1	Introduction
3	Correlation Summaries
4-17	Mitsuyasu spreading function $\theta_0 = 0, 15, 30, 45, 60, 75, 90$
18-31	$\cos^2(\theta-\theta_0)$ spreading function $\theta_0 = 0, 15, 30, 45, 60, 75, 90$
32-39	$\cos^0(\theta-\theta_0)$ spreading function $\theta_0 = 0, 15, 30, 60, 90$
40-47	$\cos^4(\theta-\theta_0)$ spreading function $\theta_0 = 0, 15, 30, 60, 90$

Introduction

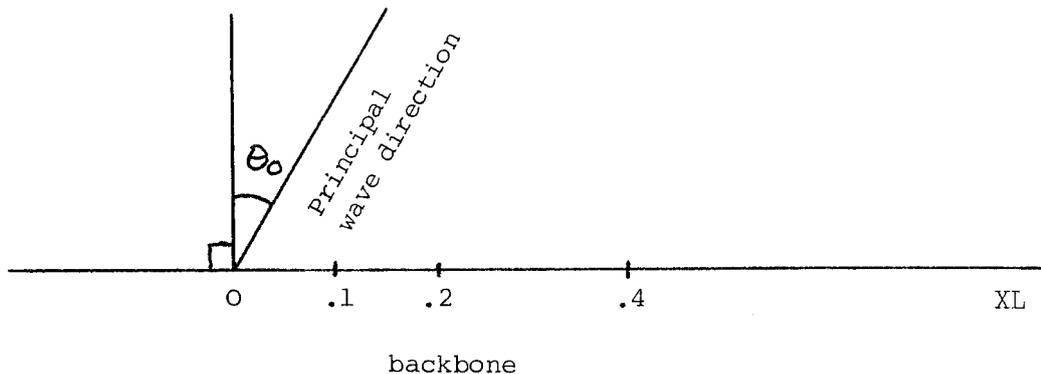

The pictures which follow are designed to give a first impression of what is happening at points along the backbone of a duck string in a directionally spread sea; in particular, to look at the correlation between wave-records and instantaneous power at pairs of points at varying distances.

The wave records have been simulated using a Pierson-Moskowitz spectrum (with low frequency cut-off at $3 \times T_e$), and directional spreading of both $\cos^s(\theta - \theta_0)$ form (s independent of frequency) and the Mitsuyasu form

$$\begin{aligned} \cos^s \omega \left(\frac{1}{2}(\theta - \theta_0) \right) \quad \text{where} \quad s_\omega &= 15.85 \left(\frac{\omega}{\omega_0} \right)^5 \quad \text{for } \omega < \omega_0 \\ &= 15.85 \left(\frac{\omega_0}{\omega} \right)^{2.5} \quad \text{for } \omega > \omega_0 \end{aligned}$$

Wave records and instantaneous power records (with power measured simply in terms of the vertical water movement - this is not the right phase for a real duck) are shown for just a part of the simulation period ($100 < t/T_e < 110$ out of a total $204.8 T_e$ simulation). The histograms on the right-hand page, showing the distribution of POW IN in terms of instantaneous power, were calculated over the whole simulation period.

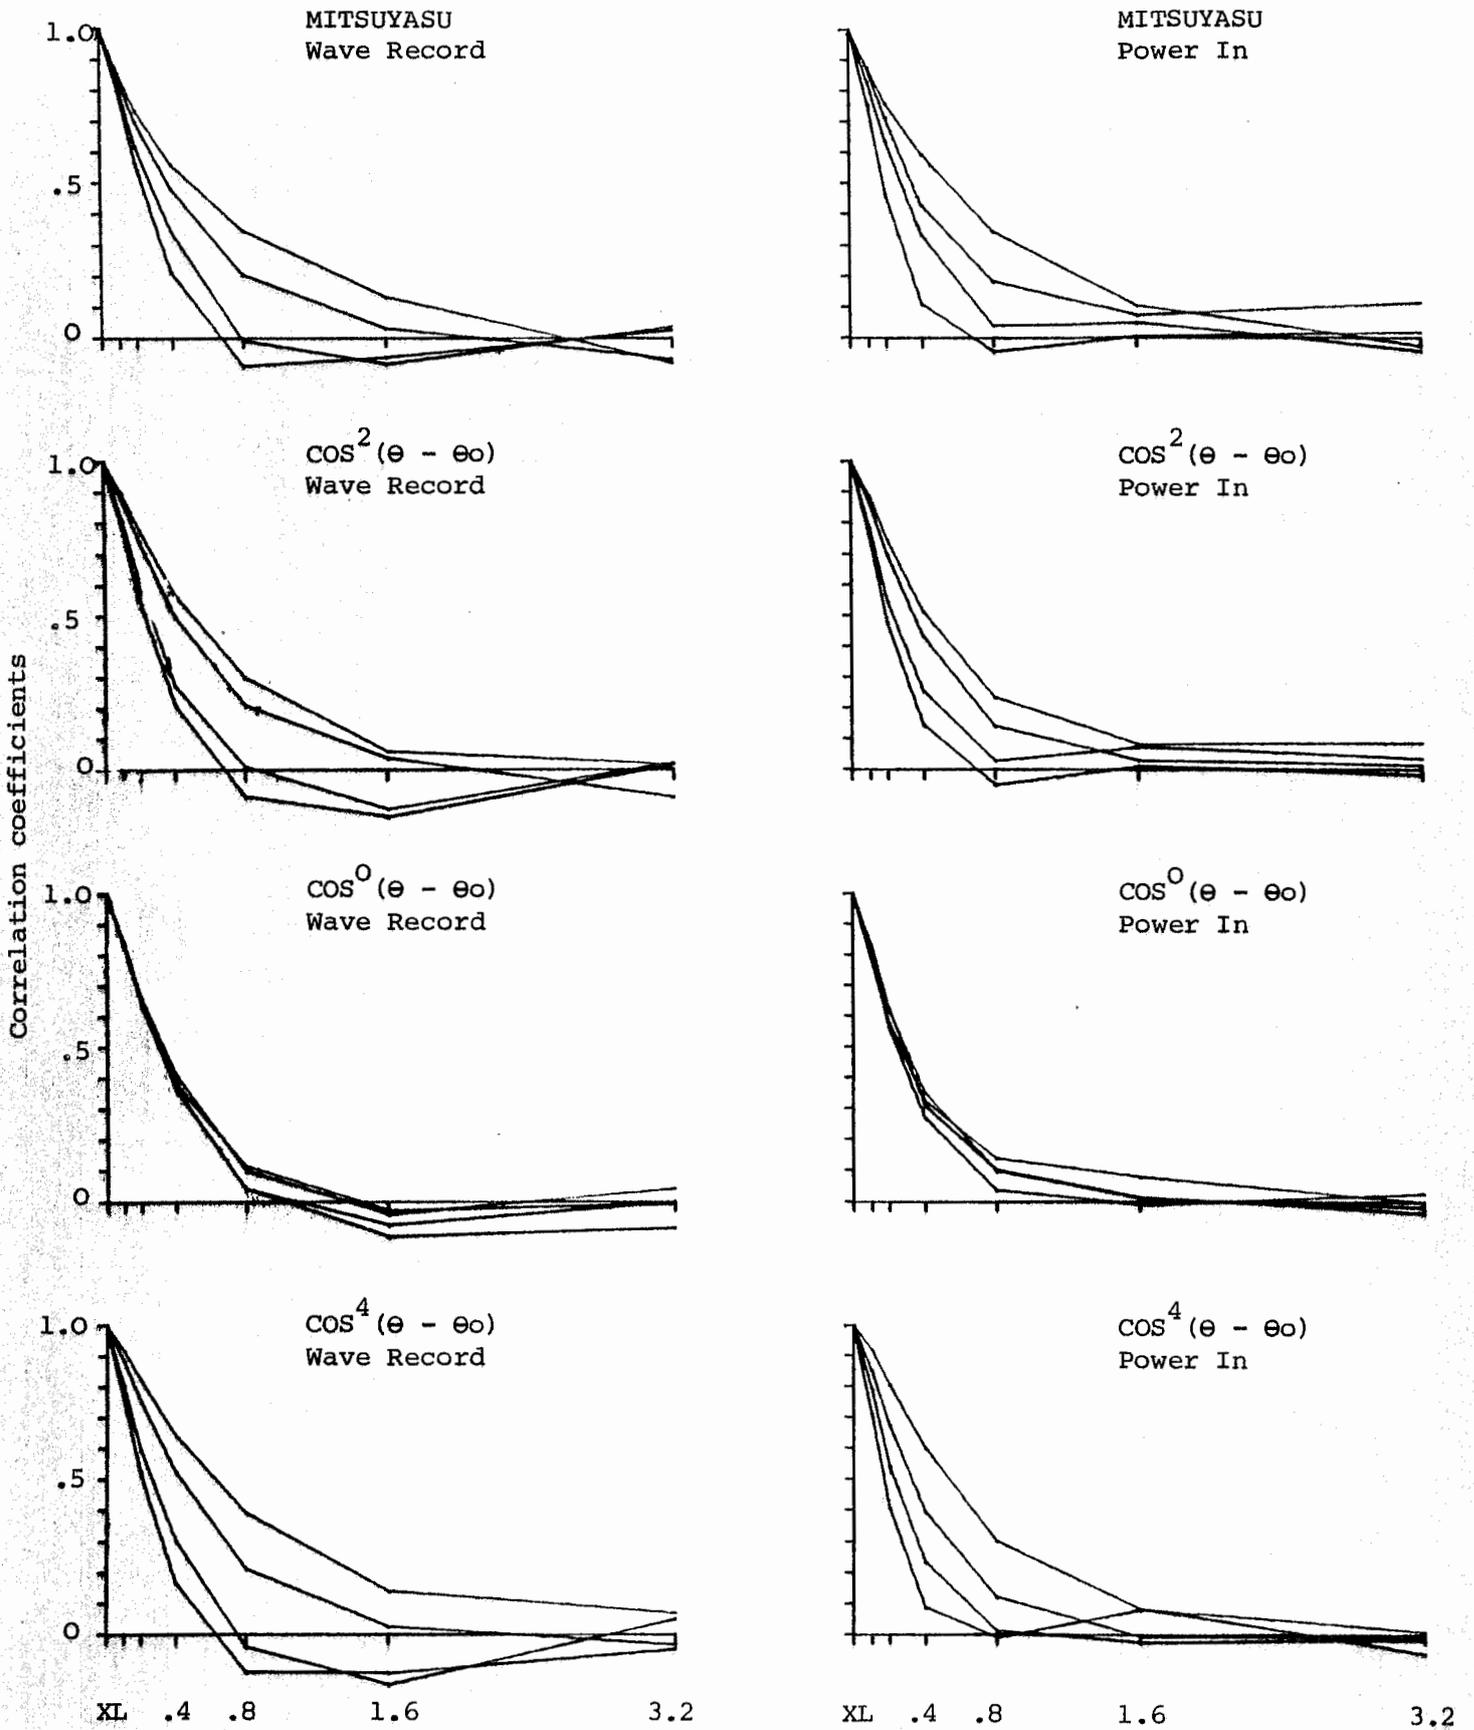

Records are shown at an origin (first record, repeated as a dotted line on top of each subsequent record), and at distances $x = XL \times \lambda_e$ ($\lambda_e = (g/2\pi)Te^2$) along a backbone. The principal wave direction θ_0 ($TH\emptyset$) is given relative to the perpendicular to the backbone, thus:

Units: time is in units of Te , height in units of H_{rms} , and power in units of average power (POW IN which is a %age of the total power POW depending on the spreading function).

Correlation coefficients between records at x and 0 are given for each x . Graphs of these correlation coefficients are shown on page 3.

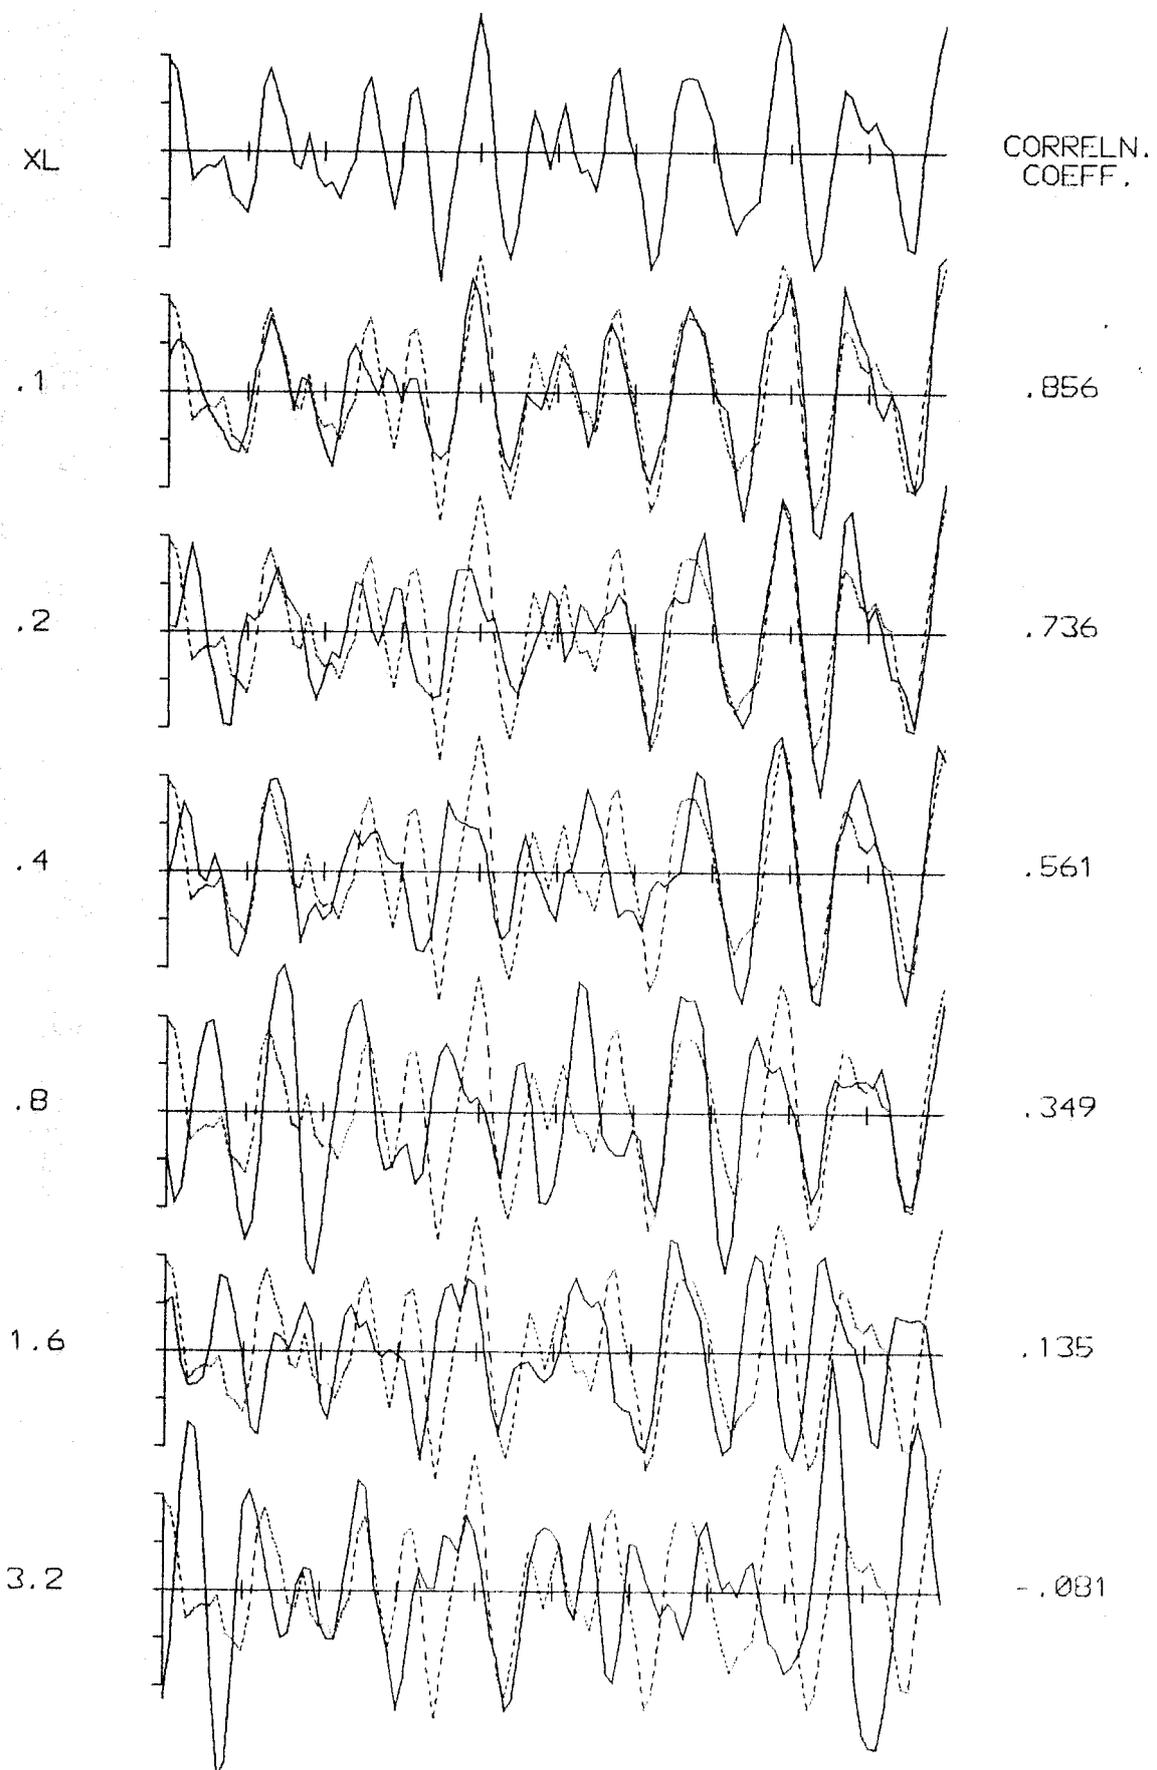

Note: The simulations decrease in reliability as θ_0 increases, because the number of spectral components contributing to the power decreases. Thus the simulations with θ_0 greater than about 60° should be taken with a pinch of salt (especially the Mitsuyasu and $\cos^4\theta$ which are most directionally concentrated).

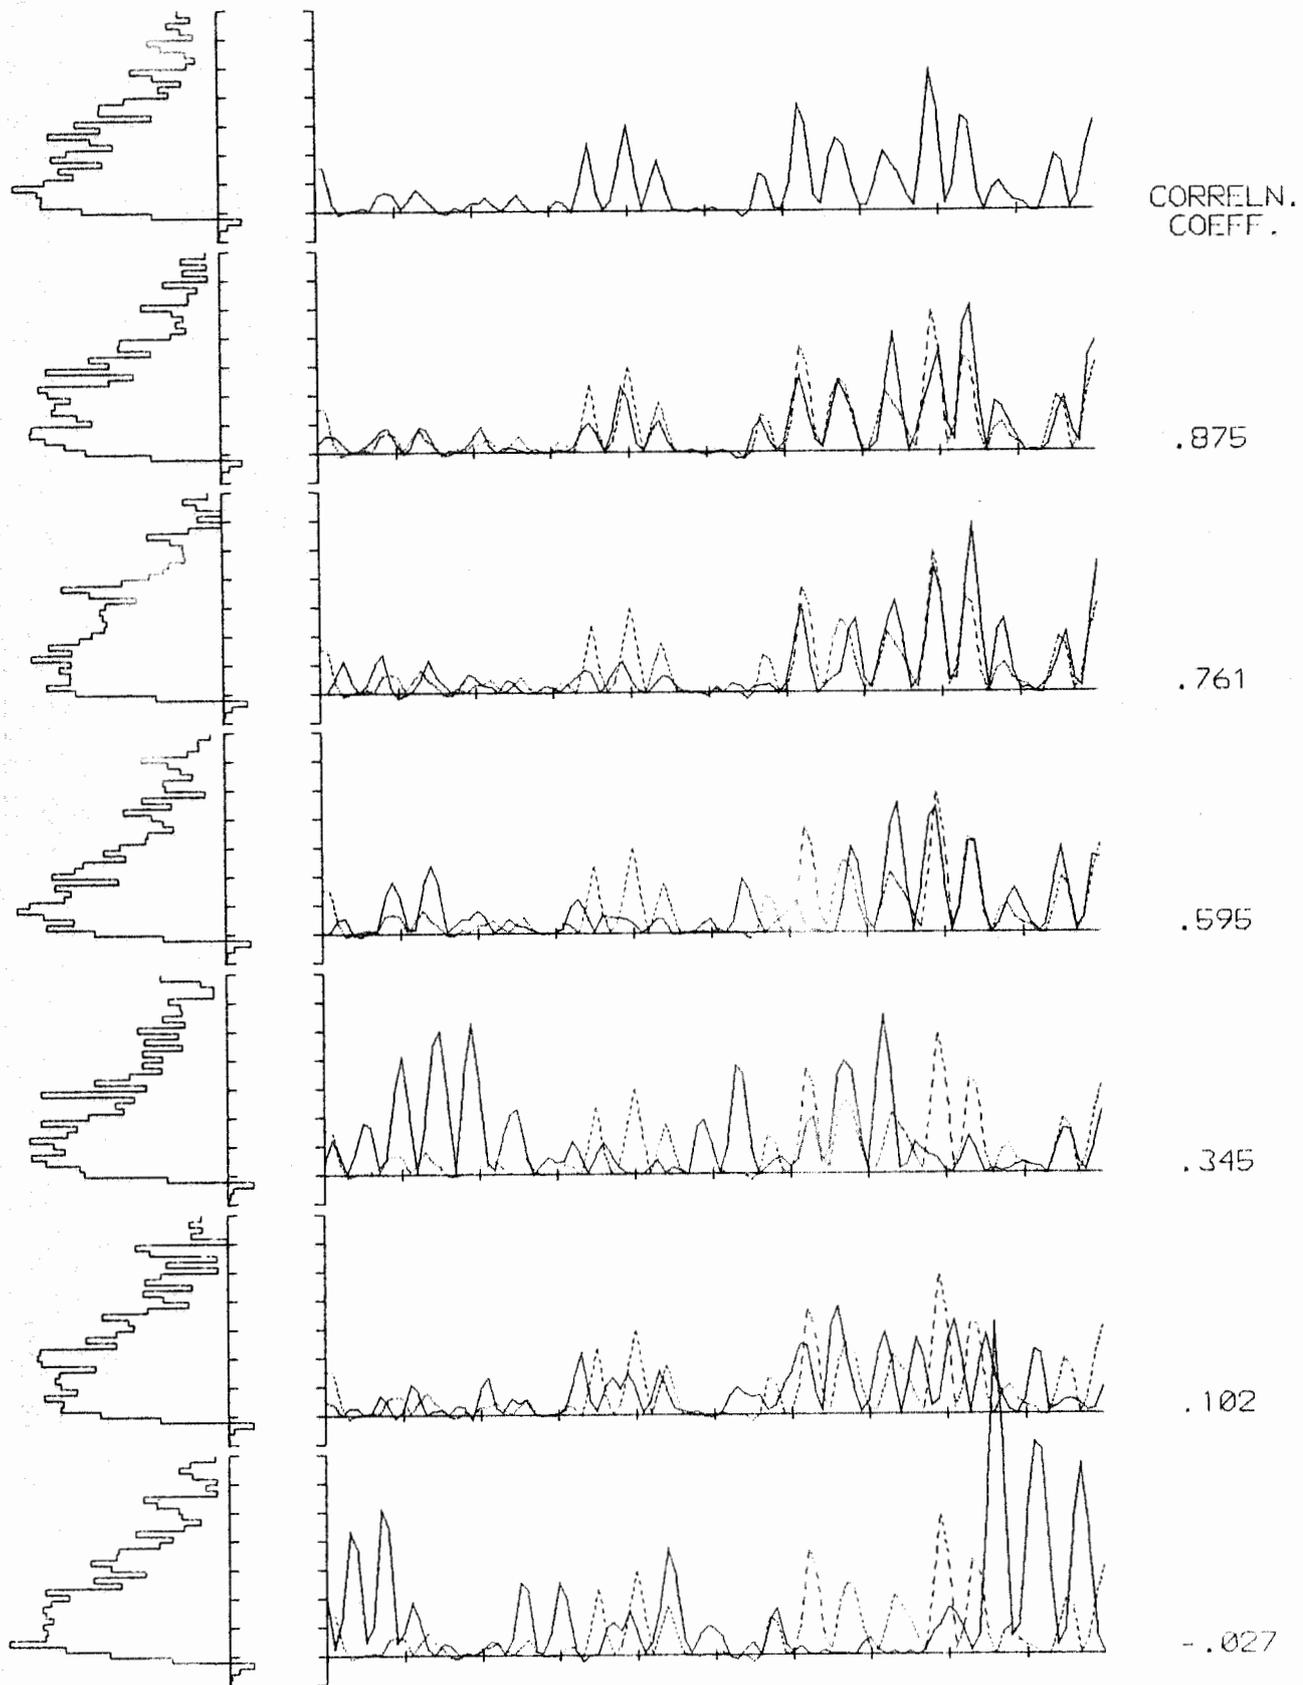

CORRELATION SUMMARIES

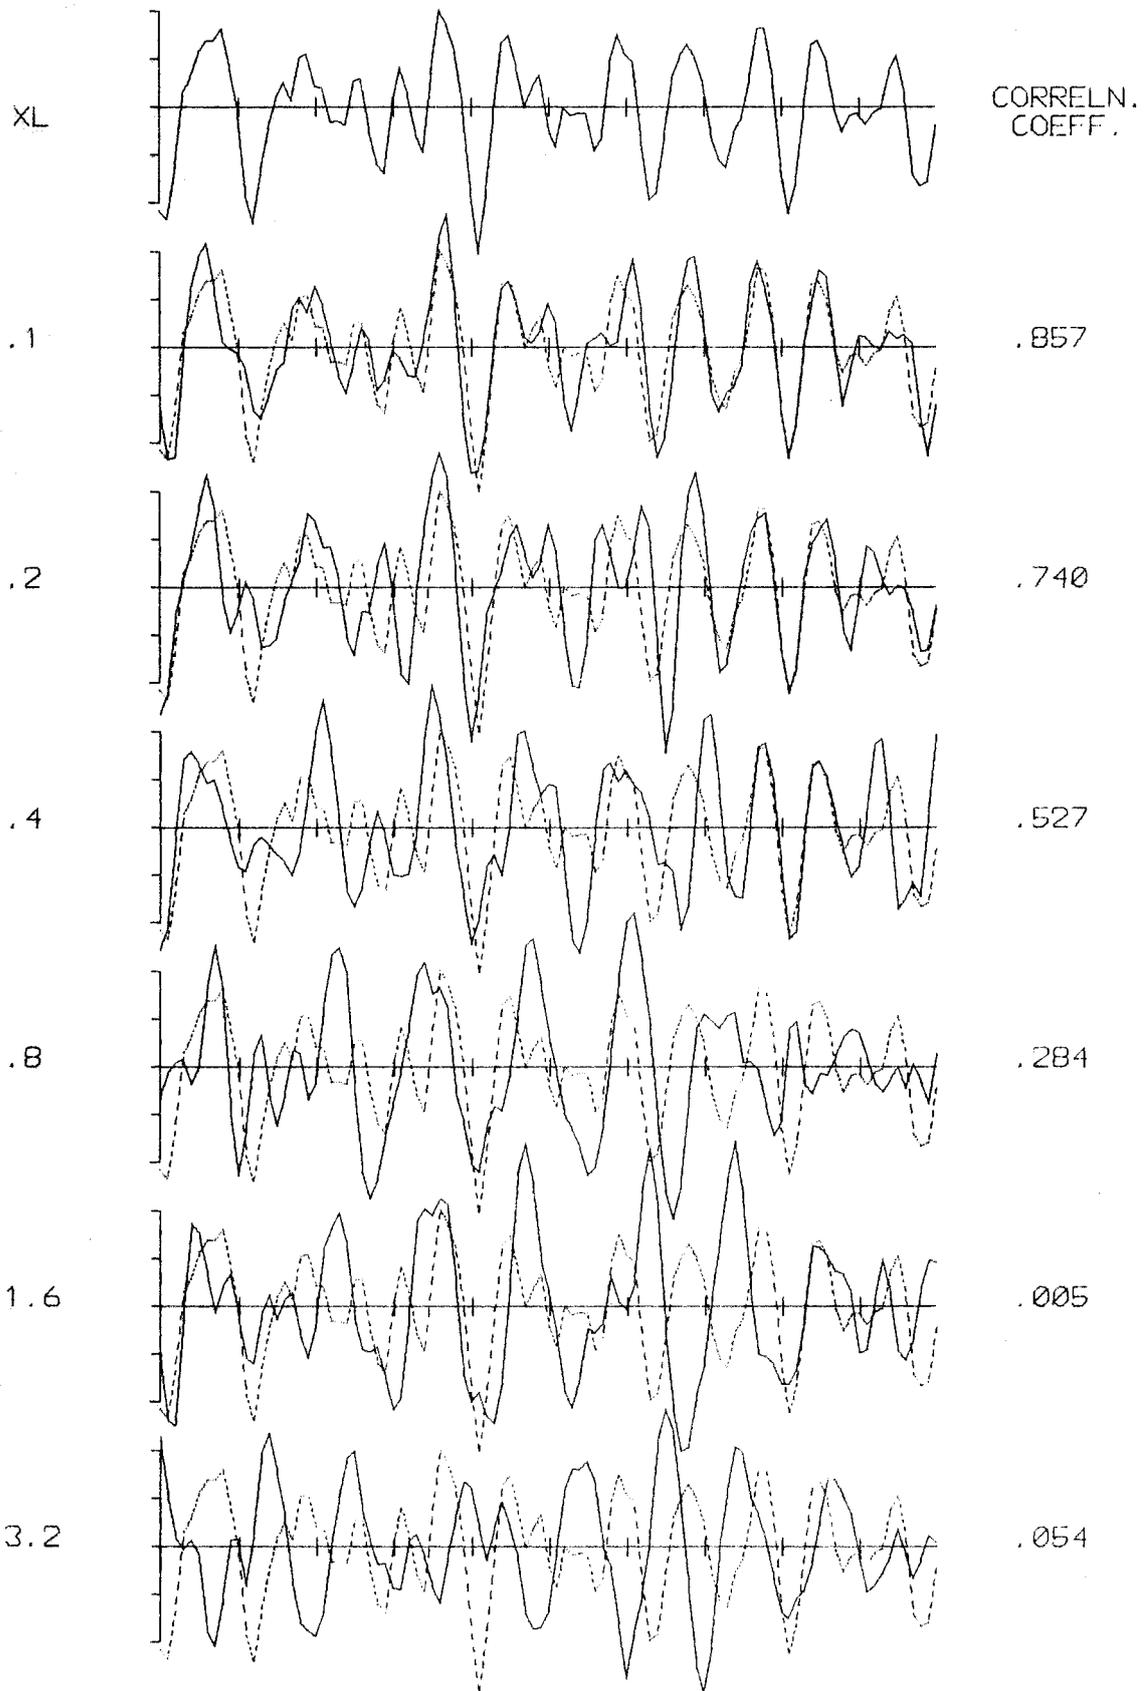

Correlation coefficients for wave-records (left) and power in (right) are plotted against XL for the four different spreading functions; in each case for (from top to bottom) $\theta_0 = 0^\circ, 30^\circ, 80^\circ$ and 90° .
