INTRODUCTION.

If, by the term Diphtheria, the derivation ~~Sidēpēd~~ were to be strictly adhered to, the diagnosis of the condition and its treatment would be simple, and the results relatively bad. The local condition and its treatment is, indeed, that part of the disease which, at the present time, gives rise to least anxiety and from which the death-rate is, in comparison, relatively low.

Trousseau.
Clinique
Médicale,
1861.

To Trousseau indeed, we owe much, who, first, gave to the term Diphtheria the meaning which we now attach to it, namely, a general constitutional affection and one causing death, not only mechanically, but by a general systemic toxæmia.

While the local condition - thanks to anti-toxine serum and the gradual perfection of Intubation and Tracheotomy - is not now regarded so gravely, far otherwise is it with the general condition - the result of the toxine.

Although the introduction of the serum treatment has been followed by results little short of extraordinary, the death-rate directly due to toxic absorption and the other minor results from the same cause, namely, degeneration of muscle and nerve causing paralysis or the toxic effects, as seen on the kidney with its consequent production of albuminuria, have by no means diminished in a corresponding degree.

Such is the truth of the above statement, namely, so low is the death-rate directly traceable to obstruction, that it would seem that, except for the introduction of a more powerful and more readily absorbed antitoxin serum, little more can be done in attacking that particular complication of the disease.

If the "obstruction treatment" appears perfect or nearly so, the Therapeutics at our command - apart from the administration of antitoxin serum - for dealing with the toxæmia must so far seem inadequate.

It would appear that, broadly speaking, a sufficiently powerful dose of antitoxine administered at a time so early in the course of the disease that the toxines are annulled before they can devitalise and cause degeneration in the tissues, is perfect treatment. Such probably is the case, but, so different is the resistant power in each individual that the correct antitoxic guage is as yet indefinable and hence methods have yet to be perfected to aid the antitoxine by increasing otherwise the resistant power of the individual.

To do so has been the object of the present investigation.

DIPHTHERIA AS UNDERSTOOD IN THESIS.

By the term Diphtheria used in the diagnosis of the following recorded cases the definition accepted by Northup has been strictly adhered to, namely: "an infectious and communicable disease characterised by the production of false membrane on a mucous or abraded skin surface and due to the presence and proliferation of the Klebs-Löffler bacillus and the toxines elaborated in its growth. The importance of the latter part of the definition, namely, the bacteriological diagnosis, has been emphasised as much as the former or clinical.

So much so is this the case that cases of purely clinical diphtheria have not been included in the following statistics, so that in every case the diagnosis of diphtheria made clinically has been supplemented and proved by the usual bacteriological investigation.

Inversely, no cases have been considered which gave a positive bacteriological result without any clinical phenomena; and again, therefore, every observation may be regarded as clinically and bacteriologically positive.

PATHOLOGY.

Heart, Nervous System, Kidneys.

Heart.

The pathological study of the Heart in Diphtheria is of comparatively recent date, namely, 1870, but, from the first carefully recorded report - that of Hagen (Archive de Physiologie 1870) - until the present time, the one constant feature is that of Fatty Degeneration of the Myocardium.

The degeneration appears in the form of fine granules or in large globules involving the greater part of the muscle cell (Northup).

It appears to be found as the first sign of change in structure of the muscle and to be an accompaniment of the later destruction in more advanced cases.

Northup also notes that simple fatty degeneration is invariably found in the severe cases of short duration, and the more destructive and degenerative changes in the prolonged cases, where there is complete breaking down of the sarcous elements and destruction of the muscle substance.

In the later stages also, there is a marked proliferation of cellular elements in the tissues

Hagen.
Archive
de Physi-
ologie,
1870.

which, however, rarely leads to fibrous change.

An important point bearing on the aetiology of Schamschin the condition has been noted by Schamschin (Ziegler's "Ziegler's Beiträge" 1895) who states that, no matter how early in the disease, one of the first features is fatty degeneration in the walls of the small blood vessels of the Heart.

Baginsky. Baginsky (Diphtheria and Diphtheritic Croup "Diphtheria and Diphtheritic Croup." 1898) sums up the main changes (i) Fatty Degeneration of the muscle elements, (ii) Fragmentation of the nuclei, and (iii) Haemorrhages from the small diseased blood vessels.

Mollet and Mollet and Regaud. Regaud. "Annales de l'Institute Pasteur 1897" have summarised the following changes:-

(a) In the muscle fibre: granular and fatty changes with occasional vacuolisation: striation often lost.

(b) In the nuclei: nuclei distorted, swollen and stain with difficulty.

(c) in the interstitial tissues: Increase of the cellular elements between the fibres.

Macroscopically there is little to note save dilatations - especially of the right side of the heart - slight paleness of the muscle: the pericardium is as a rule healthy.

It is as yet undetermined if the microscopic changes noted above are primary, namely, due to the direct action of the toxine on the muscle, or secondary, due to lack of stimulation from an already toxic nervous system.

In support of the latter theory is the fact that Lentino found similar lesions after unilateral division of the Vagus nerve.

Against this, again, is the fact of the early degeneration of the walls of the small vessels of the Heart (Schamschin) which would equally lead to impaired nutrition and fatty degeneration of the muscle supplied.

Bolton (*Lancet* 1906) advances the following theory: In the acute stage of diphtheritic toxæmia, acute degenerative changes occur in certain cells of the central nervous system, and amongst these cells the nucleus of the Vagus nerve is affected and, therefor, extensive Fatty degeneration occurs in the muscular fibres of the Heart. It is thus, he says, that acute diphtheritic poisoning proves fatal, the patient dying from a primary progressive failure of the heart as the result of acute degenerative changes in the neuro-muscular mechanism of that organ. At a later stage of the disease, if the patient survives, the poison attacks the

Bolton.
"Lancet."
1906.

peripheral nerves and voluntary muscles; a primary parenchymatous degeneration occurs in the nerves and a fatty degeneration of the muscle.

Hesse.
Jahrb. F.
Kinder-
heilk.
1894.

One other view has been advanced by Hesse, (Jahrb. F. Kinderheilk. 1894) a somewhat vague one, namely, that the changes and consequent heart failure result from the effects of the poison upon the Heart but not as a result directly either of the muscle or of the nerve degeneration.

To summarise; the various theories appear to be:

- (i) Primary Degeneration of Muscle - Schamschin
- (ii) " " " Nerve - Vincent -
- (iii) A combination of both according to the stage of the disease - Bolton.
- (iv) Toxaemia of Heart directly traceable to neither - Hesse.

It would appear that Bolton's theory - an idea shared by many other authorities - has much weight, and that the fact that death from Heart Failure may be accurately classified into at least 4 classes, viz., (a) Early, (b) Late, (α) Progressive (β) Sudden , much strengthens this view.

Whatever the true cause or causes may be, the liability to Cardiac Failure is much increased by the increased coagulability of the Blood in Diphtheria, due to reduced blood pressure and weakened

X

action of the Heart. With this additional liability to the formation of Thrombi the danger is much increased, but can hardly as Jacobi suggests (Med. News 1898) be regarded as a cause but rather as a result.

Nervous System.

Although the pathological features of the Nervous system vary, in minor points, with each individual case; in the main they are very constant and may be summarised as follows:

(i) Cord.

Here, according to Rainy (Journ. of Path. and Bact., 1900), the changes are mostly cellular. There is marked chromatolysis and vacuolation of cell protoplasm.

In the gray matter of the anterior cornu Nissl's bodies are markedly disintegrated and generally many cells are found shrunken.

Bickel and Kalish in 1894 described also a degeneration of the posterior roots where they enter the gray matter of the posterior cornu.

(ii) Brain.

Here the changes are generally circulatory, namely, hyperaemia, infiltration or haemorrhagic.

(iii) Peripheral Nerves.

Thomas (Boston Med. and S. Journ. 1898)

describes marked parenchymatous degeneration of the peripheral nerves, hyperaemia and haemorrhages, also fatty degeneration of the nerve fibres of the peripheral nerves.

(iv) Cardiac Plexus.

Vincent. "Archive de Med. Exper." 1894.
described a parenchymatous and atrophic neuritis. Degeneration of the Myelin sheath, changes in the Axis cylinder and marked absence of multiplication of the nucleus were always present which as Northup points out, show a degeneration, and not changes due to an irritant.

Kidneys.

By far the most common changes found in the kidneys are those of degeneration. The epithelial cells are enlarged and irregular and in advanced cases are completely destroyed and desquamated. The degeneration is not fatty, although a slight degree of fatty degeneration is generally present, but according to Northup, some degree of hyaline degeneration is invariably present.

He also states that lesions of the kidneys of greater or less extent are found in practically all cases of fatal diphtheria.

In most cases the amount of albumen corresponds

to the degree of degeneration present.

Welch and
Flexner.
"John Hop-
kins Bul-
letin".
1892.

Welch and Flexner (John Hopkins Bulletin, 1892) state that, experimentally, the epithelium of the tubules is rendered very granular and much swollen but not fatty. They also report a slight fragmentation of the nuclei in the epithelium of the tubules. Acute interstitial changes appear generally in conjunction with complications of the disease and are accompanied by marked increase in size of the kidney. Here the changes are most marked at the base of the cortex just beneath the capsule and around the glomeruli, and degeneration of the epithelium to a varying degree is always present.

The glomerular changes are of a chronic type and probably to be referred to an acute antecedent attack of endocarditis (Northup).

CAUSE OF ALBUMEN.

The exact cause of albumen in Diphtheria is as yet uncertain.

Rolleston
"Practi-
tioner."
1905.

Rolleston (Practitioner 1905) has shown that the quantity of albumen varies with the severity of the case.

As the amount of degeneration varies with the severity of the case, and in the same proportion, it is reasonable to suppose that there is a distinct analogy.

That the degeneration is produced by the direct action of the toxine of the Klebs-Löffler bacillus, although the most likely hypothesis, is by no means certain for the septic and anginous cases - produced by other organisms, Streptococci, etc., - are those in which it is found in largest amount.

That it is due to the presence of antitoxine has been practically disproved by Variot (*La Diphthérie et la Sérumthérapie*) who has also shown that the presence of Chronic Bright's disease is no contra-indication for antitoxine.

The balance of evidence then appears to prove that the presence of albumin in the urine is an indication of the severity of the toxine of Diphtheria or the presence in large numbers of accompanying organisms. Its almost invariable presence in fatal cases would also seem to show that the resistant power of the individual is an important factor.

The relationship of albumen to paralysis has been discussed since the times of Troussseau - who, in one case noted an increase of albumen coincident with the onset of paralysis - but Trevelyan (*Lancet* 1900) appears to state the matter clearly when he says that diphtheritic albuminuria has no other relationship to diphtheritic paralysis than that both complications are more prone to occur, where the diphtheritic intoxication is most intense.

Variot.
"La Diph-
thérie et
la Sérum-
thérapie")

Trevelyan.
"Lancet".
1900.

CARDIAC FAILURE.

Whatever the exact cause of cardiac failure in each individual case, viz., myocardial, neural or a combination of both, the condition is an easy one to recognise.

The main features are:

Vomiting, which, as a rule, is irrespective of food. It may be a simple regurgitation or accompanied by retching.

Blueness of the skin and mucous membranes and, towards the last stage, coldness of the extremities.

These symptoms are, as a rule, accompanied by obvious signs of weakening of the heart, such as:- dilatation, irregular and intermittent pulse, 1st sound faint, short, with perhaps a systolic murmur or reduplicated at the Mitral area. There may be bradycardia or a galloping rhythmic contraction; the latter, as a rule, only when the patient is in extremis.

The patient frequently complains of praecordial pain which may be very severe and may be referred, generally, to the abdomen.

As a rule, the patient lies absolutely quiet but may, towards the end, be very restless and excitable..

The temperature may be at first slightly

elevated but quickly becomes subnormal.

The patient dies on an average from 3-5 days after the first appearance is noted.

Such a type as the above is the progressive type but in other cases - usually late in the disease - the patient may die suddenly without warning.

Myers (Lancet 1900) gives the seventh day as the average number of days after the beginning of an attack of diphtheria that the symptoms and signs of cardiac paralysis are noted. He also gives the 2nd and 35th days as the two extremes.

Although so profoundly toxæmic the mental faculties of such patients are, as a rule, quite unimpaired to the end, and with this fact and symptoms and signs such as are noted above, a diagnosis is obvious and a clear division can be made between the two types, namely, progressive and sudden. The earlier symptoms of cardiac failure occur, as a rule, when the patient is and has been absolutely quiet, and are no doubt caused by the intensity of the toxæmia causing an acute degeneration. The later ones, however, frequently result from a strain - as when at stool - and this fact would appear to show that the degeneration has been present and in the myocardium, and, that the weakened muscle has been unable to respond to the additional call made on it and that the cause is not a secondary or late degeneration.

PARALYSIS.

Although in discussing the pathological changes in the nervous system it was stated that the lesions were, as a rule, constant, it by no means follows that each case of paralysis presents all features. From this fact and from the fact that some present no nervous features but muscular changes only, the aetiology of paralysis is rendered somewhat difficult.

The great varieties of paralysis and the different lesions found, all tend to render the cause obscure.

Manicatide
"Rev. mal
de l'enf."
1896.

Manicatide in 1896, for instance, reports the examination of a series of paralyses which may be divided into at least 4 groups:

- (i) Where the lesions were purely muscular with no nerve complications.
- (ii) Cases of polyneuritis.
- (iii) Lesions of the spinal cord which were either localised in the gray substance leading to atrophy of the muscle or involved the white matter of the cord in a manner such as is found in locomotor ataxy.
- (iv) Central paralysis, chiefly resulting from changes in the circulation.

Although the ataxic symptoms often seen in diphtheritic paralysis would seem to point clearly to destruction of the muscular sense, it is mostly of a reeling or cerebellar character and the most likely hypothesis would seem to be that a degeneration has spread to the muscles of the trunk and started elsewhere.

Although conflicting, the evidence in all would seem to be, that while many cases of paralysis are due to muscular degeneration and in this class the benign or localised forms have their place, most are due to a primary central disturbance - for the central lesions are not strictly speaking degenerative - followed by a Wallerian degeneration and failure of the peripheral nerves.

The paralyses may be classified as follows:

- (i) Localised or Benign Paralysis.
- (ii) General Paralysis.
- (iii) Cardio-pulmonary - which has been considered.

In the first group may be placed paralyses of palate and pharynx. This is much the most common variety and Myers and others have stated it to represent from 35%-40% of the total varieties of paralyses.

The second series includes the remaining forms of paralyses, viz., oculo-motor, extremities,

intercostals, etc.

As regards the frequency of paralyses: on an average taken from a large number of statistics it may be stated at 12%-14%, thus; the Metropolitan Asylums Board out of 8,238 cases gave 18.50% of paralyses, Sanné reports in 2,400 cases 11%.

Woolacott.
"Lancet."
1900.

Woolacott gives an interesting table divided into Cases Serious and Moderate,

Nature of Case.	Total.	Paralysis.	Percentage.
Serious	223	64	28.6
Moderate	536	75	13.2

and this would seem to prove conclusively that the paralyses is dependent on the amount of toxine.

METHODS CLINICAL AND BACTERIOLOGICAL ADOPTED.

The methods adopted in arriving at a correct diagnosis of the condition in the following recorded cases were as follows:

(i) Clinical.

Each patient was examined with lamp and spatula for, either signs of definite membrane or signs of the implantation of recent membrane.

Again, symptoms were carefully considered, namely, either the characteristic toxæmic appearance or the equally diagnostic odour, although these

symptoms were considered as merely confirmatory and on them alone no diagnosis was made.

Diagnostic importance was, in the case of suspected Nasal Diphtheria, especially attached to such symptoms as the foregoing in conjunction with a nasal discharge. The only possible exception was in the Laryngeal case where even in the absence of apparent membrane, symptoms plus croup were considered sufficient to warrant a diagnosis.

No cases apart from such as these are included in the following series and none without the accompaniment of a positive.

(ii) Bacteriological Examination.

A swab was at once taken from the throat or nose and stained for 3 minutes with Löffler's Methylene Blue solution and examined for rods and cocci.

At the same time a culture on Blood Serum was made and left for 16 hours at a temperature of 34° C.-
35° C. At the end of that time it was stained with a variation of Neisser's Stain, namely, Acetic Acid, Methylene Blue and Piero-Eythrocine solution, half a minute each.

None of the recorded cases have failed to show rods in the swab and polar staining or clumping of the Bacilli in the Culture, and both swab and culture may therefore be said to have been positive.

SKETCH OF PREVIOUS TREATMENT.

In the history of the earlier treatment of diphtheria the importance given to local at the expense of general treatment is, perhaps, the most noteworthy fact.

Until the 16th century no means were considered too harsh, thus, burning, scarification and forcible removal with pincers were the invariable rule.

In the 16th century authors on the subject began to reprobate these harsher methods, but, in lieu of better, were forced in a large number of cases to continue.

In the beginning of the 18th century, the use of drugs which destroyed the membrane by their caustic action began to be much favoured, such as Nitrate of Silver, etc.

Bretonneau (the first to clearly differentiate Diphtheria) in 1827, advocated strongly the use of alum and later, Uytterhoeven, Acetic Acid. Martin, 1858, speaks well of Hydrochloric Acid and Jenner supported this but recommended only one prolonged application. Up to this time the internal treatment was confined to stimulation by alcohol, when required, and aperients.

In 1861, Rey recommended the use of Perchloride of ^{Iron} both locally and internally, and this was for

long widely adopted.

Mercury was much used from 1880-1890 as a disinfectant either as calomel or biniode of Mercury in the shape of fumigations and internally. The general treatment consisted in alcohol and latterly strychnine.

The treatment of Diphtheria was, however, revolutionised in 1893 by Behring with Antitoxin Serum and resolved from that time until the present into treatment by serum, stimulants, as whisky, strychnine, strophanthus, digitalis and an antiseptic local treatment of the condition.

As showing more fully the treatment adopted during the past 3 years, the following detailed account has been given of the accompanying 300 control cases.

PREVIOUS TREATMENT 1904-1905 IN HOSPITAL.

- TREATMENT OF ACCOMPANYING CONTROL CASES -

The main lines of treatment were:

- (i) To prevent degenerative changes in the acute stage by rest and adequate doses of antitoxine.
- (ii) To prevent strain and consequent heart failure in the secondary stage by rest.
- (iii) By stimulation, to assist the individual to resist the toxine until the toxine was neutralised.

(iv) In Cardiac Failure to obtain rest by preventing vomiting and to stimulate the heart.

(a) UNCOMPLICATED CASES.

(a) FAUCIAL AND NASAL.

I. General Treatment.

(i) Rest.

The patient was kept in the recumbent posture with one low pillow for at least 12 days and complete mental rest was also enjoyed - no reading, etc. If at the end of that time there were no symptoms, viz., pulse irregularity, etc. the patient was given one more pillow. At the end of 3-4 days, conditions again being favourable, the patient was permitted to sit up in bed and was allowed out of bed in blankets about 6 days later.

The patient was kept in Hospital for at least 3 weeks and was not in any case permitted to leave until two consecutive bacteriological examinations had proved negative, and until clinical symptoms had disappeared.

(ii) Stimulants.

From the day of admission the patient was prescribed small doses of Whisky and Liquor Strychninae every four hours in doses varying with the age of the patient and the severity of the case. This

treatment was continued for 10 days when, with no symptoms Syrup Easton Zi-Zii was prescribed three times daily.

Occasionally for extraneous symptoms, Non, etc. was also given.

II. Local Treatment.

In cases where the membrane was very obvious a throat paint { Px Toluol . . . 36 Parts.
Sp. Vin. Rect. : 60 " was
Tinct. Ferri Perch. 4 "

applied frequently. It was found very useful both as an antiseptic and of assistance in destroying the membrane.

This was always accompanied by a swab of Boroglyceride which was continued during residence.

In cases where the fauces were apparently septic and foul-smelling, a spray of peroxide of hydrogen was given for 24-48 hours at varying intervals.

(b) LARYNGEAL CASES WITH CROUP.

On admission the patient was placed in a cot between two steam pipes. A full dose of Vin. Speciae--~~mxv-mxx~~ - to assist in loosening the membrane was at once given and this was followed by small doses - ~~mii-my~~ - every 4 hours so long as the patient remained croupy.

Tinct. Belladon. in small doses - miimiv - every 2 hours until dilatation of the pupils was obtained, was also prescribed, to dilate the passages and act as a stimulant by paralysing the terminations of the Vagus nerve in the Heart and therefore to destroy the inhibitory action of the nerve - this result, viz. acceleration of the Heart, systotic increase, etc., was found to have excellent results.

In addition to these two drugs the patient was given small doses of Whisky and Liquor Strychninae in doses again varying with the age of the patient.

Should operative interference not be necessary, these measures were continued until the croup symptoms disappeared, when treatment on ordinary lines was continued.

(β) COMPLICATED CASES.

(i) Operative Cases.

In cases where the above treatment did not ameliorate the condition, viz., where the dyspnoea, cyanosis and signs of CO₂ toxæmia manifested themselves, Intubation was performed and the tube left in position for 2-3 days and not removed until croup symptoms had disappeared. In cases where the tube could not be retained or where it proved unsatisfactory, Tracheotomy was performed.

(ii) Cases of Cardiac Failure.

At the first sign of cardiac failure the patient's pillow was removed and he was kept flat in bed or even with the head lowered.

If vomiting had occurred Liquor Strychninae was at once stopped and Brandy alone given while an effort later was made to feed the patient with peptonised milk.

Should there again be a tendency to vomit, the patient was stimulated and fed per rectum and in cases of extreme thirst and with no contra-indications, small quantities of ice were given to suck.

On signs of further cardiac failure, Hypodermic injections of Strychnine or Strophanthin were given, generally in conjunction with Adrenalin Chloride (1-1,000).

In a few cases where the patient became extremely irritable and restless, very small doses of Morphia and Atropine were given.

(iii) Cases of Paralyses.

At the onset of paralyses the patient was kept recumbent and given increased doses of Liquor Strychninae, ~~massage etc.,~~, was adopted and in the case of the spinal muscles the spine was painted with Iodine Tincture and Potassium Iodide.

In the case of the palatal and pharyngeal paralyses, all ordinary precautions were adopted as regards feeding, etc.

ANTI-TOXINE TREATMENT.

As all the accompanying cases (both 100 treated with Formic Acid and the 300 control cases) were given antitoxine doses based on the same broad lines, it may be well to shortly state the views which prompted the doses.

The two main factors under consideration were:

(i) The severity of the disease

{ a) Local Condition
 b) General Toxaemia.

(ii) The age of the disease.

(a) Faucial uncomplicated cases.

Here the dose given was, in the main, 1,000 units (P. D. & Co.) for each day of the disease, but, in cases with definite membrane, not less than 3,000 units.

If the palate or uvula was involved, the dose was not less than 4,000-5,000.

This was repeated in 12 hours if there was a further spread of membrane.

(b) Nasal Cases.

Here, as, owing to the large lymphatic area affected, the toxæmia is, as a rule, intense, the dose was seldom less than 6,000 units repeated in

24 hours if the toxæmia appeared more intense, up to a total of 24,000-30,000 units.

(c) Laryngeal Cases with Croup.

A dose of, as a rule, not less than 6,000 units in an ordinary case was given on admission and repeated every 8-12 hours until the membrane appeared to loosen.

In early Cardiac Failure, a large dose was occasionally given, repeated if the condition appeared to benefit.

CRITICISM OF PRECEDING TREATMENT.

Apart from the local treatment, and the large question of antitoxin, the treatment hitherto adopted has, as shown by this resumé, been one of stimulation, mainly by strychnine and also digitalis and strophanthus with the occasional use of hypodermic injections of strychnine or strophanthin or adrenalin chloride.

As stimulants, the one feature common to all these drugs is that they achieve their end mainly by raising blood pressure: digitalis does so partly by increasing the cardiac force and mainly by contracting the arterioles by direct action on their muscular coat and again, in a lesser degree, by

stimulation of the medullary and spinal vaso-motor centres. Strophanthus also raises blood pressure although the action on the arterioles is not present as in digitalis. Adrenalin chloride does so almost solely by contraction of peripheral vessels.

Strychnine: raises blood pressure by direct stimulation of the vaso-motor centre, which, as a result, leads to constriction of the peripheral arterioles.

In mammals while the heart is not directly affected by strychnine, stimulation of the inhibitory centre leads to a slightly slower rhythm.

It would seem therefore that, from this point of view, these drugs are not ideal in that they tend to increase the amount of work done by a heart which has a tendency to degeneration.

There are other points also in their action which appear doubtful.

Strychnine. As a nervous stimulant acts mainly on the central nervous system and it has been found that the symptoms of the drug are unaltered when the drug is prevented from reaching the peripheral nerves and muscles.

It has also been shown that almost certainly the motor cells are unaffected and that any changes such as enlargement - found in them are due to hyper-activity and not to the direct influence of the drug.

As has been shown, however:

(i) The main changes in the diphtheritic cord
are in the motor cells.

(ii) Many of the paralyses in Diphtheria are
not central but peripheral or muscular.

It would appear therefor that the therapeutic value of strychnine in such a condition must theoretically, be very limited, for, in addition, it is a known fact that, while small doses of strychnine increase the tone of the muscles - namely render them more tense so that they are prepared for immediate contraction - that this is due to the action on the cord and not on the muscle fibres.

One other doubtful feature in the treatment by strychnine is the reaction and depression which follows its use and which Cushny suggests is due to the hyper-activity of the lower parts lessening the activity of the pain.

In the treatment of a disease in which paralyses is such a marked feature, it would seem that here again there is a contra-indication and that while expecting in severe cases by pushing strychnine to obtain a temporary benefit, the final result would only be exaggerated.

One other negative point in the treatment by drugs such as those mentioned, is that they make no claim to influence the third important complication

of Diphtheria, viz. Albuminuria, and would appear again by raising blood pressure to aggravate the kidney condition.

The following is an account of a drug which would appear more nearly to meet the requirements in Diphtheria:

FORMIC ACID. H. C O O H.

History, Chemistry, Properties and Therapeutics.

It occurs in the concentrated state in the bodies of ants, in the hairs and other parts of certain caterpillars and in stinging nettles. Its stimulant properties have been known for centuries, and Arabs for long have realised this and, before commencing a long and arduous ride, were accustomed to give their horses with their ordinary diet a decoction made from Ants' eggs, the result being a marked increase for the time in their powers of endurance.

The internal administration of preparations containing Formic Acid has also for centuries figured among household remedies where they were much valued for their tonic and diuretic properties.

It was not, however, until 1903 that serious scientific experiments with it were made and in that

lement.
Société
 Nationale
 de Médi-
 cine de
 Lyons.
 1903.

year Clement in a paper read before the Société Na-
 tionale de Médecine de Lyons reported a series of in-
 teresting experiments which placed it in a new and
 important light.

Chemistry.

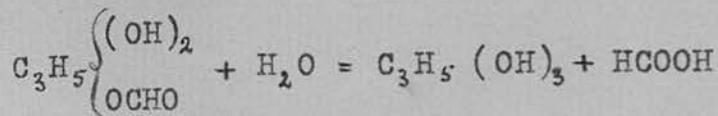

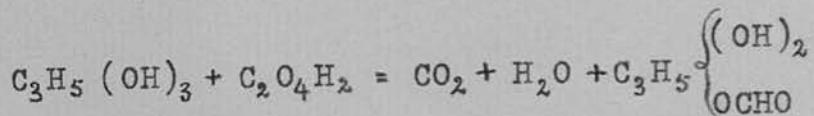

It is obtained by heating equal parts of an-
 hydrous glycerin (or mannite) and crystallised oxal-
 ic acid in a retort to 75% until carbonic acid is
 no longer evolved. A fresh portion of oxalic acid
 is then added and the distillation is continued.
 This process may be repeated several times.

The distillate finally contains 55% of the acid
 and is redistilled over anhydrous oxalic acid when
 a 75% acid is obtained. This is neutralised with
 sodium Carbonate, the dry sodium salt distilled with
 anhydrous oxalic acid when a 99% acid is obtained -
 Lorin -.

The last trace of water is removed by distilla-
 tion over boric anhydride and the acid is subjected
 several times to a freezing mixture, the crystals
 separated from the liquor and then allowed to melt;
 or the dry lead or copper salt is heated at 130° in
 a current of dry hydrogen sulphide; in the latter
 case the product is apt to be contaminated with sul-
 phur products.

In the above process the crystallised oxalic acid decomposes into water, carbonic acid and Formic acid, the last of which combines with the glycerin to form monoformine, which is subsequently decomposed by water into Glycerin and Formic Acid.

The equation is:

Properties.

The acid solidifies below 0° and exhibits the phenomenon of superfusion. The liquid acid is colourless, transparent and mobile. It has a pungent sour taste and odour, and when concentrated blisters the skin - Lubig -.

Therapeutics.

Formic acid is officially used in the form of a colourless fluid of a concentration of 25%, Sp. Gr. 1060-1063.

In 1903 Clement, in a lengthy paper, stated that he had found Formic Acid to be a powerful stimulant of striped muscle and in its toxic action closely allied to Cola, Coca and Caffeine. He stated also

that the internal administration dispelled any sensations of lassitude as seen in nervous individuals, and that, experiments controlled by dynamometrus and ergographs, showed a marked elevation of muscular power within two days of administration. At the same time he noted a marked improvement in muscular capacity manifesting itself in an exhibition of active and rapid movements.

In the same year, Krull - Munich - noted marked improvement in Chronic Kidney disease with Albuminuria after the subcutaneous injection of Formic Acid. He injected the preparation in the form of an aqueous solution (1:1,000 - 1:100,000) according to the age of the patient and the stage of the disease in doses of $mii - mxvi.$ As a result he was able to report (i) Improved nutrition, (ii) Decrease of Albuminuria, and (iii) Diuresis.

These results he obtained as a rule when there existed no advanced cardiac complications.

In 1904 Clement reported the following results:

After the administration of Formic Acid the subject performed 10 periods of work instead of 5 as before administration. In the 10 periods of work he realised with the Mosso Ergograph 479 of the weight of 5 Kgrms. instead of 132. The total work done was 106 kilogrammétres, while, before the administration of Formic Acid the subject was only

Krull.
München.
1903.

Clement.
(Tribune
Médicale)

able to do 21 kilogrammétres.

The amount of work done then after the administration of Formic Acid was increased almost five-fold.

He found also that the effect on the muscular system was very lasting and persisted for 8-10 days after the administration, and that, under the influence of the drug, the painful sensation of the muscle submitted to the repeated contraction was noticeably diminished.

Another important point was that the muscles so treated recovered their energy very rapidly.

He also in the same year reported two cases of tremor due to muscular atony in which marked improvement followed the administration of Formic Acid, although the disease had existed in both cases for 10 years.

Huchard.
(Bulletin
de l'Aca-
demie de
Medecine)

Huchard, one year later, reported the following observations:

I. Patient before administration - 5 Kgrms. .90						
"	one day after	"	= 9	"	- 60	What?
"	two days	"	"	= 9	"	.35
"	three "	"	"	= 9	"	.05
"	four "	"	"	= 10	"	.70
"	five "	"	"	= 11	"	.50
II. Patient before administration = 9 " .900						
"	one day after	"	(grms. ii) = 8	"	- 75	

Patient Two days after administration (grms. ii)-20	Kgrms .625
" Three " " " (grms. iv)-20	" .975
" Four " " " (grms. iv)-20	" .200
" Five " " " (grms. iii)-30	" .650

He also in a large series of experiments proved that the toxicity of Formic Acid was practically nil: thus grms. 60 in a single dose were required to kill a small dog, while a dose of 11 Kilogrammes, intravenously injected into another dog, produced no symptoms other than slight vomiting.

In the same communication Huchard makes important statements on the diuretic action of Formic Acid and the Formates.

He proves, in the first place, conclusively that it is eliminated by the kidneys, thus: he injected into the Jugular vein of a dog 20 c.c. of Aqua Distillata containing in solution grms. 4 of Formate of Soda. After 48 hours there was excreted 453 c.c. corresponding to 2 grms .22 of the Formate and further series of experiments confirmed these observations.

He also, as did Krull, noted its diuretic action and the rapidity with which it was produced.

In a case of sclerosis of the kidney in which the quantity excreted was 1,000 c.c., he noted that

in 4 days it rose to 2,700 after the absorption of 3 grammes of Formate of Soda.

A further series of experiments were:

Amount of urine in 24 hours	2,500 c.c.
After grammes 3 of Formate of Soda	. 3,750 c.c.
Drug stopped	2,550 c.c.
After Grammes 3 of Formate of Potash	. 4,000 c.c.
3 days after stoppage of Drug	. 2,400 c.c.

He further noted that in every case the quantity of albumen was diminished, and in most cases to a very marked degree. Again, that the acidity of the urine is much diminished and that the urine, at first, is always alkaline.

L. Garrique recorded similar results obtained with Formate of Soda, viz. an increase in the excretion of urine from 20 grms - 50 grms per day.

The injection of Formic Acid in a concentrated form has been found to raise blood pressure (Garrique, Clement, etc.), but later experiments with the dilute acid have proved that there is no increase of blood pressure either in artero sclerosis or advanced cardiac lesions. The Formates do so to a slight degree, and of them, Formate of Soda is the most pronounced.

rrique.

ticiens)
904.

SUMMARY OF CONCLUSIONS, PART I.Pathology.

1. That the main changes observed are degenerative.
2. (a) That degenerative changes occur in the nerve cells as a result of the Diphtheria toxine, and that, while they may recover, they may atrophy and that the nerves, of which they are the trophic centres, undergo Wallerian degeneration and lose their conductivity.
(b) That degeneration occurs in muscle fibres as a direct result of the toxine.
3. That Cardiac Failure is dependant on both forms or both combined, according as it is Progressive, Sudden, Early, Late.
4. That Paralysis depends on both forms or both forms combined, according as it is Benign or General.
5. That changes in the Kidney in Diphtheria are those of degeneration.
6. That Albuminuria is not caused by antitoxin but is due to toxæmia, and that the amount of albumen is an indication of the severity of the disease and the amount of general toxæmia.

Treatment.

7. That treatment, apart from antitoxine and local treatment, has hitherto depended mainly on the following drugs: Digitalis, Strophanthus, Adrenalin Chloride, and above all, Strychnine.
8. That all these drugs raise blood pressure and therefor, theoretically, add strain to the Heart.
9. That none have any effect on albuminuria and would be expected to increase degenerative changes in the kidney by raising blood pressure.
10. That Strychnine acts mainly on the Central Nervous System.
11. That many forms of paralysis are not central.
12. That Strychnine does not affect Motor Cells.
13. That it is the Motor Cells which are affected in Diphtheria when the Central Nervous System is affected.
14. That treatment by Strychnine is followed by reaction and depression and cannot with safety be pushed.

Formic Acid.

15. That Formic Acid ^{15%} ~~55%~~ does not raise Blood Pressure.
16. That Formic Acid is a powerful stimulant of all striped muscle and gives a marked increased capacity for work.
17. That Formic Acid improves the appetite and general nutrition.
18. That Formic Acid is a diuretic with an influence in reducing albuminuria.
19. That its stimulant effect on the muscular system is lasting.
20. That so far as is known it is not toxic.
21. That in its action it is allied to Caffeine or Coca.

Diagnosis of Recorded Cases.

22. That from the fact that only those cases have been recorded which were positive both clinically and bacteriologically, the following cases are those of True Diphtheria.

H. Silverlock, 82, Blackfriars Road, London.

Description of Case

Fauces congested. Tonils much enlarged. Mouth completely covered with grayish white thick membrane which is slightly loose on right tonil. Palate involved above right tonil. Throat completely covered with similar membrane. Voice is slightly husky. Pulse very soft & irregular. Drowsy pale & toxicemic.

Bwab: Thwait = insects rocks good clusters of
good short rocks. diplococci.

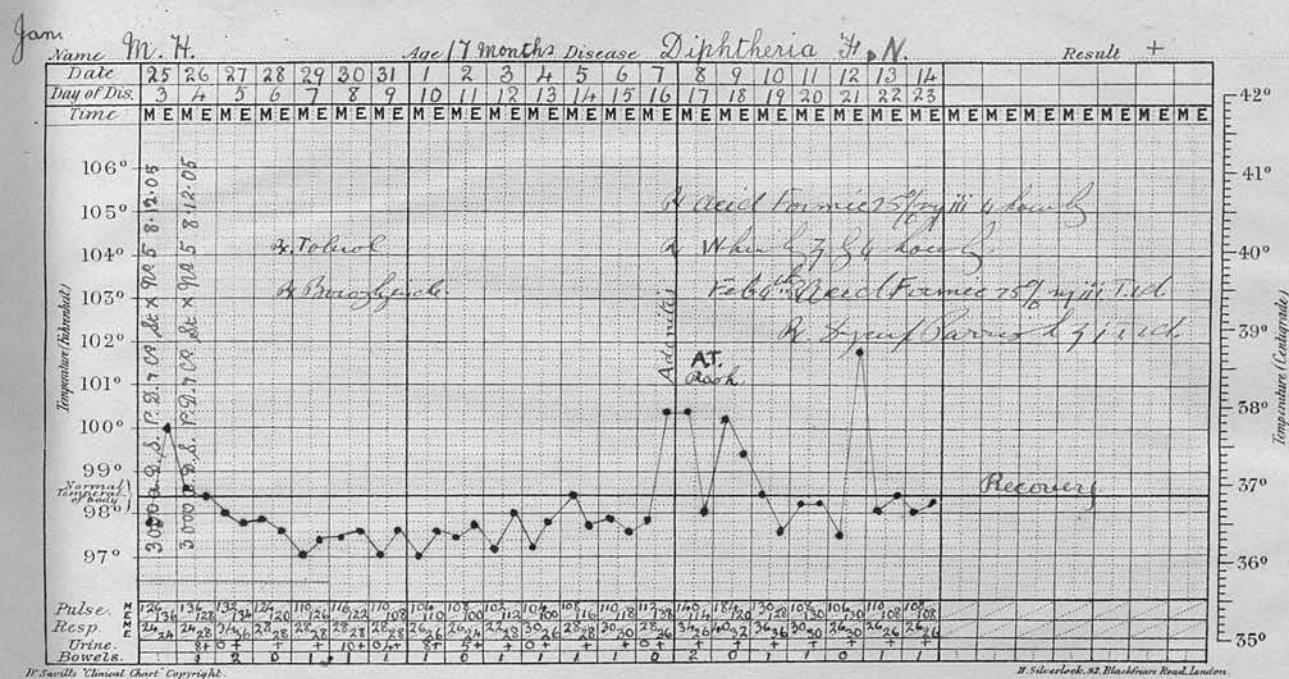

more = Some good short rocks & boulders

Culture Throat and Nose = Nunner Positive.

History

Within 4 days patient showed marked improvement and left hospital in good health.

Case IV.

Description of Case.

Slight enlargement & congestion of tonsils. There is a patch of dark gray membrane at base of right tonsil, and a smaller patch at the base of the left tonsil. Patient is very toxicemic looking. Pulse soft but regular.

Swabs = very good clusters & polar stained rods.
a few cocci.

Culture = Never Positive

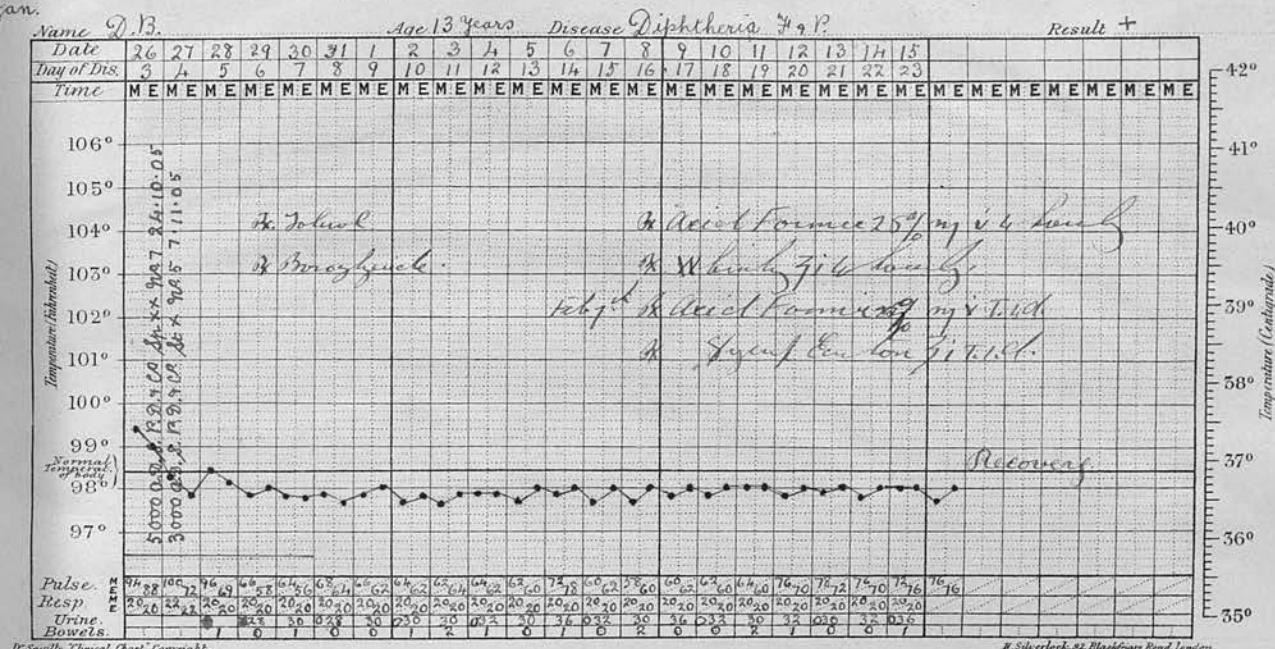

Herpes

Jan. 25th. Well marked discharge from both nostrils.

Culture = Never Positive.

Feb. 8th. Antitoxic red - morbilliform & slight adenitis. Left hospital in good health.

Case V

D. Savello 'Clinical Chart' Copyright.
No. 7.

H. Silverlock, 82 Blackfriars Road, London.

Description of Case.

Both tonsils especially left enlarged. Left tonsil completely covered with very thick grayish-white membrane. Smaller patch just posterior to left tonsil also to right tonsil. Throat free. Pulse is regular. Slightly diastolic. Patient is very pale.

Sweat = Mixed rods. Some very good rods.

Cosei. Staphylococci & Diplococci.

Culture = Never Positive.

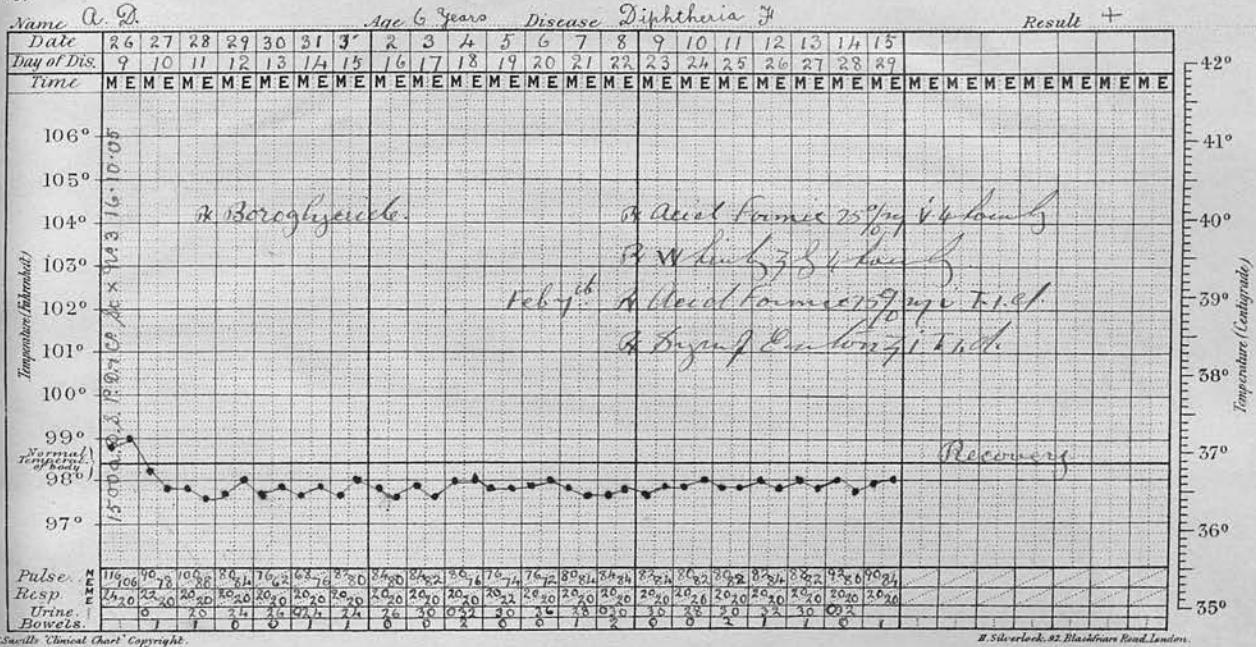

History.

Jan 25th slight speech membrane. Pulse still irregular. Jan 29th throat clear. In a better colour. Pulse no longer diastolic. Is regular.

Patient subsequently made uneventful recovery.

Case VI.

Jan.

H. Saville's Clinical Chart Copyright.

No. 7.

H. Silverlock, 92 Blackfriars Road, London.

Description of Case.

Slight congestion of Fauces. Left tonsil is a little enlarged and covered anteriorly with a filmy whitish-gray membrane. Uvula and right tonsil free. Palate is slightly ulcerous but regular.

Swab = a few wool short wools. Diplococci and Staphylococci.

Culture = Nisser Positive.

History.

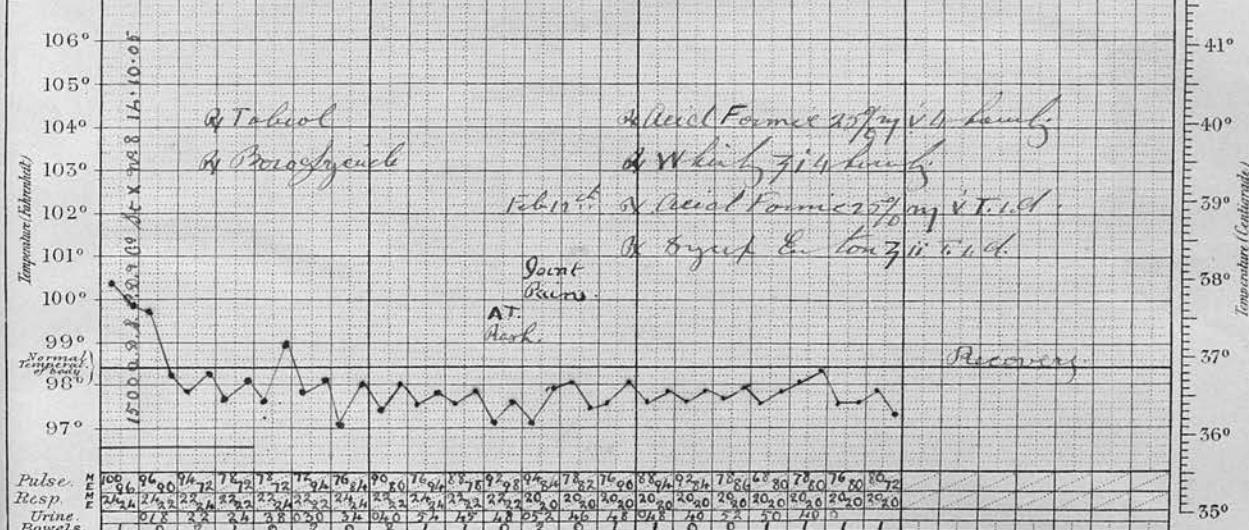

Patient made an uninterrupted recovery.

Case VII

Jan.

Name W. J. V. C.

Age 25 years Disease Diphtheria

Mr. Savills' "Clinical Chart" Copyright
No. 7.

H. Silverlock, 92, Blackfriars Road, London.

Description of Case.

Fauces slightly constricted. Left tonil is enlarged & covered with discrete patches of grayish-white thick membrane. Pulse is low tension but regular. Colour is good.

Bwab = Good short rocks. Some long, thin rocks
Staphylococci & Diplococci.

Culture = Neinver Politie

Hestway

Feb 9th Antilocapra rufus - morphology on page 2
extinct.

Feb. 10th slight joint pains. Slight stiffness in knee joint. Tendon responses unaffected.

Feb 2. 3 well & others made good recovery.

Case VIII

Jan.

Name L. H.

D^r. Savills' Clinical Chart Copyright
No. 7.

H. Silverlock, 92, Blackfriars Road, London.

Description of case.

Marked enlargement of tonsils. Both are covered at base with thick gray tenacious membrane and covered anteriorly with similar disintegrated membrane. Uvula & palate unaffected. Face is very pale a patient has pinched appearance. Pulse is regular but rather rapid.

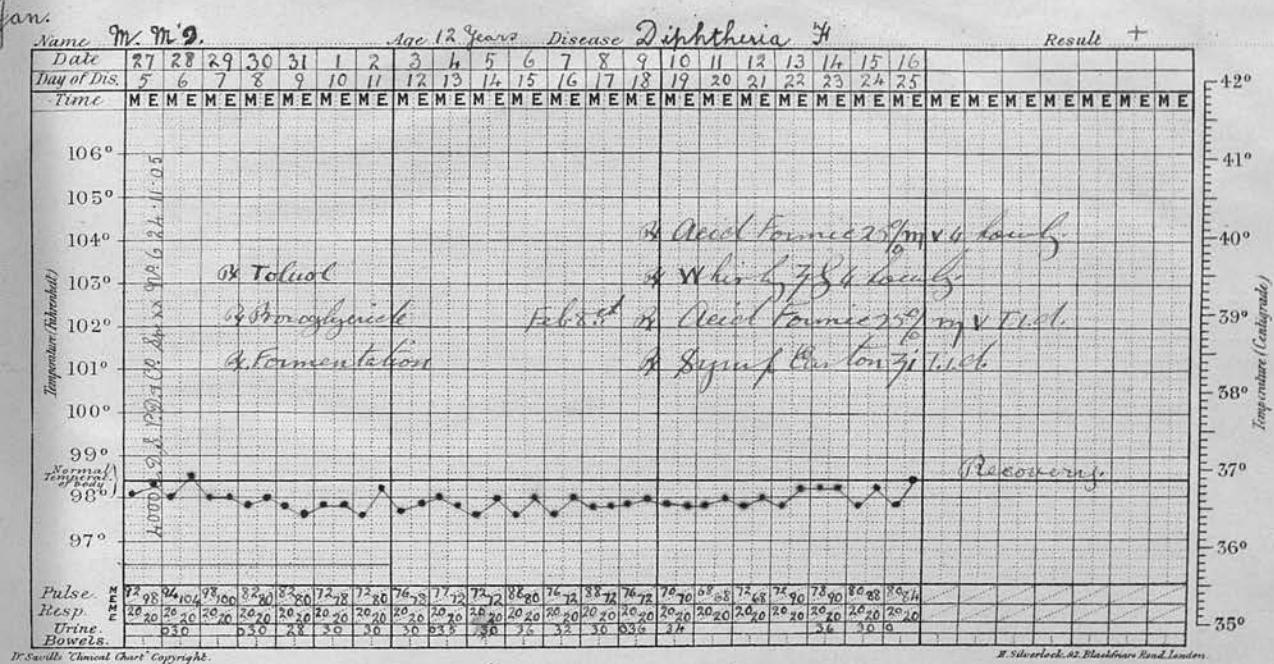

Bwab = Good rocks. mostly short rocks. Some long thin rocks. Gabbro & dolocacci.

Failure = Numer Positive.

Hirtnur

Feb 8th Pubore is irregular & volume is poor. Done of Fomie
and doubled = very heavily. Feb 9th Good colour Pubore
regular. Afterwards patient made uninterrupted recovery.

Case IX.

Description of Case

Base of each tonil covered with dark gray, thick membrane. There are about integrated patches of similar membrane on the anterior aspect of right tonil. Small patch of similar membrane on the left side of the uvula. Pups regular.

Ewabs = Many short wools. Some polar stained
Good clusters. many dislococci. Few
St. phlococci.

Cultura = Neiner Politie.

Boston

Patient made uninterrupted recovery.

Description Case X

On admission: Fauces were very congested. Slight enlargement of right tonsil. Left markedly enlarged. Base of right tonsil completely covered with dark gray thick membrane which spread far back posteriorly. Left tonsil covered at base with similar membrane. Mucula and palate free. Patient pale & very sombre looking. Pulse slightly irregular and volume and force poor.

Swab = Short polar stained rods. Many short short bacilli & a few staffle bacilli.

Culture = Neisser Positive.

History

Jan. 26th. No complaint of fulness of fauces & slight precordial pain near mitral area. There is a slight blurring myotic mitral murmur. Pulse is slightly atherositic & force & volume poor.

Jan 30th. Faeces & general condition much improved. Pulse is regular. Pain is gone.

Feb 8th. Faeces excellent. Pulse regular & good.

Mitral myotic murmur almost imperceptible.

Feb 26th. Throat painful. Left tonsil enlarged. Right tonsil slightly so. Feb 28th. Was evacuated from both tonsils. Patient afterwards made good recovery and left for home well.

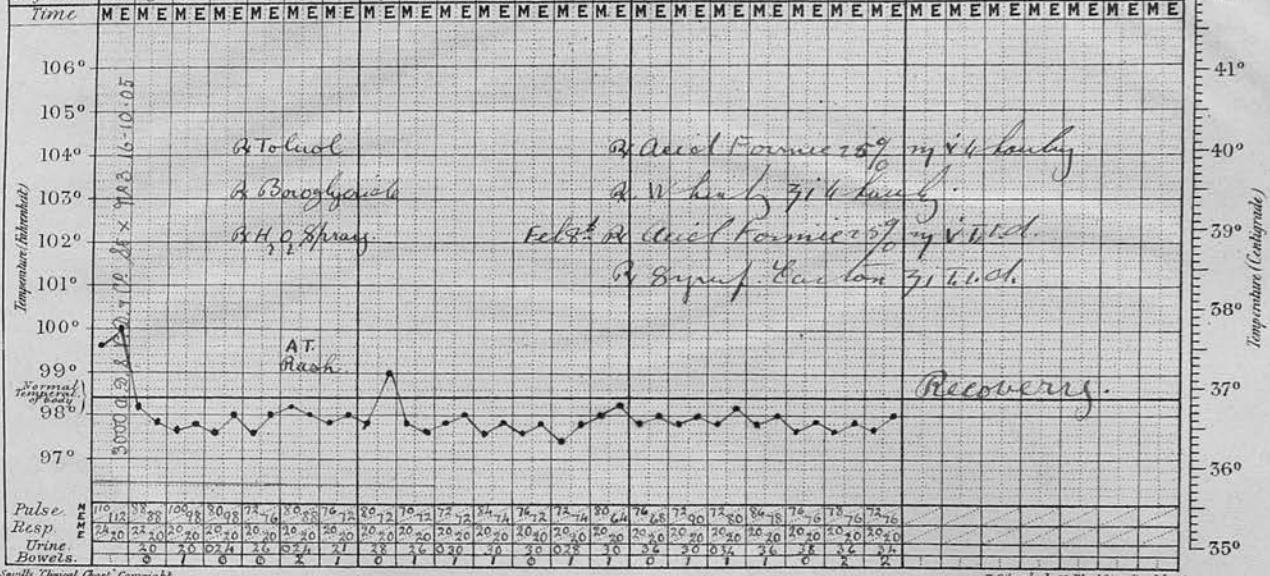

Case XI.

H. Silverlock, 92 Blackfriars Road London.

Description of Case

Faces congealed. Marked enlargement of right tonsil - almost to mid-line - right tonsil covered at base with dark gray membrane. Anterior surfaces membrane olivaceous. Surface is regular. Palate very pale.

Swab = Wool short thick wools, good churcils

Coccini and Diptero-coccini.

Culture = Never Politics

Herr Bruns

Jan 31. A. M. 1911. Anthonomus rufus.

Patient made an uninterrupted recovery. Pulse always regular & good.

Case XII

an. Name M. A.

Description of Case

Both tonsils slightly enlarged and covered at base with thick grayish white membrane. Enlargement of right submaxillary gland. Patient is very pale. Pulse is regular but poor in volume & force.

Swabs - medium sized rolls with

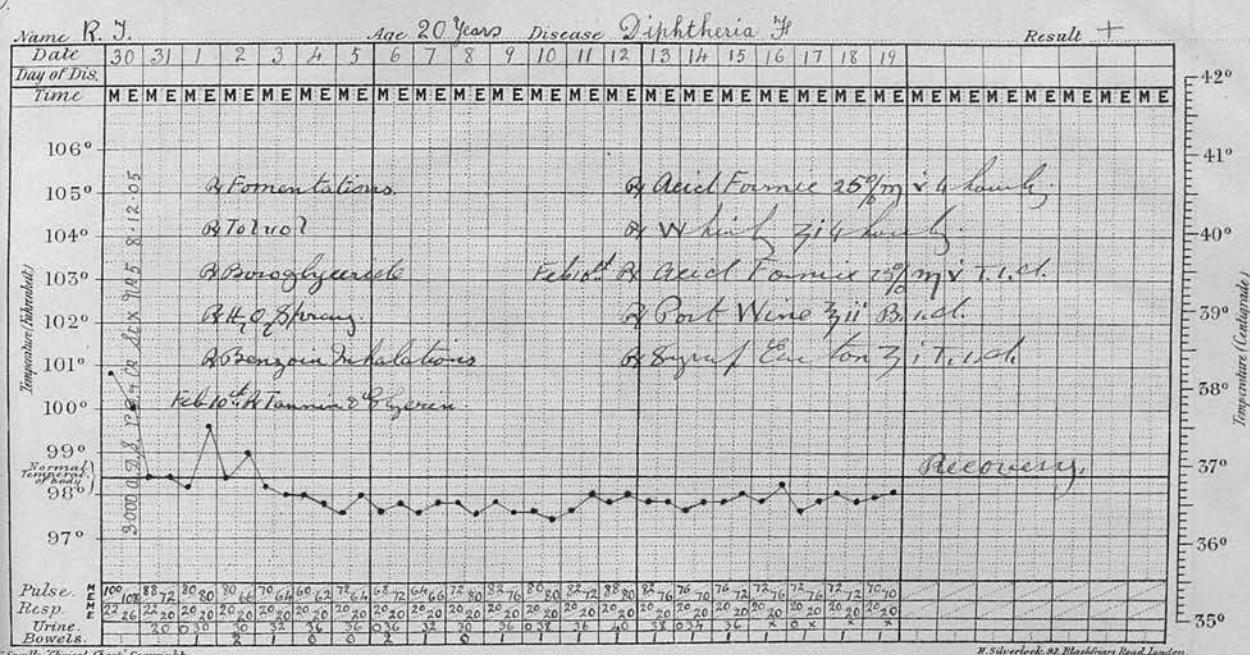

Colon staining & chart no.
diplo & staphylococci

Cultura = Never Continue.

History

Jan 3rd. Pulse improved. Patient still very pale.
Feb 6th. Patient good. Heart not enlarged. Pulse
regular. Patient afterwards made good recovery.

Case XIII

Description of Case.

Front tonsils covered at base with thick grayish-white membrane which is somewhat disintegrated at centre dark gray in colour. Marked enlargement of cervical glands. Heart: slight enlargement of left side. Heart rhythmical murmur not projected. Pulse regular but volume weak.

Swab = Thick short wools. diplococci & streptococci.

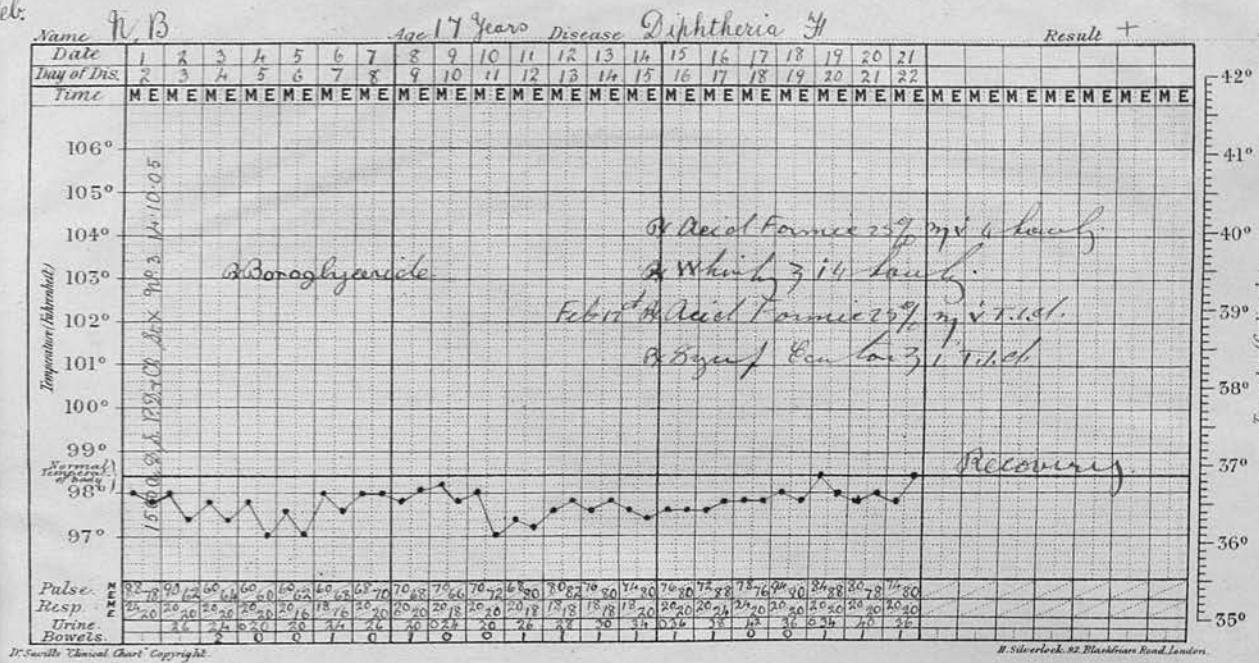

Culture = Nitro. Positive.

Habits.

Patient made good recovery. Heart when examined was still enlarged left side but murmur not so obvious. Pulse excellent.

Case XIV

Feb:

H. Silverlock, 82 Blackfriars Road, London.

1907.

Description of Case.

Faeces are a little irritable. No tonsillar enlargement. No definite membrane but patches of fibrous membrane has slight tend. Pulse is slightly irregular with poor volume.

Swab = short rods. thick rods.

Staphylococci and Diplococci.

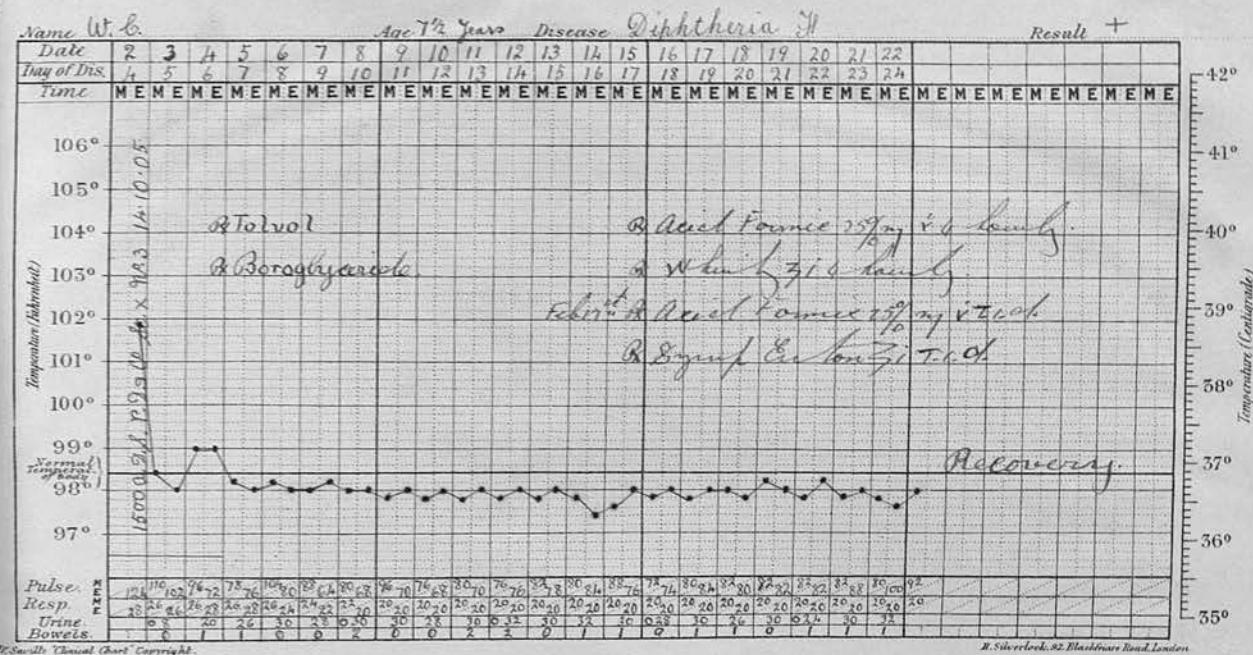

Culture = Mitis Bacillus.

History.

Feb. 9th Got up in bed & felt faint. Pulse irregular. Feb. 10. Was verted since 9th to a good colour with regular good pulse. Nothing cardiac.

Left for home in good health.

Case XV

Description of Case.

Right tonsil at base is completely covered with grayish membrane which is very tough & thick. The left tonsil has a small patch of similar membrane at base. Throat & palate free. Child is very pale & pinched looking. Pulse is slightly accelerated & irregular.

Swab = medium rods. Good clusters & polar staining. Short & floccose. Diplo- & staphylococci.

Cultures = Nunn Positive.

Incubation.

Bacilli regular & good by Feb 11th. Made good recovery.

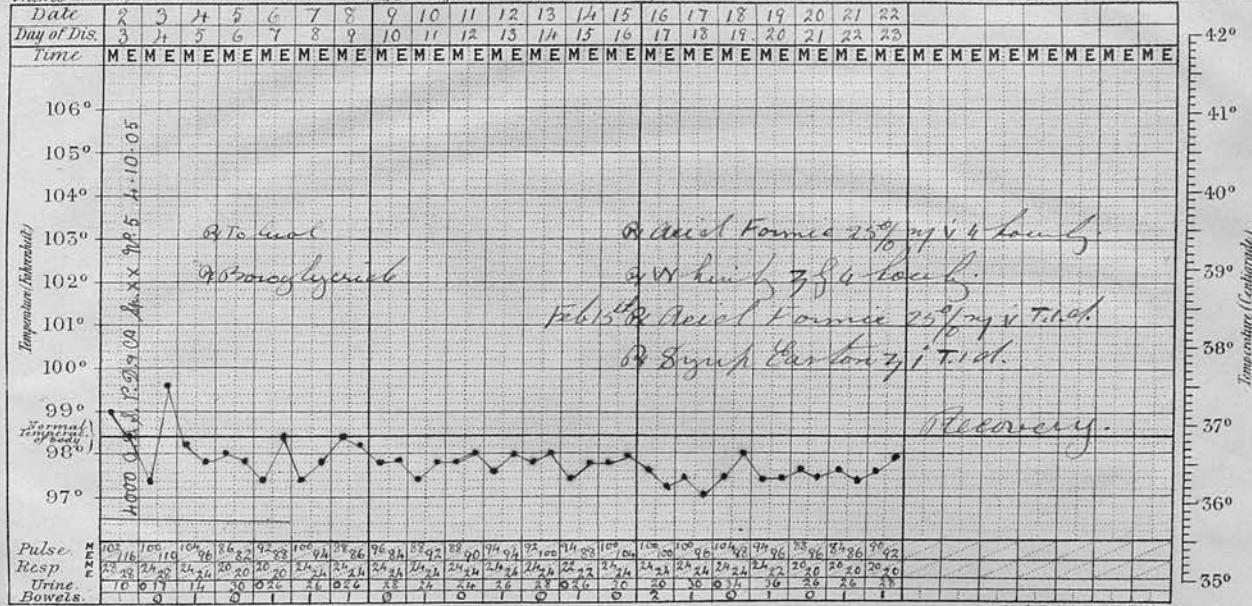

Case XVI

Description of Case.

Fences concreted. Right tonil enlarged. Left nil off.
Right tonil is completely covered with gray loose
membrane. Membrane is exceedingly thick. Left tonil
is covered at base with similar tenacious membrane.
Patient is very pale. Pulse very weak. Volume poor.

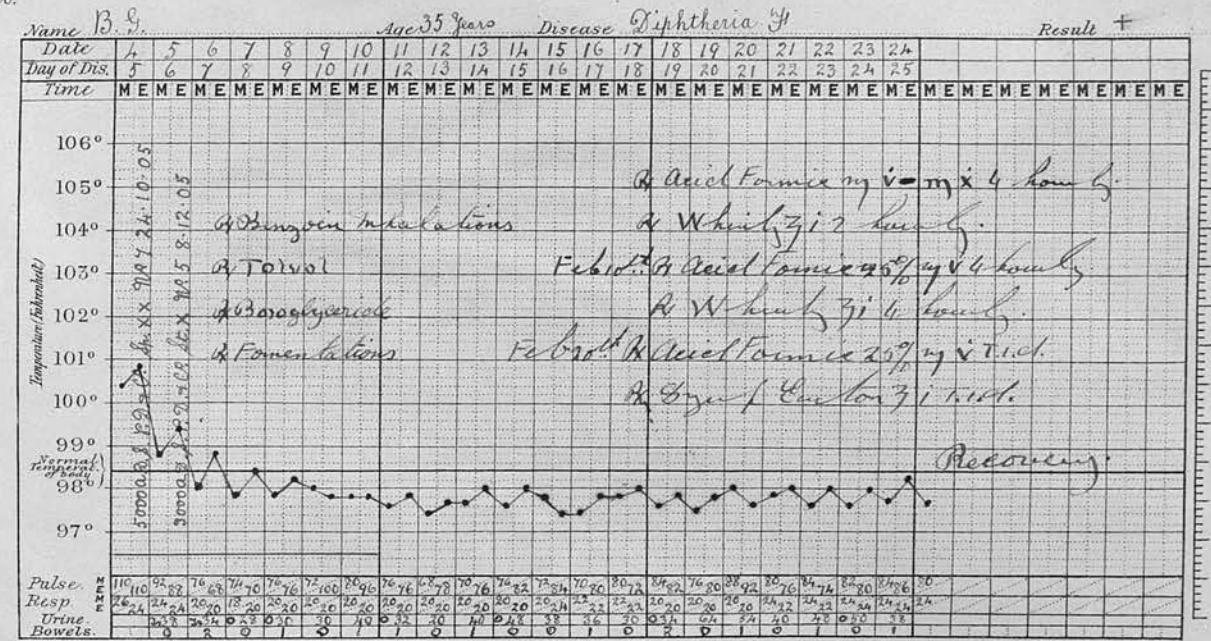

Bwah = Good Bolan stained rocks. Good
chunbris. *Staphylococcus* & *Hlococci*.

Fultone = Name Positive.
History.

Feb 7th 8 left better colour. Pulm not so
markedly irregular. Feb 15th Pulm regular
volume & strong & better. Good colour.
Left home eventually in good health.

Case XVII

Feb.

D. Smith's Clinical Chart Copyright.
No. 7.

H. Silverlock, 82 Blackfriars Road, London.

Description of Case

Right tonsil completely covered with grayish-white membrane which is tough & thick. Left tonsil also covered at base with similar membrane. Ulcerative base likewise at tip. Patient pale. Pulse regular & rapid.

Sputum = medium power stained rods. Staphylococci.

Culture = Mitis Positive.

History

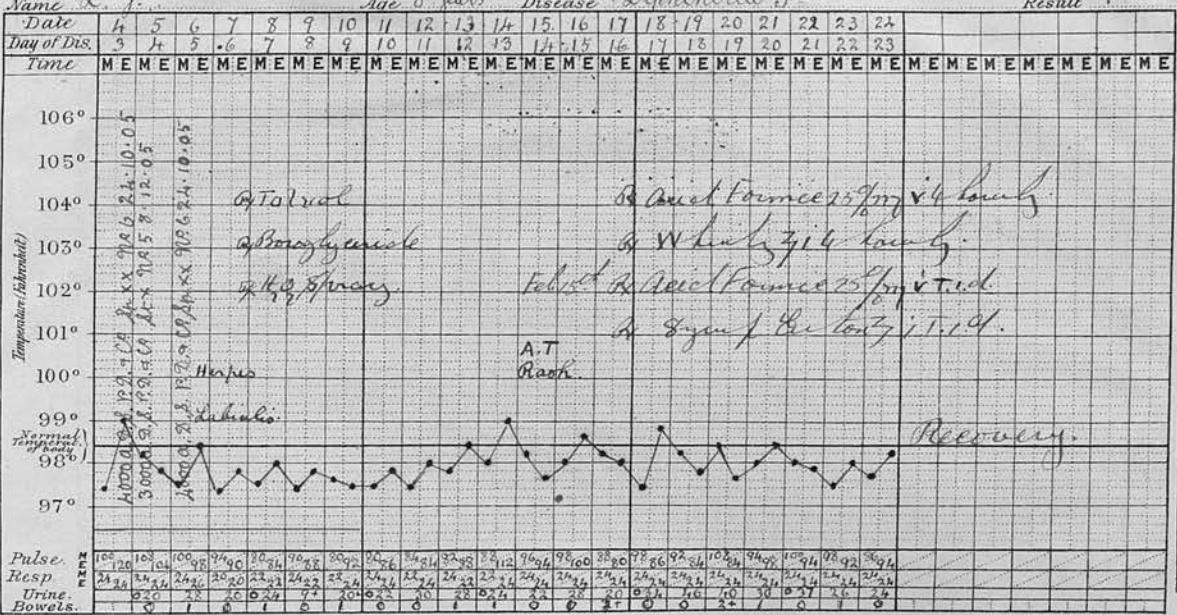

Feb. 5th. Pulse irregular. Patient very pale & toxicemic. 6.10 a.m.
Sulphon 3000 A.D.S. & Formic acid dose doubled to 10 gr 4 hourly.
Feb. 6th. Pulse improved but still slightly irregular.
Head restless night. Does not quite so pale.
Feb. 8th much improved. Pulse regular & good colour. Palor gone. Patient afebrile. Has made good recovery.

Result +

Graph showing Temperature (°F) vs. Time (Days). The graph shows a fever curve with a peak around Day 12. Annotations include:

- Initial temperature: 98.6°F
- Time of measurement: 12:45 PM on Dec 10, 1905
- Annotations: "Steam Inhalation" at Day 8, "A.T. Blank" at Day 12, and "Recovery" at Day 20.
- Notes: "Daily Formic acid 1-10 gr hourly", "Feverish 3-4 hourly", "4 vials 3 pieces. mix 4 hourly", "4 Tinct Bellad 1/2 gr hourly", "4 Formic acid 8 gr mix 1000 ml for 3 1/2 hours", "Each day 1/2 fluid drachm Formic acid 25 gr mix 1000 ml", and "Exempt from being it well."

Description of Case

Patient on admission very pale and collapsed. A frequent hard tick-like cough. Voice very hoarse. Inflammation of intercostal spaces very marked & all extensoraining muscles respiration. Pulse irregular & thin. & very restless and anxious looking. Fauces injected but free from membrane.

8 wab = 8 short polar stained rods
8th A hyphae & Siflococci

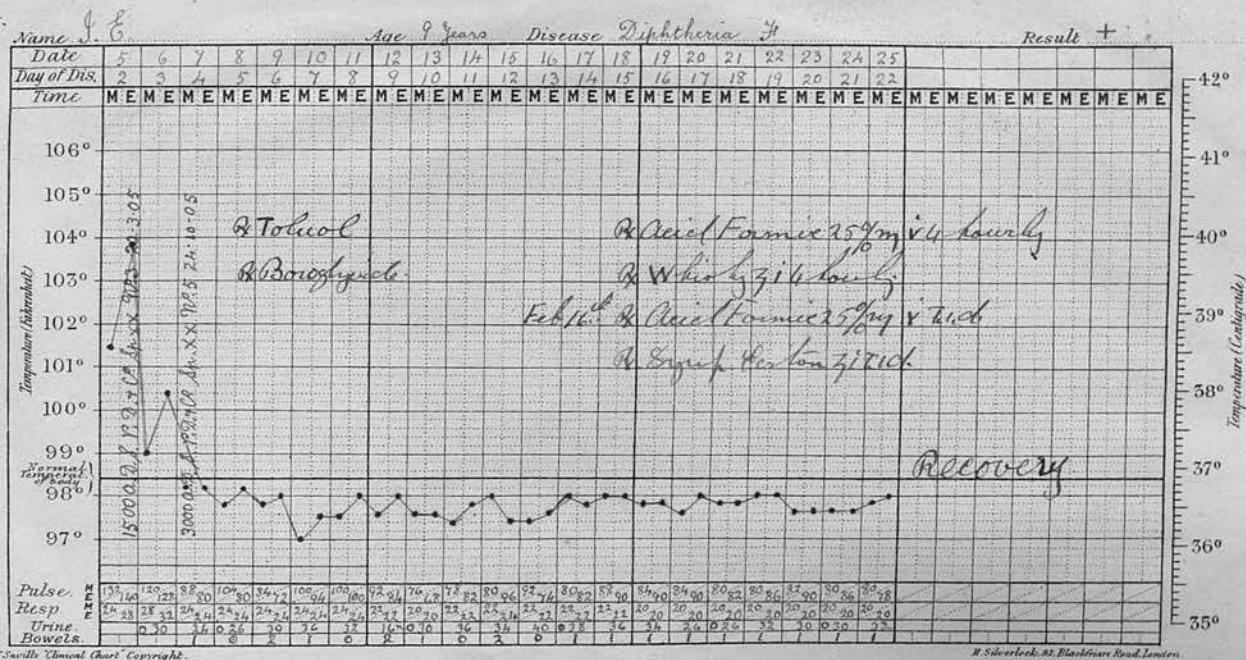

Culture = *Poecilia* *Neptuna*.

Kinston.

Was at once given 8 tecu & stimulated, one chart.

Description of Case XIX - con -
After half hour of atem as above was no improvement was intubated with No 4 vulcanite tube after two unsuccessful attempts with an ordinary tube. At 12.30 p.m. child collapsed & was given hypodermic of Erythromine Formate $\frac{1}{100}$. There was within 5 minutes a distinct improvement. 2. a.m. Pulse improved but still very feeble.
4.45. Patient became cyanosed & pulse very feeble & irregular. Was again given Formate Erythromine $\frac{1}{100}$. Pulse & colour improved within 10 minutes.
Feb 6th Pulse regular. Colour improved. Was breathing easily. Heart still labored right side slightly. 12.30 p.m. Sputils still labored & Bile acid stopped. Feb 7th Pulse & colour still good. Tube removed 12.30 p.m. 6.45 p.m. Patient had severe paroxysm of coughing & collapsed. Given Formate Erythromine $\frac{1}{100}$ & re-intubated.
8.45 p.m. Pulse regular but colour not good.
9.30 p.m. Again given Formate Erythromine $\frac{1}{100}$.
12. p.m. Pulse regular & good volume & force. Colour much improved. Feb 8th. 12 a.m. Has slept well. Breathing easily. Good pulse & colour. Tube removed 8 a.m. Headache stopped & Acid tonics 25% mg & increased to my x.
Feb. 9th. Breathing well. Good colour & pulse. Very drowsy. Patient made good recovery & left perfectly well.

Case XX

Description of Case.

Right congestion of Fauces. Left tonsil covered at base with tough, tenacious gray membrane. There is a smaller patch of similar membrane on the anterior surface of right tonsil. Throat free. Patient is good colour with good regular pulse.

Swab = Mixed rods, long thin & short rods.

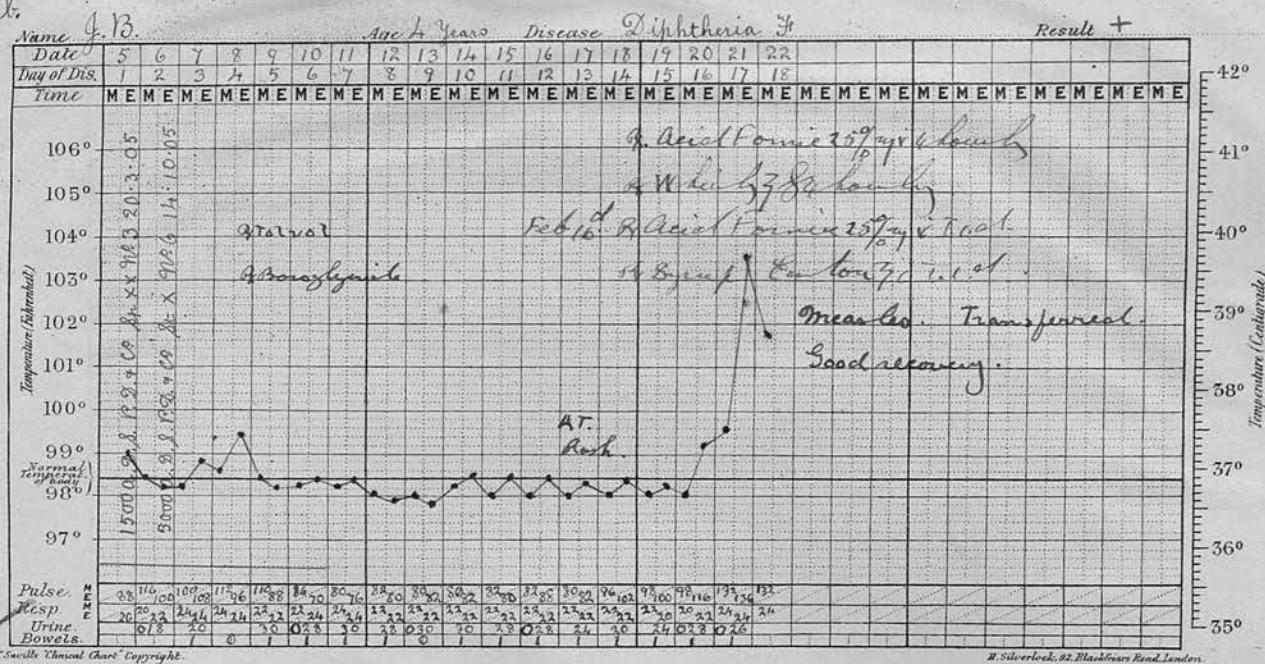

Rods are good. Cocci & diplococci.

Culture = Neisser Ponticus
Kirby

Feb 1st Membrane spread slightly on the left tonsil. Colour good. Pulse good.

Patient afterwards made an uninterrupted recovery.

Case XXI

Description of Case

Left hand covered completely at base with thick dark gray membrane. slight congestion of fingers. Base of right hand slightly affected with similar membrane.

Swabs = short root. Polar staining and Clusters.

a very few medium roots. Diplococci.

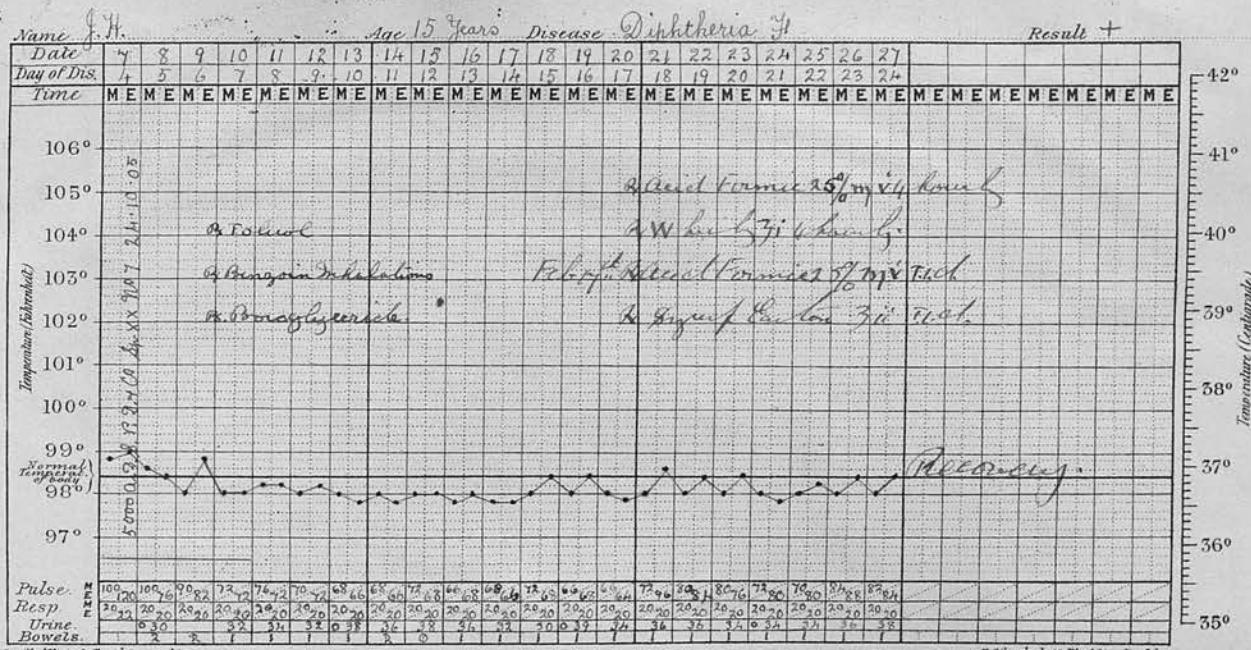

Culture = Positive Nurser.

History

Process spread on right hand by Feb 6th. Feb 9th Ulceration and toxic rash on arms.

Feb 21st Temperature rose & Koplik spots & morbilliform rash appeared. Patient was transferred to another ward and subsequently made an uncomplicated recovery.

Case XXII

Dr. Saville's Clinical Chart Copyright.
1877.

H. Silverlock, 82, Blackfriars Road, London.

Description of Case

Right tonsil is a little enlarged & completely covered with thick tenacious dark gray membrane. The left tonsil is covered at base with similar membrane. Voice is slightly hoarse. Patient is very pale, languid & fatigued looking. Pulse is poor & slightly irregular.

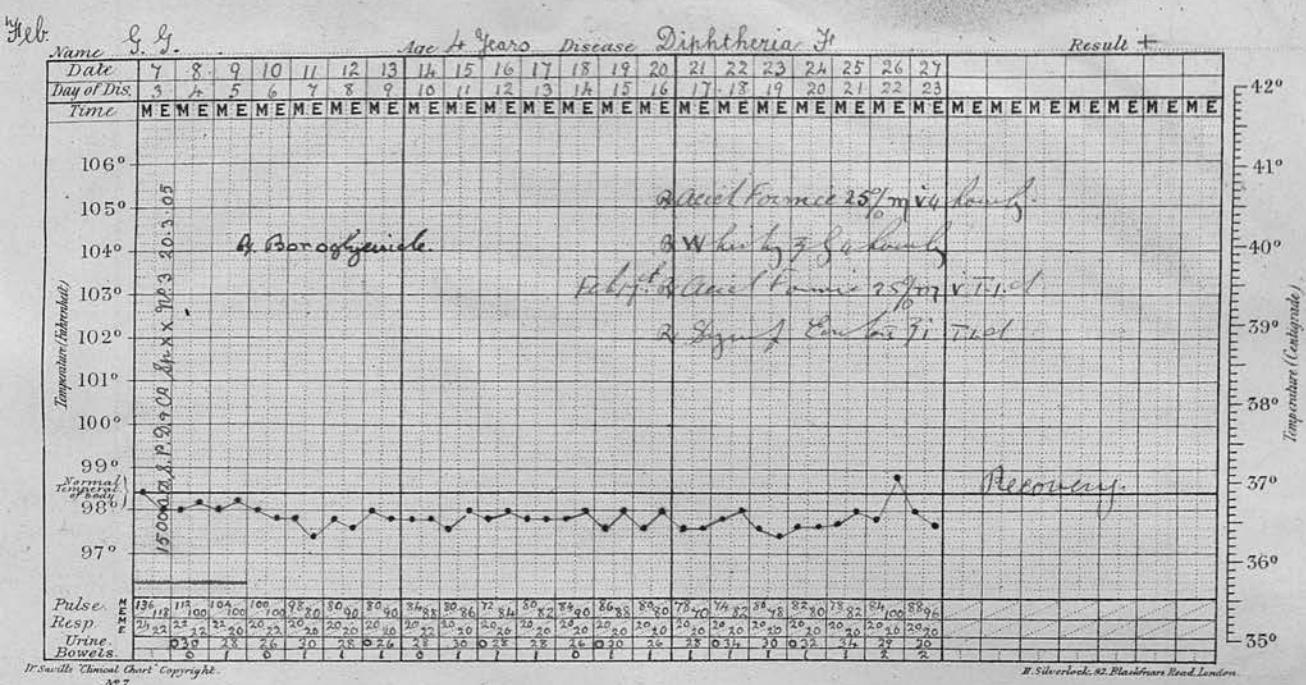

Bubo = short polar sternal root. Plaster. a few short subflococci. S. typhi & S. typhococcii.

Culture = Never Positive.

HISTORY

Feb 9th Pulse more regular, still poor in volume & force. Color very pale. Feb 14th Pulse regular. Good color. Patient afterwards made uncomplicated recovery.

Case XXXII

Dr. Saville's Clinical Chart. Copyright.
No. 7.

8 Silverlock, 92 Blackfriars Road, London.

Description of Case.

Fauces not congested. Tonsils not enlarged. Patch of fibrinous white membrane base of right tonsil off formula. Pulse regular & good.

Swab = medium sized polar stained wools.

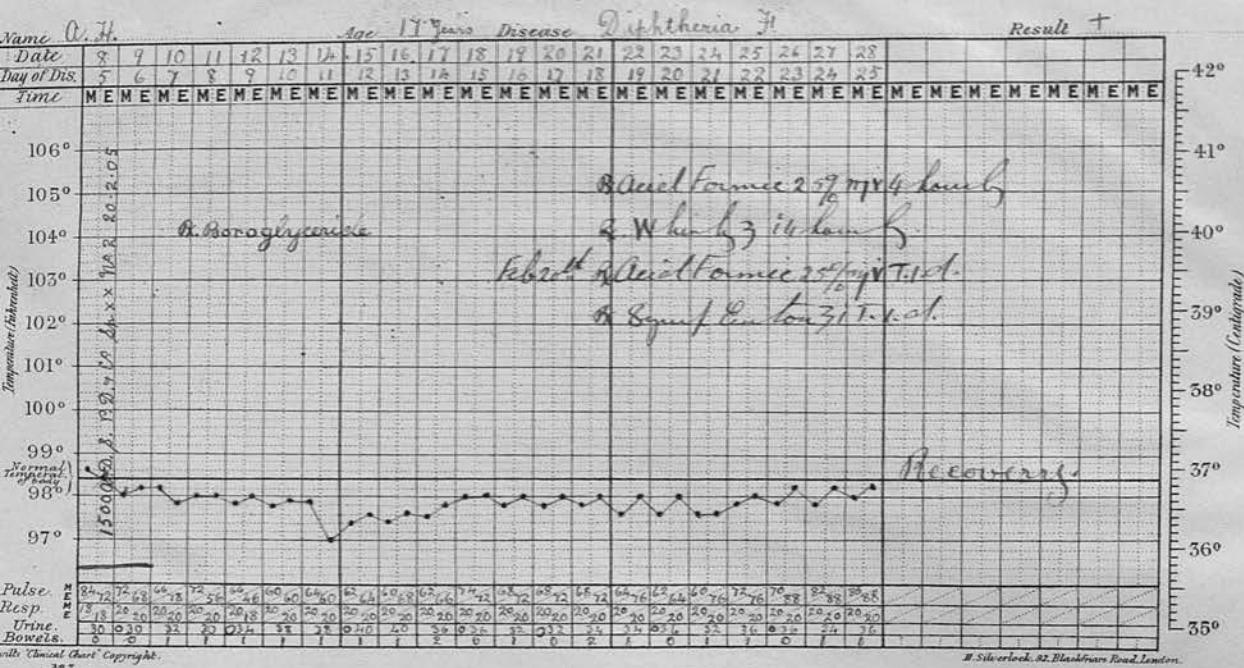

Long thin rods cocci & diplococci

Culture = Never Positive

History

Pulse remained regular & good. Labor also and patient made an uninterrupted recovery.

Case XXIV

Description of Case.

Post tonsils are slightly enlarged and covered with thin integument yellowish membrane. Throat & palate free. Pulse is slow but regular with good volume.

Swab = short Polar stained with Coxi.

Culture = Nisser Positive

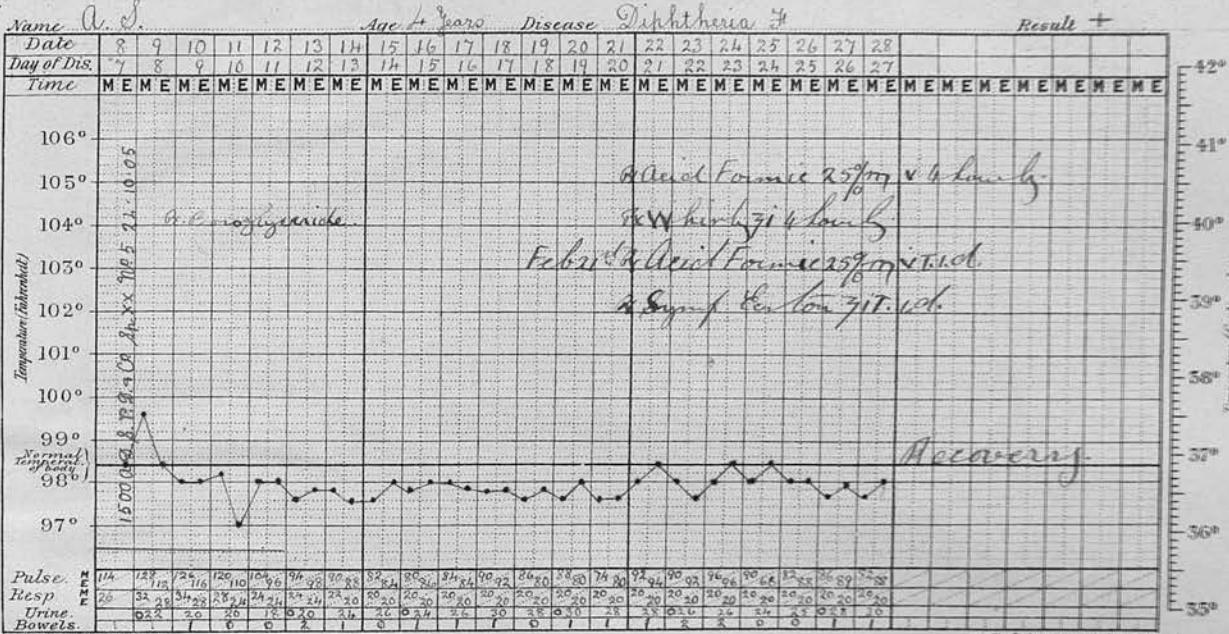

History.

Patient made uncomplicated recovery.

Case XXV

Feb.

Name A. S.

W. Smith's Clinical Chart Copyright

Description of Case.

Left tonsil is enlarged & completely covered with very thick & tenacious grayish-white membrane. Throat is involved on the same side. Throat on left side and at top is covered with a similar membrane. The voice is very hoarsely and there is an occasional short harsh cough. There is very marked enlargement of the cervical glands on the left side of the neck. Patient is pale and pulse is soft and rapid.

Sputum = Mucous sputum. mostly watery
Color stained sputum. Clusters.

Description of Case XL - con-
Staphylococci and alpha-hemolytic streptococci.

Culture = Neisser Gonorrhoeae

History

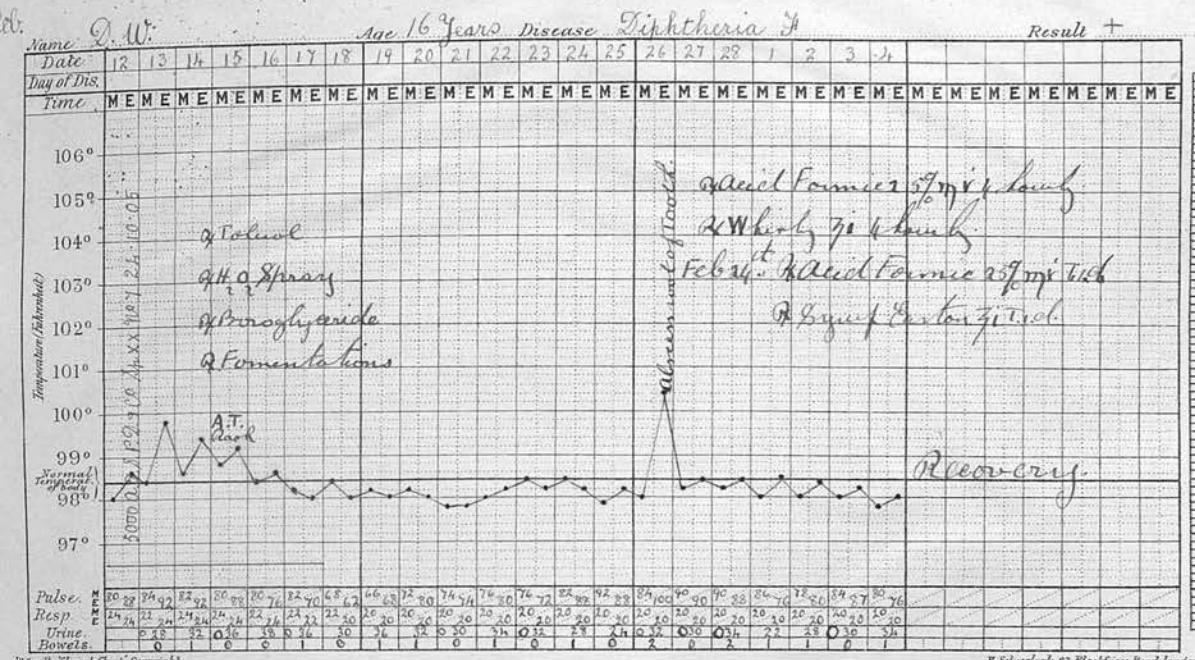

At night patient was very restless.

Feb 14th. Breasts still speak on palate and
is very thick. Patient's colour is better and
the pulse is regular and good. Heart not
enlarged. Micturition slightly soft
blowing myotonic murmur.

Feb 15th. Patient has lost her previous
appearance. Good colour. Pulse regular
and good volume and force.

Patient - appliances made an uncomplicated
recovery.

Case XII

H. Silverlock, 82 Blackfriars Road, London.

H. Scudamore's Clinical Chart Copyright 1897.

Description of Case

Both tonsils are completely covered with gray membrane which is very thick & tenacious. Slight tonsillar enlargement. Throat unaffected. Face is slightly flushed & pulse is full and regular.

Sputum = mixed sputum. Short and long thin spout sputum. Cocci and Staphylococci.

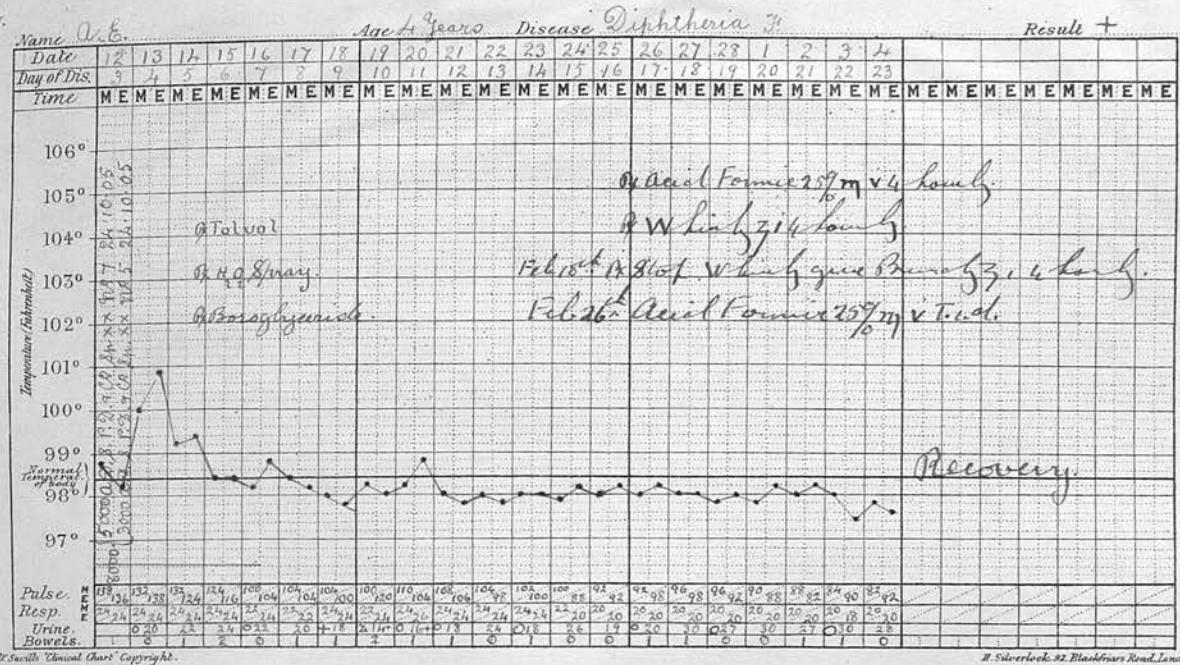

Culture = never positive

History

Feb 16th Bloody erythema antitoxicum with over extensive moist membrane on back. Had slight enlargement of right femur on 25th & 26th. Otherwise had an uncomplicated recovery.

Case XIII

Feb.

Description of Case

Both tonsils and uvula completely covered with very thick dark grey membrane. Palate not affected. Voice is clear but there is an occasional short exphorine cough. Child is very pale and pinioned looking. Pulse is soft and somewhat irregular lost in time and force 1 beat. Slight enlargement left rib. 1st sound in aortic area is faint after sounds closed.

Swab = Good short rods and cocci

Culture = Neisser Positive

History

Feb. 18th Patient vomited one and a half hours

Description of Case XVII - con-
after food. Very pale and pulse
soft but regular. Given Bismuth
instead of Whinny, peptonized milk etc.
Feb 19th Vomited last night heart. No
pain. No mucus. Pulse is still soft
but regular. A trace of albumen in urine.
Feb 21st Pulse much improved. Palor
is also much better. No further sickness.
Patient after much trouble made an
uncomplicated recovery.

A.T. Rush.

Recovery.

Temperature (Centigrade)

Description of Case

Slight congestion of fauces. Nasal discharge
marked from both nostrils. Slight
excoriations at mouth. Patient is very
pale - waxy looking - appears very toxicemic.
Pulse is regular but very soft.

Zwab - Nose = very good to hunt polar stenocel
rods. Diphlocoecia.

Short = short thick roots. *Staphylococcus*

Cultures = Neisser Positive
Chitosan

Patient improved in colour & perhaps by March 1st.
Had a taking temperature for 3 days on 25th March
otherwise an uncomplicated recovery.

Case III

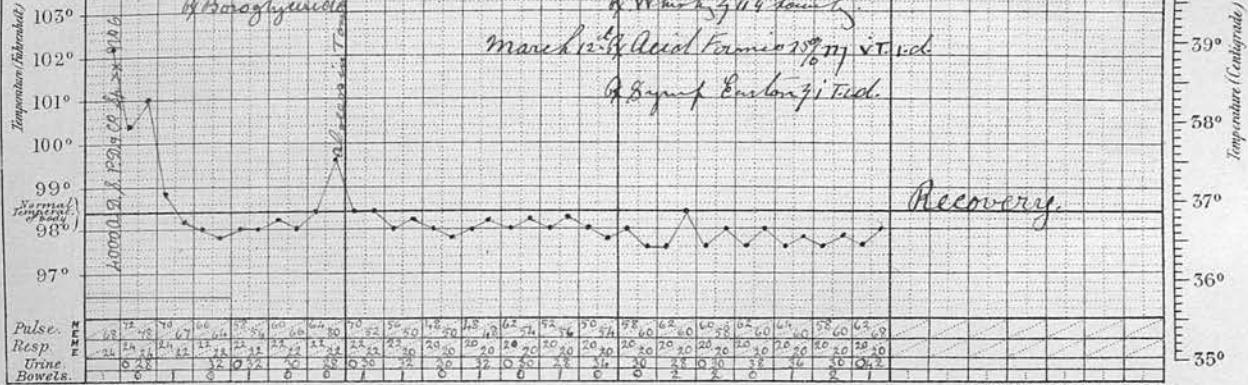

900

Ch.
Name R.P.

Age 24 Years

Diphtheria P.

Result +

W. Saville's Chemical Chart Copyright
No. 7.

B. Six o'clock, 92, Blackfriars Road, London.

Description of face.

Both tonils connect at base with white fibrous
sheet of membrane and anteriorly with
short integument membrane. Umbra free.

Curve slightly soft but regular. Colour good.

Ewab = very good short polar & stained
wols. Some medium wols. Poco.

Pulture = Nivres Pontine

History

Right hand became enlarged & painful on 7th
Small abscess at base burst on 9th. Patient
otherwise made an uncomplicated
recovery.

Description of Case.

Faeces very concreted. Both toenails enlarged
left toenail completely covered with very
thick white membrane which is loose
antrously and appears to be of older standing
than account given. Right toenail is
covered at base with similar membrane.
Marked enlargement of cervical glands.
Patient is extremely pale and very
jaundiced looking. Heart. Slight dilatation
right side. Aortic, 1st sound almost
imperceptible & occasional re-expansion of
1st sound at mitral area. Pulse is very

Description of Case III - con -

soft and irregular.

Swab = Good roots, thick short roots.

Polar stained rods. Diplococci
and Staphylococci.

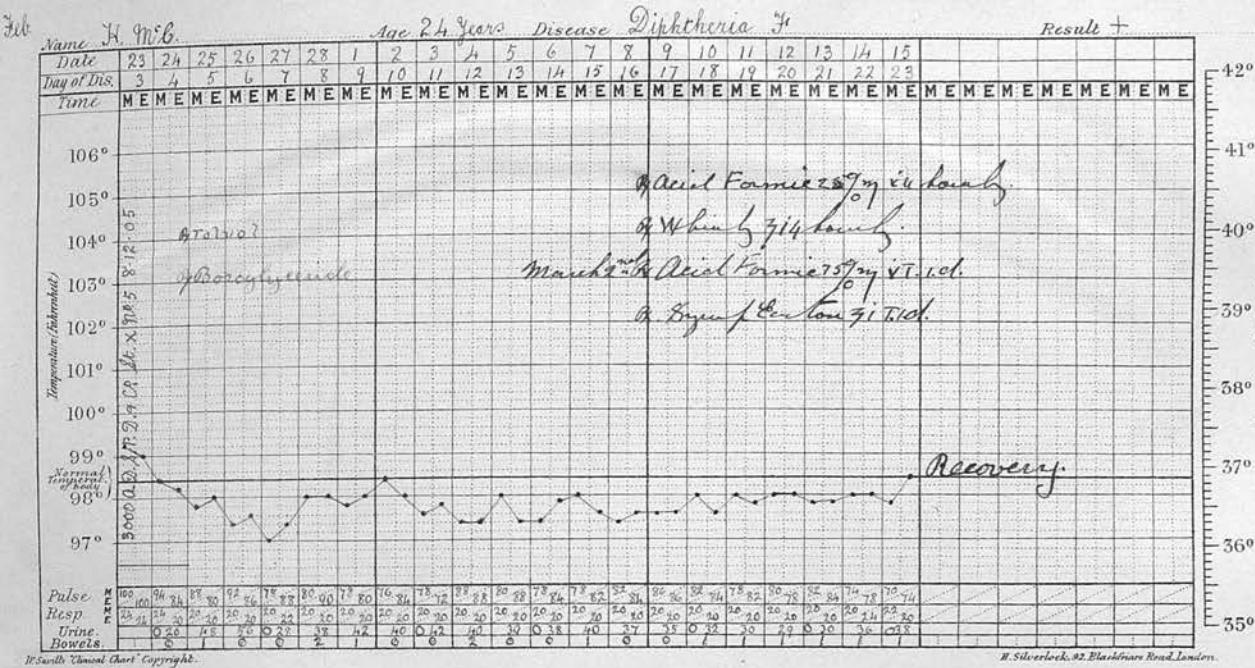

Culture = Nisser Positive

HISTORY

Patient on 28th still looked very toxicemic
and pulse was very soft and irregular.
Membrane spread slightly on right side
March 1st. Pulse is stronger and more regular.
Heart aortic 1st sound replaced by faint systolic
murmur. March 4th Patient vomited twice
irrespective of food. Pulse very irregular
& very soft. At times almost imperceptible.
During pale & listless. Hypodermics etc.
March 5th No change but no further
vomiting. March 6th Became rather at-
4 h. m. and extremely so 10 p. m. Died
at 4 a.m. March 7th.

A case apparently hopeless from the
start. Although the case is classified
as being admitted on 6th day of disease
a subsequent examination of parents proved
child to have been ill for at least 6 days.
Facts which were borne out by appearance on admission

Case IV

Description of Case.

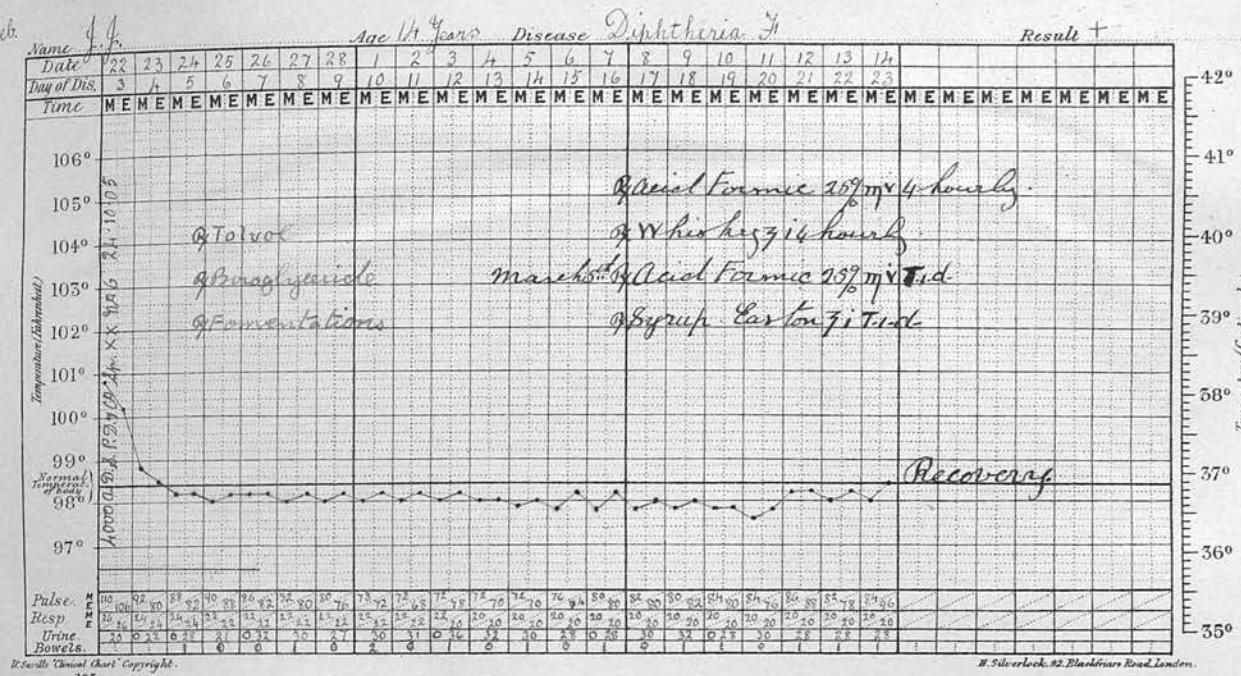

Back tonsils covered at base with grayish-white membrane which, anteriorly, is tendency to disintegrate. Patient is a good colour and pulse regular although slightly soft.

Swab - Good short rods diplococci and cocci

Culture = Gram Positive
Histology

Patient appears to made an uncomplicated recovery.

Case IV

Description of Case.

Root tonsils a little enlarged and covered with white-gray thick membrane which on right tonsil appears to be disintegrating. Marked enlargement of cervical glands. Patient is pale & listless but pulse regular & good.

Swab = Some good short rods. Long thin rods. Short streptococci and D. l. c. c & S. a. p. l. c.

Culture = never positive
History

Patient improved in colour by 2nd am & afterwards made an uneventful recovery.

Recovery

Description of Page

Boat ton is completely covered with thick white membrane which has a slight speech to palate on right side. Mucula free patient is pale and lethargic. Pulse regular and good volume. Heart nothing to note.

Swab = Good polar stained rods.

Sphacelococci and Staphylococci

Culture = Neisser Pontine

History

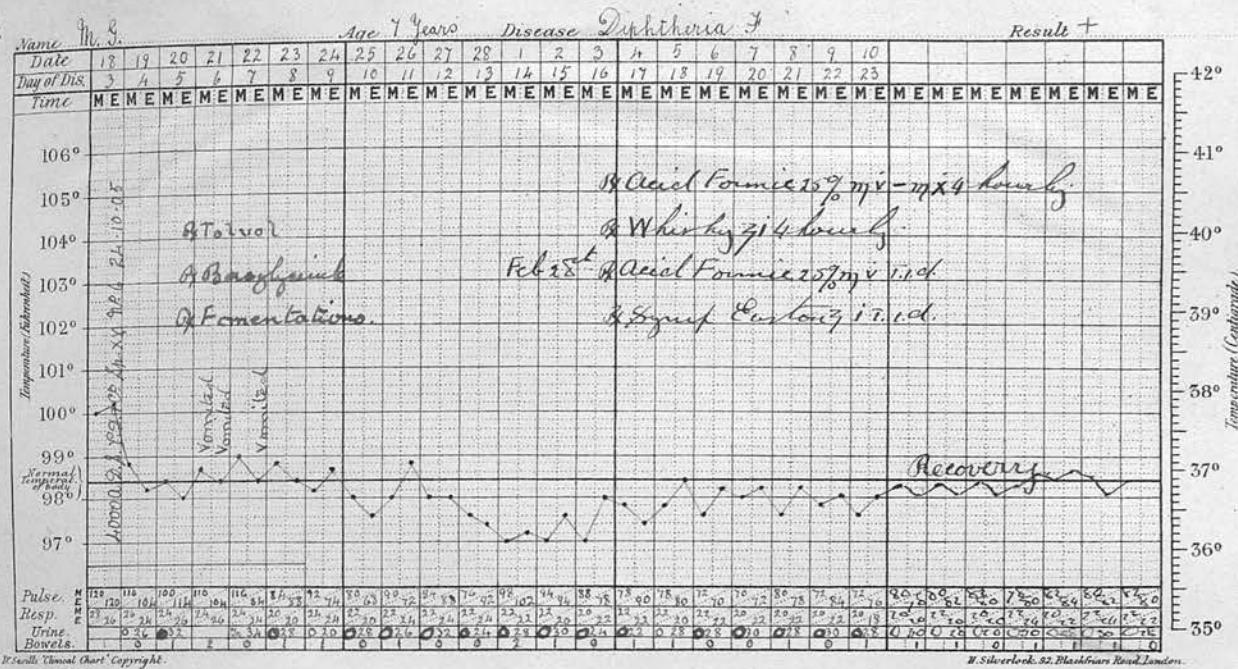

Feb 2nd. Pulse is soft & slightly irregular. Feb 25th.

Irregularity gone. 3 letter volume force.

Feb 28. Multifurc. erythematous antibiotic rash trunk.

Patient after 6 months made uncomplicated recovery.

Case XVII

Description of Case

Right tonsil completely covered with thick dark gray membrane. There is a small patch of similar membrane just posterior to left tonsil. Throat & palate free. Marked enlargement of cervical glands. Pulse is slightly irregular. Good volume. Patient is sweating and is very pale and poisoned looking.

Swab = Good medium. Polar stained and in clusters. *Staphylococcus* and *Diphlococcus*.

Culture = Neisser *Coronatus*

Histone

Description of Case LVII - con. -

History

Feb 20th Still very pale & fatigued looking. Vomited twice. Pulse still slightly irregular. 8 p.m. Patient vomited once more after peptonized milk. Feces per rectum for night Feb 21st. Again vomited. Is looking spichest. Pulse is soft but is now regular. 2 p.m. Again fed Peptonized milk & some cereal by mouth. Feb 22nd Has not again vomited. Pulse is regular.

Feb 24th Patient is a better color. Pulse is regular & not so soft. Heart not enlarged. No murmur. Heart 1st sound is faint. A trace of albumen in urine.

Feb 25th Much improved. Color good. Pulse regular & volume much better. Is bright, & takes food well. Heart not enlarged. Both sounds equal. No murmur.

Patient at present made an uncomplicated recovery. He had on one day only a trace of albumen.

Case LVIII

三

66

Age 11 Years Disease Diphtheria H.L.P.

Result +

H. Silverlock, 92 Blackfriars Road, London.

Description of Case.

Both tonsils are enlarged and completely covered with very thick, tenacious, dark-gray membrane. Uvula is also completely covered with similar membrane. Palate has a large patch of similar membrane just above left tonsil. Voice is hoarse. No cough. Patient very pale, lithamic and haemacemic. Pulse is soft but regular.

Swal - Good thick short rocks.

Strept., Staphylo and Diplococci.

Culture = Never Continuous
History

Feb. 15th. Patient is very pale. Pulse is irregular.

Description of Case VIII - con. -

discharging - con. -

and poor in volume and force. Membrane appears to be disintegrating.

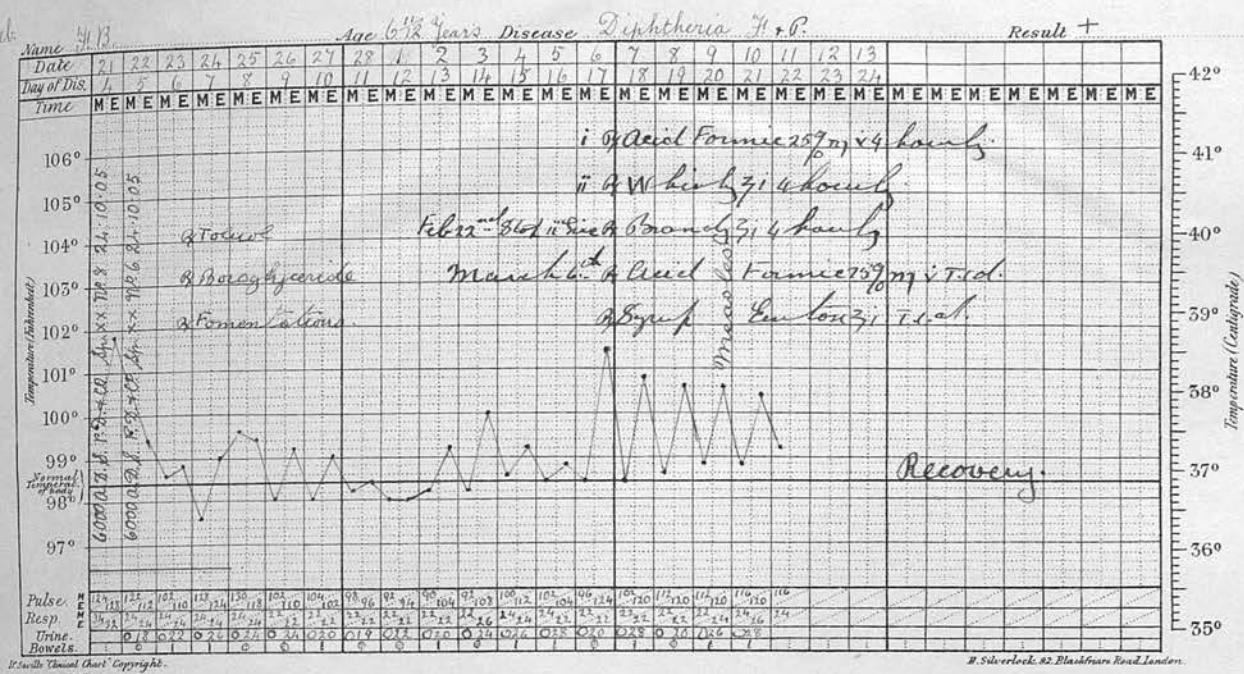

Feb 19th Patient's colour has improved. Is not so listless and fairioned looking. Pulse is now regular although still soft. Local condition has improved.

Feb 21st General condition much improved. Pulse regular. Is better volume and force.

Feb 27th Improvement continues. Heart not enlarged. No murmur.

Patient subsequently made an uncomplicated recovery.

Case LIX

Description of Case

Both tonsils are enlarged. Left tonsil is completely covered with thick white membrane. Palate also involved. Right tonsil is covered with similar membrane at base. Throat covered with similar membrane. Great enlargement of cervical glands. Patient is pale and exhausted looking. Appears very toxicemic. Pulse is soft & irregular.

Swab = Good for the stained rods
Staphylococci & Diplococci.

Culture = Mucor Positive.

Description of Case IX - con-

History.

Feb 22^d Membrane spreading on palate
is very thick and tenacious. Heart
not enlarged. Slight soft bony
mildystol sound. Other sounds
clear. Pulse still irregular now.

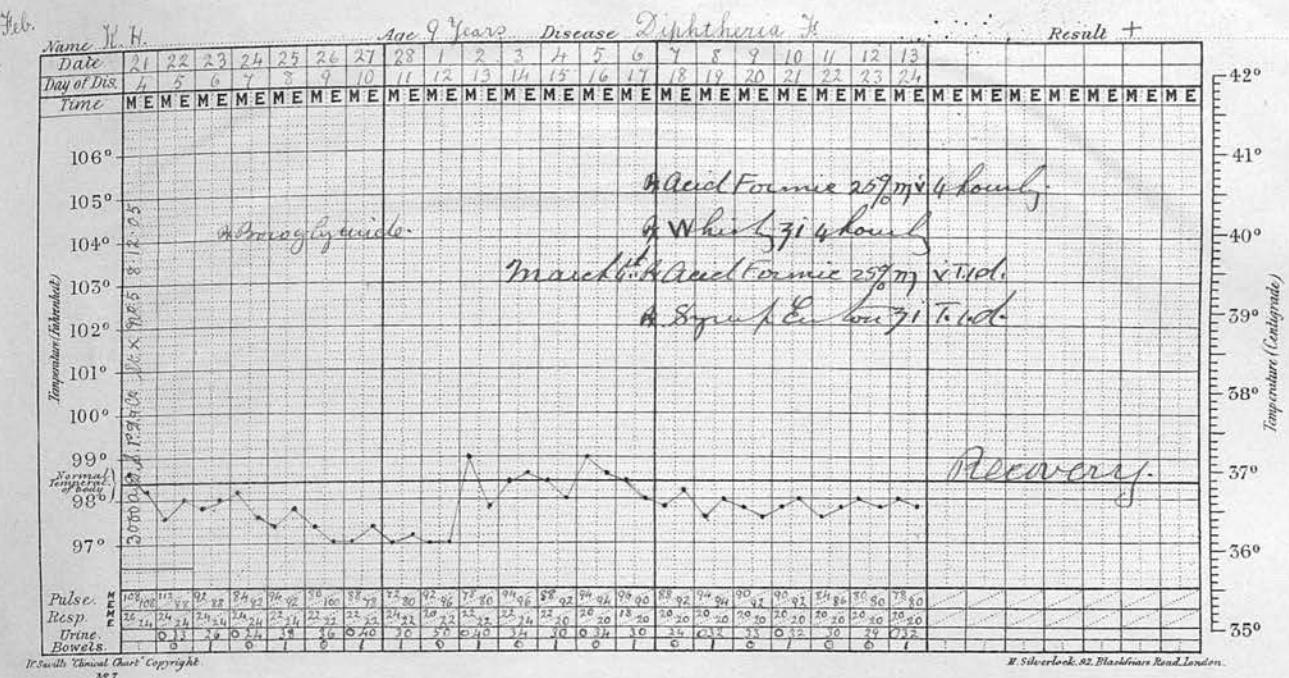

Feb 23^d Vomited after food. Color
is bad. Patient is slightly cold in
extremities. Pulse is irregular.

Feb 24. Pulse rather improved with
more regular & better volume.

Feb 25^d marked change. No belta
color. Pulse regular. No slight &
better generally.

Patient continued to improve until
March 6th when he contracted Measles.
Treatment Formic Acid was stopped
and 16 days after the stopping
of the drug he developed a slight
palatal paralysis. He subsequently
made a good recovery.

Case IX

Description of Case

Both spots at base of tonsils are covered with thick white-grey membrane which has commenced to disintegrate. Throat is involved at tip. Calcified free.

Patient's colour is good. Pulse regular and good.

Sputum = mucusy sputum. Short sputum. Foci

Culture = Neisser Coryne

History

Patient made an uncomplicated recovery.

Case LXI

Description of Case.

Both tonsils are enlarged and covered at base with thick dark-gray membrane. Uvula and palate are unaffected. Throat is raw and soft but regular. There is slightly enlarged left nodule. Arterial wound is very faint. Soft blowing micturition to lie down. Child very pale & listless.

Seal = Good thick medium rocks.

Polar stained rock & Chert.

Difcocei and Facci.

Cultivo = Nivens Positive

History

Description of Case XI-con.-

History

Feb 21st very pale & abnormally severely pained

Pulse is slightly irregular & very soft.

Feb 23rd vomited twice. Aortic 1st sound almost imperceptible. Pulse very irregular

Feb 24th same as 23rd. Given Formate of 8% &
g 1/2. Marked improvement in pulse &
color but only temporary.

Feb 25th Given stimulants (nig & chut.)

Nutritive & Salines. No improvement.

Feb 26th died at 9:15 p. m. The end
in this case was almost sudden as
patient had shown a slight improvement
in heart, pulse & color for 12 hours
previously. It is interesting also to note
the absence of albumen which at no
time was present although frequently
looked for with care. The child
was extremely toxicemic from administration.

Fauces very congested. Both tonsils are completely covered with thick white tough membrane. There is also a complete obstruction. Palate is involved on right side. There is a marked nasal discharge from both nostrils. Voice is very hoarse. Patient can only speak in a whisper. There is a frequent short crackly cough. Patient is extremely pale and poisoned looking. Respiration is poor in volume and force and is irregular. There is marked

Description of Case XXXVI - con-
enlargement of the cervical glands.

Swab - Throat = very good short polar
stained rods in clusters Diplo and
Staphylococci.

Nose = Good short rods and
large diplococci.

Cultures = Mixed Bacteria
Histology

Feb. 27th. Breathing still labored. Patient
restless. Pulse irregular. Heart left
side slightly enlarged. 1st sound
faint. Mitral soft systolic murmur.
Membrane has increased 1.8000 A.D.S.

4.30 p.m. Not having a fit intercalated pauses
marked. Cough is "looser" Pulse softer
and more irregular.

11. p.m. Attempted intubation to
relieve heart and for some paroxysm
of coughing. Large piece of thick
white membrane $2\frac{1}{2}$ inches in length
expelled after attempted
introduction of tube which failed.
Breathing very much improved.

12.30 p.m. 6000 A.D.S.

Feb 28th. Had one more fit of coughing at 1 p.m.

Description of Case XXXVI - con-

Patient still very pale. No cyanosis. Pulse is irregular and very soft. Occasional short crowing cough. Involvement of intercostal spaces is marked.

March 1st 12 p.m. Pulse is very slow irregular very soft and rapid.

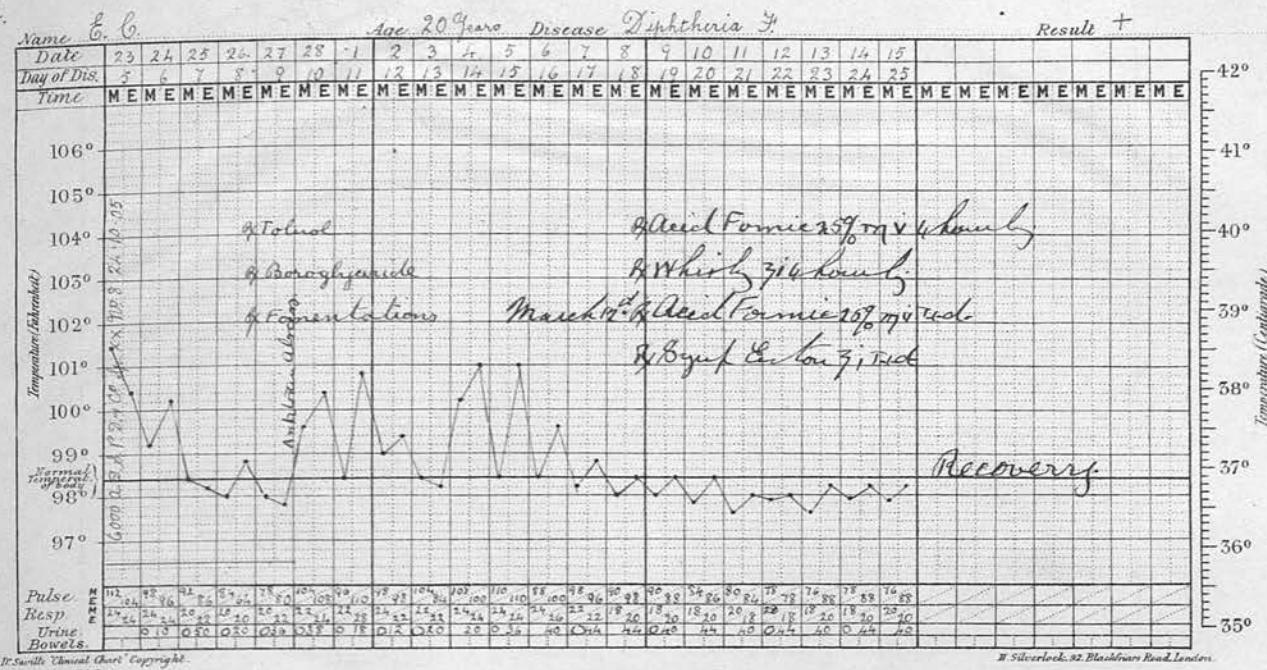

Given 1½ gr. of Salicin Formate & ½ gr. of tartaric acid at 3 after 1½ gr. of Salicin & ½ gr. of tartaric acid at 12 had no effect. Has left a pulse markedly improved. At 8 a.m. given again 1½ gr. of Salicin Formate & ½ gr. of tartaric acid. Pulse became slow & fuller and breathing also improved much. 5 p.m. Symptoms of Bronchopneumonia. Respiration very rapid. No symptoms of high obstruction. Pulse is more regular & volume better but still rapid. 8 p.m. Given 10000 units A.D.S. March 2nd 10 a.m. slight improvement. Pulse better. Pulse is regular. Has had Formate & tartaric acid ½ gr. at 4 a.m. and 9 a.m. Given 8000 units A.D.S. 8 p.m. Has slept well at intervals. Pulse is regular. No further cardiac dilatation.

Description of Case XXXVI - con-

March 3^d. Has had good night. & left.
respirations reduced and not laboured
Breath regular and good volume and
force. Pulse has much improved.

March 4th. Respirations are rapid (78)
From March 4th the patient gradually
improved and made an uncompliated
and complete recovery. Respirations
were normal by March 10th. The
cachexia enlargement markedly decreased.
An interesting point apart from the
great severity of the case is the
fact of the ordinary injection of
strychnine failing to react on March
1st and the great success of the
Formate injections each of which
was followed by marked
improvement.

Case LXXVII

Description of Case

Post tonsil complete, covered with thick white membrane which is very tenacious. Patient is very pale. Pulse regular.

Swab = Color stained short rods.

Coccidioides and Diphlococci.

Pultus = Nevers Pultus.

No. 7.

Description of Case.

Fauces are congested. Soft tonsils are completely covered with thick white membrane. Uvula & palate free. Pulse is regular but soft. Heart not enlarged. Soft blowing mitral systolic murmur. Other sounds clear.

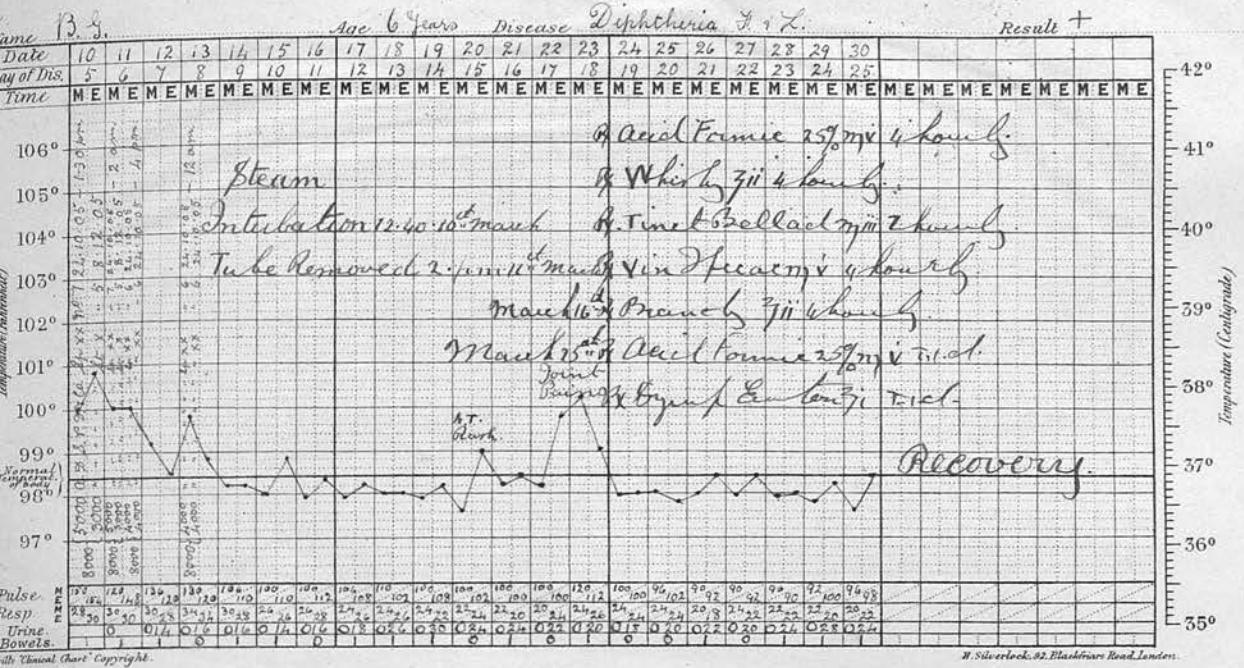

Swab = short polar stained rods. Cocci

Culture = Neisser Coccis.

History

March 4. Morbilliform eruption with on face & extremities. Patient made an uncomplicated

Case XXXXI

Description of Case.

Patient on admission very cyanosed. Vomited twice within 30 minutes of arrival. Indrawing of intercostal spaces marked. Voice extremely hoarse. Short croupy cough which is frequent. Fauces congested, with much mucus. Right tonsil confluent, covered with very thick membrane. Left tonsil confluent at base. Pulse is very soft & irregular. Heart: slight enlargement of left side. 1st sound very faint - almost inaudible. Soft blowing mitral systolic murmur.

Description of Case XXXXI - con -

Swabs = Short Colon stained rods in clusters
Staphylococci.

Culture = Neisser Gonococcus
History

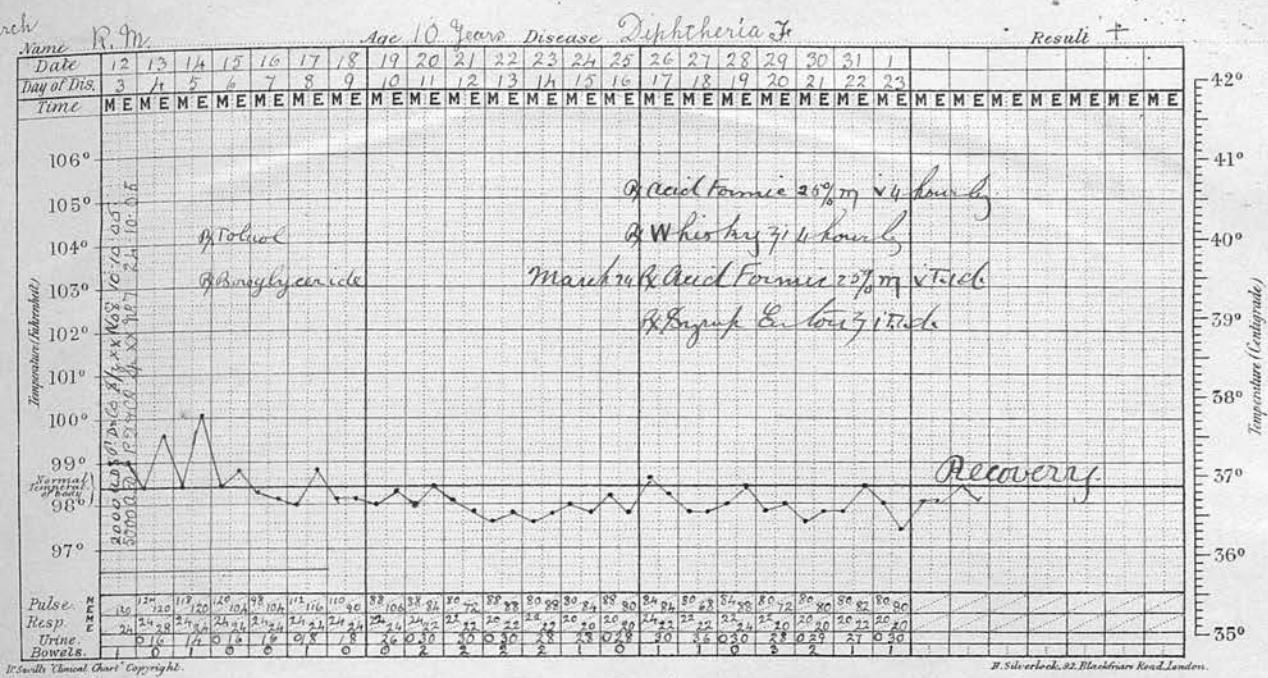

12:40 p.m. March 10th Breathing very labored. Cyanosis marked. Dr labored. Marked relief and expulsion of much thick mucus. Child is very quiet and still. March 11th Pulse is more regular but still very soft.

2 p.m. Tube removed. 1:30 p.m. Child became very cyanosed and pulse almost imperceptible. Given Hypochlorite Formate of 8 by 10¹⁰ Colon and pulse improved markedly in 30 minutes. Breathing also improved. March 13th Pulse is regular. Still soft. Colon is good. March 15th Vomited 10" after food. Colon back. Pulse regular but soft.

March 20th Right side of chest diminished. Colon is good. Pulse is regular with fair volume and force. No further rishers.

After this except for joint pains which lasted for 2 days patient made an uneventful recovery and left for home apparently quite well.

Part III.

- I. Statistics of Foregoing Cases . . .
- II. The Degree of Severity of Foregoing Cases
- III. Influences in Selection of Control Cases
- IV. The Relative Severity of Formic Acid with Control Cases
- V. Statistics of Control Cases . . .
- VI. Comparison of Statistics . . .
- VII. Analysis of Results in:-
 - (i) Cardiac Failure . . .
 - (ii) Paralysis . . .
 - (iii) Albuminuria. . .
- VIII. Conclusions

STATISTICS OF ACCOMPANYING CASES.

The accompanying statistics of the cases have been compiled with reference to the three main diphtheritic lesions, namely, Cardiac Failure, Paralysis, Albuminuria.

The deaths from Cardiac Failure - and in the case of the cases treated with Formic Acid this was the only cause of death - have been divided into 2 groups, each with 2 subdivisions, namely, (I.a) Progressive, (I.b) Sudden; (II.a) Early, (II.b) Late.

In the first group of cases the definition and dividing line is comparatively simple in most cases, but in the two cases referred to has been somewhat difficult.

In most cases the symptoms of progressive heart failure may be summed up as a gradually increasing intensity of the cardinal signs and symptoms of Cardiac Failure, namely,- Cardiac pain, vomiting, irregularity of pulse, etc., culminating in death. In the case recorded this was well exemplified. In the other case, No. 61, which has been classified as Sudden, there was also a series of progressive symptoms, but owing to the fact that the patient was apparently recovering, it has been classified

as sudden, in that it was not expected to occur when it did, if at all.

The second classification has been made on strictly orthodox lines, namely, the occurrence before or after seven days from the onset of disease - a view held by Myers, Trevelyan, and many others.

In the case of the Paralysis they are, both here, and in the control cases, minutely differentiated, but no attempt has been made to identify them with the date of onset of the disease.

The results of the statistics will be dealt with fully, later.

(each case comprised two varieties.)

Average dose of Antitoxin = 6265 units.

THE DEGREE OF SEVERITY OF FOREGOING CASES.

From the details of the foregoing cases it is evident that there are at least one or two cases of each variety of diphtheria shown among them. The cases are in no way selected, cases being taken strictly in rotation on their arrival at hospital. As before stated, the only cases rejected were those in which the clinical diagnosis was not fully borne out by the bacteriological examination.

An even more important point has been to attempt to determine the severity of the epidemic which, if mild, would modify the value of the results.

Two main factors have been investigated to determine this:-

1. The average amount of Antitoxin.
2. The average age of the patient.

The average dose of Antitoxin.

As shown before (page 24), the doses of antitoxin have been given more or less on a fixed scale in relative proportion to the severity of the cases and the complications arriving in them. This applies strictly for the preceding four years, as, before that date, the theories of the amount of

antitoxin were not so fixed as they at present are. As the doses of antitoxin in the hospital have been prescribed for the past four years and also for the 100 cases treated by Formic Acid by the same individual acting on the same fixed principles, it is possible, accordingly, to judge by the average dose the average severity of the case.

The average dose of Antitoxin for the past three years is 6,300 units, thus:- for 100 consecutive cases considered in 1904 it is 6,400 units, for 100 consecutive cases considered in 1905 it is 4,760 units, for 100 consecutive cases considered in 1905-06 it is 4,820 units, and for the 100 cases treated by Formic Acid it is 6,265 units; so that from this standpoint the cases may be judged to be of at least average severity.

The age of the patient has been the second factor observed.

Varying as the mortality does in diphtheria with the age of the patient, this must necessarily be of great importance, and Myers (Lancet 1900) has shown in a large number of cases how definitely true this is; thus in 275 cases of paralysis and paresis taken from 1,316 cases of diphtheria, the following results were obtained:-

The 275 cases taken in Five yearly periods.

Age periods.	Males.	Females.	Total.
Under 5 years	59	45	104
5 to 10 years	66	72	138
Over 10 years	22	11	33
Totals	147	128	275

Thus out of the 275 cases there were 174 cases occurring between the ages of three and eight, equalling 63·2 per cent. of the total number; again there were 40 cases between the fifth and sixth years of age, equalling 14·5 per cent; while in the cases of cardiac paralysis the great proportion of cases occurred between the ages of two and nine, the majority occurring in the sixth and seventh years' age-period.

The average age of the successive groups of one hundred cases has been 12·2, thus:- for 100 consecutive cases considered in 1904 it is 9·7 years, for 100 consecutive cases considered in 1905 it is 12·5 years, for 100 consecutive cases considered in 1905-06 it is 10·5 years, and for the 100 cases treated by Formic Acid it is 11·3 years; so that in this respect they compare more than favourably with preceding epidemics, and the fact that in the 100 cases treated by Formic Acid, twelve patients

were between five and six years of age, while fifty-five were between the ages of two and nine, would appear to prove that the ordinary percentages of paralysis and cardiac failure might have been expected.

It would seem, therefore, with such a positive result in both the factors taken into consideration, that it is safe to assume that the severity of the cases considered was at least an average one.

INFLUENCES IN SELECTION OF CONTROL CASES.

In order to analyse more thoroughly the results of treatment in the foregoing cases, a careful analysis has been made of three series of cases, each series numbering one hundred cases. Each series has been composed, as in the cases under consideration, of consecutive cases save that, as before, none have been considered which were not also bacteriologically positive.

In order that the type of the disease might be as similar as possible in the control cases as in those treated by Formic Acid, two series, each of one hundred cases, have been considered in 1904 and 1905, each as nearly as possible in the same months, viz:- January, February and March. The remaining

one hundred cases are those immediately preceding the cases treated by Formic Acid so as, if possible, to ensure that the particular epidemic did not vary to any degree with those of others.

There are then 200 cases taken from the corresponding season of the year for the past two years and 100 cases which may fairly be said to be of the same epidemic as that considered.

It may be well to state once more that by 'control cases' is meant the 300 cases dated 1904, 1905, 1905-06, and that the treatment adopted in all these cases was exactly similar, while that, as has also been stated before, the treatment by Antitoxin is the only connecting link between those cases and those treated by Formic Acid.

RELATIVE SEVERITY OF CASES TREATED BY FORMIC ACID AND CONTROL CASES.

On the same principle but with more minuteness the relative severity of the two groups of cases may be adjudged as follows:-

1. The control cases - namely, cases treated as detailed in Part I., page 9, are (a) either of the same months in the years, or (b) the same epidemic.

2. The average dose of Antitoxin for the control cases, namely:- for 1904 = 6,400 units, for 1905 = 4,760, for 1905-06 = 4,820, while that for 1906 = (the cases treated by Formic Acid) 6,265. It would appear, therefore, that from this standpoint the cases were of quite as great if not greater severity.
3. The average age of the patients in the control cases was:- for 1904 = 9.7, for 1905 = 12.5, years, for 1905-06 = 10.5, while that for 1906 was 11.3, and that again from this standpoint the cases are at least as severe as the preceding ones.
4. The two groups of cases are composed of cases both clinically and bacteriologically positive.
5. That the cases under treatment by Formic Acid were kept under observation even longer than the preceding ones (page 20) and that, therefore, paralysis occurring later in the disease was even less likely to have escaped notice.

STATISTICS OF 300 CONTROL CASES

The statistics of the accompanying control cases have been arranged in the same manner as those of the cases treated with Formic Acid.

The cases are in each series consecutive cases, nor, as has been said, are they in any way selected cases, except that no cases have been included which were not both bacteriologically and clinically positive.

As will be observed the statistics are much the same, but rather better than a wide series of statistics taken from other hospitals, namely about 11.3% for cases treated on the third and fourth day from the onset of the disease. Although the different series of cases are given separately, an average result of the three groups of cases is also appended, that a broader basis may be given for the results of comparison. The results of comparison will be discussed in detail later.

COMPARISON OF STATISTICS

The remaining statistics show a comparison between those cases already described treated by Formic Acid and the control cases treated as described on page . The results, when described together, appear more than good and the necessity of proving that the types of epidemic were equally severe the more apparent.

As will be shown later, also when dealing fully with the more severe cases in the series treated by Formic Acid, nine of the cases there described had the cardinal signs and symptoms of impending cardiac failure and yet recovered, it is therefore not too much to expect that with different treatment the statistics might have been similar. Thus the death-rate in the Formic Acid cases is 2%, while nine cases during the first five days had vomiting, irregularity of pulse, pain, etc. - and yet recovered. This would have given a percentage of 11% which is practically the percentage of the control cases and for most hospitals. It is also interesting to note, as will also be shown later, that in the cases of paralysis, two occurred in cases complicated with measles and not until 16-18 days after the accidental stoppage of the drug.

The results in Albuminuria are again more than good and are even proportionately better than those of Cardiac Failure and Paralysis.

It will be best to discuss these points under "Analysis of Results" after the statistics themselves have been considered.

ANALYSIS OF RESULTS

Although the broad results of treatment are well seen in the tables of statistics, it will be best to more minutely examine each complication in detail and to attempt to give an explanation of the results.

Cardiac Failure

With an improvement in the death-rate from 8.6% to 2% it must seem as though Formic Acid has a distinct and definite effect in this - the most serious diphtheritic complication.

Cases 10, 19, 39, 45, 57, 59, 76, 81 and 89 are all types of cases which may fairly be said to have shown symptoms and signs of heart failure sufficiently severe as to have warranted a very bad prognosis in the ordinary course of the disease. In case 89, cardiac pain, vomiting, obvious toxæmia, irregularity of pulse, pallor, occasional coldness of limbs, systolic mitral murmurs and weakness of the first sound of the heart are signs and symptoms which, in the ordinary course of the disease would warrant a prognosis of the worst type and more especially when occurring late in the course of a severe attack of scarlatina.

Still more striking is Case 76, where, with symptoms of impending heart failure and toxæmia to

a more than marked degree there was present broncho-pneumonia and, as in Case 89, complete recovery.

A specially interesting feature in Case 76, is the fact that a hypodermic injection of Strychnine Hydrochlor, given as a control experiment had no effect on the pulse or general condition, while with an equal dose of the Formate a marked improvement was visible within forty minutes, improvement which was increased and maintained with two similar doses. It may also be pointed out that at the time of administration, the pulse was running and almost imperceptible.

In the two cases which died, although one was progressive and the other - as has been shown "doubtfully" sudden - the degree of toxæmia before the first administration was extremely profound and it would seem impossible to overcome a toxæmia which had already poisoned every system and organ.

One other interesting point is that there were no threatenings of Cardiac Failure in any of the cases in the very late stages of the disease, a fact which would seem to prove how thoroughly the toxæmic element had been eliminated and how thoroughly the stimulant effect had persisted.

The main features in all the cases are:-

1. The remarkable regularity of the pulse even after irregularity has been present in

most pronounced degree. With the exception of some four cases, the pulse has been regular within five days of administration and in the great majority of cases within three days of administration.

2. The marked improvement in the general nutrition of the patients, as shown by their colour, appetite, lack of depression, etc., which has been, as is noted in the details of the cases, as a rule, within four days of administration and which would point to a successful combating of the toxæmia.

So far, then, the results appear to show that Formic Acid and the Formates have a distinct stimulant effect on the heart and that, given a not too profound toxæmia before administration, the general nutrition and vitality of the muscles is so improved as to combat with success the toxæmia of this particular disease and to prevent a subsequent degeneration.

To what may this be due?

As has been shown, the line of treatment carried out in these cases - namely by Formic Acid and by the occasional use of Belladonna - was one of stimulation by non-blood pressure raising drugs. The former treatment, on the other hand,- namely treatment by Strychnine, strophanthus, digitalis

and adrenalin chloride, - was entirely by drugs which raised blood pressure, in different ways but with the same result. If, however, as in diphtheria, the heart is weakened by toxæmia and the inhibitory apparatus is also affected, as shown by the condition of the pulse, and if degeneration is the almost constant accompaniment, as is the case, it would seem that by raising blood pressure and so increasing the amount of work which the heart has to perform, that a contrary result to what is hoped for, must ensue - namely an increase of degeneration and a further strain to the heart.

The addition, in occasional laryngeal cases, of Belladonna which, in small doses, modifies the inhibitory action of the Vagus nerve and so increases the output of the heart per minute, has been therefore strictly in accordance with views such as these.

It is possible, therefore, that the astonishing difference in the results obtained from the two courses of treatment has been due to the broad fact that, whereas the 300 control cases were treated by strychnine, strophanthus, adrenalin chloride, etc. - namely, blood-pressure raising drugs - the 100 cases treated by Formic Acid and occasionally Belladonna, were treated by non-blood-pressure raising drugs, and that, therefore, the heart was not so severely

taxed as regards the amount of work imposed upon it in the latter cases.

It seems more probable, however, that the results are due to a combination of this fact with the actual stimulant properties of Formic Acid, and that with a gradual stimulation of striped muscles all over the body and direct stimulation of the heart, the resistive power of the individual must be enormously increased unless, as has been shown in the two cases referred to, degeneration has already occurred in an advanced degree. If this is the case, the nervous system must be indirectly benefited, for the exact selective influence of diphtheritic toxine is as yet uncertain, and it is, therefore, by the combination of these two factors that results, so good as these, have been obtained.

but Stephen's
Stimulates the
heart & also
the peripheral
nerves.

?

It may be urged, that, for this complication of the disease, 100 cases does not leave a sufficient margin as to warrant the obtaining of a definite result. While this, no doubt, is true, so large a percentage of recovery among cases with undoubted signs and symptoms of impending Cardiac Failure would seem to negative this assertion and, in any case, to prove the necessity of a prolonged and exhaustive trial of the drug in the disease.

Paralysis.

While the percentage of paralysis of all varieties - namely three, is not far different from that of the deaths from Cardiac Failure, the improvement in results is much more marked.

A fall in the Paralysis rate of 11%, namely, from 14% to 3% is more satisfactory even than the results of the former complication.

While the results of the total numbers of paralysis appear more than good, the mild type of the paralysis is also satisfactory. Thus, of the three cases of paralysis recorded two were benign, namely palatal, and the third a very slight paresis of the lower extremities with only slight alteration in reflexes, and a subsequent complete recovery. In the two palatal cases there was in both cases an alteration in speech, but no difficulty in swallowing. A third interesting feature of these cases of paralysis is the fact that two out of the three recorded cases occurred during a subsequent attack of measles, and that in both cases the drug had been discontinued from 16 to 18 days before the symptoms appeared.

Thus, cases 59 and 73,- the first, a case of palatal paralysis and the second, one of paresis of the lower extremities, were both treated for diphtheria for two and a half weeks with Formic Acid;

both developed measles, and were transferred to another ward, where for sixteen to eighteen days, the drug was unfortunately discontinued and the paralysis appeared.

It is possible that the paralysis in both cases was the result of the Measles Toxaemia, following on the Diphtheritic, or again that it was due to a too early discontinuance of the drug. It would seem impossible to differentiate on account of the similarity of both cases, and it would seem safer to assume that a combination of both circumstances was the cause. This in fact must almost of necessity be so, for, with an increase in the degree of Toxaemia, the necessity for the continuance of treatment must be more apparent.

Here again as in the results of Cardiac Failure doubt might be expressed as to the severity of the epidemic, but proof as to this would seem to have been proved positive, and out of the hundred cases, at least twenty-five cases were so extremely toxæmic as to warrant a doubtful prognosis of paralysis, and, under ordinary circumstances, a percentage at least average in number and type with the cases cited as control.

The multiplicity of lesions described in this complication of Diphtheria, render it the more

difficult to give an adequate explanation of the results of this treatment. As has been shown by Manicatide, many of these lesions are purely muscular, and with the use in frequent small doses of such a drug as Formic Acid, results similar to these might be expected. In those cases where the lesion is primarily central with a Wallerian degeneration of the peripheral nerves, it would seem as though two objects might be obtained: (i) To give complete rest, and by using Formic Acid to keep the muscular system in tone and the general nutrition good, until the nervous system - if not too severely poisoned - recovered; or (ii) to attempt to prevent this occurring in a severe form by successfully combating as soon as possible the toxæmia by early large doses of Formic Acid and the Formates.

With such statistics from treatment such as this, it may be considered if hitherto the muscular element in diphtheritic paralysis has not been underestimated, and that many of the early, and less severe forms of paralysis are not muscular, with a less severe degree of nervous element than is generally supposed.

A theory such as this would appear to suit well the results obtained with Formic Acid in these cases, and might explain the diminished number of deaths from Cardiac Failure as well as the lack of paralysis of other varieties.

Albuminuria.

Although the diuretic effect of Formic Acid and the Formates in the disease has not been pronounced, the great reduction in the percentage of albumen - namely from 38% to 10% - is noteworthy.

While in one case (No. 90) the amount was great and prolonged, it may be noted that the patient was suffering from pleurisy with effusion and a high swinging temperature. In the remaining case, the appearance of albumen was within two days of admission and was only present, at the most, on two occasions. There were, apart from the absence of albumen, no noteworthy features in the urine.

That the Formic Acid exercises any direct effect on the kidney is difficult to suppose and it would seem as though the result was obtained chiefly by the general condition of the patient being so good as to be highly resistant to the toxine, while that in the percentage and doses given the blood-pressure was not raised and no diuresis ensued.

It is interesting to note that in the two cases in which antitoxine was given in largest amount - namely 76 and 81 - albumen appeared on the second day in one only and not again, and this would, in a slight degree bear out the observations of Variot that the two are in no way connected.

There can be little doubt that the amount of albumen is, as a rule, in proportion to the severity of the toxæmia and the explanation of the results obtained would seem to be as stated above, rather than any direct action of the drug on the kidneys.

CONCLUSIONS.

It is difficult not to conclude that results, such as these, are sufficiently successful as to at least warrant a thorough and prolonged trial.

It may be urged that the influence of antitoxin has not been given the prominence due to it, but has purposely been disregarded as being in the same proportion for the Control Cases.

Treatment would, therefore, appear to resolve itself into:-

1. Adequate and early doses of Antitoxin;
2. Rest in proportion to the severity of the case;
3. Gradual and proportionate stimulation by Non-blood-pressure raising drugs;
4. The use of Formic Acid and the Formates; and until proof positive negatives it, that, with such results, a thorough trial of such lines of treatment must be made at the expense of the older treatment which relied for stimulation solely on an increase of blood pressure, while it would seem to be the case that Formic Acid and the Formates, by their influence on every complication of importance in diphtheria, render them, in that disease, drugs of the greatest importance.
