Abstract

Cuc Phuong National Park (CPNP) is Vietnam's first national park, which has become a model for national parks and protected systems in Vietnam since its establishment in 1962. In spite of its importance to tourism, no systematic analysis has been undertaken thus far to understand the perceptions of its residents toward tourism in their area. Guided by the Social Exchange Theory, this study investigated Cuc Phuong National Park (CPNP) residents' perceptions of tourism impacts and their support for tourism development in their areas. Additionally, the study also explored how demographic factors (age, gender, ethnicity, place of birth, marital status and level of education, household monthly income, job status and length of residency) explain residents' perceptions and their support. It was found that residents in general have positive perceptions towards the impacts brought by tourism in CPNP especially with regards to its social-cultural and environmental impacts and they strongly supported tourism development. However, these perceptions differ according to residents' socio-demographic characteristics. The study also revealed that residents' age and gender and their perceptions of tourism impacts could be predictors for their support for tourism development in CPNP. Based on these findings, the concluding part discusses the study's implications and provides suggestions for the future.

Introduction

In recent decades, tourism has become an important component of economic development programs around the world, especially in rural

communities in developing countries where tourism often assume the important role of alleviating poverty and boosting local economies. However, the developmental

benefits gained from tourism may not always be possible, if the negative impacts on communities outweigh any economic, socio-cultural, and environmental benefits.

Tourism impact is a popular research topic in tourism whereby many researchers have studied residents' attitudes toward and perceptions of the impacts of tourism development, with the justification that the findings would be critical in tourism planning and management (see for example, Allen et al. 1993 Dyer et al. 2007; Fredline & Faulkner, 2000 and Ko & Stewart, 2002). Other reasons for interest in this topic are based on the increasing cases of evidence on how tourism can generate both positive and negative outcomes (Lankford & Howard, 1994), and that residents' support is essential for sustainable tourism growth (Chen, 2001; Ramchander, 2004). Tourism industry relies heavily upon the local residents' goodwill, participation and support, and therefore it should be developed according to the local residents' need and desires. Since the positive attitude of residents is essential for visitor satisfaction and repeat visitation, determining local residents' perception of tourism development and its impacts is critical in the future success of a destination (Andriotis, 2005; Yoon et al., 2001). Effective tourism planning requires understanding of these impacts from the residents' perspectives.

The main aim of this study is therefore to shed some light on how residents surrounding Cuc Phuong National Park (CPNP) perceive tourism impacts and its development. The awareness of residents' attitudes, perceptions and expectations from tourism impacts and its development are "paramount" (Chen, 2001) in order to identify real concerns and issues for appropriate policies and actions to take place, and eventually to gain support from the tourism industry. Residents draw their conclusions and their support based on the relative weightings they attach to the benefits and the costs that they perceive to have been brought by tourism to themselves and to their community (Andriotis & Vaughan, 2003). If the residents of a host community perceive that the total impacts are negative, the level of support from the host community is likely to be weak which in turn will

not be beneficial for the development of the destination in the long run. Thus, another aim of this study is to assess the relationships between CPNP residents' perceptions of tourism impacts, their evaluation of these impacts and their support for tourism development. In addition, the study also seeks to understand the factors, specifically the socio-demographic factors, which may explain these perceptions and support levels. The specific research questions that have guided the study are as follows:

1. What are the socio-demographic characteristics of residents in CPNP?
2. How do CPNP residents perceive tourism impacts and how do they evaluate these impacts? How do they support tourism development in CPNP?
3. Do the CPNP residents with different socio-demographic characteristics differ in their perceptions and evaluation of tourism impacts, and their support for tourism development?
4. Which of the variables under study explain the residents' support for tourism development in CPNP?

Literature review

The range of impacts from tourism is broad and often influences areas beyond those commonly associated with tourism (Kreag, 2001). Exact types and magnitudes of impacts are almost impossible to measure, as they cannot possibly be regarded separately as it is not easy to distinguish between the effects brought by tourism alone and the effects generated by other agents of change, such as modernization, development, and the influence of media (Archer & Cooper, 1994; Lickorish & Jenkin, 1997; Mathieson & Wall, 1982). The extent to which tourism has contributed to economic, social or environment problems of an area, as well as problems within the area. which have already existed prior to the existence of tourism is not often known precisely (Mathieson & Wall, 1982). Finally, the fact that different destinations experience different impacts or even the same impacts but with different degrees/stage, adds to the difficulty in comprehending impacts brought by tourism.

In addition, the challenge in assessing tourism impacts exists due to different views held by

different authors and authorities in the field. This is probably what is meant by Mathieson and Wall (1982) when they claim that "there is little consensus as to what should be included" (Mathieson & Wall, 1982: 3) as impacts from tourism development, which then leads to contradictions and ambiguities in findings of research in this area. For instance, some authors in their economic impact of tourism studies just concentrate on the balance of payments, whereas others are devoted to the generation of income or the creation of employment.

There are a number of ways to categorize the impacts of tourism. Krag (2001) in his research, divided tourism impacts into seven general categories in the form of economic, environmental, social and cultural, crowding and congestion, services, taxes, and community attitude. Archer and Cooper (1994), separated tourism impacts into economic, political, socio-cultural, environmental and ecological effects. Much earlier, Inskip (1991), in his prevalent book "*Tourism Planning - An Integrated and Sustainable Development Approach*" divided tourism impacts into just two categories namely, socioeconomic impacts and environmental impacts. However, tourism impacts are most commonly grouped into three categories, which are economic impacts, physical or environment impacts, and social impacts (Ap & Crompton, 1998; Mathieson & Wall, 1982). As the present authors feel that social impacts most often include cultural impacts, this study follows the "traditional categories" (Ap & Crompton, 1998) and categorizes tourism impacts as economic, physical or environmental and social-cultural impacts.

Findings from previous studies indicate that socio-demographic characteristics such as age, gender, ethnicity, education, income, job status, etc. might or might not significantly influence residents' attitudes, perceptions and evaluation of tourism impacts and tourism development. However, ambiguities in these findings exist. While some studies found socio-demographic characteristics of residents to significantly explain differences in residents' attitudes, perceptions and evaluation of tourism

impacts (Andriotis, 2004; Chen, 2000, 2001; Haralambopoulos & Pizam, 1996; Kuvan & Akan, 2005; Nunkoo & Ramkissoon, 2010; Ritchie & Inkari, 2006; Williams and Lawson, 2001), contrary findings were produced by other studies (Allen et al., 1993; Brayley & Var, 1989, Harvey, Hunt & Harris, 1995; Johnson, Snepenger & Akis, 1994; King, Pizam & Milman, 1993; McCool & Martin, 1994; Milman & Pizam, 1988; Perdue, Long & Allen, 1990; Ryan & Montgomery, 1994; Ryan, Scotland & Montgomery, 1998; Tosun, 2002). This create a vagueness, which can be attributed to the fact that different tourism destinations having different population characteristics and that tourism impacts are formed by site specific conditions under which tourists and hosts interact (Kuvan & Akan, 2005; Tosun, 2002). This study attempts to test the association between residents' socio-demographic characteristics (age, gender, ethnic, place of birth, marital status, level of education, household monthly income, job status, length of residency) and residents' perceptions of tourism impacts, their evaluation of tourism impacts, and their support for tourism development.

Several models and theoretical perspectives have been developed or utilized to help explain residents' perceptions of and attitudes toward tourism development and its impacts. Among these models are the equity theory, growth machine theory, power theory, stakeholder theory, identity theory (see for more detail in Easterling, 2004; Harill, 2004; Kayat, 2000 and Nunkoo, Gursoy & Juwaheer, 2010), social exchange theory, Doxey's Irridex Model (see for more detail in Harrill, 2004), Butler's (1980) Tourist Area Life Cycle Model, and community attachment model.

The Tourism Cycle Development Framework models by Doxey and Butler offer a reflection of residents' perceptions of tourism. The framework explains that resident attitudes towards tourism change as the tourism industry develops (Hernandez et al. 1996) and suggests that communities have a certain capacity to absorb tourists. Although this framework provides useful assessment criteria for exploring the community's attitudes at certain

stages of tourism development, the models are restricted as they do not take into account the fact that different individual residents react differently to tourism development. Besides the fact that residents' perceptions can be influenced by the complexity of factors, these models overlook the fact that residents are not homogeneous in terms of their attitudes towards tourism (Kayat, 2000). Moreover, these models have only one direction in community reactions, which is rather unrealistic (Kayat, 2000).

Community attachment, on the other hand, can be another important variable that influence residents' perceptions towards tourism, tourism impacts and support for tourism development. Generally, community attachment is dependent upon length of residence. Community attachment and residents' attitudes towards tourism development suggest that highly attached residents tend to view tourism development more favourable. In this study, community attachment is assessed through length of residency.

Thomason et al. (1979) and Lankford and Howard (1994) began their studies with the guidance of the Tourism Cycle Development Model and came up with similar findings: resident attitudes are influenced by what they value. Wang and Pfister (2008) shared the same findings in their studies when indicating that residents' attitudes toward tourism are not simply the reflections of residents' knowledge about tourism impacts but also influenced by residents' values and personality. It can be concluded then, that how residents assess the costs and benefits of tourism plays a role in determining their attitude – a suggestion offered by social exchange theory, which is discussed next. Since then, many studies have confirmed that residents' attitudes toward and perceptions of tourism and tourism impacts can be explained using social exchange theory (Andereck, et al. 2005; Andriotis, 2005; Andriotis & Vaughan, 2003; Ap, 1990, 1992; Chen, 2000, 2001; Getz, 1994; Gursoy, Jurowski & Uysal, 2002; Jurowski, et al., 1997; Kayat, 2000, 2001, 2002; Lindberg & Johnson, 1997; McGehee, Andereck & Vogt, 2002; McGehee & Andereck, 2004; Nunkoo, Gursoy & Juwaheer, 2010; Nunkoo & Ramkissoon, 2010;

Sirakaya, Teye & Sönmez, 2001, 2002; Wang & Pfister, 2008; Yoon et al., 2001;). Social exchange theory is "a general sociological theory concerned with understanding the exchange of resources between individuals and groups in an interaction situation" (Ap, 1992: 668), which suggests that people evaluate an exchange based on the costs and benefits incurred as a result of that exchange. Voluntary actions of individuals are motivated by the returns they expect to receive from others. With these returns acting as goals, an individual or a party engages into an exchange with others. In other words, an individual who perceives benefits resulting from an exchange is likely to evaluate it positively, while one who perceives costs is likely to evaluate it negatively. Thus, residents who find that the exchange benefits them and increase their well-being are more likely to have positive reactions to tourism and therefore support tourism development. Residents who find the exchange problematic, correspondingly, will oppose tourism development. Jurowski et al. (1997) applied the social exchange theory to examine community support for tourism in five counties surrounding the Mt. Rogers National Recreation Area located in southwest Virginia and found that resident perception of tourism impact is a result of assessing benefits and costs, and that this evaluation clearly depends on what the resident value. For example, the study found that respondents with strong eco centric attitudes did not perceive tourism favourably as they put high value on the environment and feel that tourism have the potential to harm the environment. In addition to value held by residents, Kayat (2000) also found that residents' evaluations of tourism impacts is influenced by their ability and willingness to adapt to the changes brought by tourism in their community. Cordero (2008) suggested that if the social exchange theory is to gain academic and practical acceptance, the theory need to be further tested due to the complex nature of the interrelationship proposed in the model and to the complexity of residents as both isolated and collective individuals.

For the purpose of this study, social exchange theory is used to guide the investigation on residents' perceptions of tourism impacts and their support for tourism development in the

case of CPNP, Ninh Binh, Vietnam. The reason is due to the fact that residents' perceptions of the impacts of tourism development are partially based on the socio-cultural, economic and environmental trade-offs and they, in turn, may influence to residents' support for tourism development. Furthermore, social exchange theory is a logically and intuitively appealing theory to formulate the basic of an investigation of the residents' perceptions of tourism impact and their support for tourism development in the case of CPNP.

Problem statement

Earlier researchers and scholars have suggested that numerous research examining tourism impacts and residents' attitudes have been conducted in developed and industrialized economies, with only a few studies carried out in developing countries (Nepal, 2008; Nunkoo, Gursoy & Juwaheer, 2010 and Teye, Sönmez & Sirakaya, 2002). In addition, and that despite the availability of some research on residents' attitudes toward tourism and its impacts, it is necessary to conduct additional research on this topic in other geographical locations, in different settings, and over a period of time. This will not only reinforce earlier findings but also identify and explore other factors that may influence the host residents' perceptions of and attitudes toward tourism, its impacts, and their support for tourism development; such studies will further the development of theory in this field (Andriotis, 2004, 2005; Cavus & Tanrisevdi, 2003; Haralambopoulos & Pizam, 1996; Kuvan & Akan, 2005; Sheldon & Var, 1984; Smith & Krannich, 1998; Yoon et al., 2001).

Since the early 1990s, tourism has received considerable attention in the economic development strategy of Vietnam. It is seen as an important component to diversify rural economic opportunities (UNDP, 1997). Local communities associated with tourism destinations are looking increasingly to tourism to provide economic opportunities and funds (Sheed, 2003). In fact, communities living in and around tourism destinations may thus be affected by tourism impacts, either positively or negatively. The recent years have seen growth in community-based tourism in Vietnam. Unfortunately, research on its development,

planning, and impacts have not been given much attention.

The site selected in this study is Cuc Phuong National Park (CPNP), in Ninh Binh province, Vietnam. This particular site was chosen for the case study because it is a well-established and well-known tourist site in Vietnam. CPNP was established in 1962 as Vietnam's first national park. Ever since its foundation, Cuc Phuong has been the model for other national parks and protected systems in Vietnam. In spite of the importance of tourism to Cuc Phuong and the knowledge that the attitudes and perceptions of local residents are vital for the success of tourism, little is known about the local residents' perceptions of tourism. Numerous research have been undertaken to study tourism activities in CPNP. However, no published research has, so far, dealt with the residents' perception of the impacts of tourism and their attitudes toward and support for tourism development in Cuc Phuong. Hence, there is a need for a study that will build on the existing, albeit limited body of knowledge concerning the local residents' perceptions of tourism impacts and their attitudes toward and support for tourism development. A systematic analysis of these aspects among the CPNP residents can help local authorities, planners, community decision-makers, tour-operators, and tourism promoters to identify real concerns and issues in order to implement appropriate and effective policies and actions in the area, thus optimizing the benefits and minimizing the problems associated with tourism.

The conceptual framework and the research hypotheses

Conceptual framework

Based on the literature review, a conceptual framework for the study is depicted in Figure 1. According to the framework, residents' perceptions of tourism impacts as well as their overall evaluation of tourism impacts and their support for tourism development are determined by their socio-demographic characteristics. Residents' socio-demographic characteristics, their perceptions of tourism impacts and overall evaluation of tourism impacts determine their support for tourism development.

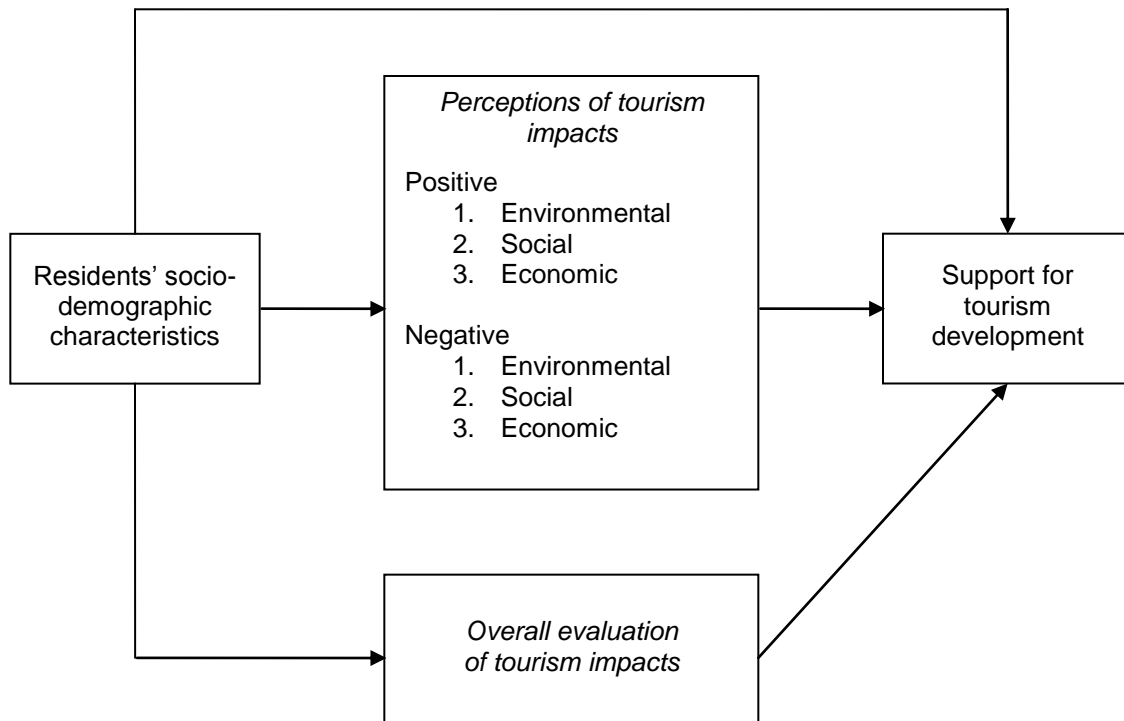

Figure 1. A framework on residents' perceptions and support levels

It is proposed that the social exchange theory is useful in explaining residents' perceptions towards tourism impacts and support for tourism development, this theory proclaims that if residents perceive that the positive impacts of tourism development will be greater than negative impacts, they are inclined to be involved in the exchange and, therefore, support tourism development in their community (Yoon et al., 2001).

Research hypotheses

The hypotheses developed for this study are:

Hypothesis 1: There are no differences among residents' socio-demographic characteristics with respect to perceptions of tourism impacts, overall evaluation of impacts, and their support for tourism development.

Hypothesis 2: The independent variables (residents' socio-demographic characteristics, residents' perceptions of tourism impacts, residents' evaluation of tourism impacts) do not significantly explain the dependent variable (residents' support for tourism development).

Research methods

Survey instrument

A survey questionnaire method was used for data collection. The questionnaire consisted of 53 items which are divided into 4 parts as follows:

1. Parts 1-3: Forty-three statement items meant to measure residents' perceptions of tourism impacts, their overall assessment of tourism impacts, and their support for tourism development in CPNP were included in these parts, followed by a five-point Likert scale for the respondents' opinions (1= strongly disagree, 2 = disagree, 3 = undecided/neutral, 4 = agree, 5 = strongly agree).

2. Part 4: This part comprised of nine questions pertaining to the socio-demographic characteristics of residents. The last question in Part 4 requested the respondents to provide any additional comments that they wished to make regarding tourism development in their community and in CPNP.

Figure 2. Location of Cuc Phuong National Park

Source: http://wikitravel.org/en/Cuc_Phuong_National_Park (2008)

Population and sampling unit

According to the CPNP statistics (2004), CPNP extends over three provinces (Figures 2, 3); it covers 4 districts containing 14 communes and a population of 68,828 inhabitants. However, there are only 5 communes (with 8 hamlets) located wholly or partly within the boundaries of the park, accounting for a total park population of 2,200 residents.

Due to a limited financial budget and time constraints, it was decided that the surveys would be conducted using a manageable method. Specifically, the study only included the five communes located wholly or partly within the boundaries of CPNP (see Figure 3) namely Cuc Phuong, Yen Quang, Yen Tri, An Nghia, and Thach Lam communes as its primary sampling unit. These communes are located in the areas where tourism activities occur (in the form of informal settlements, restaurants, hotels, guesthouses, homestays,

etc.). Residents living in these areas include both those who earn an income from tourism and those who are not involved in tourism.

Sample size and sampling technique

Since the data regarding the population size has not been recently updated, the research surmised that the actual park population could be far above the abovementioned figure of 2,200 residents (about 3000 residents); hence, it was decided that the representative sample size would comprise approximately 220 - 300 residents, or equal to 10% of the total population of the study area (Krejcie & Morgan, 1970, cited in Jennings, 2001: 148).

A combination of systematic and stratified random sampling approaches was employed for the sample selection. Decisions regarding the number of resident to sample at each commune were based on the following formula:

Residents' perceptions of tourism impact and their support for tourism development:
the case study of Cuc Phuong National Park, Ninh Binh province, Vietnam.

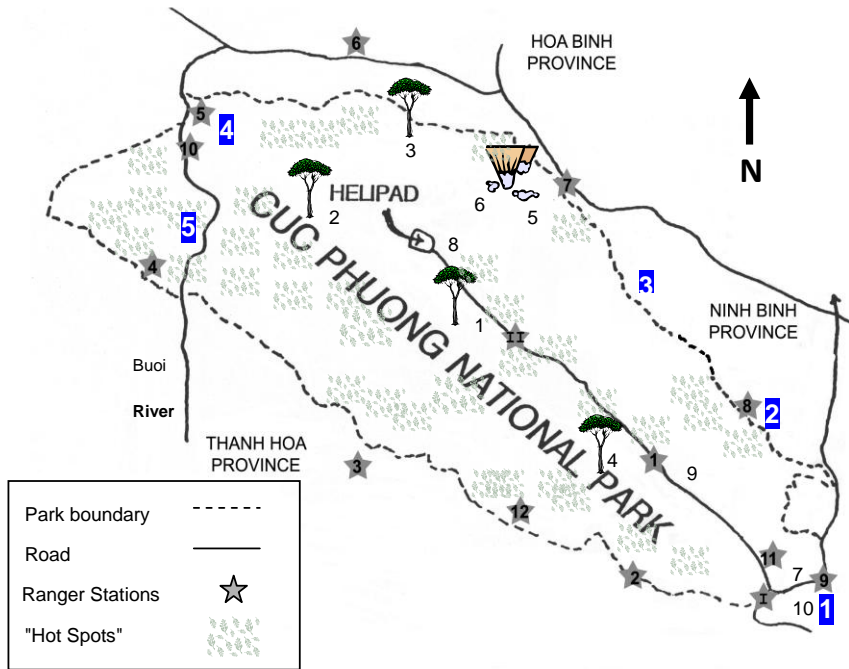

Figure 3. Cuc Phuong study areas

Note: 1. Cuc Phuong Commune; 2. Yen Quang Commune; 3. Yen Tri Commune; 4. An Nghia Commune; 5. Thach Lam Commune.

Communes=5=k
n =250 households
n/k=250/5=50

Therefore, 50 households in each commune were approached to participate in this study, after which they were sent the survey questionnaires. In this manner, a total of 250 households were contacted, with 238 individuals agreeing to participate; this indicates a response rate of 95.2%. Most of the questionnaires were completed in the presence of the survey teams, while some were left with the respondent and were collected either later that day or on the following day.

The returned questionnaires with missing data were eliminated from the analysis, because any statistical result based on a data set with missing values would be biased to the extent that the variables included in the analysis are influenced by the missing data process. Following this elimination process, a total of

201 response questionnaires with complete data were retained for the analysis, which indicates a response rate of 80.4%.

Findings and discussion

Profile of the respondents

The sample appeared to suitably represent the population in terms of the demographic profiles of the respondents, which are presented in Table 1.

The study's participants were mostly male (62.7%), concentrated in the 26-55 years age group (69.1%). The majority of respondents were married (81.1%), born in CPNP (67.2%), and from the Muong ethnic group (65.7%). A large section of the sample (77.1%) had jobs that were not related to tourism, and 65.2% of the total respondents had been living in the area for over 20 years. In terms of education level, there was a concentration at the secondary and high school level (32.8% and 21.9%, respectively); college graduates

constituted 17.4% of the sample, and 12.9% had completed university-level education. The monthly household income of the majority of respondents (84.1%) was below 1,500,000 Vietnamese Dong (VND).

Perception towards tourism

Table 2 and Figure 4 present the responses to the 43 perception-related statements. The survey questionnaire was divided into six sub-sections, based on three categories of tourism impact: positive/negative economic impacts, positive/negative socio-cultural impacts, and positive/negative environmental impacts. In addition, the respondents were asked to

evaluate the overall impact of tourism in CPNP, and to indicate their support for tourism development in CPNP.

In general, the results of this study indicate that the CPNP residents tend to have positive perceptions of tourism impacts. Remarkably, respondents agreed to all the positive statements. They especially felt that tourism had improved the quality of products and services ($m=4.0896$) in that region, increased residents' pride in the local culture ($m=4.0547$), contributed to the preservation of the natural environment and protection of wildlife in CPNP ($m=3.8856$), and provided an incentive for the

^a n = 201; 1 = *strongly disagree* to 5 = *strongly agree*

restoration of historic buildings ($m=3.7363$). The respondents also agreed that tourism has positive economic impacts, but the mean scores for this aspect (ranging from $m=3.1194$ to $m=3.7214$) were not as high as those for positive socio-cultural and environmental impacts. Meanwhile, the respondents in their statements expressed their concerns over the fact that the prices of real estate, and many goods and services in their community have increased because of tourism ($m=4.0547$ and $m=3.6915$), and that the income from tourism is not distributed equally among residents in their community ($m=3.1194$). They agreed, albeit to a very slight extent that the natural landscapes and agricultural lands in their area had diminished in recent years because of tourism ($m=3.3035$), and that tourism has had some negative impacts on the natural resources ($m=3.0597$). The respondents also tended to disagree with the statement that tourism is damaging their culture ($m=2.1692$), and has limited their use of recreational facilities ($m=2.3930$). The respondents, however, indicated uncertainty in nearly all the statements regarding the negative impacts of tourism, especially those related to the socio-cultural impacts of tourism.

In line with the findings by Tatoglu et al.(2000), Andriotis (2004), and Kuvan & Akan (2005), the present study found that the CPNP residents strongly agreed that tourism creates positive socio-cultural and environmental impacts. However, contrary to the findings of those earlier studies, which suggest that residents value positive economic impacts the most, the CPNP residents tended to value positive socio-cultural as well as environmental impacts more, while ascribing a higher score to the latter aspect.

Another prominent finding of this study suggests that support for tourism development in CPNP is strong among its residents. They firmly believe that their community should support tourism development and are willing not only to be personally involved in the future development of ecotourism in CPNP, but also to welcome more tourists ($m=4.2239$, $m=4.0945$, and $m=4.0249$, respectively).

These findings are similar to those of other studies such as Milman and Pizam (1988), King, Pizam, and Milman (1993), Haralambopoulos and Pizam (1996), and Rátz (2000), whereby the respondents not only support the current extent of tourism, but also look forward for its expansion.

Difference in perceptions among residents

A series of ANOVAs and *t*-tests was conducted to examine the differences in perceptions among respondents with different socio-demographic characteristics towards tourism impact, their overall evaluation of the impacts and their support for tourism development in CPNP.

The findings of this study revealed that socio-demographic characteristics significantly influence residents' perceptions of tourism impacts, evaluation of tourism impacts, and their support for tourism development. However, perceptions of CPNP residents differed according to nine socio-demographic characteristics.

Similar to findings by Kuvan and Akan (2005) among residents in Belek, Turkey, but contrary to findings by Kayat (2000) among residents in Langkawi, monthly household income was the most significant variable affecting CPNP residents' perceptions of tourism impacts, evaluation of tourism impacts and their support for tourism development (Table 3). The result of this study shows that, generally, CPNP residents who had average and higher income were likely to favor tourism and supported tourism development. In contrast, residents who had lower income seemed to value tourism lower and were less supportive of tourism development. This result has helped to confirm the usefulness of social exchange theory in explaining residents' perceptions of tourism as there are indications that those residents who benefit economically from tourism are supportive of it. This result is also useful to confirm that residents' perceptions towards tourism development are context-specific.

Other socio-demographic characteristics found to explain CPNP residents' perception towards tourism development are ethnicity (Table 4), education level (Table 5), job status (Table 6), age (Table 7).

Those residents belonging to Kinh group have more positive views towards tourism's positive impacts, and they also support tourism development more compared to the residents belonging to Muong and others ethnic groups.

Superscript numbers indicate that mean values are significantly different from the mean values in the equivalent columns. Numbers denote columns 2-7, i.e. 1=No schooling, 2=Primary school, 3=Secondary school, 4=High school, 5=College, 6=University and others. For example, the first line reads that significant differences existed between those that hold primary school level and those that hold secondary school level, between those that hold primary school level and those that hold high school level, between those that hold primary school level and those that hold college level, between those that hold primary school level and those that hold university or others level, and so forth.

A closer observation by the researcher reveals that most of Kinh people have tourism related-jobs. This may help explain why the residents in this group have more positive views than Muong and others.

In addition, those residents with lower level of education (primary school holders in this case) have a critical views about tourism, mainly because they feel that local residents have suffered by living in a tourism destination area, they imitate the behavior of the tourists and relinquish cultural traditions, and tourism reduces the natural landscapes and agricultural lands in their area. They also do not believe that tourism increases the recreation opportunities for the local resident. However,

they still believe that benefits of tourism exceed the costs to the people of the CPNP. Those residents holding higher level of education (college level, university and other levels) are likely to enthusiastically welcome tourism. They appreciate tourism's positive impacts, and disapprove of its negative impacts. In this manner, the findings of this study are congruent with the result of study by Haralambopoulos and Pizam (1996), which indicates that the more educated the residents are, the more positive perceptions they have towards tourism. But, these findings contradict the findings of Andriotis (2004) and Kayat (2000), which indicates that highly educated respondents are more likely to express concern about the negative impacts of tourism

I would like to see more tourists in CPNP	4.00	4.30 ⁴	4.10 ⁴	3.26 ^{2,3}	3.23	9.194	196	0.000
I am willing to be a part of tourism planning for CPNP in the future	3.90	4.09	3.92	3.16	3.85	3.630	196	0.007
I am willing to be involved in the development of CPNP for ecotourism in the future	4.20	4.25	4.21	3.21	3.69	5.502	196	0.000

Superscript numbers indicate that mean values are significantly different from the mean values in the equivalent columns. Numbers denote columns 2-6, i.e. 1=18-25 years old, 2=26-35 years old, 3=36-55 years old, 4=56-60 years old, 5=Over 60 years old. For example, the first line reads that significant differences existed between those their ages are 26-35 and 56-60; and between those their ages are 36- 55 and 56-60.

(specifically, negative environmental impacts of tourism).

For the job status (Table 6), as found by other studies (Haralambopoulos & Pizam, 1996; Tatoglu et al., 2000; Andriotis, 2004; Kuvan & Akan, 2005), findings from this study indicate that those residents with tourism-related jobs tend to approve tourism more than those with non-tourism related jobs. This finding confirms findings by Kayat (2000) that the explanation offered by social exchange theory that benefits received by residents influence their support for tourism needs to be complemented with other explanation as other variables appear to also play a role in resident forming attitudes. As found by the present study, those residents who depend on tourism view tourism favorably

compared to those who do not depend on tourism.

For age groups (Table 7), the results of this study are in line with the results of the study by Haralambopoulos and Pizam (1996) as it is found that generally, the younger the residents are, the more positive perceptions they have towards tourism. Gender, place of birth, length of residency also have limited influence on residents' perceptions of tourism impacts, evaluation of tourism impacts, and support for tourism development. Interestingly, marital status has not exhibited any significant effect on residents' perceptions of tourism statements, similar to the result of the study by Kuvan & Akan (2005).

Table 8. *Multiple Regression of Support for Tourism Development in CPNP*

Independent Variables	B	t	Sig.
Age	-0.141	-2.571	0.011
Gender ^a	0.152	2.801	0.006
Positive socio-cultural impacts	0.471	7.471	0.000
Positive environmental impacts	0.251	3.956	0.000
Negative environmental impacts	0.244	4.419	0.000

Note. $R^2=0.44$, adjusted $R^2=0.43$, $F=30.583$, $p<0.001$

^a.Dummy coded: 0=female, 1=male.

The above findings do not support hypothesis 1, which assumes that there are no differences among residents' socio-demographic characteristics with respect to perceptions of tourism impacts, evaluation of tourism impacts and their support for tourism development. As a result, we reject the hypothesis 1 and accept that there are significant differences among residents' socio-demographic characteristics with respect to perceptions of tourism impacts, evaluation of tourism impacts, and their support for tourism development.

Support for tourism development

To test hypothesis 2, this study used the method of computing multiple regression simultaneously between the dependent variable (support for tourism development) and the independent variables (residents' socio-demographic characteristics, residents' perceptions of tourism impacts, and residents' evaluation of tourism impacts) in order to predict support for tourism development from a combination of a total of 16 independent variables.

Table 8 shows the results of the multiple regression pertaining to support for tourism development in CPNP. As can be seen from this table, $R^2=0.44$, and the adjusted R^2 value for 5 out 16 independent variables considered in the equation is 0.43, indicating that the model explains 43% of the variance in support of tourism development.

In particular, the CPNP respondents in support of tourism development were found to have the following perceptions and socio-demographic characteristics:

- The younger the respondent, the more likely he or she was to support tourism development.

- Males were more supportive of tourism development than females.
- Respondents who believed that tourism has positive socio-cultural impacts tended to support tourism development.
- Respondents who believed that tourism has positive environmental impacts tended to support tourism development.
- Finally and interestingly, respondents who believed that tourism has negative environmental impacts also supported tourism development.

It is worth noting that only two out of the nine socio-demographic variables entered the regression equation. Other socio-demographic variables such as ethnicity, place of birth, marital status, level of education, monthly household income, job status, and length of residency did not have a shared effect on the residents' support for tourism development. Interestingly, the other variables that did not have a combined effect on the support levels included the residents' perceptions of positive/negative economic impacts of tourism, their perceptions of negative socio-cultural impacts of tourism, and their evaluation of tourism impact.

These findings are also consistent with the first finding of this study, which signifies that residents in CPNP consider positive socio-cultural and environmental impacts of tourism to be more important than positive economic impacts of tourism, implying that they do not support tourism development merely on the grounds of economic aspect. Furthermore, this finding echoes the findings by Andereck and Vogt (2000) and, King, Pizam, and Milman (1993), who concluded that support for tourism development could be associated with the

belief that tourism induced positive as well as negative impacts. Despite their awareness of tourism's negative impacts, the local residents still support tourism development.

The findings also allow us to reject hypothesis 2, which assumes that the independent variables (residents' socio-demographic characteristics, perceptions of tourism impacts, and evaluation of tourism impacts) do not significantly explain the dependent variables (residents' support for tourism development).

The findings denote that the theoretical perspective of this research, the social exchange theory, is helpful in guiding research on residents' perceptions of and support for tourism development. Residents in CPNP perceive greater positive impacts of tourism than negative ones, leading to their support for tourism development in CPNP. In addition to the perception of the positive impacts, the study finds that variables such as degree of dependency on tourism may complement the above argument brought about by social exchange theory.

Conclusion

This study attempts to contribute to the existing body of work on local residents' perception of tourism impacts, their evaluation of tourism impacts, and their support for tourism development. The study develops a research instrument to determine these aspects which may be adopted by other researchers seeking to assess local residents' perceptions of tourism in different geographical areas, especially in Vietnam, where research instruments like this one are still scarce.

The conceptual framework developed and tested in this research offers a theoretical basis for the study of tourism impacts and local support for tourism development. Further testing of residents' perceptions in different areas using this conceptual framework can provide more comprehensive grounds for the comparative study of a variety of residents' perceptions of tourism impacts and support for tourism development. The addition of new variables to the framework may further elucidate these aspects.

This study also further validates to the theoretical predominance in the field of tourism research by confirming the usefulness of the social exchange theory in explaining residents' perceptions of tourism. The findings reveal that when residents perceive that the positive impacts of tourism (regardless of whether they are economic, socio-cultural, or environmental impacts) are likely to be greater than the negative impacts, they are inclined to accept the exchange and, therefore, support tourism development in their community.

One prominent finding of this study is that residents in CPNP valued the socio-cultural and environmental impacts of tourism higher than its economic impacts, and they supported tourism development, in general, but not merely for its economic benefits, unlike the findings of the earlier studies. Consequently, this study obtained its significant results that depending on the residents' socio-demographic characteristics, extent of tourism's influence, and different geographical areas, the local residents' perceptions of and attitudes toward tourism may differ; residents generally tend to support tourism if they feel that tourism brings them more benefits than costs (regardless of whether these are socio-cultural, environmental, or economic benefits). In CPNP, residents value the social-cultural and environmental impacts of tourism more than its economic impacts (because most of them are still dependent on the park's resources and they have not received significant economic benefits from tourism so far); these findings may differ if a similar study is conducted in other destinations.

This research provides tourism planners, policymakers, tourism strategists, and tourism promoters with helpful information about local residents' perceptions, evaluations of tourism impacts, and their support for tourism development; this information can be used to formulate plans and policies not only to gain residents' support for tourism but also to implement sustainable tourism development. The more attentive tourism leaders are to residents' concerns, the greater the support they are likely to receive in their community development efforts (Ramchander, 2004). The

study findings reveal that at the time of this research, CPNP residents tended to have positive perceptions of tourism and that they largely supported tourism development, especially due to its socio-cultural and environmental impacts. However, to maintain sustainable tourism, it is necessary to take into account a long-term perspective of residents' perceptions of tourism. Furthermore, it is important to involve residents in both tourism-related decision-making processes and the tourism activity itself, since the findings indicate the local residents' willingness to be involved and participate in these activities. The researcher's observations suggest that thus far the local residents, particularly the Muongs, have very limited involvement in such activities (participating in tourism as the hosts of homestays, selling goods and services, etc.).

This study demonstrates that socio-demographic characteristics of local residents influence their perceptions, evaluation of impacts, and their support for tourism development. In turn, residents' perceptions of tourism impacts brought by ecotourism development in CPNP and their socio-demographic characteristics influence their overall support for tourism development. Future research is needed to investigate why the specific socio-demographic characteristics influence the CPNP residents' perceptions towards tourism in order to make appropriate plans and policies.

In addition, although the local residents' view are critical for analyzing tourism development, in that the greatest impacts of the tourism industry are experienced and judged by the host residents (Andriotis, 2000), further research should investigate the perceptions of tourism organization managers and, local authorities to identify the real concerns and conflicts pertaining to tourism development in CPNP. Such information would lead to a better understanding of the tourism structure in CPNP and help the relevant authorities formulate effective tourism development plans and policies.

This study examines the factors, and variables that explain local residents' perceptions and

evaluation of tourism impacts, and their support for tourism development. In order to further understand "why" and "how" the CPNP residents' react to tourism development in a particular manner (that is, why and how residents perceive a specific impact as positive or negative), it is necessary to analyze additional data using qualitative methods in order to collect more insightful and comprehensive information.

The research instrument and conceptual framework developed and tested in this research can be expanded and tested in other geographical locations using larger samples to identify and examine other variables and factors that may influence the residents' abovementioned opinions. Such information will be useful in providing more comparative results and findings in this topic.

Based on previous studies, which had indicated that socio-demographic characteristics might or might not influence residents' perceptions, evaluation of tourism impacts, and their support for tourism development, the findings of this study show that socio-demographic characteristics, especially income, ethnicity, education level, job status, significant influence residents' perceptions. The results of this study also offer some variables, which explain for residents' support for tourism development in CPNP.

In conclusion, let us reflect on the view of McGehee and Andereck (2004: 139) that "a great deal of progress has been made in the study of residents' attitudes towards tourism, but a great deal is left to be done. No matter what future direction resident attitude research takes, the most important goal must be to assure that the varied voices of the community are heard".
