.p.m.

Synthesis of 3-( $\left.\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}, 5$

A thf solution of $\mathrm{Li}\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]$ ( 1.079 mmol ) (made from equimolar amounts of ${ }^{\mathrm{t}} \mathrm{BuLi}$ and $\mathrm{C}_{13} \mathrm{H}_{10}$ at $-0^{\circ} \mathrm{C}$ ) was added dropwise to a cooled $\left(\mathrm{O}^{\circ}\right)$, stirred, suspension of $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right](0.583 \mathrm{~g}, 1.079 \mathrm{mmol})$ and $\mathrm{Co}(\mathrm{acac})_{3}(0.384 \mathrm{~g}, 1.079 \mathrm{mmol})$ in thf ( 20 ml ). After three hours the mixture was filtered and the filtrate evaporated in vacuo. $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added to the resulting brown solid, the product filtered and the filtrate concentrated to a small volume. Tlc $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ :hexane, $\left.1: 1\right)$ on silica plates afforded 5
as an amber band ( $R_{\mathrm{f}} 0.45$ ) in low yield ( $<5 \%$ ). Dark red needles were grown by diffusion of hexane into a $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution at $-30^{\circ} \mathrm{C}$, and an $X$-ray structure determination carried out, details of which are found in Section B of this chapter.

## Synthesis of " $\left[\left(\mathrm{C}_{9} \mathbf{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2} "$

Typically, $\mathrm{RhCl}_{3} .3 \mathrm{H}_{2} \mathrm{O}(2 \mathrm{~g}, 7.6 \mathrm{mmol})$ and freshly distilled indene $(3.5 \mathrm{ml}$, 30.1 mmol ) were refluxed in methanol ( 50 ml ) for 15 hours, during which time a brown solid was deposited. This was isolated by filtration, washed successively with methanol ( $2 \times 10 \mathrm{ml}$ ) and ether ( $2 \times 10 \mathrm{ml}$ ) and dried in vacuo. Further reflux ( 15 hr ) of the original filtrate afforded a second crop of material which was similarly recovered. Combined yield 0.95 g , $43 \%$. Calculated (for $\mathrm{C}_{18} \mathrm{H}_{14} \mathrm{Cl}_{4} \mathrm{Rh}_{2}$ ): \%C 37.4, \%H 2.42; Found: \%C $36.7 \% \mathrm{H}$ 2.74. I.r. $v_{\max } 3100(\mathrm{br}), 3050(\mathrm{br}, \mathrm{sh}), 2960(\mathrm{~m}), 2930(\mathrm{w})$ (all C-H), 1515(w), 1450(m), 1385(m), 1335(s), 1260(w), 885(m), 835(m, br), 750(sh), 745(s), 735(sh), 570(m), 490(m), 340(sh), 335(sh), 330(w), 325(m), 240(w) and $230(w) \mathrm{cm}^{-1}$.

## Reaction between " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " and $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$

$\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (10ml) was added to a solid mixture of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " (0.101g, $0.175 \mathrm{mmol})$ and $\mathrm{Tl}_{2}\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right](0.203 \mathrm{~g}, 0.35 \mathrm{mmol})$ at $-196^{\circ} \mathrm{C}$. The mixture was allowed to warm to room temperature with stirring. After 2.5 hours the mixture wàs filtered under $\mathrm{N}_{2}$ and the brown filtrate evaporated in vacuo to give a dark brown solid. Preparative tlc $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ :hexane, 3:1) afforded three main bands, yellow $\left(\mathrm{R}_{\mathrm{f}}\right.$ ca. 0.8 ), apricot ( $\mathrm{R}_{\mathrm{f}} c a .0 .6$ ) and orange ( $\mathrm{R}_{\mathrm{f}} c a .0 .5$ ), each of which was collected and recrystallised $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ :hexane, $\left.1: 3,-30^{\circ} \mathrm{C}\right)$ to afford microcrystals of the rhodium carbaborane compounds $\mathbf{6 a}, \mathbf{6 b}$ and $\mathbf{6 c}$ respectively.

## 3-( $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)-\mathbf{-}-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathbf{R h}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-\mathbf{3 , 1 , 2 - c l o s o}-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}, \mathbf{6 a}$

## Reaction of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " with $\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{NC}$

A solution of cyclohexyl-isocyanide, $\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{NC}$, (4.3mmol) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added dropwise to a stirred suspension of " $\left[\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{RhCl}_{2}\right]_{2}$ " $(0.1 \mathrm{~g}, 0.174 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 25 ml ). After two hours the dark brown filtrate was evaporated to yield an oily brown solid. Column chromatography [florisil (100-200 mesh) column, thf eluant] afforded a mobile amber band, which was collected and solvent removed in vacuo to give a brown solid. The ${ }^{1} \mathrm{H}$ n.m.r. spectrum of this product could not be interpreted, and in any case did not contain resonances in the aromatic region, indicating the absence of an indenyl ligand. Thus it was concluded that the reaction did not proceed in an analogous manner to that of $[\mathrm{CpRhCl}]_{n}$ with cyclohexyl isocyanide, (which gave an almost quantitative yield of $\mathrm{CpRhC}_{6} \mathrm{H}_{11} \mathrm{Cl}_{2}$ ), ${ }^{78}$ but rather gave a mixture of unidentified products which were not easily separated.

## Reaction between $\mathbf{1 , 2 , 3}$-trimethylindene and $\mathbf{R h C l}_{3} \cdot \mathbf{3 H} \mathbf{2} \mathbf{O}$

A mixture of $1,2,3$-trimethylindene, $\mathrm{C}_{12} \mathrm{H}_{13},(0.72 \mathrm{~g}, 4.59 \mathrm{mmol})$, prepared by a previously described method, ${ }^{80}$ and $\mathrm{RhCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(0.3 \mathrm{~g}, 1.14 \mathrm{mmol})$ was refluxed in methanol ( 15 ml ) for 60 hrs . The solution was filtered and the filtrate evaporated to yield a dry reddish-brown solid. Microanalysis figures indicated a very low hydrocarbon content, i.e. inconsistent with the formulation for the target compound, trimethylindenyl rhodium dichloride.

## Synthesis of 1,2-Ph $-\mathbf{1 , 2}$-closo- $\mathbf{C}_{2} \mathbf{B}_{10} \mathrm{H}_{10}, 10$

The following method is a modification of procedure published by M.M. Fein and co-workers. ${ }^{95}$ Decaborane ( $3 \mathrm{~g}, 24.6 \mathrm{mmol}$ ) was dissolved in benzene ( 20 ml ), and $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~S}$ ( 5 ml ) added, following which the mixture was refluxed for 6 hrs . After cooling, and addition of $\mathrm{PhC}=\mathrm{CPh}(4.51 \mathrm{~g}, 25.3 \mathrm{mmol})$ the mixture was stirred for 30 mins at room temperature, and then refluxed for a further 15 hrs . Solvent was removed in vacuo, resulting in a thick yellow oil. On addition of methanol ( 20 ml ), a bright yellow solid precipitated, and the suspension was filtered after 1 hour. The filtrate was stirred for another 4 hrs , the volume of methanol then reduced to $c a .5 \mathrm{ml}$, during which time a white precipitate of pure diphenylcarbaborane formed. This was filtered, washed with small amounts of methanol, and dried. Further diphenylcarbaborane was isolated from the yellow precipitate as follows: hot hexane was added to the latter, with vigorous stirring, and the mixture filtered while still warm. On evaporation of solvent from the filtrate, a pale yellow solid was obtained, which, after recrystallisation (acetone/water) afforded colourless crystals of pure 1,2- $\mathrm{Ph}_{2}-1,2$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$. Overall yield 2.38 g (33\%). Calculated (for $\mathrm{C}_{14} \mathrm{H}_{20} \mathrm{~B}_{10}$ : \%C 56.76, \%H 6.76; Found: \%C 56.00, \%H 6.89 .
N.m.r. Spectrum ( $\mathrm{CDCl}_{3}$ )
${ }^{11} \mathrm{~B}-\left({ }^{1} \mathrm{H}\right): \delta-1.73(2 \mathrm{~B}),-8.45(4 \mathrm{~B}),-9.72(4 \mathrm{~B})$ p.p.m.

## Synthesis of $\mathrm{Tl}_{2}\left[\mathbf{7 , 8}-\mathrm{Ph}_{\mathbf{2}} \mathbf{- 7 , 8 - \mathrm { C } _ { 2 } \mathbf { B g } _ { 9 } \mathbf { H } _ { \mathbf { 9 } } ]}\right.$

1,2- $\mathrm{Ph}_{2}-1,2$-closo $-\mathrm{C}_{2} \mathrm{H}_{10} \mathrm{H}_{10}(0.91 \mathrm{~g}, 3.07 \mathrm{mmol})$ and $\mathrm{KOH}(1.07 \mathrm{~g}, 19.1 \mathrm{mmol})$ were stirred in ethanol for 45 mins, and the mixture then refluxed for 6 hrs. After the solution cooled, solvent was removed in vacuo, and the resulting white solid dissolved in degassed water ( 15 ml ). The solution was filtered, and an aqueous solution of thallium acetate ( $3 \mathrm{~g}, 12 \mathrm{mmol}$ ) added to the filtrate, which caused immediate precipitation of a bright yellow solid. This was filtered, washed with water, ethanol and diethyl ether, and dried under vacuum. Yield $1.5 \mathrm{~g}, 64 \%$ Calculated (for $\mathrm{C}_{14} \mathrm{H}_{19} \mathrm{~B}_{9} \mathrm{Tl}_{2}$ ): \%C 24.24, \%H 2.80; Found: \%C 24.9, \%H 3.31.

## Synthesis of 7,8- $\mathrm{Ph}_{\mathbf{2}} \mathbf{- 1 0}$-endo- $\mathrm{PPh}_{\mathbf{3}} \mathrm{Hg}$-7,8-nido- $\mathrm{C}_{\mathbf{2}} \mathrm{B}_{\mathbf{9}} \mathrm{H}_{\mathbf{9}}, \mathbf{1 1}$

Degassed methylene chloride ( 15 ml ) was added to a mixture of $\mathrm{Tl}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right] \quad(0.349 \mathrm{~g}, \quad 0.504 \mathrm{mmol})$ and $\left[\mathrm{PPh}_{3} \mathrm{HgCl}_{2}\right]_{2} \quad(0.269 \mathrm{~g}$, 0.252 mmol ) at $-196^{\circ} \mathrm{C}$. The mixture was warmed to room temperature with stirring (in a foil covered vessel), and after 20 mins was filtered to afford a pale yellow solution. Solvent was reduced to 2 ml , and a vast excess of hexane added. A creamy white flocculate precipitated, which was separated from a green oil, and dried in vacuo. This was dissolved in methylene chloride, and slow evaporation of this solution afforded very pale yellow crystals, which were identified as the target compound, 11. Yield $10 \%$. I.r. $v_{\max } 2540 \mathrm{~cm}^{-1}$ (B-H).
N.m.r. Spectrum $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$
${ }^{11} \mathrm{~B}-\left\{{ }^{1} \mathrm{H}\right\}: \delta-11.22$ (5B,coincident), -13.67 (2B), $-23.70(1 \mathrm{~B}),-28.87(1 \mathrm{~B})$.

Synthesis of 1,2- $\mathrm{Ph}_{2}$-3-(p-cymene)-3,1,2-closo-RuC $\mathbf{C}_{2} \mathrm{~B}_{\mathbf{9}} \mathbf{H}_{\mathbf{9}}, 12$
Methylene chloride ( 20 ml ) was added to a mixture of $\left[\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{RuCl}_{2}\right]_{2}(0.2 \mathrm{~g}$, $0.33 \mathrm{mmol})$ and $\mathrm{Tl}_{2}\left[7,8-\mathrm{Ph}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}\right](0.453,0.66 \mathrm{mmol})$, and the products stirred at room temperature for 15 hrs . Filtration yielded a deep red solution, evaporation of
solvent from which resulted in a reddish-brown solid. Preparative tlc (methylene chloride:hexane, $1: 1$ eluant) afforded one major orange band ( $R_{\mathrm{f}} 0.85$ ), which was collected and identified as the target compound, 12, by analysis of spectral data. Yield $15 \%$. I.r. $V_{\max } 2580 \mathrm{~cm}^{-1}$.

## :Section B: Crystallographic Techniques

This section describes the experimental procedures involved in data collection and processing, and structure solution and refinement for each of the structures presented in Chapters 2-4. All data were collected on an Enraf-Nonius CAD4 diffractometer, fitted with a ULT-1 low-temperature device. Diffraction quality crystals of compounds 2-6a, 10, 11 and 13 were grown as described in the main body of the work.

Data were collected using graphite monochromated Mo- $K_{\alpha} X$-radiation, $\lambda=$ $0.71069 \AA$, by $\omega-2 \theta$ scans in 96 steps, with $\omega$ scan width $0.8+0.34 \tan \theta$. Data were corrected for Lorentz and polarisation effects, and (where necessary) for decay during data collection (CADABS ${ }^{96}$ ). Heavy atoms were located by automatic direct methods (SHELX86 ${ }^{97}$ ) or by inspection of a Patterson map (SHELX7698); see individual complexes. Subsequent atom location was by $\Delta F$ syntheses and iterative full-matrix least-squares refinement. ${ }^{98}$ Where appropriate, cage $\mathbf{C}$ atoms were identified by a combination of refined (as B) isotropic thermal parameters and interatomic distances. Scattering factors for $\mathrm{C}, \mathrm{H}, \mathrm{B}, \mathrm{O}, \mathrm{P}$ and Cl were those inlaid in the programs. Those for $\mathrm{Co}, \mathrm{Rh}, \mathrm{Hg}, \mathrm{Cu}$ and Ru were from International Tables for X-ray Crystallography. ${ }^{99}$

After isotropic convergence, data were corrected empirically for absorption. ${ }^{100}$ Thereafter, non-hydrogen atoms were generally allowed anisotropic thermal motion. Towards the end of the refinement process data were weighted according to $w^{-1}=$ $\left[\sigma^{2}(F)+\mathrm{g}\left(F^{2}\right)\right]$, where g is a variable. Each structure was than refined, usually by full-matrix least-squares, to convergence.

Geometrical calculations were performed using $C A L C^{101}$ and the molecular drawing facility used was EASYORTEP ${ }^{102}$, a modification of ORTEP-II. ${ }^{103}$

The isotropic thermal parameter takes the form $\exp \left[-8 \pi^{2} U\left(\sin ^{2} \Theta\right) / \lambda^{2}\right]$.

For anisotropic thermal parameters
$U i j=\exp \left[-2 \pi^{2}\left(U 11 a^{*} h^{2}+U 22 b^{* 22} k^{2}+U 33 c^{*} l^{2}+2 U 23 b^{*} c^{*} k l+2 U 13 a^{*} c^{*} h l+2 U 12 a^{*} b^{*} h k\right)\right]$

The equivalent isotropic thermal parameter is defined as
Ueq $=\left[\Sigma_{i} \Sigma_{j}\right.$ Uija $\left._{i}{ }^{*} a_{j}{ }^{*} a_{i} a_{j}\right] / 3$

## Crystal Data

$\mathrm{C}_{17} \mathrm{H}_{22} \mathrm{~B}_{9} \mathrm{CO}, M=382.59$, monoclinic, space group $C 2 / c a=17.732(11), b=$ $13.186(3), c=17.739(7) \AA, \beta=117.00(4)^{\circ}, V=3695.0 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(12<\theta<16^{\circ}\right)$ at $185 \pm 1 \mathrm{~K}, Z=8, D_{c}=1.375$ $\mathrm{gcm}^{-1}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)=9.22 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=1568$.

## Data Collection and Processing

Variable scan speeds between $0.79-2.35^{\circ} \mathrm{min}^{-1}$. 2768 independent reflections measured ( $1<\theta<25^{\circ},+\mathrm{h}+\mathrm{k} \pm 1$ ), of which 2741 had $F>2.0 \sigma(F)$. Data was corrected for slight crystal decay ( $8 \%$ ) over the period of data collection ( 99 hrs ).

## Structure Solution and Refinement

Co position from Patterson synthesis; $\mathrm{B}, \mathrm{C}$ and $\mathrm{H}_{\text {cage }}$ from full matrix least-squares refinement $/ \Delta \mathrm{F}$ syntheses. Cage H atoms refined positionally, subject to a single $\mathrm{X}-\mathrm{H}$ distance of $1.10(2) \AA$, indenyl and phenyl hydrogens set in fixed positions (C-H $1.08 \AA$ ). Empirical absorption correction applied after isotropic convergence; thereafter all non- H atoms allowed anisotropic thermal motion, H atoms refined with a common thermal parameter $\left(U_{\mathrm{H}}=0.0434(23) \AA^{2}\right)$ at convergence. $\mathrm{g}=0.000303 . R$ $=0.0434(23), R_{\mathrm{w}}=0.0525, S=1.293$. Max. and min. residues in final $\Delta F$ map 0.20 and $-0.20 e^{-3}$.

## 1- $\mathrm{CH}_{2} \mathrm{OCH}_{3}-\mathbf{3 -}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)-\mathbf{3 , 1 , 2}$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}, \mathbf{3}$

## Crystal Data

$\mathrm{C}_{13} \mathrm{H}_{22} \mathrm{~B}_{9} \mathrm{CoO}, \mathrm{M}=350.54$, monoclinic, space group $P 2_{1} / c, a=12.382(3), b=$ 8.914(5), $c=15.523(9), \beta=103.60(4)^{\circ}, V=1665 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(14<\theta<16^{\circ}\right)$ at $185 \pm 1 \mathrm{~K}, Z=4, D_{c}=1.398 \mathrm{gcm}^{-1}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)$ $=10.21 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=720$.

## Data Collection and Processing

Variable scan speeds between 0.79 and $2.35^{\circ} \mathrm{min}^{-1} .2654$ independent reflections measured ( $1<\theta<25^{\circ},+\mathrm{h}+\mathrm{k} \pm 1$ ), yielding 2651 with $F>2.0 \sigma(F)$. No crystal movement or decay noted.

## Structure Solution and Refinement

Co position from Patterson synthesis; B, C, O, and H atoms from full matrix least-squares refinement $/ \Delta \mathrm{F}$ syntheses. All hydrogen atoms fully refined. Empirical absorption correction applied after isotropic convergence; thereafter all non-H atoms allowed anisotropic thermal motion, H atoms having isotropic thermal parameters in the range $U_{\mathrm{H}}=0.021(5)-0.102(13) \AA^{2}$ at convergence. $\mathrm{g}=0.002296 . R=0.0269, R_{\mathrm{W}}$ $=0.0428, S=0.832$. Max. and min. residues in final $\Delta F$ map 0.24 and $-0.47 \mathrm{e}^{-3}$.

## Crystal Data

$\mathrm{C}_{15} \mathrm{H}_{26} \mathrm{~B}_{9} \mathrm{COO}_{2}, M=394.58$, monoclinic, space group $P_{2} / n, a=10.927(4), b=$ 14.743(4), $c=11.789(6), \beta=90.61(4)^{\circ}, V=1899.0 \AA^{3}$, from least-squares refinement of 25 centred reflections $(14<\theta<16)$ at $185 \pm 1 \mathrm{~K}, Z=4, D_{c}=1.380 \mathrm{gcm}^{-3}, \mu\left(\mathrm{Mo}-\mathrm{K}_{\alpha}\right)$ $=9.06 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=816$.

## Data Collection and Processing

Variable scan speeds between $0.82-2.06^{\circ} \mathrm{min}^{-1}$. 3094 independent reflections measured $(1<\theta<25,+\mathrm{h},+\mathrm{k}, \pm 1)$, yielding 3087 with $F=2.0 \sigma(F)$. No crystal movement or decay noted.

## Structure Solution and Refinement

Co position from direct methods; $\mathrm{B}, \mathrm{C}, \mathrm{O}, \mathrm{H}$ atoms from iterative full-matrix least-squares refinement/ $\Delta \mathrm{F}$ synthesis. Empirical absorption correction applied after isotropic convergence. All non- H atoms allowed anisotropic thermal motion. All H atoms fully refined with thermal parameters in the range $U_{\mathrm{H}}=0.014(5)-0.078(11) \AA^{2}$ at convergence. $\mathrm{g}=0.001416 . \mathrm{R}=0.0290, R_{\mathrm{w}}=0.0488, S=1.169$. Max. and min. residues in final $\Delta F$ map 0.29 and $-1.29 e^{-3}{ }^{-3}$.

3- $\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)-3,1,2-$ clos $O-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}, 5$

## Crystal Data

$\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{~B}_{9} \mathrm{Co}, M=356.55$, orthorhombic, space group $P 2_{1} 2_{1} 2_{1}, a=8.759(3), b=$ 13.037(3), $c=15.366(4) \AA, V=1754.7(8) \AA^{3}$, from least-squares refinement of 25 centered reflections $(5<\theta<12)$ at $291 \pm 1 \mathrm{~K}, Z=4, D_{c}=1.349 \mathrm{gcm}^{-3}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)=9.66$ $\mathrm{cm}^{-1}, F(000)=728$.

## Data Collection and Processing

Variable scan speeds between $0.824-1.83^{\circ} \mathrm{min}^{-1}$. 3050 independent reflections measured $\left(1<\theta<25^{\circ},+\mathrm{h},+\mathrm{k}, \pm \mathrm{l}\right)$, of which 2182 had $F>2.0 \sigma(F)$. No crystal movement or decay noted.

## Structure Solution and Refinement

Co position from direct methods; $\mathrm{C}, \mathrm{B}, \mathrm{H}_{\text {cage }}$ atoms from iterative full-matrix least squares refinement $\Delta \mathrm{F}$ syntheses. Empirical absorption correction applied after isotropic convergence. Equivalent reflections (hol and $h 0-l ; 0 k l$ and $0 k-l$; and $00 l$ and $00-l$ ) merged ( $\mathrm{R}_{\text {merge }}=0.032$ ) to afford a final set of 1930 reflections. All non- H atoms refined with anisotropic thermal parameters. Cage H atoms allowed positional refinement subject to a single X-H distance of $1.05(1) \AA$, fluorenyl H atoms set in idealized positions with C-H 1.08 $\AA$. Cage and fluorenyl H atoms refined with separate group thermal parameters, $0.039(8)$ and $0.103(12) \AA^{2}$ respectively at convergence. $\mathrm{g}=0.000473$. $R=0.0793, R_{\mathrm{w}}=0.0605, S=1.16$. Max. and min. residues in final $\Delta F$ map 0.86 and $-1.36 e^{\AA^{-3}}$.

## 3-( $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)-8-\left\{\left(\mathrm{C}_{9} \mathrm{H}_{6}\right) \mathbf{R h}\left(\mathrm{C}_{9} \mathrm{H}_{7}\right)\right\}-\mathbf{3 , 1 , 2 - c l o s o - \mathrm { RhC } _ { 2 } \mathrm { B } _ { 9 } \mathrm { H } _ { 1 1 } , \mathbf { 6 a }}$

## Crystal Data

$\mathrm{C}_{22} \mathrm{H}_{34} \mathrm{~B}_{18} \mathrm{Rh}_{2}, M=698.91$, orthorhombic, space group Pbca, $a=12.296(8), b=$ 19.69(4), $c=29.030(18) \AA, V=7028.8 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(2<\theta<11^{\circ}\right)$ at $185 \pm 1 \mathrm{~K}, Z=8, D_{\mathrm{c}}=1.321 \mathrm{gcm}^{-1}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)=9.38$ $\mathrm{cm}^{-1}, \mathrm{~F}(000)=2768$. $D_{\mathrm{c}}, \mu$ and $\mathrm{F}(000)$ assume no solvate.)

## Data Collection and Processing

Variable scan speeds between $0.79-2.35^{\circ} \mathrm{min}^{-1} .4140$ independent reflections measured ( $1<\theta<15^{\circ}$, th $\pm \mathrm{k} 1$ ), of which 1759 had $F>2.0 \sigma$. No crystal movement or decay was noted.

## Structure Solution and Refinement

Rh positions from direct methods; B and C from full matrix least-squares refinement $\Delta \mathrm{F}$ syntheses. Cage C atoms, $\mathrm{C}(1)$ and $\mathrm{C}(2)$, were identified by combination of refined (as B) isotropic thermal parameters and interatomic distances, and agree with the conclusions from the n.m.r. studies that this cage is substituted at $B(8) . C\left(1^{\prime}\right)$ was identified by its refined (as B) isotropic thermal parameter, but definitive location of the other cage carbon atom was not possible, and sites ( $2^{\prime}$ ) and $\left(4^{\prime}\right)$ were assigned occupancies of $5.5 \mathrm{e}((\mathrm{B}+\mathrm{C}) / 2)$. Indenyl H atoms were set in calculated positions, riding on their respective C atoms, and given an invariant U value of $0.07 \AA^{2}$. Cage H atoms were not located. Following isotropic convergence, an empirical absorption correction was applied, and data were then merged to afford 985 unique reflections, $R_{\text {merge }}=0.038$. Rhodium atoms were allowed with anisotropic thermal motion, and in the final stages data were weighted with $g=0.00168$. 6a crystallises with badly disordered solvate molecules, the best model of which involved 8 carbon atoms with fixed $U$ of $0.04 \AA^{2}$ and a (common) refined population parameter of $0.614(24)$. Even this model does not represent a chemically recognisable
fragment of either $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ or hexane. $R=0.1072, R_{\mathrm{w}}=0.1210, S=1.319$. Max. and min. residues in final $\Delta F$ map 1.10 and $-0.81 \mathrm{e}^{-3}$.

## 1-Ph-3-( $\left.\mathrm{C}_{9} \mathrm{H}_{7}\right)$-3,1,2-closo- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$, 8a

Crystal Data
$\mathrm{C}_{17} \mathrm{H}_{22} \mathrm{~B}_{9} \mathrm{Rh}, M=426.56$, monoclinic, space group $C 2 / c, a=17.710(16), b=$ 13.214(8), $c=18.81(3) \AA, \beta=119.86(10)^{\circ}, V=3817.5 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(3<\theta<8^{\circ}\right)$ at $291 \pm 1 \mathrm{~K}, Z=8, D_{c}=1.484 \mathrm{gcm}^{-1}$, $\mu\left(\mathrm{Mo}-K_{\alpha}\right)=8.78 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=1712$.

This compound is isomorphous with previously characterised cobalt analogue, 2, and this fact, coupled with its weak diffraction, did not justify data collection.

## Crystal Data

$\mathrm{C}_{14} \mathrm{H}_{20} \mathrm{~B}_{10}, M=296.41$, monoclinic, space group $P 2_{1} / c a=10.832(4), b=$ 24.890(13), $c=13.924(2) \AA, \beta=111.88(2)^{\circ}, V=3483.0 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(6<\theta<12^{\circ}\right)$ at $291 \pm 1 \mathrm{~K}, Z=8, D_{c}=1.13 \mathrm{gcm}^{-1}$, $\mu\left(\mathrm{Mo}-K_{\alpha}\right)=0.51 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=1232$.

## Data Collection and processing

Variable scan speeds between $1.10-3.30^{\circ} \mathrm{min}^{-1} .6121$ independent reflections measured ( $1<\theta<25^{\circ},+\mathrm{h}+\mathrm{k} \pm 1$ ), of which 3779 had $F>2.0 \sigma$. No measurable crystal decay or movement.

## Structure Solution and Refinement

C , and B atom positions from direct methods, and $\mathrm{H}_{\text {cage }}$ from full matrix least-squares refinement $\Delta \mathbf{F}$ syntheses. Phenyl hydrogens set in fixed positions ( $\mathrm{C}-\mathrm{H} 1.08 \AA$ ). Empirical absorption correction applied after isotropic convergence; thereafter all non-H atoms allowed anisotropic thermal motion. Independent molecules refined in alternate cycles ( 248 variables in each cycle). Phenyl and cage H atoms refined with a common thermal parameter $\left(U_{\mathrm{H}}=0.077(2) \AA^{2}\right)$ at convergence. $\mathrm{g}=0.000200 . R=$ $0.0703, R_{\mathrm{w}}=0.0992, S=0.928$. Max. and min. residues in final $\Delta F$ map 0.18 and $-0.29 \mathrm{e}^{-3}{ }^{-3}$.

## $\left.\mathbf{7 , 8}-\mathrm{Ph}_{2} \mathbf{- 1 0 - e n d o - (} \mathbf{( P P h} \mathbf{3} \mathbf{H g}\right)-\mathbf{7 , 8}$-nido- $\mathbf{C}_{\mathbf{2}} \mathbf{B}_{9} \mathbf{H}_{\mathbf{9}} \cdot \mathrm{CH}_{\mathbf{2}} \mathrm{Cl}_{\mathbf{2}}, \mathbf{1 1}$

## Crystal Data

$\mathrm{C}_{32} \mathrm{H}_{24} \mathrm{~Pb}_{1} \mathrm{HyCH}_{2} \mathrm{Cl}_{2}, M=822.33$, monoclinic, space group $P_{1} a=10.953(2), b=$ $13.274(3), c=11.528 \AA, \quad \beta=90.074(12), V=1676.1 \AA^{3}$, from least-squares refinement of 25 centred reflections ( $12<\theta<13^{\circ}$ ) at $291 \pm 1 \mathrm{~K}, Z=2, D_{c}=1.629$ $\mathrm{gcm}^{-1}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)=48.22 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=796$.

## Data Collection and processing

Variable scan speeds between $0.87-2.35^{\circ} \mathrm{min}^{-1} .2677$ independent reflections measured ( $1<\theta<25^{\circ},+\mathrm{h}+\mathrm{k} \pm 1$ ), of which 2656 had $F>2.0 \sigma$. No measurable crystal decay or movement.

## Structure Solution and Refinement

Hg position from Patterson synthesis, $\mathrm{P}, \mathrm{C}, \mathrm{B}, \mathrm{Cl}$ and and $\mathrm{H}_{\text {cage }}$ from full matrix least-squares refinement $\Delta \mathrm{F}$ syntheses. Cage H atoms allowed positional refinement subject to a single B-H distance of $1.06(1) \AA$. Phenyl hydrogens set in fixed positions (C-H $1.08 \AA$ ). Empirical absorption correction applied after isotropic convergence; thereafter all non-H atoms allowed anisotropic thermal motion. Model refined by least-squares on $F$ in two blocks (mercury triphenylphosphine and carbaborane cage, 182 and 264 variables respectively) to convergence. Phenyl and cage H atoms refined with a common thermal parameter $\left(U_{\mathrm{H}}=0.037(5) \AA^{2}\right)$ at convergence. Data weighted according to $w^{-1}=\left[\sigma^{2}(F)+0.000200 F^{2}\right] . R=0.0214, R_{\mathrm{w}}=0.0241, S=$ 1.078. Max. and min. residues in final $\Delta F$ map 0.20 and $-0.18 e^{\AA} \AA^{-3}$.

## Crystal Data

$\mathrm{C}_{24} \mathrm{H}_{34} \mathrm{~B}_{9} \mathrm{Rh}, M=522.74$, monoclinic, space group $P 2_{1} / a a=17.622(10), b=$ $18.266(3), c=18.039(6) \AA, \beta=118.410(35)^{\circ}, V=5107.2 \AA^{3}$, from least-squares refinement of 25 centred reflections $\left(10<\theta<12^{\circ}\right)$ at $185 \pm 1 \mathrm{~K}, Z=8, D_{c}=1.359$ $\mathrm{gcm}^{-1}, \mu\left(\mathrm{Mo}-K_{\alpha}\right)=6.69 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=2144$.

## Data Collection and Processing

Variable scan speeds between $1.20-2.75^{\circ} \mathrm{min}^{-1}$. 4852 independent reflections measured $\left(1<\theta<22^{\circ},+\mathrm{h}+\mathrm{k} \pm \mathrm{l}\right)$, of which 4823 had $F>2.0 \sigma(F)$.

## Structure Solution and Refinement

$\operatorname{Rh}(3 \mathrm{~A})$ and $\mathrm{Rh}(3 \mathrm{~B})$ positions found from Patterson synthesis; C, B and two ghost rhodium atoms, $\mathrm{Rh}(3 \mathrm{X})$ and $\mathrm{Rh}(3 \mathrm{Y})$, were located by full matrix least-squares refinement $/ \Delta F$ syntheses. The latter were assigned as such by their chemically non-sensible positions, and the fact that their co-ordinates are pseudo symmetry related to $\operatorname{Rh}(3 \mathrm{~A})$ and $\mathrm{Rh}(3 \mathrm{~B})(\mathrm{x}, 0.5-\mathrm{y}, \mathrm{z})$. After free refinement $\mathrm{Rh}(3 \mathrm{X})$ had a part occupancy of $10 \%$ and $\mathrm{Rh}(3 \mathrm{Y})$ part occupancy of $5 \%$. This implies that there is $10 \%$ and $5 \%$ disorder in molecules $\mathbf{A}$ and $\mathbf{B}$ respectively. After initial location carbon atoms in five- and six-membered rings were refined in fixed planar rings. Phenyl hydrogen atoms were fixed subject to a C-H distance of $1.08 \AA$, and methyl hydrogens fixed subject to a similar distance from the methyl carbon atom, and at a common distance $[2.1(0.02) \AA$ ] to the relevant ring carbon atom. Cage H atoms, in calculated positions, subject to a single X-H distance of $1.10(2) \AA$, were not refined. Empirical absorption correction applied after isotropic convergence; thereafter atoms were refined with a mixture of isotropic and anisotropic thermal parameters. Independent molecules refined in alternate cycles, of 261 variables. All non-cage H atoms refined with a common thermal parameter $\left(U_{\mathrm{H}}=0.129(6) \AA^{2}\right)$ at convergence. $\mathrm{g}=0.001621$.
$R=0.1236, R_{\mathrm{w}}=0.1499, S=1.394$. Max. and min. residues in final $\Delta F$ map 0.78 and $-0.86 e^{-3}{ }^{-3}$.

## Section C: Extended Hückel Molecular Orbital Calculations

## Introduction

Extended Hückel molecular orbital (EHMO) calculations ${ }^{104,105}$ have been widely used for probing general structural problems in organometallic chemistry. Although the molecular orbital energies obtained are often inaccurate, the results do reflect maximum overlap criteria and broad electronegativity trends. In consequence, the preferred conformation and rotational barriers are often accurately predicted by the extended Hückel method.

## General Methodology ${ }^{106,107}$

In order to run an EHMO calculation, a model of the molecule is required, with co-ordinates in orthogonal Angstrom space, together with a basis set of atomic orbital (AO) parameters, for all the elements in the molecule.

Molecular orbitals (MO's) are derived by the linear combination of atomic orbital (LCAO) approach. $\Psi$, the mathematical function for an MO, is derived from corresponding AO's, $\Psi_{i}$ and $\Psi_{j}$, according to the following equation:

$$
\Psi=c_{i} \Psi_{i}+c_{j} \Psi_{j}
$$

where $c_{i}$ and $c_{j}$ are the AO coefficients.

The AO wavefunctions are represented by normalised Slater-type orbitals (STO's) which have the form:

$$
\Psi_{\mathrm{Imn}}=\mathrm{r}^{\mathrm{n}-1} \exp ^{-\zeta \mathrm{F}} \mathrm{Y}_{\mathrm{ml}}(\theta, \phi)
$$

where n is related to the principal quantum number, and $\mathrm{Y}_{\mathrm{ml}}(\theta, \phi)$ are spherical
harmonics.

The orbital exponent, $\zeta$, defines the diffuseness of STO's in physical terms, and is related to the effective nuclear charge, i.e.

$$
\zeta=(\mathrm{Z}-\sigma) / \mathrm{n}
$$

where Z is the nuclear charge, and $\sigma$ a screening constant
In order to calculate orbital energies, a secular determinant is set up from equations of the type shown below, using evaluated Hamiltonian operators $\left(\mathrm{H}_{\mathrm{ii}}\right.$ and $\mathrm{H}_{\mathrm{ij}}$ ) and overlap intergrals ( $\mathrm{S}_{\mathrm{ij}}$ ).

$$
\Sigma c_{i j}\left(H_{i j}-S_{i j} E\right)=0
$$

where $\mathrm{H}_{\mathrm{ii}}=\int \Psi_{\mathrm{i}} \mathrm{H} \Psi_{\mathrm{i}}, \mathrm{H}_{\mathrm{ij}}=\int \Psi_{\mathrm{i}} \mathrm{H} \Psi_{\mathrm{j}}=\int \Psi_{\mathrm{j}} \mathrm{H} \Psi_{\mathrm{i}}$ and $\mathrm{S}_{\mathrm{ij}}=\int \Psi_{\mathrm{i}} \Psi_{\mathrm{j}}$.

The $\mathrm{H}_{\mathrm{ii}}$ 's used are the valence shell ionisation energies (VSIE's), which may be optimised by charge iteration procedures. $\mathrm{H}_{\mathrm{ij}}$ 's are calculated using the modified Wolfsberg-Helmholtz formula:

$$
\begin{gathered}
\mathrm{H}_{\mathrm{ij}}=\mathrm{K}^{\prime} \mathrm{S}_{\mathrm{ij}}\left(\mathrm{H}_{\mathrm{ii}}+\mathrm{H}_{\mathrm{ij}}\right) / 2 \\
\text { where } \mathrm{K}^{\prime}=\mathrm{K}+\Delta+\Delta^{2}+\Delta^{4}(1-\mathrm{K}) \\
\text { and } \Delta=\left(\mathrm{H}_{\mathrm{ii}}-\mathrm{H}_{\mathrm{ij}}\right) /\left(\mathrm{H}_{\mathrm{ii}}+\mathrm{H}_{\mathrm{ij}}\right)
\end{gathered}
$$

## Optimisation of $\mathbf{H}_{\mathrm{ii}}$ 's by Charge Iteration

For models of compounds $1->5, \mathrm{H}_{\mathrm{ii}}$ 's for cobalt were initially optimised by charge iteration. This involves implementing a complex function, of the form:

$$
\mathbf{H}_{i i}=-\operatorname{VSIE}(\mathrm{Q})
$$

$$
\text { where } \operatorname{VSIE}(\mathrm{Q})=\mathrm{AQ}^{2}+\mathrm{BQ}+\mathrm{C}
$$

where the parameters $\mathrm{A}, \mathrm{B}$, and C are defined from multiconfigurational spectral data on the atoms and their charged ions. ${ }^{108}$ The cycles are repeated until self-consistent charges result (i.e. $<10^{-4} \mathrm{e}$ change in any atomic charge between cycles).

Atomic orbital parameters used for the calculations discussed in this work are the following:

| AO | $\mathrm{H}_{\mathrm{ii}}(\mathrm{eV})$ | $\zeta_{1}{ }^{\mathrm{a}}$ | $\zeta_{2}{ }^{\mathrm{a}}$ | $\mathrm{c}_{1}{ }^{\mathrm{b}}$ | $\mathrm{c}_{2}{ }^{\mathrm{b}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{H} 1 s$ | -13.60 | 1.30 |  |  |  |
| $\mathrm{~B} 2 s$ | -15.20 | 1.30 |  |  |  |
| $\mathrm{~B} 2 p$ | -8.50 | 1.30 |  |  |  |
| $\mathrm{C} 2 s$ | -21.40 | 1.625 |  |  |  |
| $\mathrm{C} 2 p$ | -11.40 | 1.625 |  | 0.56786 | 0.60586 |
| $\mathrm{Co3d}$ | -12.075 | 5.55 | 2.10 |  |  |
| $\mathrm{Co4s}$ | -9.128 | 2.00 |  |  |  |
| $\mathrm{C} 4 p$ | -5.515 | 2.00 |  |  |  |

${ }^{a}$ exponents, ${ }^{\text {b }}$ co-efficients in double-zeta expansion

## Bond Overlap Populations

The bond overlap population between two atoms, $r$ and $s$, is defined by:

$$
P_{r s}=\Sigma \Sigma\left(N C_{i n} c_{j n} S_{i j}\right.
$$

where there are $n$ MO's, $c_{i n}$ is the coefficient of $\Psi$ in the $n^{\text {th }} M O, N$ is the number of electrons in the orbital.
$P_{r s}$ is a measure of the bond strength and thus calculated overlap populations may be compared with structurally observed bond distances between certain atoms.

## Calculations Performed on Models of 1 to 5

A series of molecular orbital calculations were performed on models of 1 to 5 , to generate the sum of one-electron energies for different conformations of the models. The models implemented were made up of two molecular fragments; an idealized model of an icosahedron, representing the $\left\{\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9} \mathrm{R}^{1} \mathrm{R}^{2}\right\}$ fragment, and an idealized model of $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{-}$(or $\left[\mathrm{C}_{13} \mathrm{H}_{9}\right]^{-}$). The bond distances and angles used were the following: $\mathrm{B}-\mathrm{B}=\mathrm{B}-\mathrm{C}=\mathrm{C}_{-\mathrm{C}_{\text {cage }}}=1.75 \AA, \mathrm{~B}-\mathrm{H}=\mathrm{C}-\mathrm{H}_{\text {cage }}=1.20 \AA, \mathrm{Co}-\mathrm{B}=\mathrm{Co}-\mathrm{C}$ $=2.05 \AA, \mathrm{C}-\mathrm{C}_{\text {hydrocarbon }}=1.40 \AA, \mathrm{C}-\mathrm{H}_{\text {hydrocarbon }}=1.08 \AA, \mathrm{C}-\mathrm{C}_{\text {methyl }}=1.54 \AA$, $\mathrm{Co}-\mathrm{C}-\mathrm{C}-\mathrm{H}_{\text {methyl }}=0^{\circ}, \mathrm{Co}-\mathrm{C}-\mathrm{C}-\mathrm{H}_{\text {phenyl }}=90^{\circ}$.

## Cage substituent coordinates for $\left(\mathrm{C}_{9} \mathrm{H}_{7}\right) \mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{CH}_{3}$, model of 3

| C111 | 1.6795 | -2.3118 | 1.4287 |
| :--- | :--- | :--- | :--- |
| H111 | 2.1364 | -2.9407 | 0.6789 |
| H112 | 1.0216 | -2.9064 | 2.0450 |
| H113 | 2.4484 | -1.8698 | 2.0450 |

(Note that for this calculation the ether function, $\mathrm{CH}_{2} \mathrm{OCH}_{3}$, is modelled by a methyl group, which has replaced H11).

Co-ordinates for the cage substituents in the idealized model of 4

| C71 | -1.6795 | -1.2044 | 0.74432 |
| :--- | :--- | :--- | :--- |
| H71 | -2.1364 | -2.9407 | 0.6789 |
| H72 | -1.0216 | -2.9065 | 2.0450 |
| H73 | -2.4484 | -1.8698 | 2.0450 |
| C111 | 1.6795 | -2.3118 | 1.4287 |
| H111 | 2.1364 | -2.9407 | 0.6789 |
| H112 | 1.0216 | -2.9064 | 2.0450 |
| H113 | 2.4484 | -1.8698 | 2.0450 |

(Note that in this calculation both ether functions are modelled by methyl groups, replacing H 7 and H 11 ).

Co-ordinates for the indenyl (or fluorenyl) ligands were varied according to rotation of the fused-aromatic ligand about the $\mathrm{Co} \cdots \cdot \mathrm{B}(10)$ (called B 1 in the model) axis, in steps of $18^{\circ}$. By plotting the sum of energies calculated for each different conformation of the models representing 1 to 5 against the angle of rotation, $\theta$, the minimum energy conformation for each model could be deduced (See Chapter 2).

Atom co-ordinates for the idealized model of $\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{-}$

| C95 | 1.40000 | -2.17590 | 3.82240 |
| ---: | ---: | ---: | ---: |
| C92 | 0.00000 | 1.19090 | 3.82240 |
| C94 | 0.70000 | -0.96350 | 3.82240 |
| C99 | -0.70000 | -0.96350 | 3.82240 |
| C98 | -1.40000 | -2.17590 | 3.82240 |
| C96 | 0.70000 | -3.38830 | 3.82240 |
| C97 | -0.70000 | -3.38830 | 3.82240 |
| C91 | -1.13260 | 0.36800 | 3.82240 |
| C93 | 1.13260 | 0.36800 | 3.82240 |

| H98 | -1.30304 | 3.03101 | 3.82240 |
| H97 | -3.72881 | 2.51538 | 3.82240 |
| H96 | -4.49517 | 0.15675 | 3.82240 |
| H95 | $-2.83577-1.68623$ | 3.82240 |  |
| C913 | $2.50203-0.65909$ | 3.82240 |  |
| C910 | 1.63678 | 2.00387 | 3.82240 |
| C912 | 3.43878 | 0.38130 | 3.82240 |
| C911 | 3.00615 | 1.71278 | 3.82240 |
| H910 | 1.30304 | 3.03101 | 3.82240 |
| H911 | 3.72881 | 2.51538 | 3.82240 |
| H912 | 4.49517 | 0.15675 | 3.82240 |
| H913 | $2.83577-1.68623$ | 3.82240 |  |

Where the angle of rotation, $\theta$, is $0^{\circ}$, corresponding to the conformation in which C94 and C99 lie directly above the cage carbon atoms, $\mathrm{C}(1)$ and $\mathrm{C}(2)$.

## Calculations performed on Model of 10

The sum of one-electron energies was calculated for varying conformations of a model of 10 , in which two phenyl substituents were synchronously rotated about the $\mathrm{C}(1)-\mathrm{C}(11)$ and $\mathrm{C}(2)-\mathrm{C}(21)$ bonds (C9-C91 and C12-C121 in the model), in steps of $10^{\circ}$. The sum of energies for conformations at each angle, $\theta$, of twist away from a $90^{\circ}$ torsion about $\mathrm{C} 9-\mathrm{C} 91$ and $\mathrm{C} 12-\mathrm{C} 121$ (i.e. where $\mathrm{C} 9-\mathrm{C} 12-\mathrm{C} 121-\mathrm{C} 122 / \mathrm{C} 126=$ C12-C9-C91-C92/C96 $=90^{\circ}$ ), giving the energy curve shown in Figure 4.3, Chapter 4. The model was constructed using the bond distances and angles previously described in this Section for models of compounds 1-5.

Calculations were also carried out on models of 1-Ph-1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ and 1,2 -closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$, where one or both phenyl groups in the model of 10 were replaced by $H(1)$ and $H(2)$ respectively.

where $\theta=0^{\circ}$

## Appendix 2: Lectures and Courses Attended

Recent Advances in Inorganic Chemistry

Drs. A.J.Welch, L.J.Yellowlees, S.K.Chapman and M.Schroeder

Inorganic Medicinal Chemistry
Dr. S.K.Chapman

Sructural Methods in Inorganic Chemistry
Professors D.H.W.Rankin and E.A.V.Ebsworth

Departmental Research Seminars and Colloquia

Inorganic Section Meetings

European Collaboration on BNCT, Plenary Meeting, Munich, 1989

Workshop on the Chemistry of BNCT, Ross Priory, University of Strathclyde, 1990

Intraboron IX, X and XI, Annual Meetings of British Boron Chemists

Imeboron VII, International Meeting on Boron Chemistry, Torun, Poland, 1990
B.C.A. Residential Crystallography School, Aston, Birmingham, April 1991
