ABSTRACT

A Data Grid is an organized collection of nodes in a wide area network which contributes to various computation, storage data, and application. In Data Grid high numbers of users are distributed in a wide area environment which is dynamic and heterogeneous. Data management is one of the current issues where data transparency, consistency, fault-tolerance, automatic management and the performance are the user parameters in grid environment. Data management techniques must scale up while addressing autonomy, dynamicity and heterogeneity of the data resource. Data replication is a well known technique used to reduce accesses latency, improve availability and performance in a distributed computing environment. Replication introduces the problem of maintaining consistency among the replicas when files are allowed to be updated. The update information should be propagated to all replicas to guarantee correct read of the remote replicas. An

asynchronous replication is a commonly agreed solution for the problem in consistency of replicas. A few studies have been done to maintain replica consistency in Data Grid. However, the introduced techniques are neither efficient nor scalable. They cannot be used in real Data Grid since the issues of large number of replica sites, large scale distribution, load balancing and site autonomy where the capability of grid site to join and leave the grid community at any time have not been addressed.

This thesis proposes a new asynchronous replication protocol called Update Propagation Grid (UPG) to maintain replica consistency over a large scale data grid. In UPG the updates reach all on-line secondary replicas using a propagation technique based on nodes organized into a logical structure network in the form of two-dimensional grid structure. The proposed update propagation technique is a hybrid push-pull and dynamic technique that addresses the issues of site autonomy, efficiency, scalability, load balancing and fairness.

A two performance analysis studies have been conducted to study the performance of the proposed technique in comparison with other techniques. First study involves mathematical and simulation analysis. Second study is based on Queuing Network Model. The result of the performance analysis shows that the proposed technique scales well with high number of replica sites and with high request loads. The result also shows the reduction on the average update reach time by 5% to 97%. Moreover the result shows that the proposed technique is capable of reaching load balancing while providing update propagation fairness.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk Ijazah Doktor Falsafah

**TEKNIK PENYEBARAN KEMASKINI YANG BAGI MENGEKALLAN
KONSISTENSI REPLIKA KE ATAS GRID DATA BERSKALA BESAR**

Oleh

Fakulti: Sains Komputer dan Teknologi Maklumat

Grid Data merupakan koleksi nodus terancang di dalam rangkaian kawasan luas yang menyumbang kepada pelbagai pengiraan, data penyimpanan dan aplikasi. Di dalam Grid Data, jumlah pengguna yang tinggi disebar di dalam persekitaran kawasan luas yang dinamik dan heteroginious. Pengurusan data adalah isu semasa di mana ketelusan, konsistensi, toleransi-kesilapan, pengurusan automatik dan pencapaian merupakan parameter pengguna di dalam persekitaran grid. Teknik-teknik pengurusan data semestinya mampu berkembang di samping mengutarakan autonomi, kedinamikan dan heteroginiti sumber data. Replikasi data merupakan teknik yang terkenal yang digunakan untuk mengurangkan kependaman kemasukan, memperbaiki kesediaan dan prestasi di dalam persekitaran pengkomputeran teragih (*distributed computing environment*).

Replikasi membawa kepada masalah mengekalkan konsistensi di antara replika-replika apabila fail-fail dibenarkan untuk dikemaskini. Informasi kemaskini

hendaklah disebarkan ke semua replika bagi menjamin ketepatan bacaan dari replika-replika jauh. Pereplikaan tak segerak (*asynchronous*) merupakan satu penyelesaian yang dipersetujui ramai bagi permasalahan konsistensi replika. Beberapa kajian telah dijalankan bagi mengekalkan konsistensi replika di dalam Grid Data. Walaubagaimanapun, teknik-teknik yang diperkenalkan adalah tidak efisien dan tidak boleh dikembangkan. Teknik-teknik tersebut tidak boleh digunakan di dalam Grid Data sebenar memandangkan isu-isu mengenai jumlah laman-laman replika yang tinggi, pengedaran berskala besar, keseimbangan muatan dan autonomi laman di mana kebolehan laman grid untuk masuk dan keluar dari komuniti grid pada bila-bila masa belum lagi ditangani.

Tesis in mencadangkan satu protokol replikasi tak segerak (*asynchronous*) baru yang dinamakan Grid Propagasi Kemaskini (Update Propagation Grid - UPG) bagi mengekalkan konsistensi replika ke atas grid data berskala besar. Di dalam UPG, semua kemaskini sampai ke semua replika pendua dalam talian menggunakan teknik penyebaran yang berasaskan nodus terancang ke dalam rangkaian struktur logik dalam bentuk struktur grid dua-dimensi. Teknik penyebaran kemaskini yang dicadangkan merupakan hibrid teknik tolak-tarik dan teknik dinamik yang mengutarakan isu-isu autonomi, kecekapan, pengembangan, keseimbangan muatan dan kesaksamaan.

Dua kajian analisa prestasi telah dijalankan bagi mengkaji prestasi teknik dicadangkan berbanding teknik-teknik yang lain. Kajian pertama melibatkan analisa matematik dan simulasi. Kajian kedua adalah berasaskan Model Penggiliran Jaringan (Queuing Network Model). Keputusan analisa prestasi menunjukkan bahawa teknik dicadangkan mengimbang baik dengan laman-laman replika dan muatan permintaan

tinggi. Keputusan Juga menuunjukkan penurunan purata masa tiba kemaskini dari 5% hingga 97%. Selanjutnya, keputusan juga menunjukkan teknik dicadangkan mampu mencapai muatan seimbang di samping memberikan kesaksamaan penyebaran kemaskini.

ACKNOWLEDGEMENTS

I would like to take this opportunity and thank my supervisor, Assoc. Prof .Dr. Ali Bin Mamat, for his support, guidance's, and understanding. Through the course of my study I have had the great fortune to get to know and interact with him. His comments and suggestions for further development as well as his assistance during writing this thesis are invaluable to me. His talent, diverse background, interest, teaching and research style have provided for me an exceptional opportunity to learn and made be become a better student.

I would also like to thank the committee members, Prof. Dr. Mustafa Mat Deris, Assoc. Prof. Dr. Hamidah Ibrahim, and Dr. Shamala Subramaniam for their help and valuable suggestions.

I would also like to thank Al-Aqsa University –Palestine -Gaza University and Palestinian National Authority for their financial support during my study.

Finally, I would like to thank my family and friends, without whose support I would ever have managed to complete this project.

I certify that an Examination Committee met on 20 January 2009 to conduct the final examination of Mohammed A A Radi on his Doctor of Philosophy thesis entitled "maintaining replica consistency over large-scale data grid using update propagation technique " in accordance with Universiti Pertanian Malaysia (Higher Degree) Act 1980 and Universiti Pertanian Malaysia (Higher Degree) Regulations 1981. The Committee recommends that the candidate be awarded the relevant degree.

Members of the Examination Committee are as follows:

Abdul Azim Abd. Ghani, PhD

Associate Professor
Faculty of Computer Science and Information Technology
Universiti Putra Malaysia
(Chairman)

Mohamed Othman, PhD

CHAPTER 1

INTRODUCTION

Data grid provides an environment for data intensive, high performance computing applications in many fields such as science, engineering and commerce. A data grid infrastructure has to manage a large scale, geographically distributed computers and storage resources and terabytes or betabytes of information while allowing flexibility for resources joining or leaving the system. Data management plays a very important role in data grid and replication. It can reduce access latency, improve data locality, increase robustness, scalability and performance, and improve data availability. One of the challenges for replication environment is maintaining replicas consistency. This thesis addresses the problem of maintaining replica consistency in large scale data grid.

1.1 Overview

Many large-scale scientific applications such as high energy physics, data mining, molecular modeling, earth sciences, and large scale simulation produce large amount of datasets (Ann, Ian, et al. 2001); (Bill, et al. 2002) (in order of several hundred gigabytes to terabytes). Analysis and mining of such datasets require more resources than available in single computing unit, be it a workstation, a supercomputer, or even a cluster within a single domain. The resulting output data of such application need to be stored for further analysis and shared with collaborating researchers within scientific community who are spread around the world.

Grid computing is the new computing paradigm that combines distributed, high-throughput and collaborative systems for the effective sharing and distributed coordination of resources which belong to different control domains. Grid computing accommodate a very diverse resource types including storage device, CPU power, files and in special cases, devices such as sensors, telescopes, satellite receivers and others. These resources may be distributed across many organizations among different geographical locations.

There are two main types of grids developed to satisfy special requirements; computational grid and data grid. A computational grid is designed for high performance computing. On the other hand, data grid (Ann, Ian, et al. 2001) primarily deals with providing services and infrastructure for distributed-intensive applications that need to access, transfer and modify massive data sets stored in distributed storage. Data grid is a grid where data, resources and data management utilities play vital role. It is important to enable users to take maximum advantage of the data grid infrastructure by ensuring efficient access and distribution of data resources based on real time users and application.

Data Grid infrastructure has to serve data intensive, high performance applications and has to manage a large scale geographically distributed computers and storage resources and terabyte or betabytes of information (Srikumar, Rajkumar and Kotagiri 2006). Grid allows resources flexibility to join and leave the group. Data grid architectures facilitate these requirements by applying the various technologies in a coordinated fashion. In a typical data grid, the components that enable grid services form a four-layer architecture (Ian, Carl and Steven 2001). In this architecture, the

components of a Data Grid can be organized in a layered architecture including Grid Fabric, communication, data grid service and application.

The size and distribution of the data in data grid create the needs for scalable and robust data management services (EDG 2004). These services need to manage replication of large amount of data across wide area network and provide a transparent access to distributed storage system holding the data.

The major challenge for Grid designer is to support a set data management and system requirements (Esther, Patrick and Marta 2007). Data management issues such as data transparency, data consistency, query efficiency and autonomic management, system issues such as autonomy and dynamicity, and fault-tolerance issues such as efficiency and QoS, cannot be solved by simply combining distributed database techniques and Web services into the Grid environment. New data management techniques are necessary.

1.2 Replication in Data Grid

Replication is a common strategy used in Data Grid as well as in many distributed environments (Jim, et al. 1996) to achieve availability and to reduce access latency, improve data locality, increase robustness, scalability and performance of distributed applications. Replication techniques have been used to keep copies of data sets across different sites within data grid. Important issues in data replication include replica management, access control, replication granularity, replica placement, replica selection, and replica consistency. Replication management can be very

expensive; the main goals of replica management are to be dynamic, efficient, adaptable and scalable (Tan and Feng 2006).

An important aspect of replication-based systems is the protocol used to maintain replica consistency among objects' replica. The main issue of such system is maintaining scalability and efficiency with large number of replicas distributed over a wide area network while maintaining the same view of all replicas. Many existing research works address the access protocols for generally distributed systems (Philip, Vassos and Nathan 1989) (Rivka, et al. 1992) (Divyakant, Amr and Robert 1997) (Jim, et al. 1996) (Yasushi and Marc 2005) depending on the consistency requirements. The issues of replica access protocol and the algorithms to handle the update request will be extensively addressed in this thesis.

In data grid, several data replication techniques (Asad and Heinz 2001) (Ann, Ewa, et al. 2002) (David 1994) and (Houda and Boleslaw 2007) have been developed to support high-performance data access, improving data availability, and load balancing to remotely produced scientific data. Most of those techniques do not provide the replica consistency in case of updates. Grid data management middleware usually assumes that (1) whole files are the replication unit, and (2) replicated file is read only. Replica consistency is not an issue when data is treated as a read-only. This implies that inconsistency may only be due to system failure or accidental corruption (D. Andrea, et al. 2004). It can be stated that the consistency can reach the highest degree. However there are necessities for mechanisms that maintain consistency for a modifiable data. Once the update is allowed on the replica, the degree of consistency has to be decreased.
