

Extracting the diffusivity ratio from point contact Andreev reflection spectroscopy and upper critical field measurements in MgB₂

Abstract

The diffusivity ratio ζ , which measures the relative intraband scattering in the $1/4$ and $3/4$ bands in MgB₂ has been determined by fitting the $H_{c2}(T)$ at $T \gg T_c$ and by Point Contact Andreev Reflection. We find a satisfactory agreement between the values for ζ obtained by both methods for c-axis orientated MgB₂ thin films. Point contact Andreev Reflection was then applied to bulk MgB₂ containing Mg vacancies. Spectra obtained in zero field indicate a distribution of the two gaps $\zeta^{3/4}; 1/4$ but no merging of the values with increased magnesium deficiency. Spectra fitted as a function of field are consistent with an increase in $1/4$ intraband scattering with increasing magnesium deficiency. Measurement of the point contact Andreev reflection spectra as a function of temperature revealed features not immediately expected from current theoretical models.
