34 **Abstract**

35 **Background:** The quality of the home learning environment has a significant
36 influence on children's language and communication skills during the early years with
37 children from disadvantaged families disproportionately affected. This paper
38 describes the protocol and participant baseline characteristics of a community-based
39 effectiveness study. It evaluates the effects of '*smalltalk*', a brief group parenting
40 intervention (with or without home coaching) on the quality of the early childhood
41 home learning environment.

42 **Methods/Design:** The study comprises two cluster randomised controlled trials (one
43 for infants and one for toddlers) designed and conducted in parallel. In 20 local
44 government areas (LGAs) in Victoria, Australia, six locations (clusters) were
45 randomised to one of three conditions: standard care (control); *smalltalk group-only*
46 program; or *smalltalk plus* (group program plus home coaching). Programs were
47 delivered to parents experiencing socioeconomic disadvantage through two existing
48 age-based services, the maternal and child health service (infant program, ages 6-12
49 months), and facilitated playgroups (toddler program, ages 12-36 months). Outcomes

50 were assessed by parent report and direct observation at baseline (0 weeks), post-
51 intervention (12 weeks) and follow-up (32 weeks). Primary outcomes were parent
52 verbal responsiveness and home activities with child at 32 weeks. Secondary outcomes
53 included parenting confidence, parent wellbeing and children's communication,
54 socio-emotional and general development skills. Analyses use intention-to-treat using
55 random effects ("multilevel") models to account for clustering.

56 **Recruitment and baseline data:** Across the 20 LGAs, 986 parents of infants and
57 1200 parents of toddlers enrolled and completed baseline measures. Eighty four
58 percent of families demonstrated one or more of the targeted risk factors for poor
59 child development. There were no baseline differences in parent characteristics by
60 group allocation.

61 **Discussion:** This study will provide unique data on the effectiveness of a brief group
62 parenting intervention for enhancing the early home learning environment of young
63 children from disadvantaged families. It will also provide evidence of the extent to
64 which additional one-on-one support is required to achieve change and whether there
65 are greater benefits when delivered in the first year of life or later. The program has
66 been designed for scale-up across existing early childhood services if proven
67 effective.

68 **Trial Registration:** 8 September 2011; ACTRN12611000965909

95

The skills acquired in the early years of life are key foundations for a successful transition to kindergarten and school, and strongly influenced by the quality of the home learning environment [1-3]. Impoverished early life home environments are associated with a range of poorer developmental outcomes [4, 5]. Large-scale community interventions to improve the quality of young children's home learning environments have seldom been rigorously evaluated [6, 7]. This paper describes a large community-based effectiveness study designed to address this gap. The study comprises two cluster randomised controlled trials (RCTs), one for infants and one for toddlers. The trials are conducted in parallel and evaluate the effects on home learning environment of a brief group parenting intervention for disadvantaged families. The intervention has been designed for future use in early childhood services, and the study additionally seeks to address implementation questions regarding the optimal timing and amount of individual support required for change.

92

93

94

Twenty-three percent of Australian children lack key early learning skills when they commence school [8]. Socioeconomic disparities in learning and development are evident from birth and persist across childhood [9]. To narrow these gaps, programs are needed that successfully engage disadvantaged families and are effective in changing the modifiable mechanisms that underpin socioeconomic differences. As described below, the daily interactions that occur between parents and children are one such mechanism.

95

Parenting and the Home Learning Environment

96

97

A home environment rich in language and age-appropriate stimulating play activities has a strong positive impact on children's development in early childhood

98 [3, 10-13]. Responsive interactions characterised by parental sensitivity, warmth and
99 cognitive stimulation promote neurological development and the acquisition of
100 cognitive and language skills [14, 11, 15-18]. Parenting sensitivity refers to parents'
101 attunement to their child's cues, emotions, interests, and capabilities in ways that
102 balance the child's need for support with the need for autonomy. Parenting warmth
103 refers to parents' expressions of affection and respect toward their children supporting
104 skills for learning such as mastery, security, autonomy, and self-efficacy. Cognitive
105 stimulation refers to parental efforts to enrich their children's cognitive and language
106 development through language-rich interactions and activities that promote learning.

107 Early childhood parent-child interactions have been shown to mediate the
108 effects of family socioeconomic disadvantage on developmental outcomes [19, 20].
109 For example, Raviv and colleagues [21] found that maternal sensitivity and cognitive
110 stimulation partially mediated the association between socioeconomic disadvantage
111 and poorer expressive and receptive language abilities at three years of age. Similarly,
112 in a longitudinal study of a large, ethnically diverse, low-income sample, Lugo-Gil
113 and Tamis-Lemonda [12] found that parenting quality mediated the effects of family
114 economic resources on children's cognitive ability at ages 14, 24 and 36 months.
115 Supporting high-quality parenting may therefore be an effective way to mitigate the
116 developmental risks faced by young children from disadvantaged families.

117

118 **Early Childhood Parenting Interventions for Disadvantaged Families**

119 Parenting interventions can be effective in supporting parents to provide a rich
120 home learning environment for their young children [6, 22]. Intensive interventions
121 such as nurse home visiting have shown some success but results have been highly
122 varied [23]. Improvements in parenting and/or child outcomes have been reported for

123 home visiting interventions that are intensive (visits provided monthly or more often,
124 over 1-2 years) and delivered by professionally-qualified staff who adhere to detailed
125 session protocols and receive regular supervision [24, 25]. Home visiting programs
126 have limited potential for large scale provision, as they are costly to deliver and tend
127 to be reserved for the most high risk families. These programs can have difficulties
128 engaging and retaining families over time. Up to a quarter of families offered nurse
129 home visiting decline the service and 20% to 60% drop out before program
130 completion [23, 26].

131 While there is a clear need for interventions that can be provided on a wider
132 scale, only a few studies have examined the efficacy of brief programs addressing the
133 quality of the home learning environment [27]. One study conducted with 264 parents
134 of infants, found that a 10 session home-based curriculum was associated with
135 increases in responsive parenting behaviours and improved infant social and cognitive
136 skills at 3 months post intervention [28]. Similarly, a trial of a 5 session home-based
137 program with 371 disadvantaged mothers of 3- to 5-year olds, found that mothers who
138 received the intervention were more likely than wait list control mothers to use home
139 learning strategies and display responsive parenting at 6 month follow-up [29]. While
140 promising, home-based interventions are costly to provide and it is unknown whether
141 similar effects could be obtained via community-based group programs.

142 **The Current Study**

143 In Australia, no large-scale experimental studies have evaluated the
144 effectiveness of brief parenting interventions that seek to enrich the early home
145 learning environment of children from disadvantaged families. The current research
146 was commissioned by the State Government of Victoria to address this research gap.
147 The goal was to conduct a large-scale effectiveness study to determine whether a brief

148 group parenting intervention (the *smalltalk* program) delivered within existing
149 community services could improve the capacity of parents experiencing social and
150 economic disadvantage to provide a rich home learning environment to their young
151 children. This presented a unique opportunity to embed a major service development
152 initiative within a rigorous scientific framework and to build knowledge that would
153 guide future early childhood policy and services.

154 **Development of the *smalltalk* programs**

155 The *smalltalk* programs were designed for delivery within the existing
156 structures and human resources of the Australian early childhood sector. Five
157 pragmatic and scientific criteria guided program design: evidence-informed
158 intervention strategies; developmental appropriateness; content able to be delivered
159 reliably and proficiently by early childhood workers; compatibility with existing
160 services; and capacity to provide additional individualised support. The first two of
161 these criteria are described next.

162 ***Developmentally appropriate, evidence-informed content***

163 *Smalltalk* employed active skills training to increase parent behaviours that
164 would promote children's development of language and communication skills [30,
165 13]. Targeted parent behaviours (quality parent-child interactions and provision of a
166 stimulating home learning environment) are defined in Table 1. To support the
167 maintenance of these behaviours, information was provided about self-care, having
168 confidence in one's parenting skills and building connections with other parents and
169 relevant services.

170 Children's developmental skills undergo considerable, rapid development
171 across the first three years of life. Approaches for promoting, reinforcing and

172 extending these skills change accordingly. Two versions of the *smalltalk* program
173 were developed: one for parents of infants (6-12 months) and one for parents of
174 toddlers (aged 12-36 months). Key intervention strategies remained consistent across
175 the two formats but different age-appropriate examples were used.

176 ***The service context***

177 Government-funded programs in the state of Victoria are provided free and
178 universally to disadvantaged families with young children through two key
179 community services – the maternal and child health service and facilitated playgroups.
180 Both services have a policy focus on the enhancement of early child development and
181 offer group programs to parents. Program delivery is coordinated by local government
182 authorities (i.e. councils), either directly or in partnership with community
183 organisations. The maternal and child health service has its highest rates of
184 participation by parents of infants, declining after 12 months of age [31]. Facilitated
185 playgroups are designed to enhance toddlers' skills through structured play activities
186 and to support parents in their parenting role [32, 33].

187 Session timing and the methods of instruction employed in the *smalltalk*
188 groups were tailored to these contexts and the skills of existing staff. For the parents
189 of infants, the intervention was structured as a weekly parent education group,
190 established for the purpose of delivering the *smalltalk* content. For the parents of
191 toddlers, *smalltalk* content was delivered via incidental teaching methods within
192 weekly playgroup sessions structured around play activities.

193 An additional home-based component was developed (*'smalltalk plus'*) to
194 address concerns that parents facing multiple sources of socio-economic disadvantage
195 may struggle to achieve and maintain behaviour change in the absence of
196 individualised support [34]. It comprised a DVD-based intervention delivered in a

197 series of home visits by a coach as an adjunct to group participation. The narrated
198 DVD provided video modelling of strategies discussed in the group sessions. The
199 DVD prompted the coach to guide the parent through practicing each strategy and to
200 videotape the practice for review and goal setting.

201 **Aims and Hypotheses**

202 The aim of this study was to conduct two parallel cluster RCTs to evaluate the
203 effectiveness of the *smalltalk* and *smalltalk plus* programs with parents from
204 economically and socially disadvantaged circumstances. The RCTs were conducted
205 with parents of infants aged 6 to 12 months and toddlers aged 12 to 36 months
206 respectively. The *smalltalk* programs sought to: (i) improve the quality of parent-child
207 interactions and the home learning environment (primary outcomes, parent focussed)
208 (ii) improve parenting confidence, parents' wellbeing and community connectedness
209 (secondary outcomes, parent focussed); and consequently (iii) improve children's
210 early communication, socio-emotional and general developmental skills (secondary
211 outcomes, child focussed).

212 We hypothesised that in both the infant and toddler trials, families who
213 received the *smalltalk group only* and *smalltalk plus* interventions would show greater
214 improvements in primary outcomes (parent verbal responsivity, home activities with
215 the child at 32-week assessment) and secondary outcomes (parent-reported and
216 directly observed parent-child interactions; the home literacy environment and
217 household disorganisation; parent wellbeing, self-efficacy and community
218 connectedness; and directly observed and parent reported child communication skills)
219 compared to parents who received the *standard* (control) program. In the absence of

220 prior evidence regarding differential outcomes by child age, we made no hypotheses
221 regarding differences in program effectiveness for the infant versus toddler samples.

222

223 **Methods and Design**

224 **Approval and Registration**

225 Ethics approval and permission to conduct the research were obtained from
226 the Victorian Government Department of Health Human Research Ethics Committee
227 (HREC08/10) and the Department of Education and Early Childhood Research
228 Committee. The study is registered as a cluster randomised controlled trial with the
229 Australian New Zealand Clinical Trials Registry (ACTRN 1261 1000965909;
230 Registration date 8 September 2011).

231 **Design**

232 The study design comprises two cluster RCTs conducted in parallel, one in the
233 maternal and child health service (for parents of infants) and the other in the
234 facilitated playgroup service (for parents of toddlers). The study was conceptualised
235 as an effectiveness trial [35] designed to assess program outcomes as delivered under
236 real-world conditions. It has been implemented and reported in accordance with the
237 requirements of the CONSORT statement for cluster RCTs [36].

238 In each RCT, there were three trial arms (intervention conditions): standard,
239 *smalltalk group-only*, *smalltalk plus*. Clusters were randomised to condition (1:1:1
240 allocation ratio), stratified by LGA. Clusters were the geographical location where
241 group programs were to be delivered. Approximately six locations were randomised
242 in each LGA to deliver one of the three programs: standard, *smalltalk group-only*, or
243 *smalltalk plus* programs. Parents were allocated to the location nearest to their

244 residential address and received the intervention delivered by that location. Figure 1 is
245 a diagrammatic representation of the study design for each RCT.

246 **Site Recruitment**

247 The trial was designed to be implemented within funding by the state
248 government with a goal of program delivery to 2,000 parent-child dyads across a two-
249 year period. As part of their service agreements, each of the participating LGAs (10
250 providing infant programs and 10 providing toddler programs) were funded to recruit
251 and provide programs to 100 parent-child dyads. LGAs were also funded to appoint a
252 site coordinator to oversee recruitment, staff employment, service delivery and
253 reporting.

254 Twenty LGAs were recruited in metropolitan and rural areas as follows. All
255 79 LGAs in the state of Victoria were informed about the study through a letter of
256 introduction to Chief Executive Officers, followed by briefings in each administrative
257 region. Meetings with service managers were held as requested, and interested LGAs
258 were invited to apply to participate. Applications were accepted from LGAs that met
259 the following criteria: evidence from administrative data of significant levels of
260 socioeconomic disadvantage in the community; prior successful collaboration with
261 external agencies; willingness to adhere to the design and reporting requirements of
262 the research trial; and experience and capacity to deliver parent groups or facilitated
263 playgroups.

264 **Allocation**

265 Cluster randomisation of locations was chosen to reduce the potential for
266 cross-condition contamination arising from parents gaining exposure to another
267 condition through others in their immediate community. Additionally, staff were only
268 trained in one of the three program conditions.

269 Allocation of locations was stratified by LGA using block randomisation with
270 a fixed block size of 3. Locations were allocated in the order that they were consented,
271 in blocks of 3 to maintain blinding during the recruitment of locations. Randomisation
272 was performed by a biostatistician (OU) who was unaware of the identities of the
273 locations and played no role in the recruitment of locations or parents. Researchers
274 involved in parent recruitment and baseline assessment were blind to the trial arm status
275 of the locations, thus, allocation concealment was ensured.

276 **Intervention Delivery**

277 *Smalltalk program development and content*

278 Program content, methods of delivery and staff training were developed
279 through extensive consultation and a co-production process. In 2010, two one-day
280 forums were conducted with practitioners and service managers to seek input on
281 program content, strategies for engaging disadvantaged families and potential logistic
282 issues. From April to September 2010, members of the research team attended
283 weekly sessions of two existing facilitated playgroups and undertook home visits with
284 a subgroup of families. Parents were asked for feedback on the program content, with
285 particular attention to the way the ideas were expressed, the language used and
286 examples given. Facilitators provided feedback on program content, how it could be
287 used, and the training and resources needed. Finalised program content and staff
288 training processes were then fully field tested in four LGAs from September to
289 December 2010 with the parents (n=39) and staff (n=4) participating in one infant and
290 three toddler groups.

291 Program content focussed on building parents' use of 10 daily parenting
292 strategies (summarised in Table 1). Parents were provided with information and active
293 skills training in 5 strategies for enhancing the quality parent-child interactions (e.g.,

294 parent responsiveness; positive verbal exchanges where parents respond to and build
295 on the child's interests) and 5 strategies for providing a stimulating home learning
296 environment (e.g., use of books and toys to extend the child's developing skills; the
297 provision of daily activities and routines that are language- and literacy-rich).
298 Information was also provided about the importance of looking after oneself (parental
299 self-care), having confidence in one's parenting skills (personal agency) and building
300 connections with individuals and services in the local community (community
301 connectedness).

302 ***Program delivery formats – infants***

303 The infant program comprised six weekly two-hour group parenting sessions,
304 designed for attendance by 6 or more parents and their infants. Parents allocated to the
305 active intervention (*smalltalk group-only*, *smalltalk plus*) received a parent DVD and
306 printed resources illustrating the program's key parenting strategies (Table 1).
307 Facilitators introduced and guided the practice of the strategies in the group, and
308 assisted parents to plan and report on their use of the strategies at home.

309 Parents allocated to the *smalltalk plus* program received the group program
310 plus six 60-minute individual home visits from an early childhood-qualified 'home
311 coach'. Sessions were structured around a narrated DVD to maximise program
312 fidelity. The DVD contained filmed exemplars of the intervention strategies and
313 guided the activities for the session. Parents were videotaped practicing the strategies
314 with their child and the footage was jointly reviewed for feedback and goal setting.
315 The DVD included scenes of the program's strategies being used well and scenes that
316 illustrated missed opportunities for using these strategies.

317 For parents allocated to the *standard condition*, group sessions focused on
318 issues relevant to parenting a 6-12 month old infant (e.g. feeding, sleeping, safety,
319 exercise, and behaviour). No elements of the *smalltalk* program were discussed.

320 ***Program delivery formats – toddlers***

321 The toddler program comprised 10 two-hour weekly facilitated playgroup
322 sessions. These were designed for attendance by 10-15 parents and their children and
323 offered in four terms corresponding to the school calendar. Parents allocated to the
324 active intervention (*smalltalk group-only*, *smalltalk plus*) received a parent DVD and
325 printed resources. They were introduced to the *smalltalk* program content during their
326 first term of attending the facilitated playgroup. Using incidental teaching methods,
327 facilitators discussed the parenting strategies one-on-one or in small groups,
328 structured play activities to provide practice of the strategies, and assisted parents to
329 plan and report on their use of the strategies at home. At the end of the 10 week
330 program parents could remain in the playgroup but were not directly targeted by the
331 playgroup facilitator for incidental teaching activities.

332 Parents allocated to the *smalltalk plus* condition received the group program
333 plus six 60-minute individual home visits from an early childhood-qualified ‘home
334 coach’. Sessions were structured in the same way as for the infant home coaching
335 program, directed by a narrated DVD.

336 Parents allocated to the *standard condition* attended playgroups conducted
337 according to the objectives and activities of current facilitated playgroups in Victoria,
338 with no *smalltalk* program content.

339 **Facilitator Training and Support**

340 *Smalltalk* was designed for delivery by existing early childhood staff.

341 Facilitators and home coaches were employed by the LGAs and received standardised

342 training from the research team. Of the 109 staff who were trained to deliver
343 programs almost all were female (n=108), aged from 23 to 59 years (mean=42).
344 Fourteen percent had post-graduate qualifications, 28% had a bachelors degree and
345 56% had post-secondary vocational qualifications. Qualifications were in the fields of
346 community services (46%), education (29%), health (12%), or other (13%). On
347 average staff had 15.5 years of experience in the early childhood community sector
348 (range 0 to 37 years).

349 All staff received half- or full-day training in group facilitation (for infant and
350 toddler groups respectively). *Smalltalk* facilitators and home coaches received an
351 additional 2-3 days training in the program content and delivery procedures. Training
352 resources included a comprehensive training manual, tip sheets, activity sheets and
353 wall posters illustrating the intervention strategies. Home coaches also received
354 session planning guides, record keeping books and the home coaching DVD. The
355 research team offered post-training support by email, telephone and text messaging to
356 address any arising issues.

357 **Participant Recruitment and Eligibility Criteria**

358 LGAs were responsible for recruitment of families into the trial. Eligibility
359 criteria were: living within the geographical boundaries of a trial location; having at
360 least one child in the age range for the offered program (6-12 months for infant
361 programs and 12-36 months for toddler programs); and evidence of at least one
362 identifiable risk factor for poor child development, including low family income;
363 receipt of government benefits or holder of a Health Care Card (provided for low
364 income families); single, socially isolated or young parent (≤ 25 years); and culturally
365 and linguistically diverse background. Parents were not eligible for participation if

366 they were aged less than 18 years; did not speak English; were involved with child
367 protection services; already received in-home support; or were deemed to require
368 more intensive services.

369 Information on inclusion and exclusion criteria was available through each
370 LGA's maternal and child health administrative database. LGAs were encouraged to
371 identify potential participants via case finding (e.g. searches of the database for
372 eligible families) and rolling recruitment (e.g. assessing families for eligibility at
373 routine child health checks; outreach through relevant community services). Staff in
374 the LGAs were provided with scripts for recruiting participants, and promotional
375 brochures and flyers to enhance the visibility of the study.

376 Participants identified as eligible for the study were contacted by the LGA site
377 coordinator who explained the research and obtained verbal consent for participation
378 and for their contact details to be sent to the research team. Verbal consent was
379 repeated at the start of the baseline telephone interview and full written consent was
380 obtained at the baseline visit to collect in-home observation data.

381 Based on previous experience with similar populations [37, 38], we aimed to
382 retain at least 85% of the enrolled sample to follow-up (T=32 weeks). Strategies to
383 support participation included a \$50AUD payment and a children's book provided at
384 each time-point (pre, 12 weeks and 32 weeks) to parents who completed the
385 assessments in full. Payments were reduced to \$20AUD for parents who provided
386 partial data.

387 **Measures**

388 Multi-method data collection occurred at three main time points: baseline (0
389 weeks); post-intervention (12 weeks); and follow-up (32 weeks) (see Figure 1).

390 Participant characteristics and individual-level outcomes data were collected by

391 parent report and direct observation. Process data were collected by administrative
392 records and staff report.

393 *Parent-report data* were collected via computer assisted telephone interviews
394 (CATI) to allow inclusion of parents with low literacy. These were conducted at pre,
395 post (12 weeks), and follow-up (32 weeks) by trained interviewers, independent of the
396 research team and blinded to participant allocation. As summarised in Table 2, the
397 CATI included a number of brief, validated measures of parent and child outcomes
398 (all time points), parent, child and family characteristics (baseline only), and ratings
399 of satisfaction with the program and barriers to participation (post only; asked at the
400 end of the interview to avoid unblinding the interviewer during the collection of
401 outcomes data). Included measures were primarily sourced from the Longitudinal
402 Study of Australian Children [39] or other evaluation studies [38]. Parents also
403 completed a pencil and paper version of the Communicative Development Inventory
404 (CDI) during the home visit (see below), or over the telephone with a research staff
405 member.

406 *Observational data* were collected in the parent's home by trained and
407 accredited research staff or home coaches, at pre, post and follow-up (Table 2). Data
408 were collected according to standardised protocols for two 'Individual Growth and
409 Development Indicators' assessment procedures (described below) [40]. These
410 assessments provide good capture of the parent and child outcomes targeted by the
411 *smalltalk* programs, have been validated for use with parents of children aged 2-42
412 months, and have demonstrated reliability and validity among disadvantaged
413 populations [40, 41].

414 The Indicator of Parent-Child Interaction (IPCI) assesses the extent to which
415 parents respond to their child in ways that promote positive communication and

416 social-emotional behaviours during 8-10 minutes of: free play (4 minutes); looking at
417 books (2 minutes); a dressing task (2 minutes); and a distraction task (2 minutes; only
418 for children 12 months and older). Interactions were videotaped for later frequency
419 coding. Six parent behaviours (four ‘facilitating’ and two ‘interrupting’ behaviours)
420 were tallied for each task and then an overall rating was made for all tasks combined
421 (behaviours coded as ‘0 = never occurs’ to ‘3 = occurs often). Scores are the
422 frequencies for each behaviour separately and summed for the facilitators (warmth
423 and acceptance; descriptive language; follows child’s lead; maintains child’s interest)
424 and interrupters (harsh comments; restrictions) [41].

425 The Early Communication Indicator (ECI) assesses four child communication
426 skills (use of gestures, vocalisations, single words and multiple word utterances),
427 demonstrated during a 6-minute parent-child play activity with standardised toys.
428 Later coding involved tallying the number of skills demonstrated per minute. The
429 final score was a weighted sum that gives greater weight to more advanced
430 communication skills (a weighting of two for single words and three for multiple
431 word utterances) and allows for comparisons between children of different ages [40].

432 Coding was undertaken by two accredited, expert coders according to
433 standardised protocols. Coders were blind to the study design, participant allocation
434 and the data collection time point. Twenty percent of observations were independently
435 coded by both assessors to determine inter-rater reliability (percent agreement).

436 Due to the high costs of coding, an initial 600 observations (100 participants
437 each from the maternal child health and playgroups services assessed at three time
438 points) were randomly selected, stratified by location (to preserve the clustered
439 design) for coding.

440 *Administrative records:* Numbers of parents who expressed interest, were
441 recruited and retained at each phase of the study were collected via administrative
442 reporting procedures and tracking databases.

443 *Program staff ratings:* Program fidelity, program quality, participant
444 attendance and participant engagement in sessions were rated using standardised
445 checklists by facilitators and home coaches at the end of each group or home coaching
446 session (see Table 2). Reliability was checked by comparison with the independent
447 ratings by research members attending a sample of group sessions.

448 **Sample Size**

449 Our target was to recruit 22 locations (clusters) and 308 parent-child dyads (14
450 parent-child dyads from each location) in each of the three arms (*smalltalk plus*;
451 *smalltalk group-only*; *control*) for each RCT (infant and toddler). The intended
452 sample size is large enough to detect a difference of 0.3 standard deviation units
453 (effect size) between any two trial arms within each of the infant and toddler trials
454 with 90% power at the 5% level of significance, allowing for an intra-cluster (intra-
455 location) correlation coefficient of 0.01 and 15% loss to follow-up at the parent-child
456 dyad level.

457 **Data Analyses**

458 Baseline characteristics will be summarised by trial arm (intervention
459 condition) using means and standard deviations for continuous data and frequencies
460 and percentages for categorical data. For all hypotheses, individual-level outcomes
461 will be compared between the *smalltalk group-only* and control arms and between the
462 *smalltalk plus* and control arms at post-intervention (12 weeks) and follow-up (32
463 weeks), separately for each of the infant and toddler programs. These comparisons
464 will be based on the intention-to-treat principle analysing the parent-child dyads

465 according to the trial arm their location (cluster) was randomised to without regard to
466 the amount of intervention actually received. Random effects (“multilevel”) linear
467 regression models [42] will be used to compare continuous outcomes between the trial
468 arms. Marginal logistic regression models using Generalised Estimating Equations
469 (GEEs) with information sandwich (“robust”) estimates of standard error will be used
470 to compare binary outcomes. An exchangeable correlation structure will be specified
471 for the GEE method. The random effects model and GEE method allow for
472 correlation between the responses of dyads from the same location cluster. Crude
473 (unadjusted) estimates (mean difference and odds ratio) and estimates that are
474 adjusted for the baseline score of the outcome, child age and gender, single parent
475 family status, language other than English spoken at home, mother 25 years of age or
476 younger, education below year 12, and unemployment status will be reported.

477 **Trial Status and Baseline Data**

478 Site recruitment occurred in two stages in mid-2010 and early 2011. Staff
479 training, parent recruitment and baseline assessments commenced in 2011. Programs
480 were delivered across seven school terms from February 2011 to October 2012.
481 Follow-up data collection was completed by March 2013. Findings from preliminary
482 data analyses (partial data only) have been presented to the government funders to
483 inform service planning [43]. This report has not been publically released. Analyses
484 of outcomes, process and baseline data are ongoing. The state government has
485 subsequently funded the Parenting Research Centre in Melbourne to oversee the
486 integration of *smalltalk* programs into usual practice across the state. In partnership
487 with the state government, funding has also been obtained to assess the maintenance

488 of program effects on parent and child outcomes when the children are aged 7-8 years
489 (NHMRC Partnership Grant Application APP1076857).

490 **Recruitment and Participant Characteristics**

491 The study was successful in recruiting twenty LGAs (110 locations) to
492 participate in the study. Ten LGAs ran infant programs and 10 ran toddler programs,
493 with a total of 389 programs provided from 109 locations (clusters): 51 in the infant
494 trial; 58 in the toddler trial. Figures 2 and 3 present the participant flow for each RCT.
495 Across the trial arms, 76-80% of those recruited were able to be recontacted, gave full
496 study consent and provided baseline data.

497 Participants (see Table 3) assessed at baseline were 2,186 parents: 986 were
498 parents of infants (aged 6-12 months) enrolled through the maternal and child health
499 service and 1,200 were parents of toddlers (aged 12-36 months) enrolled through the
500 facilitated playgroup service. Of those enrolled, 86% (n=1890) attended at least one
501 group session. Retention to follow-up was excellent. Data were provided at 32-week
502 follow-up by 75-78% of parents in the infant trial (see Figure 2) and 78-79% of
503 parents in the toddler trial (see Figure 3).

504 Parents in the infant RCT were mostly biological mothers (99%), with a mean
505 age of 31 years. Thirteen per cent were single parents and 14% were born outside
506 Australia. Parents in the toddler RCT were also mostly biological mothers (96%),
507 with a mean age of 33 years. Eleven per cent were single parents and one-third (32%)
508 were born outside Australia. Across the two RCTs, very few participating parents or
509 children identified as Indigenous (1% and 2% respectively). Around 5% came from
510 households where there was no parent in paid employment, and around 20% had a
511 very low income or received their main income from government benefits. As shown

512 in Table 3 there was no evidence of baseline differences in the characteristics of
513 parents by group allocation.

514 The study was successful in recruiting families experiencing socioeconomic
515 disadvantage. At baseline, 84% of participating families displayed one or more of the
516 following risk factors for poor child development: young parent, single parent,
517 language other than English spoken at home, low parental education, low family
518 income, receipt of government benefits, low parenting self-efficacy, or parent
519 psychological distress. The study was also successful in attracting families
520 experiencing multiple challenges. Over half the families reported two or more risk
521 factors and approximately 20% reported four or more risk factors.

522

523 **Discussion**

524 This cluster randomised controlled trial is the largest experimental study
525 undertaken in Australia to improve the quality of the home learning environment
526 during a child's formative years. The study seeks to determine whether a brief group
527 parenting intervention can assist parents from socially and economically
528 disadvantaged circumstances to enhance the home learning environment of their 6-36
529 month old children. By concurrently undertaking two independent cluster RCTs, the
530 study will provide new information regarding the relative effectiveness of intervening
531 during infancy compared to the toddler years. The study will also provide insight into
532 the relative benefits of adding an individualised, highly structured home-based
533 component to the group intervention.

534 The way the intervention was developed and the conduct of the research trial
535 within existing community services, addresses a number of the concerns that are

536 directed at traditional efficacy studies [44, 35]. In particular, it was designed to ensure
537 the trial service delivery conditions were a good match to how the programs would be
538 used in the future. Locally-based services received program funding based on
539 enrolments and were responsible for parent recruitment, staff employment and
540 program scheduling. This ensures that the resulting trial data are relevant to the state
541 government funders and community service providers. Co-production and extensive
542 consultation during program development, further aimed to enhance future uptake of
543 the programs by ensuring end-user acceptability and maximising the sense of program
544 ownership. Early indicators suggest that the program has been successful in attracting
545 families from the target population.

546 In seeking to design and implement a study that has strong external validity,
547 we have not ignored internal validity and data quality. Strengths of the design include:
548 the collection of observational data in addition to parent self-report; collection of
549 detailed process data to guide future refinements; the use of an attention-matched
550 control condition; and the use of a cluster design to minimise cross-condition
551 contamination. A possible weakness is the absence of a fourth trial arm that evaluates
552 the effectiveness of the home-coaching component alone. Home coaching alone was
553 considered unlikely for future implementation. Group-based programs are more
554 efficient to deliver and building social connections was an important policy goal. The
555 results of this trial will provide valuable data of international relevance on a novel
556 approach to enhancing the home learning environment for young children from
557 disadvantaged circumstances, whilst providing practical information to service
558 providers in Australia.

559

560 **Abbreviations**

561 AUD: Australian dollars (\$1AUD roughly equivalent to \$0.70US); ECI: Early
562 Communication Indicator; IPCI: Indicator of Parent-Child Interaction; LGA: Local
563 Government Area; RCT: randomised controlled trial

564

565 **Competing Interests**

566 The authors declare that they have no financial or non-financial competing interests.

567

568 **Authors' contributions**

569 JN, NH, DB, VH, and MT drafted the manuscript with contributions and revisions
570 from JM, WC, OU, EW, TH and SB. WC led the tendering process for study funding.
571 NH was the Project Director for the study. WC, JM, DB, and JN conceived and
572 developed the study design. OU undertook the power analysis and randomisation
573 procedures and advised on statistical analyses. All authors contributed written
574 sections to study protocols and reports that formed the basis of the manuscript, and
575 have read and agreed to the content of the final manuscript.

576 **Acknowledgements and Funding**

577 This research was commissioned and funded by the Victorian Government
578 Department of Education and Early Childhood (now the Department of Education and
579 Training, DET). JN, MT, SB, TH, VH, EW and NH were employees of the Parenting
580 Research Centre when this study was designed and conducted. JN, SB, EW & NH are
581 currently supported by the Australian Communities Foundation through the Roberta
582 Holmes Transition to Contemporary Parenthood Program (Coronella sub-fund); EW
583 was part-funded by the Centre for Research Excellence in Child Language at

584 Murdoch Children's Research Institute (NHMRC grant 1023493). OU is funded by
585 the UK National Institute for Health Research (NIHR) Collaboration for Leadership
586 in Applied Health Research and Care (CLAHRC) for the South West Peninsula at the
587 Royal Devon and Exeter NHS Foundation Trust. The views expressed in this
588 publication are those of the authors and not necessarily those of the funding bodies.
589 We thank the many Parenting Research Centre staff who made valuable contributions
590 to this project: Jane Bennetto, Kim Campbell, Eloise Cameron, Olivia Clayton; Hilary
591 Davis, Simon Fox, Emily Gutierrez, Laurel Johnson, Nicola Johnson, Michelle
592 Kehoe, Tammy Kendall, Tracey Phan, Monique Seymour, Amanda Scicluna, Alvin
593 Vista, Rona Weerasuriya and Maggie Yu. In addition, we thank participating parents
594 and children, the Maternal and Child Health nurses and coordinators across the
595 Victorian local government authorities who assisted recruitment, the numerous staff
596 employed to facilitate groups and deliver home coaching, the study Steering
597 Committee members from the state government of Victoria, and external scientific
598 members of the study Research and Implementation Advisory Groups.

Key Parenting Strategies (active skills training in-session and exemplified in DVDs)

1. **Quality parent-child interactions:** Responsive interactions characterised by parental sensitivity, warmth and cognitive stimulation
 - Tuning in: refers to moments when the parent is fully focussed on what the child is doing, saying and possibly feeling. This creates the opportunity for the parent to be sensitive and responsive to the child’s needs.
 - Following the child’s lead: involves paying attention to and building on the child’s interests. This provides opportunities for teachable moments
 - Listening and talking more: involves increasing exposure to language (both the frequency and variety of words) in a way that promotes ‘conversation’ (e.g., interactive turn-taking that involves both listening and talking). This is a powerful driver of language development from a very young age.
 - Using teachable moments: involve capitalising on everyday opportunities for learning. Children are most open to learning when they are interested in something. A teachable moment arises when a parent encourages a child to extend their knowledge or experience of something with simple comments and questions (e.g., “Yes, it’s a car – what colour is that car?”).
 - Being warm and gentle: relates to the tone or quality of the interaction. The expression of affection and acceptance strengthens the relationship between parent and child and has powerful effects on child development and wellbeing.

2. **Stimulating home learning environment:** An environment rich in language and age-appropriate play activities
 - Shared reading: a dialogic (shared) approach to reading that is interactional and relationship-building and promotes the use of both book and non-book literacy resources. Where parents have low literacy themselves, they are encouraged to ‘tell a story’ based on the pictures.
 - Learning through everyday routines: predictable, positive daily routines that help children feel secure and provide a daily ‘infrastructure’ for parent-child interactions that promote learning and development (e.g., a bedtime routine that involves reading to children).
 - Supporting children’s play: provision of developmentally appropriate play objects and activities essential for child development. Emphasis is given to the use of inexpensive, safe household objects that make excellent toys for learning.
 - Using community resources: involves introducing parents to activities and resources in the community such as libraries and toy libraries.

- Monitoring use of media: emphasis is given to choosing age appropriate programs and limiting exposure to advertising and 'background' television (e.g., television that is on in the background, which interrupts and distracts children from their activities).

Supporting Information Provided on strategies to build parents':

- Personal agency: building confidence, efficacy and reflective practice around parenting
 - Self-care: enhancing/maintaining wellbeing, accessing practical, emotional & informational support, stress management
 - Community connectedness: increasing parental awareness of and ability to access needed services, being supported by and involved with their community
-

784 Table 2 Summary of Study Measures

Variable	Measure	Data collection	
		Method ^a	Collected ^b
Primary outcomes			
Parental verbal responsivity	StimQ-T [45]: 4 items on a 4-point scale E.g. “Talk about the day while your child is eating”, summed to produce a total score between 4 and 16.	CATI	Pre, post, FU
Home learning activities	Home activities with child: 5 items on a 4-point scale assessing parental engagement of child in home activities that stimulate development [46] E.g. “Read books to your child”, summed to produce a total score between 4 and 20.	CATI	Pre, post, FU
Secondary outcomes			
<i>Parent-child interactions</i>			
Parental warmth	Warmth: 6 items on a 5-point scale scale from the Longitudinal Study of Australian Children (LSAC) [39], “Thinking about the last 6 months, how often do you...” E.g. “Hug or hold your child for no reason”, summed to produce a total score between 6 and 30.	CATI	Pre, post, FU
Parental irritability	Irritability: 5 items on a 5-point scale from LSAC [39], “Thinking about the last 4 weeks, how often have you...” E.g. “Lost your temper with your child”, summed to produce a total score between 5 and 25.	CATI	Pre, post, FU
Parent interactions	Indicator of Parent Child Interaction: Caregiver interactions coded as ‘facilitators’ or ‘interrupters’ [41] E.g. “conveys acceptance and warmth” and “uses criticism or harsh voice”. Interactions are rated on a 4-point scale of relative frequency, from 0=never to 3=often/consistently.	Observed	Pre, post, FU
<i>Home environment</i>			
Home literacy	Home Literacy Environment Scale: 6 items on various scales, [47], E.g. “How many books does your child own?”, summed to produce a total score ranging from 0 to 11.	CATI	Pre, post, FU

Early home learning intervention: Study protocol

Disorganisation	Confusion, Hubbub and Order Scale (CHAOS-SF): 6 items on a yes/no scale [48, 49], E.g. “The atmosphere in our home is calm”, summed to produce a total score ranging from 0 to 4.	CATI	Pre, post, FU
<i>Parent focused outcomes</i>			
Psychosocial distress	Kessler-6 (K6): 6-item psychosocial screener on a 5-point scale assessing emotional distress in the last four weeks [50]. “About how often did you feel:” E.g. “nervous”, summed to produce a total score between 0 and 24.	CATI	Pre, post, FU
Wellbeing	SF-12: 12-item health related quality of life [51] on various scales E.g. “How much does your health limit you in climbing several flights of stairs?” and “How much of the time during the past 4 weeks have you felt calm and peaceful?”, producing a Physical Health summary score and a Mental Health summary score.	CATI	Pre, post
Psychological adjustment	I-PANAS-SF: 5-item positive affect subscale on a 5-point scale [52], “Thinking about yourself in the last four weeks, about how often did you feel...E.g. “alert?”, summed to produce a total score between 5 and 25.	CATI	Pre, post, FU
Parent confidence	1 item on a 5-point scale, overall efficacy as a parent from LSAC [53], “Overall, as a parent, do you feel that you are...” E.g. “a better than average parent”, producing a score between 1 and 5.	CATI	Pre, post, FU
Parental self-efficacy	4 items on a 5-point scale, infant and toddler versions of parental self-efficacy from LSAC [38], “In general, do you feel that you are...?” E.g. “Very good at keeping your child amused”, summed to produce a total score ranging from 5 to 20.	CATI	Pre, post, FU
Community connectedness	Use of early childhood services: 6 items on a yes/no scale, study-developed to assess past, current or intended use of similar early childhood programs. “Have you or your child ever attended any other services or programs to assist you and your child?” E.g. “early intervention program”.	CATI	Post
	Contact with other parents: 2 items assessing contact with other parents outside the program [38] “Have you had contact with any of the other parents outside the sessions?” and if so, “Do you think this contact will continue?”	CATI	Post
<i>Child focussed outcomes</i>			

Communication skills	Ages and Stages Questionnaire (ASQ) Communication subscale [54]: 6 items on a 3-point scale. E.g. “Does your child point to, pat, or try to pick up pictures in a book?” Scored yes=10, sometimes=5, not yet=0; summed to a total score between 0 and 60.	CATI	Pre, post, FU
Vocabulary	MacArthur-Bates Communicative Development Inventory (CDI) [55, 56]. Three age versions of the Short Form vocabulary checklists. Level I, up to 18 months: 89 words the child “understands” or “understands and says” (e.g. “mummy” and “meow”). Level II, 19-30 months: 101 words (e.g. “book” and “finish”) and 1 item assessing use of word combinations. Level III, 31 months and older: 100 words (e.g. “then” and “today”), 12 sentence pairs to evaluate complexity of language use, and 12 yes/no items assessing language comprehension.	Parent-report	Pre, post, FU
	Early Communication Indicator (ECI)[57]: frequency of gestures, vocalisations, single words and multiple words generated for each minute of 6-minute play activity. Instances of communication are tallied, with weightings for single words (multiplied by 2) and multiple words (multiplied by 3) to produce a total communication score.	Observed	Pre, post, FU
Socio-emotional skills	ASQ Personal-Social subscale [54]: 6 items on a 3-point scale, E.g., “Does your child play with a doll or stuffed animal by hugging it?” Scored yes=10, sometimes=5, not yet=0; summed to a total score 0-60.	CATI	Pre, post, FU
General development	ASQ Fine Motor subscale: [54] 6 items on a 3-point scale, E.g. “Does your child stack three small blocks or toys on top of each other by herself?” Scored yes=10, sometimes=5, not yet=0; summed to a total score 0-60.	CATI	Pre, post, FU
Process measures			
Parent engagement	Attendance checklist and facilitator ratings of parent engagement [38] E.g. “Parent engagement with other parents” on a 5-point scale from 1=did not talk with other parents to 5=talked to many other parents.	Staff ratings	Each session
Program delivery	Program quality and integrity: 6 items rated by facilitators [38], E.g. “Level of rapport and engagement established” on a 5-point scale from 1=much less than expected to 5=much better than expected.	Staff ratings	Each session
Program intensity	Study designed, facilitator checklist of content coverage.	Staff ratings	Each session

Early home learning intervention: Study protocol

Parent satisfaction	6 items on a 4-point scale assessing parents satisfaction with the program, staff and knowledge gains [37] E.g. “Overall, how satisfied or dissatisfied were you with the program?”	CATI	Post
Participation barriers	13 items on a yes/no scale assessing barriers to program participation [37] E.g. “difficulties relating to other parents”, “work commitments”.	CATI	Post
Staff training	Ratings of program quality (2 items: clarity, usefulness), preparedness to deliver it (3 items: confidence, well-prepared, difficulty), and satisfaction with training (5 items: clarity, usefulness of materials/presentation) on 5-point scales.	Staff ratings	After training
Staff self-assessment	6 skills for program delivery with the target population, E.g. “Identifying specific needs of families” on a 5-point scale from 1 = ‘no level of skill/knowledge in the area’ to 5 = ‘advanced level of skill/knowledge’.	Staff ratings	Before, after training
Covariates			
Demographics	Parent age, ethnicity, language spoken, education, income, employment status family structure and size	CATI	Pre
Child characteristics	Child age, ethnicity, general health, disability, special health services, birth weight	CATI	Pre
Child temperament	4 items on 3-point and 4-point scales, modified version of the NEILS Scales of Developmental Competency [37, 58], E.g. “Would you say that your child is easy to manage, sometimes hard to manage or often hard to manage?”, scores ranging from 4 to 12.	CATI	Pre, post, FU
Parent depression	Single item yes/no rating from LSAC, “In the past year, have you had 2 weeks or more during which you felt sad, blue or depressed, or lost pleasure in the things that you usually cared about or enjoyed?” (0=no; 1=yes).	CATI	Pre
Parent coping	Single item on a 5-point scale from LSAC, “How well do you think you are coping?” producing a score 0-5.	CATI	Pre, post, FU
Stressful life events	List of Threatening Experiences (LTE-Q): 7-item yes/no list of life adverse life events in last 12 months, [59] E.g. “You had a major financial difficulty”, producing a total score between 0 and 7.	CATI	Pre, post, FU

^a CATI = Computer Assisted Telephone Interview. ^b Pre = completed prior to program commencement; post = completed after last program session, approximately 12 weeks after pre; follow-up (FU) = completed 32 weeks after pre.
