Abstract.

**BACKGROUND:** Aromatase inhibitors (AIs) might have a detrimental impact on bone health in breast cancer (BC) women. Denosumab has been shown to reduce the risk of fractures, but the appropriate time for starting is yet to be clearly defined. **OBJECTIVE:** To evaluate the effects of early treatment with Denosumab ( $\leq 12$  months after starting AIs) compared to a delayed treatment in BC women.

**METHODS:** In this retrospective case-control study, we included medical records of BC post-menopausal women, treated with AIs therapy; they were divided as: study group (starting Denosumab  $\leq 12$  months after AIs) and control group (> 12 months). At the baseline (T0) and at 18 months (T1), we evaluated the lumbar spine (LS) Tscore and femoral neck (FN) Tscore. Furthermore, at T1 we assessed the incident fragility fractures.

**RESULTS:** Fifty-nine BC survivors (mean age:  $61.5 \pm 11.5$  years) were included: 28 with Early Denosumab and 31 with Late Denosumab. At T1, the study group did not show any incident hip or vertebral fragility fracture, whereas the Late Denosumab group showed 2 incident hip fractures (6.5%) and 4 (12.9%) vertebral fragility fractures. Early Denosumab showed a significant positive effect on both LS (p = 0.044) and FN (p = 0.024) Tscore variations.

**CONCLUSION:** Taken together, our findings suggest that an early start of Denosumab might be considered for the osteoporosis management in BC women undergoing AIs.

Keywords: Osteoporosis, risk of fractures, breast cancer, denosumab, bone health

# 1. Introduction

<sup>1</sup>These authors equally contribute as first authors.

D. Scaturro et al. / Early Denosumab for the prevention of osteoporotic fractures in BC women undergoing AIs

has been changed in recent years with a great im-6

provement of the 5-years survival estimated about 90% 7 worldwide [2], and 87% in Italy [3]. 8

BC management might consist of several thera-9 peutic strategies, including surgery (mastectomy and 10 quadrantectomy), often followed by local radiother-11 apy and chemotherapy, guided by tumor histology sub-12 type. These interventions might lead to several dis-13 abling complications, including breast cancer-related 14 lymphedema, BC-related fatigue, shoulder dysfunction, 15 postural imbalance, axillary web syndrome, physiolog-16 ical disorders [4–6]. 17

Breast surgery might lead to a significant physical 18 and psychological impact in post-menopausal women, 19 suffering range of motion limitation, pain and dis-20 comfort, a patient-tailored rehabilitation intervention is 21 mandatory to prevent or resolve these complications. In 22 the literature, several studies have shown that, regard-23 less of surgery received, a low-intensity rehabilitation 24 program is effective in recovering upper limb mobility 25 and reducing disability and pain [7,8]. 26

Adjuvant hormonal treatment is indicated in all pa-27 tients with breast cancer with hormone receptor pos-28 itive (ER+) after surgery to prevent disease recur-29 rence [9,10]. Hormone Replacement Therapy (HRT) 30 can be individualized based on the clinical evalua-31 tion, as various drugs can be administrated, such as 32 estrogen receptor modulators (SERMs), aromatase in-33 hibitors (AIs) and luteinizing hormone-releasing hor-34 mone (LHRH) agonists [9]. Among the SERMs, the 35 most used in common practice is tamoxifen, in associa-36 tion or not with LHRH analogues, which is indicated 37 in the treatment of pre-menopausal women with hor-38 mone receptor positive breast cancer [11]. On the other 39 hand, AIs are utilized in post-menopausal women with 40 ER + [12].41

In this scenario, AIs are considered as powerful 42 inhibitors of estrogen production, acting by binding 43 reversibly (non-steroidal inhibitors), or irreversibly 44 (steroidal inhibitors) and deactivating the aromatase en-45 zyme, responsible for the conversion of androgens into 46 estrogens [13]. However, these therapies could have a 47 detrimental impact on bone health in BC women, pro-48 moting bone resorption [14,15]. Indeed, the low circu-49 lating estrogen levels could lead to a high differentiation 50 of the pre-osteoclasts, an increase in the survival of os-51 teoclasts and an increased apoptosis of osteoblasts [14]. 52 As a result, the osteoclasts activity will be greater than 53 the activity of osteoblasts, with a negative effect on bone 54 remodeling, leading to a cancer treatment-induced bone 55 loss (CTIBL), during AIs administration or after the 56

end of treatment [14–16]. Therefore, AIs assumption represents a noteworthy risk factor for the development of osteoporosis in BC survivors, as their prolonged use inevitably leads to a reduction in bone mineral density (BMD) [17] and an increased risk of fragility hip and vertebral fractures [18].

In this context, CTIBL is considered an emerging issue in BC survivors [19], and the Italian National Regulatory Agency for Drugs included BC women aged  $\geq$  50 years treated with AIs in the subjects respecting the reimbursement criteria for anti-osteoporotic pharmacological treatments [20], thus recommending bisphosphonates (alendronate, risedronate, zoledronate) or Denosumab as a first-line approach [20].

Denosumab is a fully human IgG2 monoclonal antibody that binds and inhibit the receptor activator of nuclear factor kappa-B ligand (RANKL), a key mediator for bone resorption, with high affinity and high specificity. RANKL signaling cascade normally intervenes in promoting the survival of osteoclasts [21]. Denosumab assumption reduces bone resorption at both cortical and trabecular level [14]. Moreover, it has been shown that Denosumab 60 mg subcutaneously administered every 6 months in combination with vitamin D supplementation might reduce the risk of fragility fractures in BC survivors [14]. In addition to its antiresorptive effect, Denosumab also plays a role in improving BC survival, mainly by reducing the development of bone metastases [22], and reducing back painrelated disability [23,24]. Furthermore, patients undergoing Denosumab showed high persistence and adherence that might lead to a high therapeutic effect on bone health, reducing the risk of fragility fractures [25].

Although the effectiveness of Denosumab in reducing bone loss in BC women undergoing AIs is well recognized [11,13,15,18,22], the appropriate time for intervention is yet to be clearly defined. Some studies [14,15,18] showed the effectiveness of Denosumab in preventing fragility fractures and BMD loss at the start of HRT therapy; these findings have been confirmed by a recent metanalysis [26] in post-menopausal women undergoing AIs. On the other hand, evidence also showed that the effectiveness of Denosumab on BMD might still be preserved even if started after adju-100 vant therapy [15,27,28]. Therefore, in the present study, 101 we sought to evaluate the effects of an early treatment 102 with Denosumab ( $\leq 12$  months after starting AIs) com-103 pared to a delayed treatment in BC post-menopausal 104 women 105

#### **106 2. Materials and methods**

#### 107 2.1. Participants

In this retrospective case-control study, we included 108 medical records of BC survivors referring to the Osteo-109 porosis Outpatient Service, "Paolo Giaccone Univer-110 sity Hospital", Palermo, Italy over a 24-month period, 111 from January 2017 to January 2019. Inclusion crite-112 ria were: 1) post-menopausal women aged > 50 years; 113 2) diagnosis of histologically confirmed non-metastatic 114 BC; 3) Als therapy; 4) absence of prevalent osteo-115 porotic fractures; 5) use of Denosumab 60 mg subcuta-116 neously each 6 months as anti-osteoporosis treatment. 117 We excluded: 1) women that previously assumed anti-118 osteoporosis drugs; 2) women in treatment with others 119 anti-neoplastic therapy; 3) women with metastases. 120

The study was approved by the Ethics Committee of the "Paolo Giaccone University Hospital" in Palermo, Italy (approval number: 06/2019). Researchers provided to protect the privacy and the study procedures according to the Declaration of Helsinki, with pertinent National and International regulatory requirements.

# 127 2.2. Intervention

All study participants underwent Denosumab 60 mg by subcutaneous injection every 6 months, combined with an oral supplementation of cholecalciferol 25,000 IU (once every 15 days) and calcium citrate 500 mg (once per day).

The study cohort was divided according to the timing of the start of Denosumab treatment: study group, starting Denosumab no more than 12 months after the first AIs administration, and control group, starting Denosumab more than 12 months after the first AIs administration.

# 139 2.3. Outcome measures

At the baseline (T0) and at the 18-month follow-140 up evaluation (T1), we collected the following data: 141 lumbar spine (LS) bone mineral density (BMD), LS 142 Tscore, LS Zscore, femoral neck (FN) BMD, FN 143 Tscore, FN Zscore, serum levels of 25-hydroxyvitamin 144 D [25(OH)vit.D], calcium, parathyroid hormone (PTH), 145 and alkaline phosphatase (ALP). Furthermore, at T1 146 we assessed the number of incident hip and vertebral 147 fragility fractures. 148

149 2.4. Statistical analysis

<sup>150</sup> The statistical analysis was performed using R soft-

ware (R Foundation for Statistical Computing, Vienna, Austria). Continuous variables were expressed as means and standard deviations, whereas the categorical variables were expressed as absolute numbers and percentages. For the statistical modeling we used the classical linear regression model to evaluate the effect net of any confounding variables. P-values < 0.05 were considered statistically significant.

### 3. Results

Of the 255 subjects recruited, 196 did not match the 160 eligibility criteria and were excluded. Thus, 59 BC post-161 menopausal women (mean age:  $61.5 \pm 11.5$  years) were 162 included in the final analysis. The study cohort was di-163 vided into two groups based on the start of Denosumab 164 treatment: the study group (Early Denosumab) included 165 28 patients, while the control group (Late Denosumab) 166 included 31 patients. No statistically significant differ-167 ences were found between the two groups at baseline 168 for the collected outcomes, as shown in Table 1. 169

At T1, the study group did not show any incident hip 170 or vertebral fragility fracture. On the other hand, it was 171 interesting to notice that the Late Denosumab group 172 showed 2 (6.5%) incident hip fractures and 4 (12.9%) 173 incident vertebral fragility fractures. At T1, the study 174 group showed higher BMD values compared to control, 175 both for LS  $(0.79 \pm 0.1 \text{ g/cm}^3 \text{ vs } 0.74 \pm 0.2 \text{ gr/cm}^3)$ 176 and FN (0.88  $\pm$  0.1 g/cm<sup>3</sup> vs 0.80  $\pm$  0.3 g/cm<sup>3</sup>), 177 and consequently higher T-scores (LS  $-1.75 \pm 1.3$  vs 178  $-1.97 \pm 1.1$  and FN  $-1.25 \pm 1.7$  vs  $-1.51 \pm 1.1$ ). 179

We also performed a linear regression model consid-180 ering the T-score at T0 to assess any difference between 181 groups depending on the baseline status of the patient. 182 Table 2 shows the estimates of the regression coeffi-183 cients of the model for the variation of the LS T-score 184 and the FN T-score. Considering the results of the main 185 effects, an early administration of Denosumab 60 mg 186 within one year from AIs therapy initiation showed a 187 statistically significant positive effect on the variation 188 of the T-score in both LS Tscore (+0.169; p = 0.044) 189 and FN Tscore (+0.234; p = 0.024) 190

# 4. Discussion

Als are considered to be the most administered hormonal therapies in post-menopausal women with BC. However, their assumption is detrimental for bone health in these patients, as they might cause reduction

191

<sup>196</sup> of BMD, with consequently hip and vertebral fragility

<sup>197</sup> fractures [17,18].

In the present retrospective case-control study, we 198 assessed the effects of Denosumab 60 mg sc. every 199 6 months in women with non-metastatic BC on AIs 200 therapy started no more than 12 months after the first 201 AIs administration compared with the same therapy ini-202 tiated more than 12 months after the first AIs adminis-203 tration. We showed that an early treatment with Deno-204 sumab might have a preventive effect on incident verte-205 bral and hip fragility fractures, and a greater improve-206 ment in FN and LS T-scores compared to a delayed 207 treatment. We also documented greater improvements 208 in patients with previously deteriorated bone. 209 In the literature, several studies have shown the ef-210

In the literature, several studies have shown the effectiveness of Denosumab in preventing negative effects on bone mineral metabolism in patients affected
by BC under AIs treatment. Firstly, Ellis et al. [15]

analyzed the efficacy of Denosumab versus a placebo in preventing bone health in women treated with AIs. The results of the study confirmed the efficacy of Denosumab compared to placebo in increasing BMD levels in the trabecular and cortical bone; however, the time of administration was not evaluated, as they only stratified patients by duration of AIs therapy (six months or more) stating no significant differences [15].

The phase III Adjuvant Denosumab in postmenopausal patients with hormone receptor-positive Breast Cancer (ABCSG-18) trial showed that Denosumab treatment resulted in increased lumbar and femoral neck BMD compared to placebo, as well as delaying onset of clinical fragility fracture [18]. However, the authors reported that 16% of the patients were enrolled at start of AIs therapy, whereas 84% of the patients were already under treatment; no clear assessment between the adequate time to initiate Denosumab was stated. D. Scaturro et al. / Early Denosumab for the prevention of osteoporotic fractures in BC women undergoing Als.

A recent meta-analysis [26] compared Denosumab 232 versus zoledronic acid to prevent AI-associated frac-233 tures in postmenopausal early BC, showing that Deno-234 sumab started within 12 months from AIs might reduce 235 the risk of fracture significantly compared with delayed 236 treatment. However, the latter was performed only on 237 two studies versus placebo and considering a subset of 238 patients that crossed over due to deterioration of bone. 239 Moreover, immediate vs late administration was com-240 parable at the 18 month cut-off, while the risk of frac-241 ture was reduced only at 36 months. On the other hand, 242 Nakatsukasa et al. [28] evaluated the efficacy of Deno-243 sumab in the treatment of AIs-associated bone loss in 244 a Japanese population, assessing a similar increase in 245 LS BMD in patients who received AI and Denosumab 246 simultaneously and in patients who had received AI 247 before the initiation of the Denosumab therapy, with no 248 significant difference. 249 In the present study we found that BC women un-250

dergoing AIs starting the treatment with Denosumab 251 within 12 months from AIs therapy might beneficiate 252 in terms of fragility fracture prevention at 18 months 253 follow-up compared to the same therapy performed 254 after 12 months. Moreover, the early treatment with 255 Denosumab seems to lead to a further increase of LS 256 and FN T-scores compared to delayed treatment, and 257 these effects might be greater in patients with reduced 258 BMD. Indeed, it is crucial to define the better timing for 259 starting antiresorptive agents to prevent fragility frac-260 tures in BC women undergoing AIs therapy. This study 261 might be a step towards the better clinical management 262 of these fragile patients. 263

As bone metabolism is still a growing field of knowl-264 edge, several mechanisms might contribute to CTIBL, 265 such as inflammation, hematological alterations, and 266 different hormonal disbalance [29,30]. 267

However, it should be stressed that aside from phar-268 macological treatments, an adequate physical activity 269 might play an important role in the prevention of bone 270 loss in BC patients [31]. 271

We are aware that the present study is not free from 272 limitations: first, the monocentric study design might 273 not guarantee a high external validity; second, the sam-274 ple size was small due to the strict eligibility criteria; 275 third, the study lacked a long-term follow-up evalua-276 tion, which could provide more information on the ad-277 herence and compliance to Denosumab therapy by the 278 study participants. 279

# 5. Conclusion

Taken together, these findings suggest that an early 281 starting of Denosumab treatment might be consid-282 ered for the management of osteoporosis in BC post-283 menopausal women undergoing AIs. The present study 284 could be considered as a starting point in this complex 285 scenario and further studies are warranted to provide 286 BC patients undergoing AIs with adequate indications 287 to prevent CTIBL and its detrimental complications. 288
