Abstract

Since 1988, the Greenland Institute of Natural Resources has annually conducted a bottom trawl survey off West Greenland. The survey was initially designed as a shrimp survey with the focus to evaluate the biomass and abundance of the Northern shrimp (*Pandalus borealis*). The survey has been continuously developed during the years particularly reflecting the needs of the shrimp assessments. Fish catches have systematically been recorded since 1992. The gear was changed prior to the 2005 survey. The East Greenland area was has been surveyed since 2008. This paper contains; Biomass and abundance indices for East and Westgreenland, and length frequencies from West Greenland for Greenland halibut (*Reinhardtius hippoglossoides*), Atlantic cod (*Gadus morhua*), redfish (*Sebastes marinus* and *Sebastes mentella*), Atlantic wolffish (*Anarhichas lupus*), Spotted wolffish (*Anarhichas minor*), American plaice (*Hippoglossoides platessoides*) and Thorny skate (*Amblyraja radiata*). Maps of tow biomass and abundance densities from 2013 for the West and East Greenlandic parts of the survey. Biomass and abundance estimates for Elasmobranchs, Teleosts, Cephalopods and crustaceans excl. Shrimp for the West-Greenland part of the GINR shrimp fish survey including the West-Greenlandic Shelf part of NAFO div 0A. Greenland halibut abundance and biomass are among the highest observed in 2013. Golden and deep-sea redfish biomass has increased in the past few years, but the abundance of redfish, mainly juvenile, has decreased about a factor 20 since the beginning of the time series. Spotted wolffish abundance and biomass indices have increased throughout the time series and the 2013 biomass estimate is the highest observed.

Materials and Methods

The Greenland Shrimp and Fish survey in West Greenland (SFW survey)

The survey has throughout the time series been conducted with the 722 GRT stern trawler M/Tr 'Pâmiut'. The survey design, the area coverage and the trawl and its rigging has been unchanged since 2005. The years prior to 2005 experienced a number of survey developments that are detailed below. The survey period is July to September.

Survey area and stratification: The trawl survey initially covered the traditional offshore shrimp area, between 60° - 72° North, depth 150-600m. In 1991 the area was extended to include the Disko Bay. The area is delimited by a line 3nm off the base line and the 600 m depth curve. Areas shallower than 150 m was initially rather unsystematically covered but from 2004 two extra depth zones have been formally included (50-100m, and 100-150m).

The stratification is based on designated ‘Shrimp Areas’ that is divided into depth zones of: 151-200, 201-300, 301-400 and 401-600 m, as based on depth contour lines (figure. 1). The depth zones 0-100 m and 100-150m is delimited by the NAFO Subdivision boundaries. The “shrimp Areas” and their sizes are provided in table 1. The number of valid hauls by year and stratum is listed in table 2.

Cod, as well as other ground fish species that historically have been assessed by NAFO, was up to 2007 analysed using a re-stratification that followed the NAFO divisions. Re-stratification implies a potential bias and the survey information from 2005 and onwards has therefore been reanalysed in accordance with the shrimp strata actually used in the survey.

If a strata had no stations in a given year, the neighbouring strata in that year is geographically enhanced with area of the non-visited strata.

The Survey Gear and trawl: The survey initially used a Skjervoy 3000/20 trawl with steel bobbin gear and double bag. In 2005 the skjervoy trawl was replaced by a “Cosmos” trouser trawl (Wieland and Bergström, 2005). Until 2003, *Greenland Perfect* trawldoors were used (9.25 m², 2.4 tons), but they were replaced in 2004 by Injector International trawl doors (7.5 m², 2.8 tons) to facilitate the trawl change in the year after. Calibration experiments with the two trawls were conducted in the main shrimp areas in 2004 and 2005 and a formal analysis of conversion factors were established for shrimp (Rosing and Wieland, 2005). However the calibration factors for the different fish species were never finally evaluated. Preliminary conversion factors were derived as described by Rosing and Wieland (2005) and are given in table 3.

Tow duration. Tow duration has over the years been gradually reduced from 60 min. (prior to 1997) to 30 and has been fixed to 15 min since 2005 (Wieland and Storr-Paulsen 2006). Towing speed has been about 2.5 knots throughout the years. Survey abundance and biomass is expressed per swept area: Wingspread*towed distance, where wingspread is inferred from Scanmar recordings and the towed distance is measured by GPS.

Allocation of trawl hauls. Trawl stations are allocated to strata with the objective to minimise the variances of the shrimp biomass. The allocation algorithm utilises the historically observed shrimp variances where highest weight is placed on the most recent information. Stations positions were initially selected at random but since 1999 station positions were chosen to secure a minimum distance between stations. Since 1998 about half of the haul positions were randomly selected from the previous year hauls; the rest of the hauls being selected at random.

The Greenland Shrimp and Fish survey in East Greenland (SFE survey)

The survey is carried out with the same gear and survey protocols as used in West Greenland after 2005. Stratification is based on the “Q-areas” used for the East Greenland survey for Greenland halibut. The areas are further depth stratified into 0-200 m, 200-400m and 400-600 m zones, the areas are shown in figure. 1. and the area sizes are given in table 1.

The major difference between West and East Greenland is the bottom conditions that severely restrict the areas that can be trawled off East Greenland. Stations were randomly selected from historical known trawl-able sites.

Results

Greenland halibut (*Reinhardtius hippoglossoides*).

In Westgreenland, Greenland halibut can be found in all divisions, but is most abundant in the important nursery areas in division 1A and 1BN and 1AX (Disko Bay) (table 4 and5). Both abundance and biomass indices for Greenland halibut increased during the 1990's (figure 2). The abundance index is mainly driven with the year to year variability in 1 year old recruits and the 2013 abundance is among the highest observed (figure 2). The biomass index varied from 45,000 tons to more than 70 000 tons since 2005 and the 2013 estimate is around average for the period. Clear modes can be found in the length distribution at 15 and 23 cm every year probably corresponding to yearclasses 1 and 2 (figure 14). Distribution of survey catches in number pr. km² and kg pr. km² are given in figure 21.

In East-Greenland, recruits are rarely seen and both abundance and biomass indices are much lower on the East Greenlandic shelf areas.

Greenland halibut recruitment.

A recruitment index was estimated for the entire survey area. By means of the Petersen-method ages 1, 2 and 3+ were separated in the survey catches. The number of one-year-old fish in the total survey area including Disko Bay increased gradually from 1996 to a peak of 500 million in 2001 (figure 9). During the 00' the recruitment was stable at around 300 mill. The number of one-year old increased in 2011 to 530 million, which is an increase from 310 million in 2010 and the highest in the time series. The recruitment decreased in 2012 where the 2011 year-class was estimated to 175 mill. - the lowest estimate since 1996 and at the level of the early 90'es. The recruitment increased again in 2013 where the 2012 year-class was estimated at 444 mill. which is the 3. largest estimate in the time series (Fig. 10a, b, c).

To allow comparison of abundance throughout the time series, the 2005 to 2013 catches were divided by a conversion factors to adjust the new Cosmos trawl catches to the old Skjervoy trawl catches. For Greenland halibut the conversion were length dependent and x in the equations is the individual fish length (Table 3).

The offshore recruitment has been rather stable between 2003 and 2010. The recruitment increased to the highest level in the time series in 2011 to decrease to lowest level seen since 1997 (1996 year-class). The offshore recruitment (2012 year-class) increased again in 2013 the estimate is the second largest in the time series. In 2013 79% of the one year old fish was found in the off shore areas (Fig. 11). The increase in recruitment between 2012 and 2013 was seen in all divisions except Div. 1C-1F (Fig. 12).

In Disko Bay the recruitment has been decreasing between 2003 and 2008 and increased since then to the highest level seen since 2001 in 2011. In 2012 the recruitment decreased to the lowest level seen since 2008 to increase again in 2013, but not as significantly as in the of shore areas (Fig. 12).

Generally there is a steep decline between abundance at age 1 and age 2 and 3+ which also was observed in the 2013 survey. Further, it has been noted, that the year-classes estimated to be a very strong year-class at age 1 have not shown up as a particularly strong year-classes at age 5-8 in the fishery catches or in the 1CD survey for Greenland halibut.

Cod (*Gadus morhua*)

For cod, both the abundance and biomass indices are the highest observed throughout the time series, mainly driven by the 2009 year-class. 2 year old recruits (2011 yc) are mainly observed in Division 1A and B and the 2009 year-class is mostly abundant in division 1DEF (Figure 15). Distribution of survey catches in number pr. km² and kg pr. km² are given in figure 22. For further information on cod see the ICES Report of the North-Western Working Group (Anon., 2013)

Demersal Redfish (*Sebastes sp.*) combined.

Two species of redfish are common in the area, golden redfish, *Sebastes marinus* and deep-sea redfish *Sebastes mentella*. Due to difficulties in identification of species in some years redfish were classified as *Sebastes* (prior to 2007). Juvenile redfish less than approximately 20 cm are classified as juvenile "*Sebastes sp.*". The distinction is however not straight forward and often small redfish are classified as *Sebastes* *Mentella*, which in Westgreenland has also dominated individuals less than 30 cm in recent years (figure 16). Redfish are present in all divisions, but recruits are most abundant in division 1B (table 8, 9 and figure 16). The abundance indices have decreased about a factor 20 throughout the time series (tabel 7, figure 4), mainly caused by the disappearance of recruits. Biomass of demersal species of redfish combined decreased to about a third the initial values throughout the 1990's but stabilized during the 2000's and has been increasing since 2009 (table 9 and figure 4). Annual growth increments of 4 cm were indicated by repeatedly pronounced peaks in length compositions at 7-8 cm and 12 cm probably corresponding to age 1 and 2 (Nedreaas, 1990). Densities by haul in number pr. km² and kg pr. km² are given in figure 23 - 26.

In East-Greenland *sebastes mentella* is further divided into a demersal and two pelagic stocks of redfish (beeked redfish), a shallow and deep pelagic stock.

Classification of redfish species.

In Westgreenland, Separation of redfish by haul has been attempted since 2007 (table 10-15, figure 16). Particularly the separation of *sebastes mentella* and juvenile redfish varies from year to year. The decrease in juvenile redfish is therefore cancelled by an increase in deep-sea redfish (table 10-13). Larger individuals are easier to separate, leading to increased credibility of the classification of golden redfish. Golden redfish biomass has increased since 2009 (table 15). The increase was seen particularly in division 1 E and 1F and was caused by few hauls of large individuals (figure 26) giving more than half the total West Greenland biomass. The sudden increase in larger individuals of golden redfish could indicate a connection with the Icelandic and East Greenlandic stock of Golden redfish or stocks inside the west Greenlandic fjords.

In East-Greenland *sebastes mentella* is further divided into a demersal and two pelagic stocks (beeked) of redfish, a shallow and deep pelagic stock.

American plaice (*Hippoglossoides platessoides*).

In Westgreenland, American plaice is common in all divisions, but the main areas are division 1A to 1E (table 16,17 and figure 27). The 2013 biomass and abundance indices are among the highest observed and the general impression is an increasing stock (table 16,17 and figure 5). Clear modes can be found at 5 and 15 cm indicating new incoming year-classes and individuals larger than 45 cm are rarely seen (figure. 17). Densities by haul in number pr. km² and kg pr. km² are given in figure 27.

Atlantic wolffish (*Anarhichas lupus*)

In Westgreenland, Atlantic wolffish is common in all divisions, but the distribution has shifted further north since the beginning of the time series. Previously Atlantic wolffish was mainly found south of 68°00'N (table 18,19 and figure 6). The 2013 indices of both abundance and biomass are among the highest observed. The length distribution reveals the dominance of fish < 35cm and although the proportion of larger individuals has increased in the past years, individuals above 65 cm are virtually absent (figure. 18). Densities by haul in number pr. km² and kg pr. km² are given in figure 28.

Spotted wolffish (*Anarhichas minor*)

In Westgreenland, spotted wolffish are located in all divisions, but the highest concentrations are found in divisions 1A and 1B (Table 20,21). Both abundance and biomass indices have increased throughout the time series and particular the 2013 biomass estimate is by far the highest observed. (figure 19). In length distribution ranges from 10-120 cm and occasionally weak modes at 13 cm can be identified. (figure. 13). Densities by haul in number pr. km² and kg pr. km² are given in figure 29.

Thorny skate (*Amblyraja radiata*)

In Westgreenland, thorny skate is common in all divisions but the majority of both the biomass and abundance is located in division 1A and 1B. The only significant change happened from 2004 to 2005 indicating a poor calibration factor. The general impression is a slightly increasing stock over the time series (table 22,23 , figure 7). In recent years Thorny skate length distributions have revealed clear modes at 12 cm and 42 cm probably corresponding to recruits and adult individual (figure. 20). Individuals larger than 55 cm are rarely observed. Densities by haul in number pr. km² and kg pr. km² are given in figure 30.

Other species

The Appendix contains biomass and abundance estimates for elasmobranchs, teleosts, cephalopods and crustaceans excl. Shrimp for the West-Greenland part of the GINR shrimp fish survey including the West-Greenlandic Shelf part of NAFO div 0A.

Discussion

Catchability is set at 1 for all species. However, since swept area is calculated for the trawl excluding doors and bridles, catchability may be higher than 1 for some species and below 1 for other species, implying that both biomass and abundance should be regarded as index values only, not absolute values.

Index changes from the end of the 1990's to 2001 for species related to shallow water and banks (50-150m) could reflect better coverage of these depths during the past decade. Changes from 2003 to 2004 could be influenced with the trawl door update from Greenland perfect to injector and may be species dependant, as no calibration experiments were made on this account. Index changes from 2004 to 2005 could be related to species specific data quality in the calibration experiments.

The main purpose of the survey is to evaluate the biomass of northern shrimp and the effort is concentrated in areas and depths where the commercial shrimp trawling is taking place, especially on the northern slopes of the bank Store Hellefiskebanke (67°50'N 55°00'W) and in the inshore area Disko Bay. As Store Hellefiskebanke and Disko Bay are important nursery areas for Greenland halibut and redfish, as well as other important species (Smidt, 1969; Tåning, 1949) it is likely, that the abundance estimates of the survey reflects the juvenile stock situation of these species.

The 2002 estimates in division 1AN may have been affected by low coverage in this division, since only 2 hauls was performed in this division in 2002 and therefore not all strata can have been covered. No record exists on whether any compensation for low coverage was made in subarea 1AN in 2002.

2007. Strata 1C 50-100 no stations - included in 1C 100-150.

2008. All strata surveyed.

2009. Strata 1A:50-100 no stations - included in 1A 100-150.

2010. Strata 1A:50-100, 1A:100-150 no stations - included in U1 150-200.

2011. Strata W1:400-600, C0:200-300, C0:300-400, C0:400-600 no stations - included in W1 300-400.

2012. Strata C0:200-300, C0:300-400, C0:400-600 no stations - included in W1 300-400.

2013. Strata C0:400-600 no stations - included in C0 300-400. Strata W9:400-600 no stations - included in W9 300-400.

Table 2 - continued. Numbers of valid hauls in Eastgreenland, 2008-2013.

| East Greenland | | | | | | | |
|-----------------------|----|----|----|----|----|----|-------|
| Year | Q1 | Q2 | Q3 | Q4 | Q5 | Q6 | Total |
| 2007 | | | | | | | 35 |
| 2008 | 8 | 6 | 12 | 7 | 7 | 12 | 52 |
| 2009 | 21 | 12 | 26 | 19 | 6 | 13 | 97 |
| 2010 | 19 | 14 | 24 | 9 | 6 | 10 | 82 |
| 2011 | 20 | 11 | 21 | 12 | 7 | 14 | 85 |
| 2012 | 19 | 16 | 28 | 13 | 7 | 15 | 98 |
| 2013 | 25 | 12 | 22 | 14 | 5 | 14 | 92 |

Note:

2007 Survey startup year. Only 35 hauls. No results presented.

2008. Strata Q1,Q2,Q4:0-200 no stations - included Strata Q1,Q2,Q3:200-400.

2009. Strata Q1:0-200 m no stations – included in Q1:200-400.

2010. Strata Q1:0-200 m no stations – included in Q1:200-400.

2011. Strata Q1:0-200 m no stations – included in Q1:200-400.

2012. Strata Q1:0-200 m no stations – included in Q1:200-400.

2013. Strata Q1:0-200 m no stations – included in Q1:200-400. Strata Q5:0-200 m no stations – included in Q4:0-200.

Table 3. Preliminary calibration factors to adjust the Cosmos trawl catches to the former Skjervoy trawl standard. For Greenland halibut and American plaice the conversion were length dependent and for those species x in the equations represents the individual fish length.

| Fishspecies | Greenland halibut | Redfish | American plaice | Atlantic wolffish | Spotted wolffish | Cod | Thorny skate |
|----------------------|----------------------|----------|----------------------|----------------------|---------------------|----------|-----------------|
| Conversion factor | 0.0404x+0.6527 | 2.4 | -0.0825x + 5.3307 | 2.3 | 2.3 | 1.78 | 5.1 |
| Trawl size factor | 1/1.1516 | 1/1.1516 | 1/1.1516 | 1/1.1516 | 1/1.1516 | 1/1.1516 | 1/1.1516 |
| Final factor | 0.035x+0.567 | 2.0 | -0.072x + 4.629 | 2.0 | 2.0 | 1.5 | 4.4 |

Table 4. Greenland halibut (*Reinhardtius hippoglossoides*). Abundance indices (Millions) for West Greenland with 95% confidence limits in percent of the stratified mean.

| Year | 0A | 1AN | 1AS | 1AX | 1BN | 1BS | 1C | 1D | 1E | 1F | W-Grl | cv | E-Grl | cv |

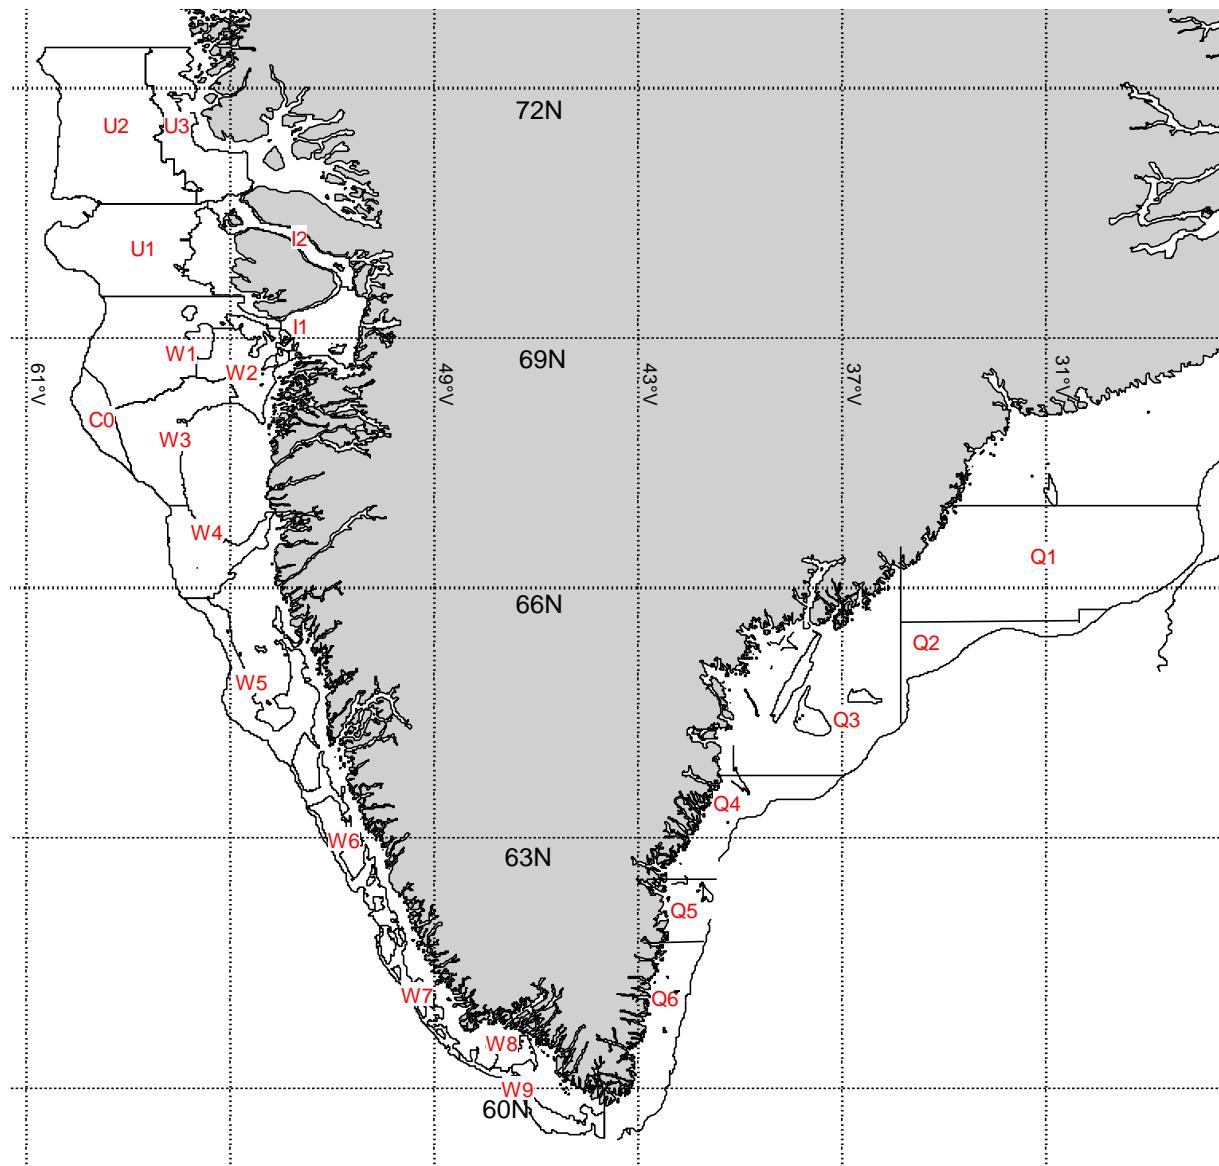

Fig 1: The Stratification areas used in the Greenland Shrimp and Fish survey. In West Greenland each strata is divided in depth strata of 150-200m, 200-300m, 300-400m and 400-600m. “Shallow” water strata of 0-100m and 100-150m delimited by the 3 nm line and the NAFO Div. Borders of the shallow water stratas are not shown. In East Greenland each strata is divided in depth strata of 200-400m and 400-600m. “Shallow” water strata of 0-200m is delimited by the 3 nm line.

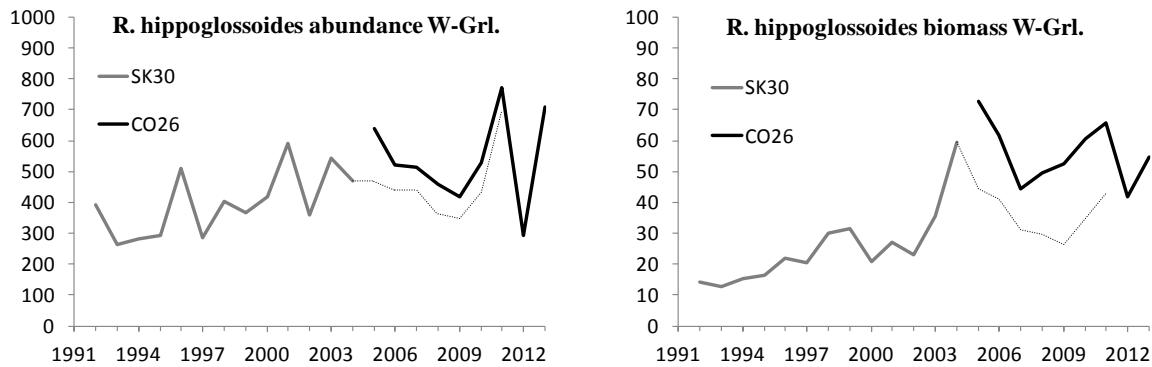

Fig 2. Greenland halibut abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

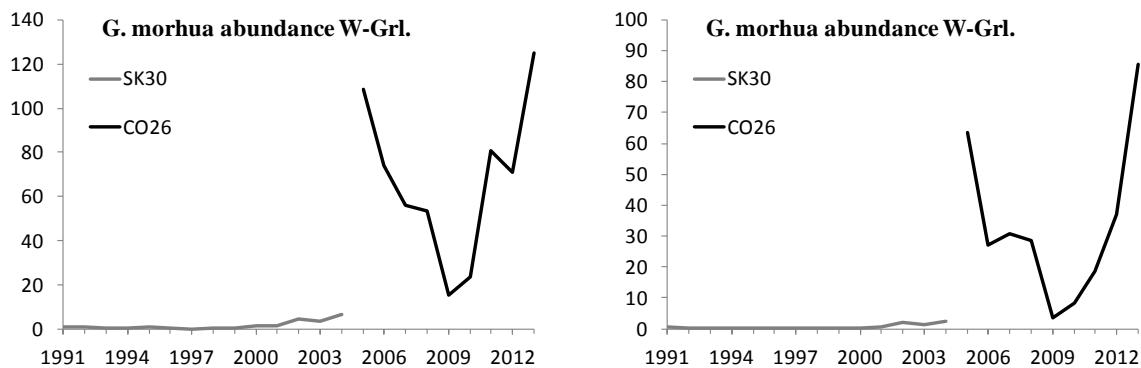

Fig 3. Atlantic cod abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005.

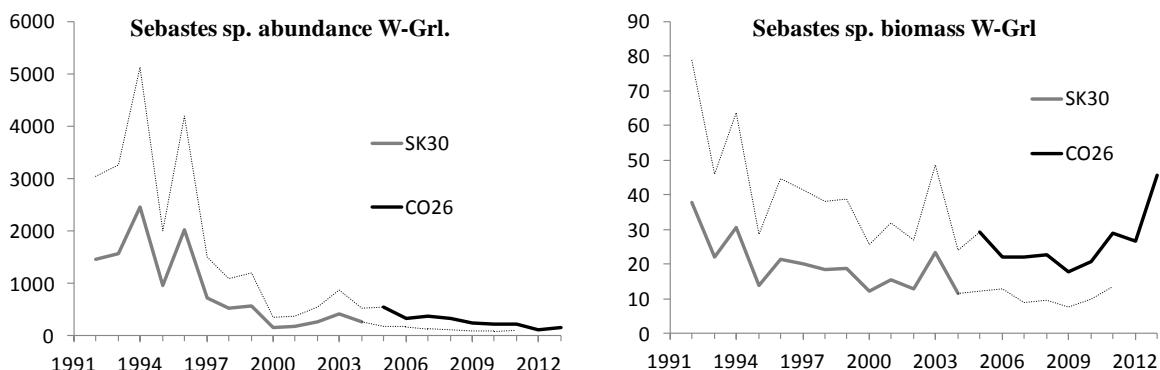

Fig 4. Redfish species (*S. mentella* and *S. marinus* combined) abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

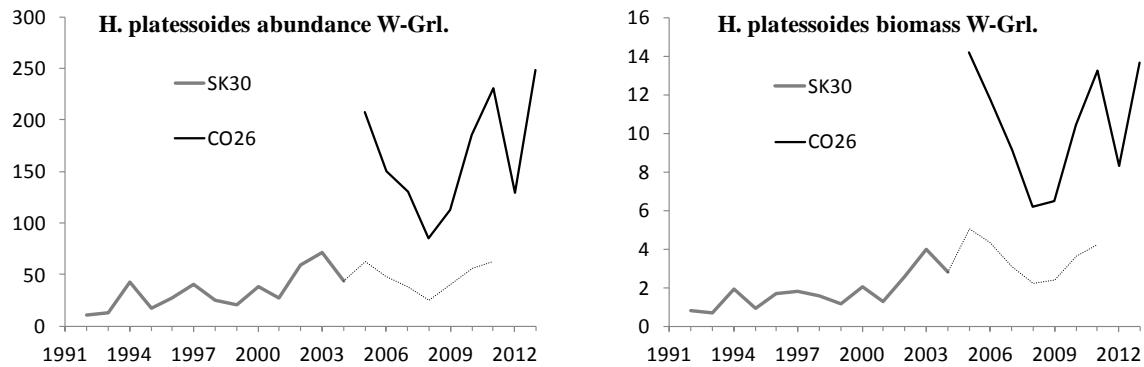

Fig 5. American plaice abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

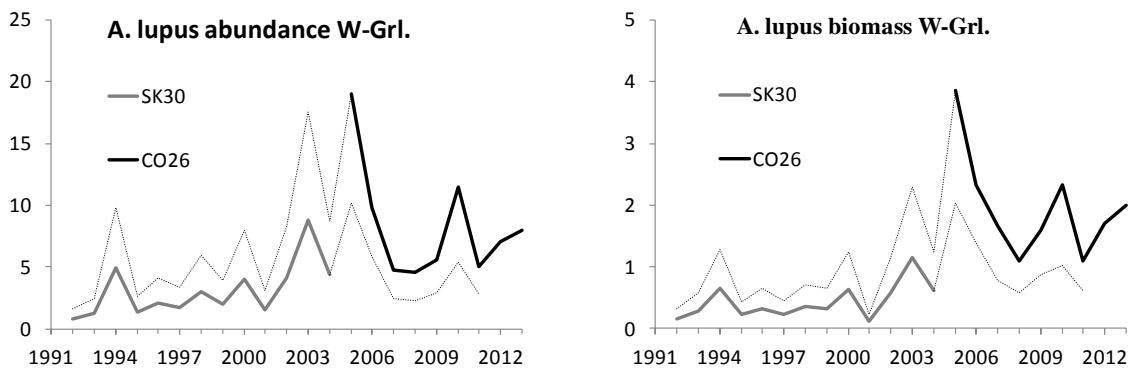

Fig 6. Atlantic wolffish abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

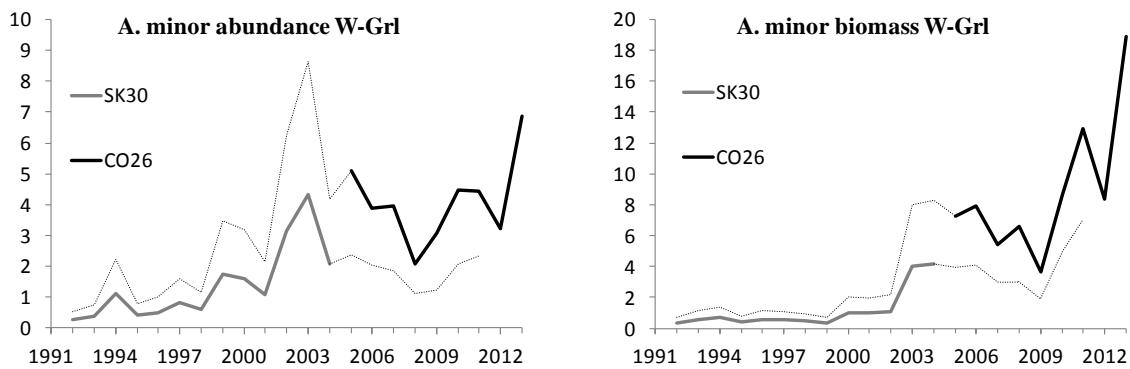

Fig 7. Spotted wolffish abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

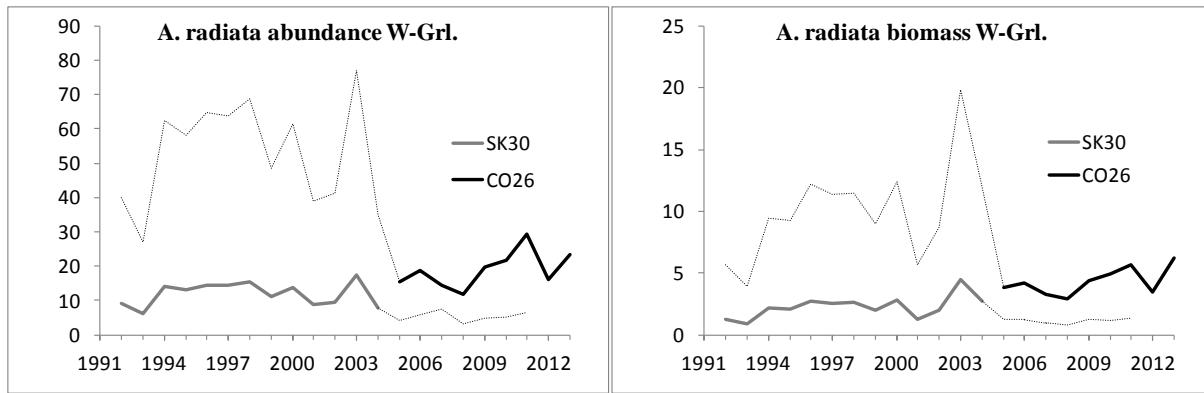

Fig 8. Thorny skate abundance (million) and biomass (Kt) for Westgreenland. SK30 is the Skjaervoy trawl used from 1990 to 2004. CO26 is the Cosmos trawl used since 2005. Dashed lines are trawl calibrated indices.

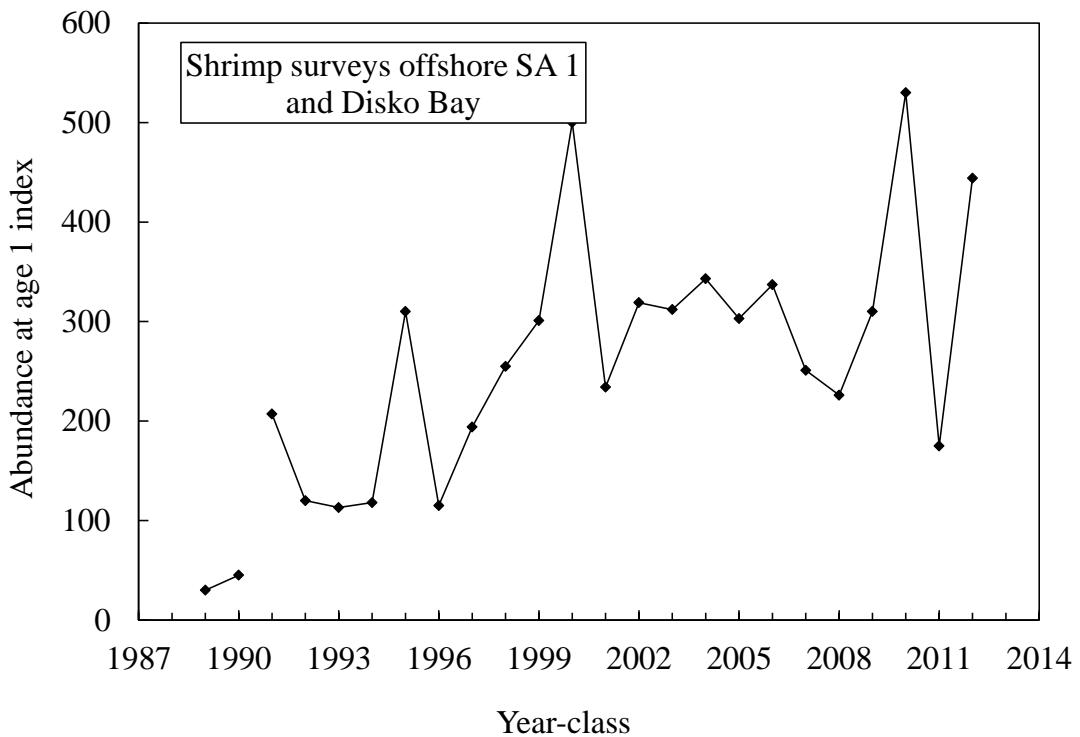

Fig 9. Total recruitment of age one including Disko Bay.

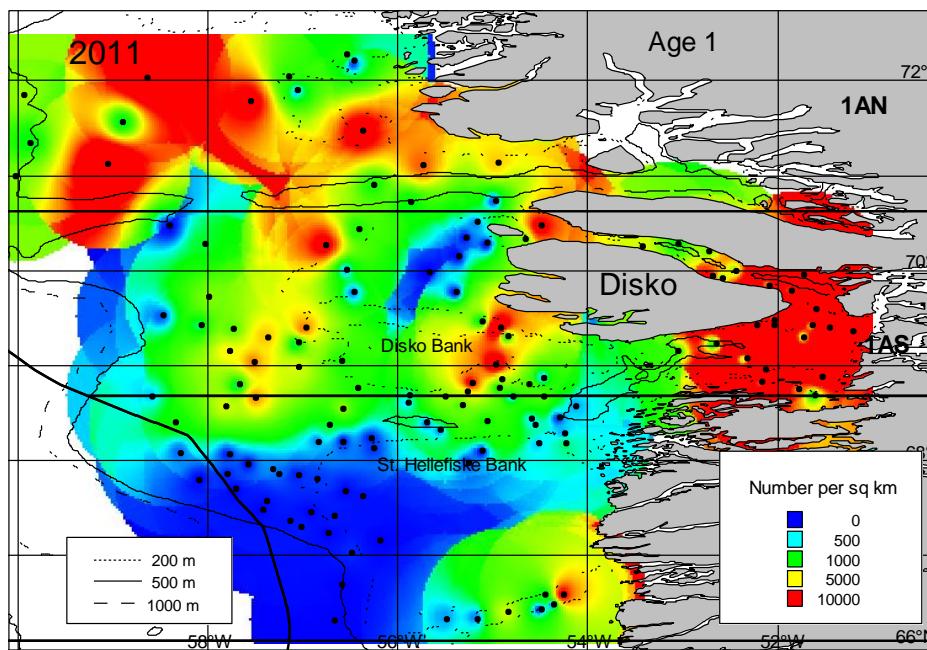

Fig 10a. Distribution of one year old Greenland halibut (2010 year-class) in the 2011 survey.

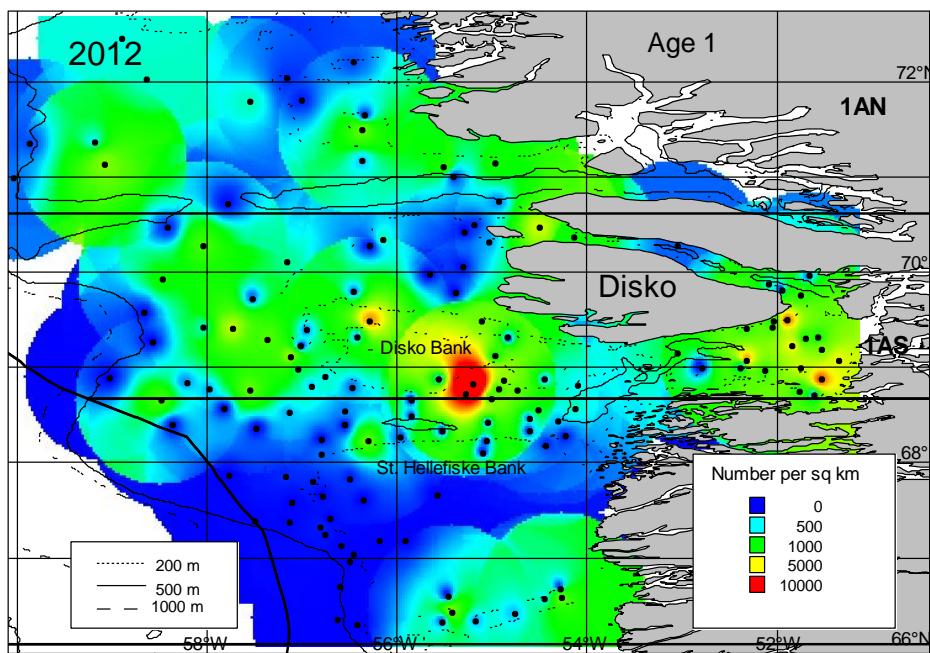

Fig 10b. Distribution of one year old Greenland halibut (2011 year-class) in the 2012 survey.

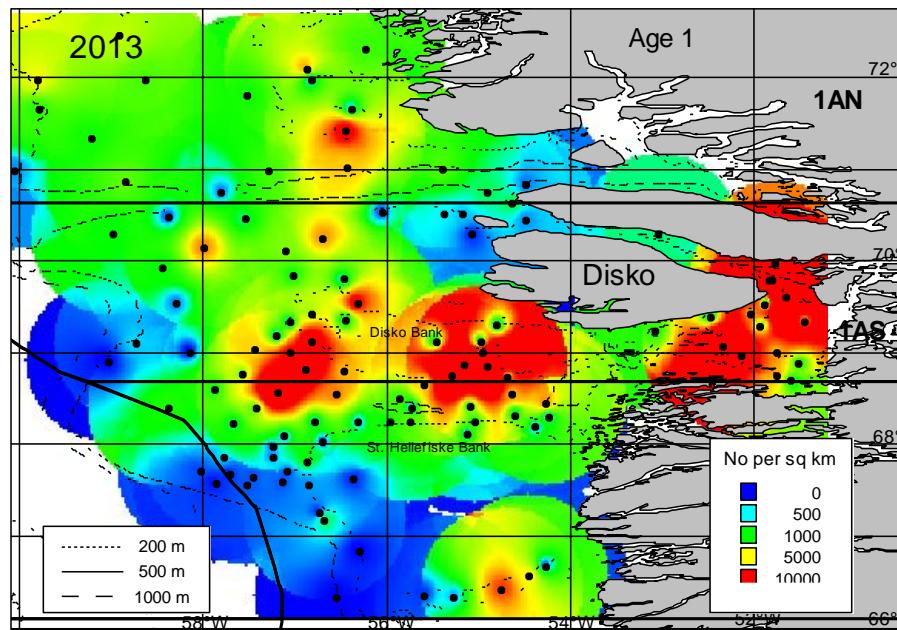

Fig 10c. Distribution of one year old Greenland halibut (2012 year-class) in the 2013 survey.

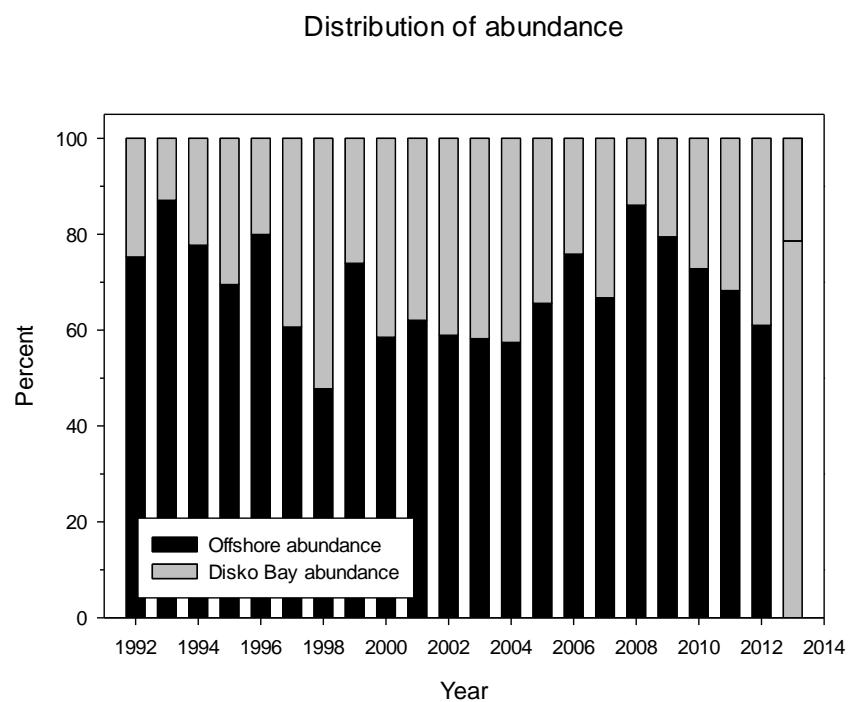

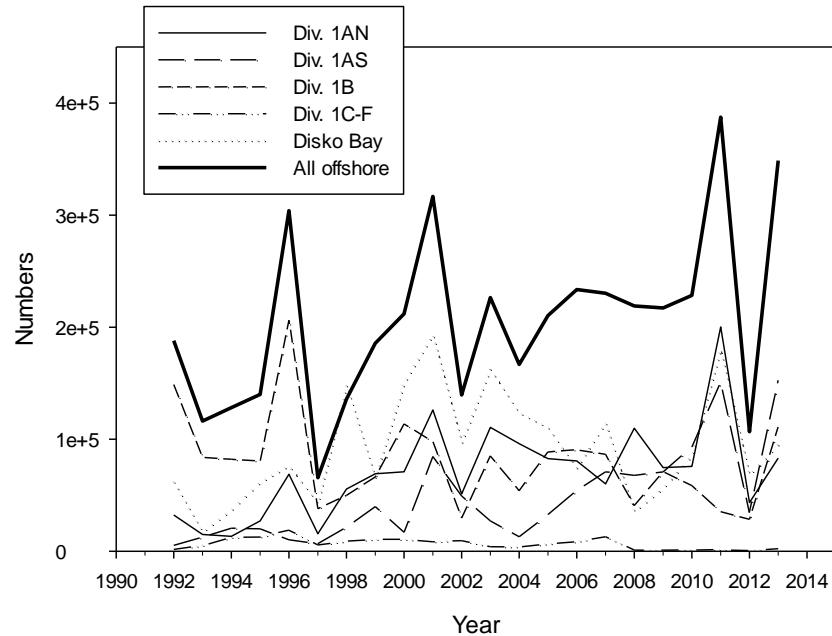

Fig 11. Relative distribution of one-year old Greenland halibut between offshore areas and inshore Disko Bay.

12. Number of one-year of Greenland halibut by division and year.

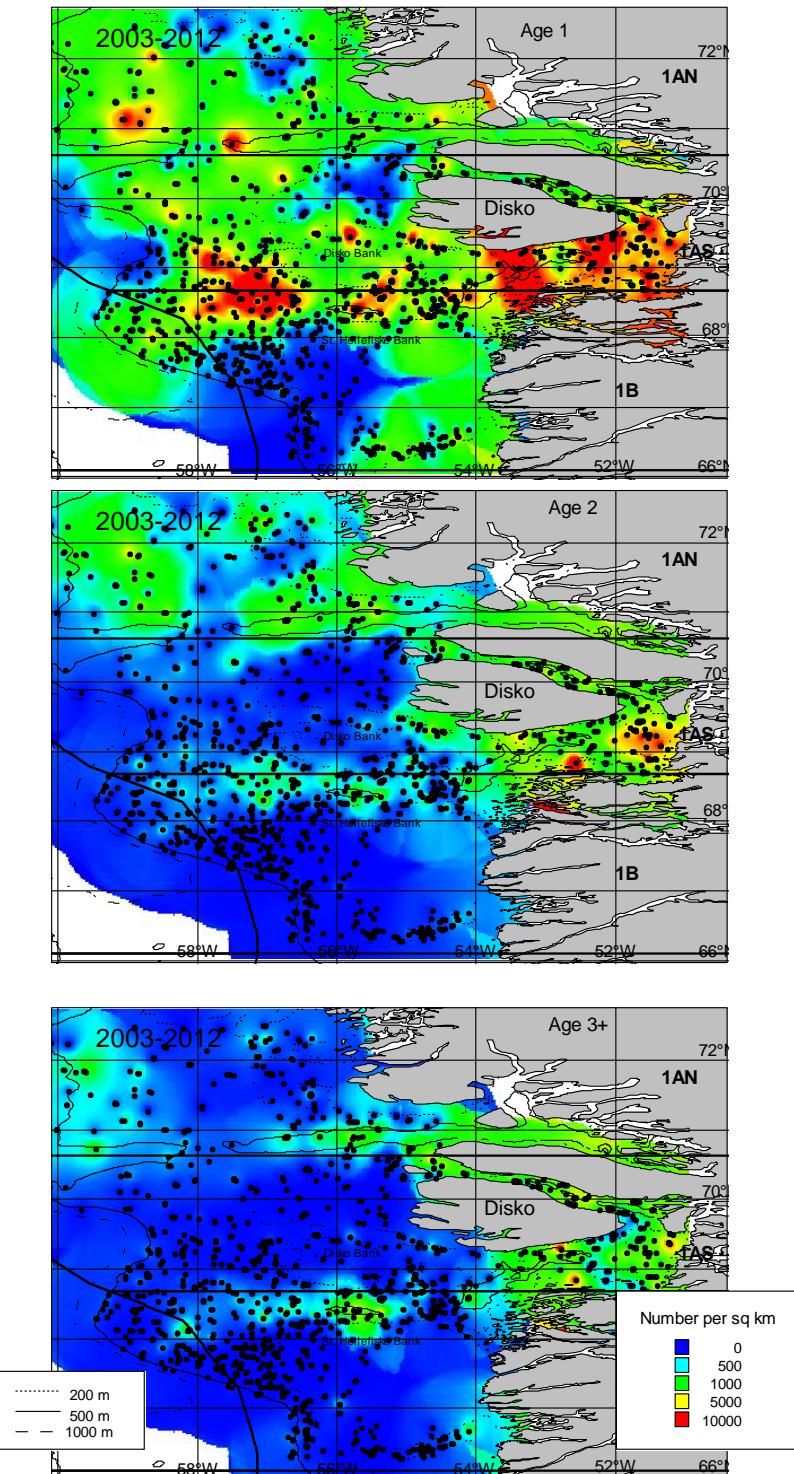

Fig 13. Distribution of 1-year, 2-year and 3+ old Greenland halibut. Data from 2003-2012 pooled.

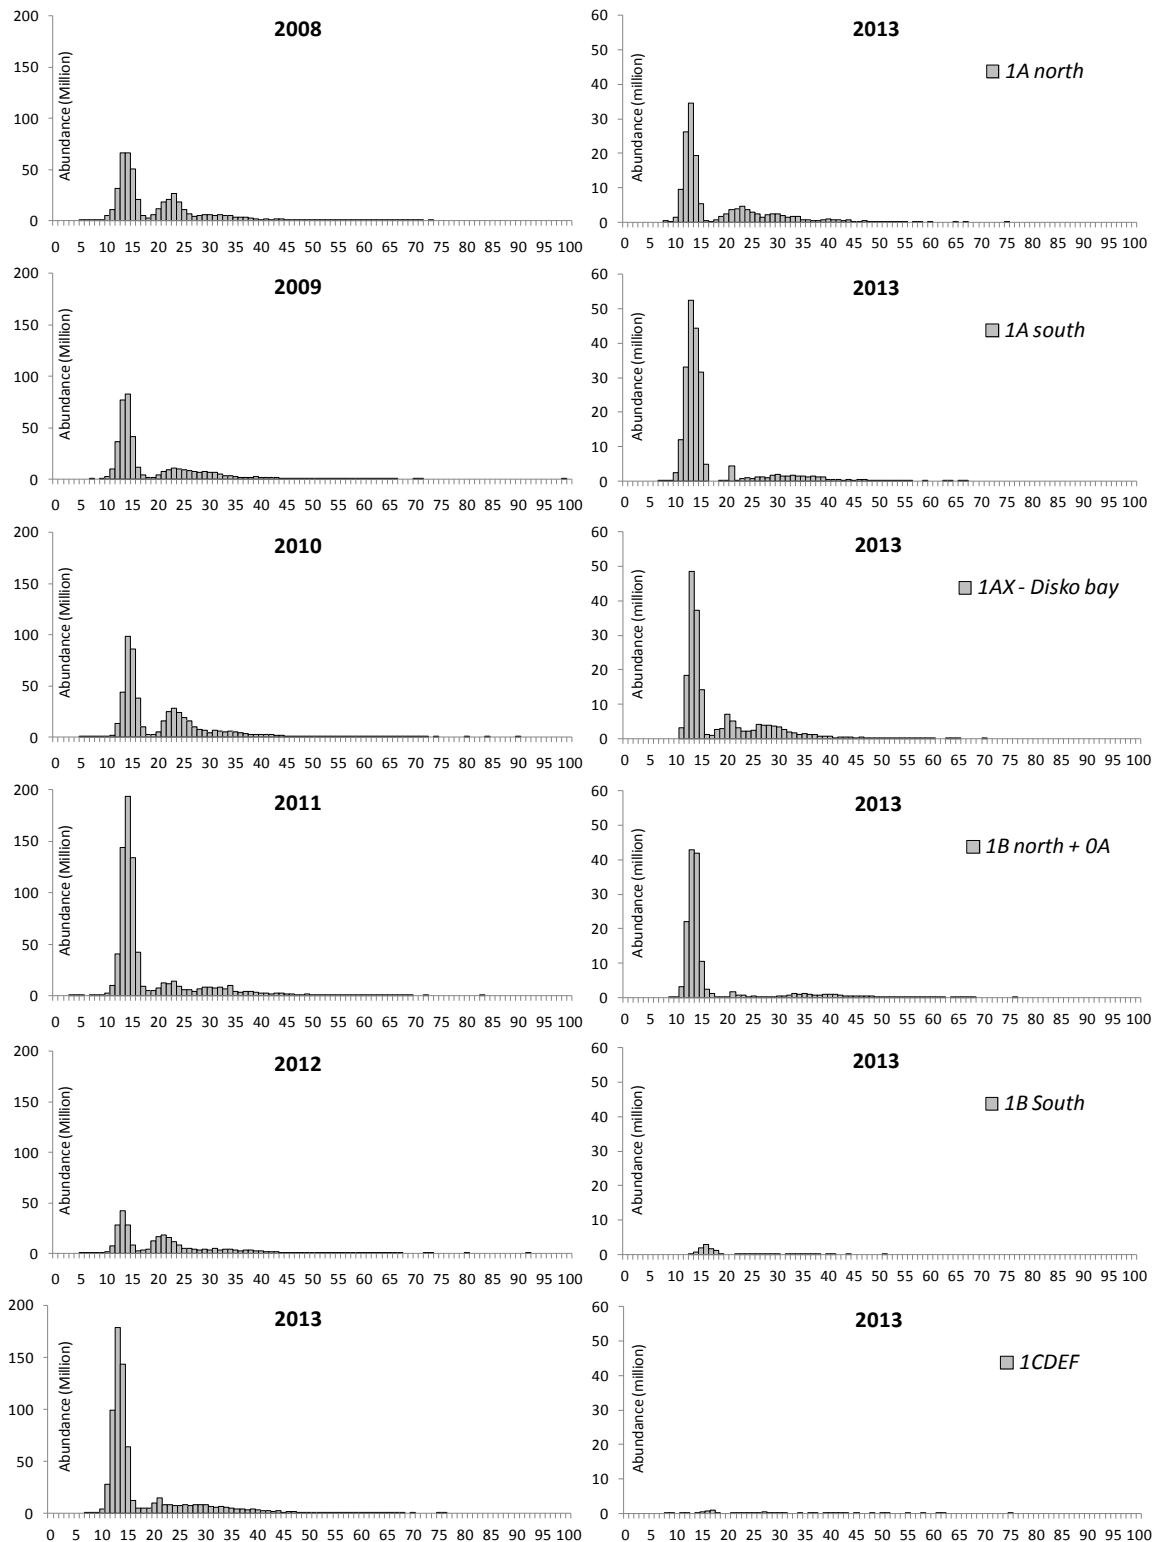

Fig. 14. Greenland halibut (*Reinhardtius hippoglossoides*). Length frequencies for West Greenland 2008-2013 (left) and length frequencies per division in 2013 (right).

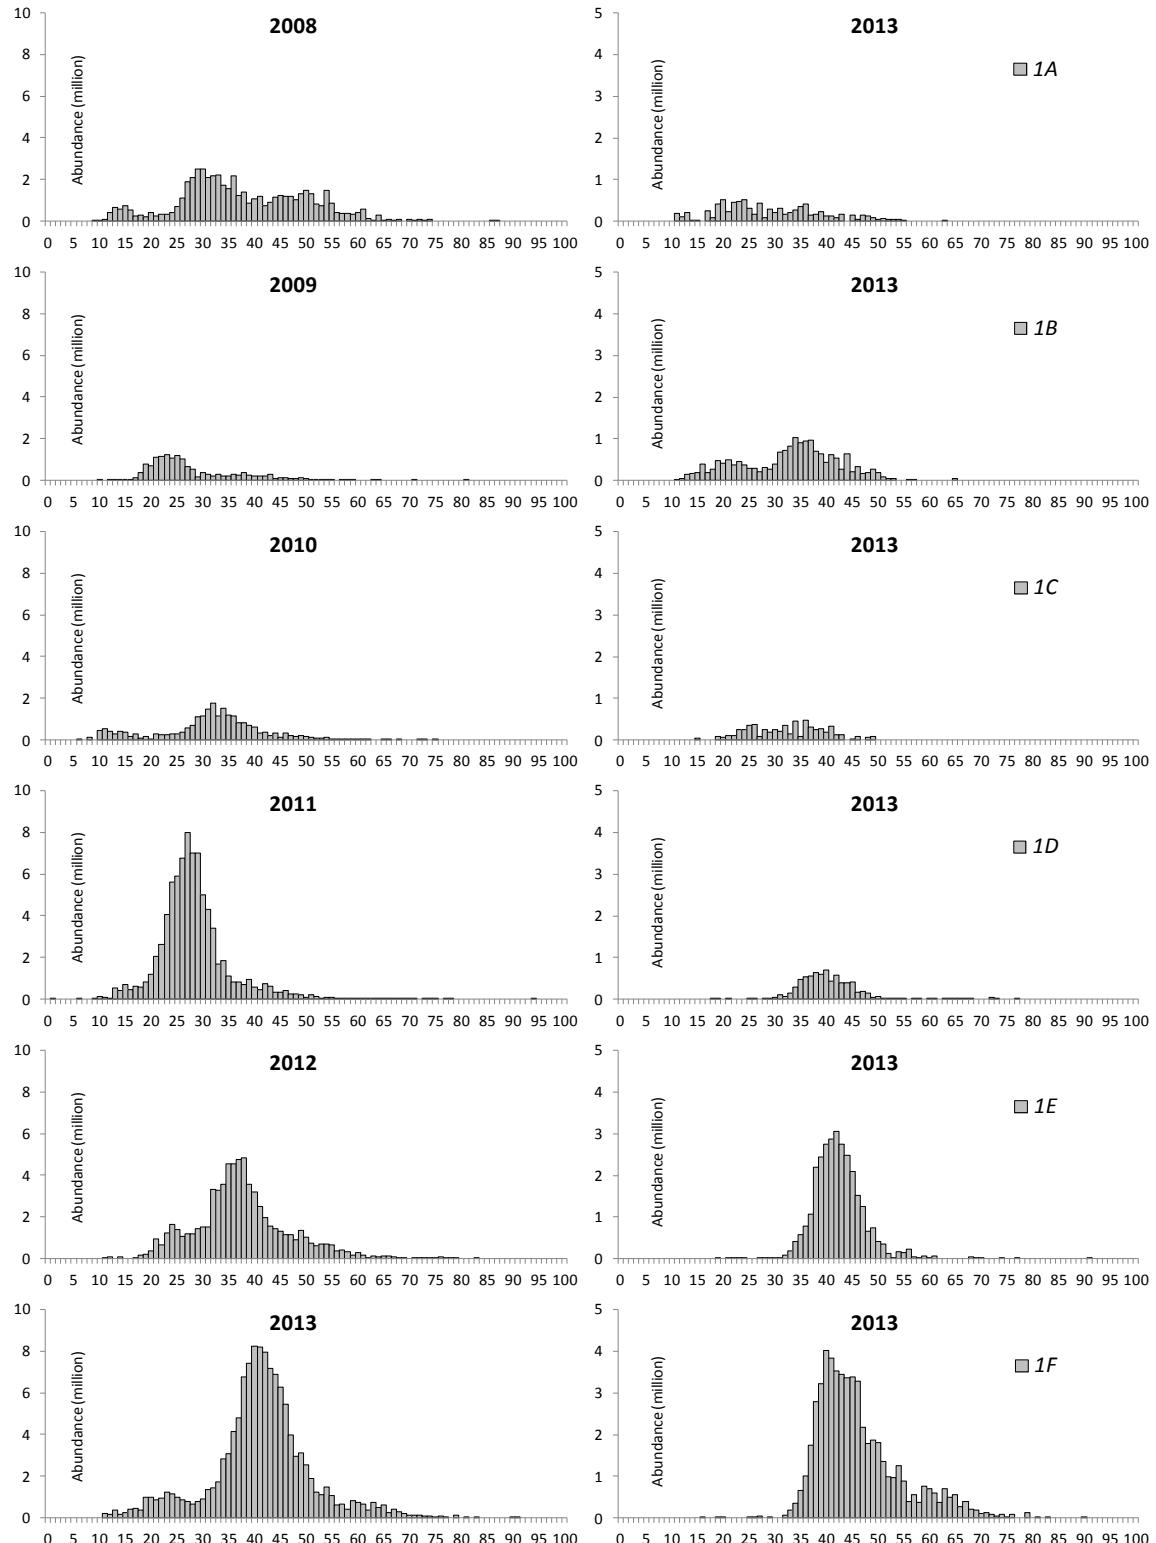

Fig. 15. Atlantic cod (*Gadus morhua*). Length frequencies for West Greenland 2008–2013 (left) and length frequencies per division in 2013 (right).

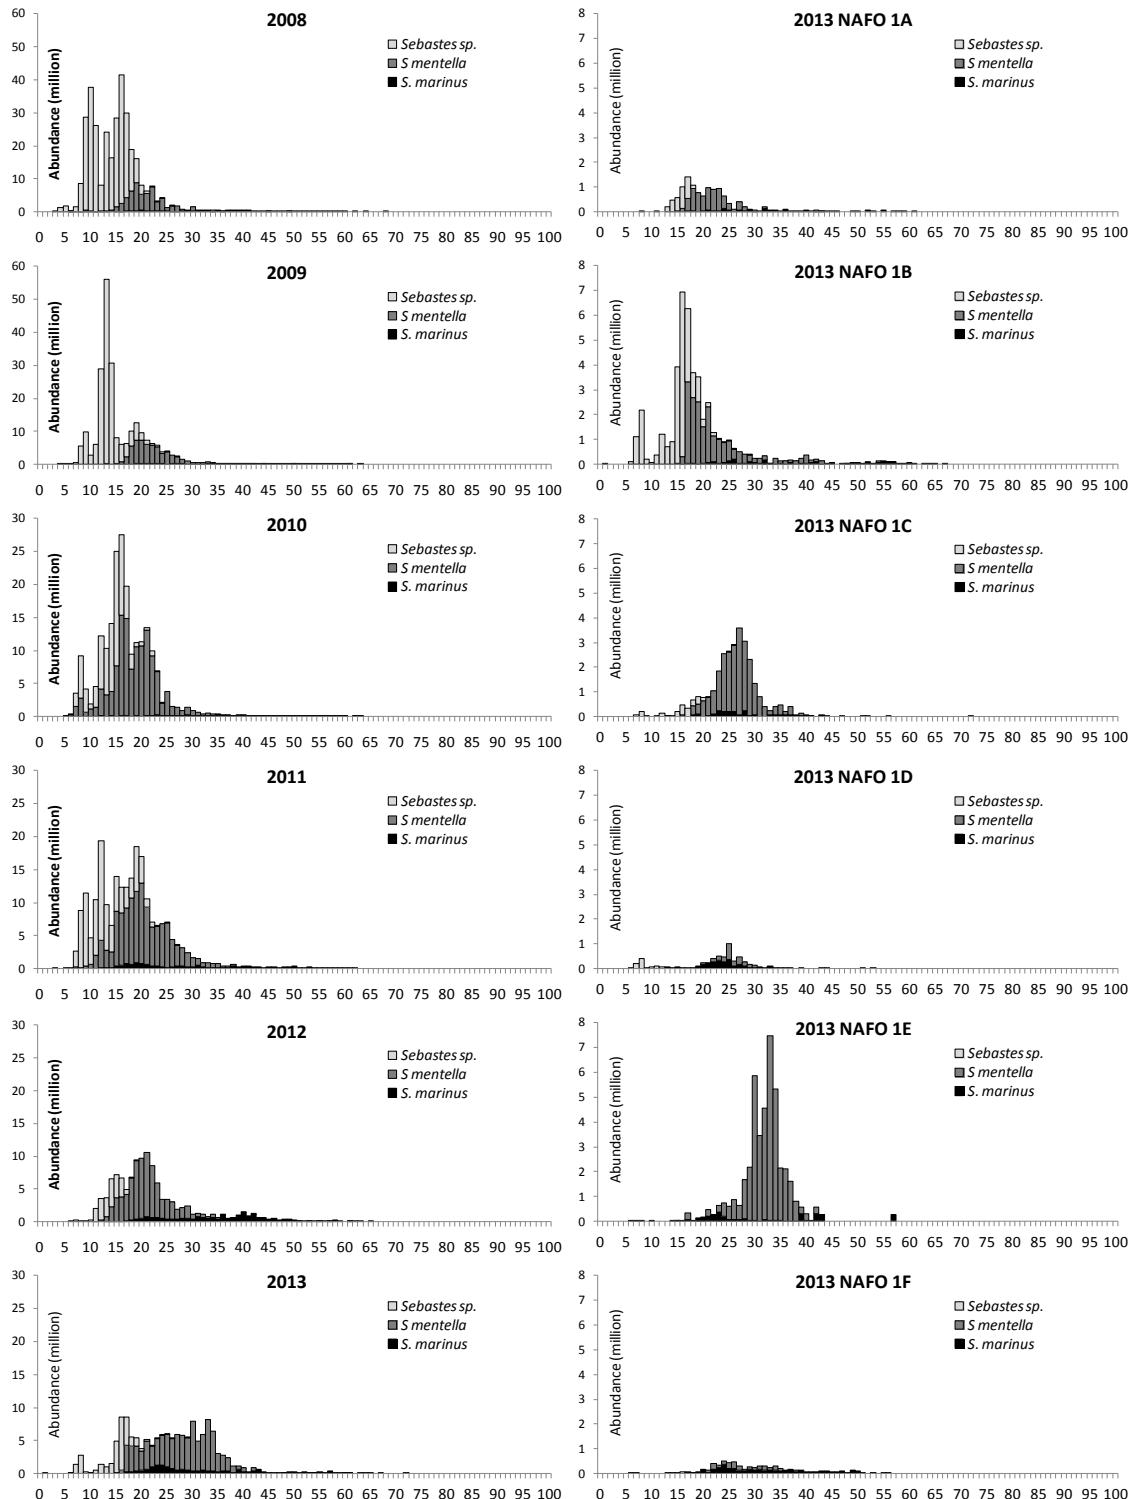

Fig. 16. Stacked Length frequencies for golden redfish (*Sebastodes Marinus*), Deep-sea redfish (*Sebastodes mentella*) and juvenile redfish (*Sebastodes sp.*) for West Greenland 2008-2013 (left) and length frequencies per division in 2013 (right).

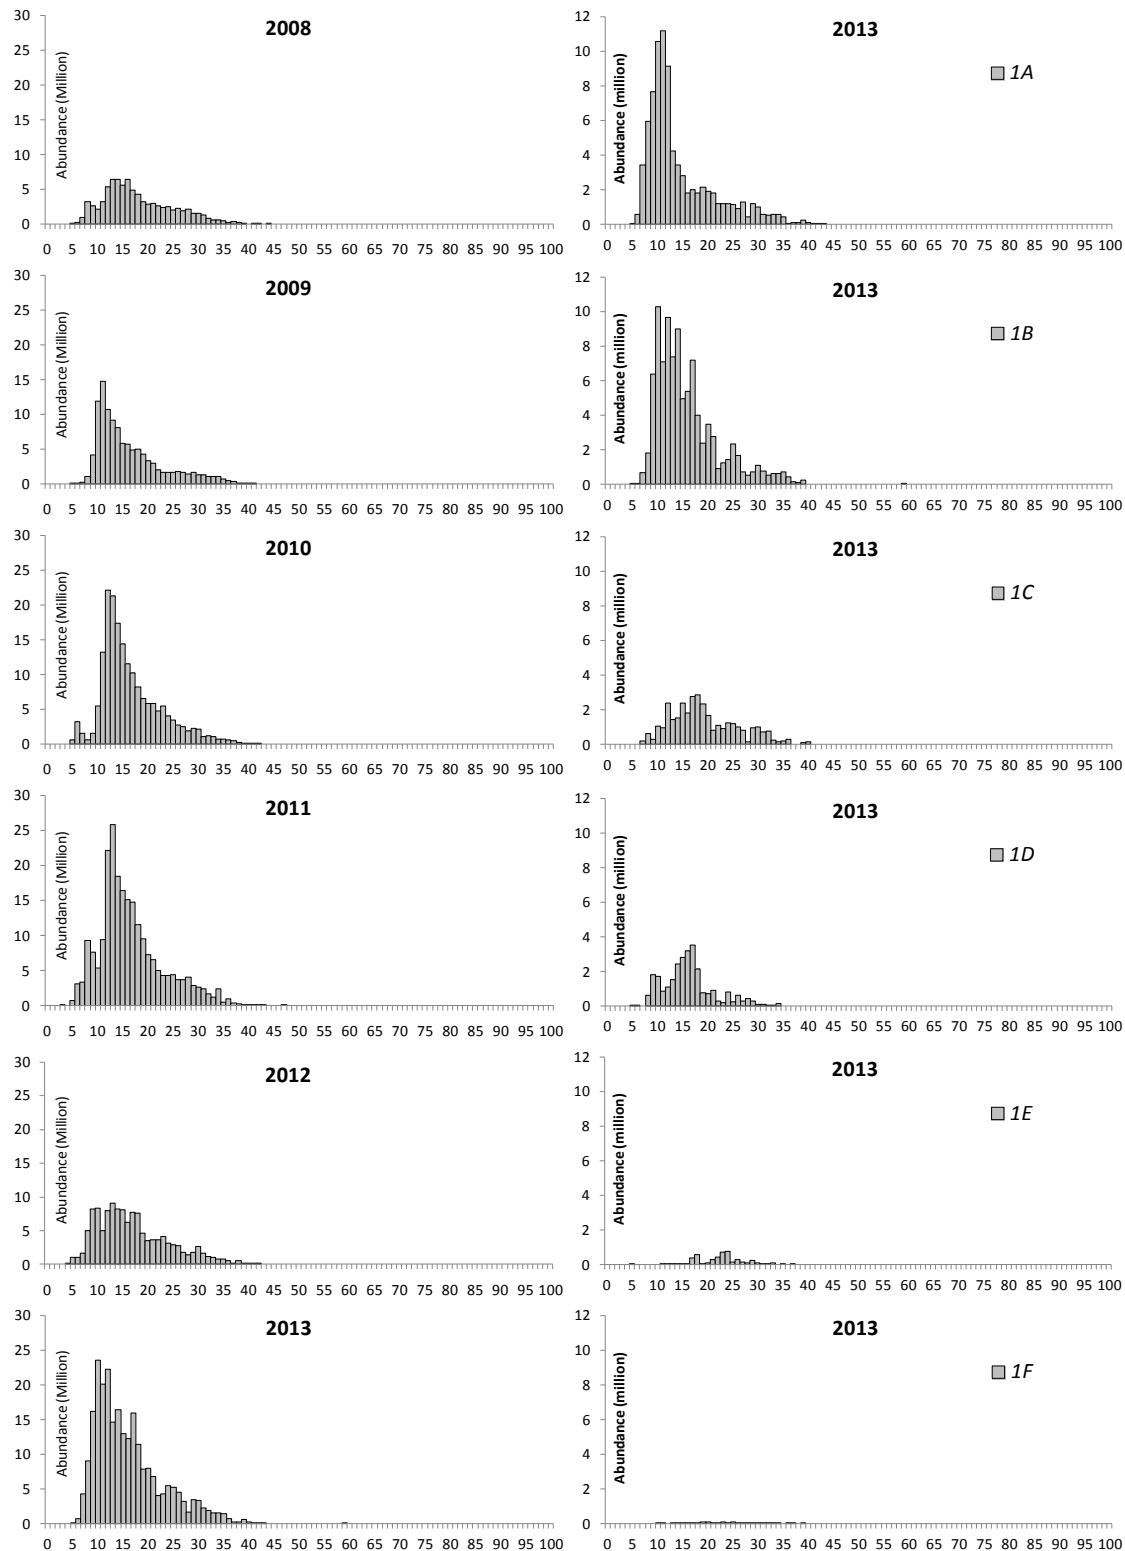

Fig. 17. American place (*Hippoglossoides platessoides*). Length frequencies for West Greenland 2008-2013 (left) and length frequencies per division in 2013 (right).

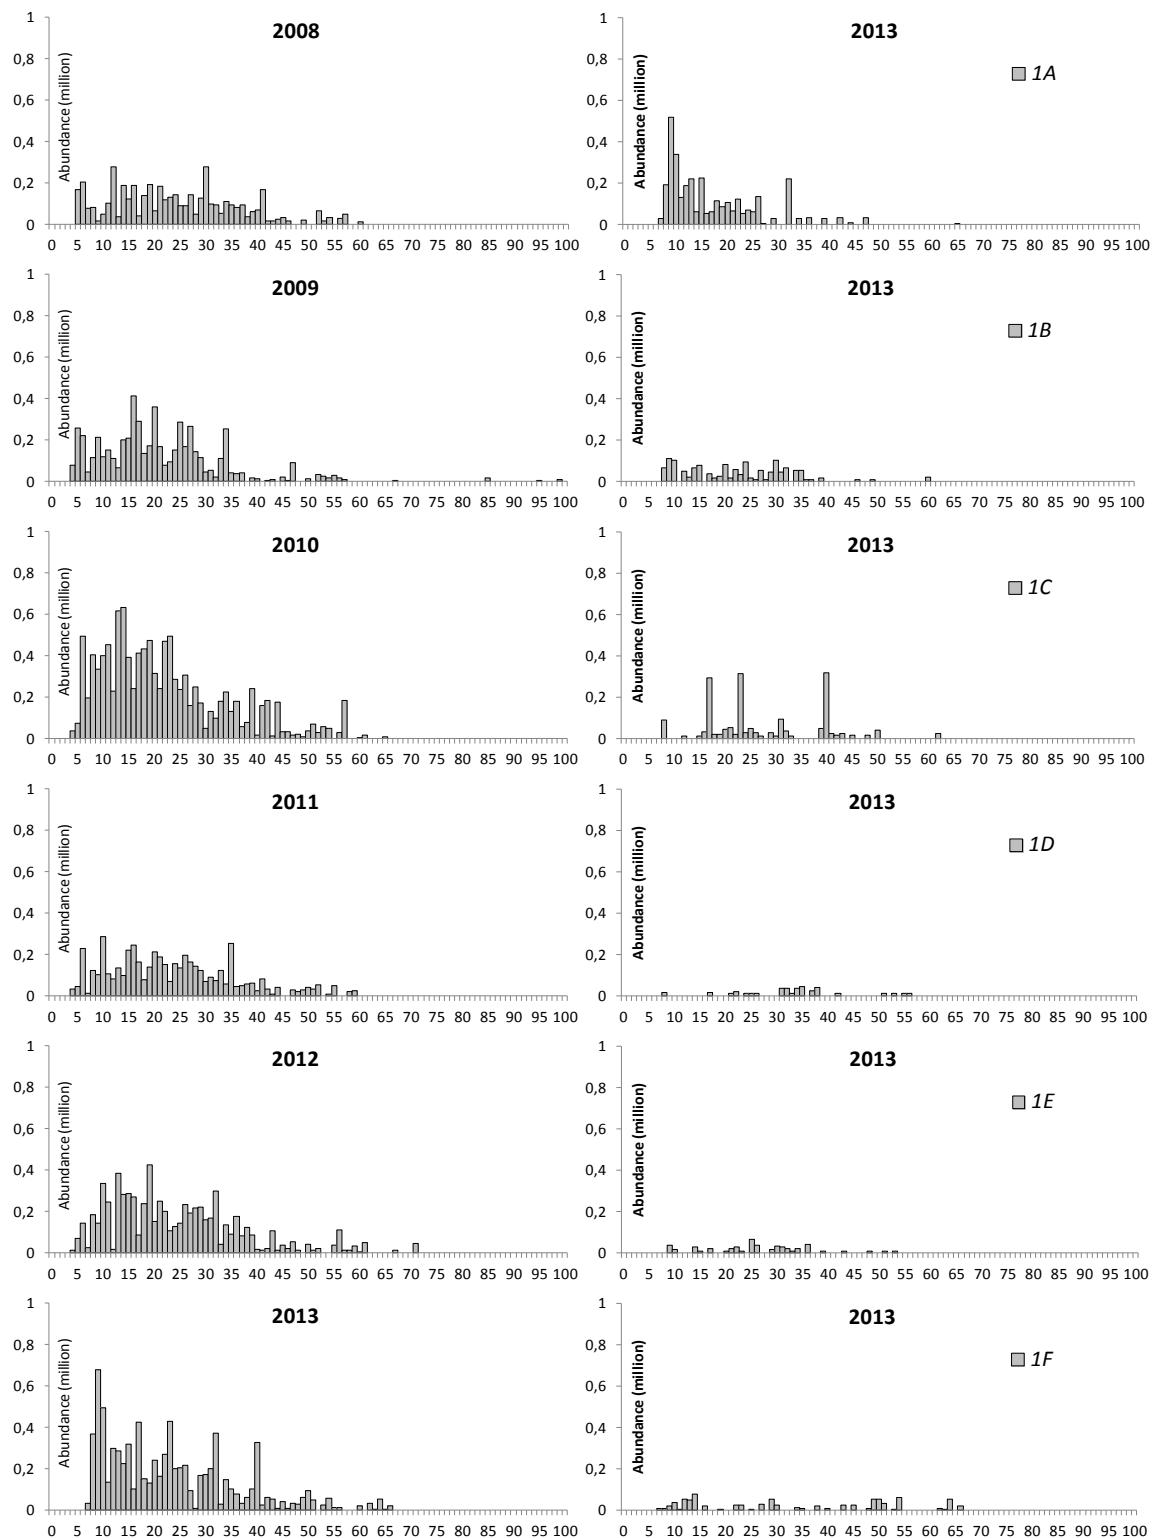

Fig. 18. Atlantic wolfish (*Anarhichas lupus*). Length frequencies for West Greenland by year (left) and length frequencies per division (right).

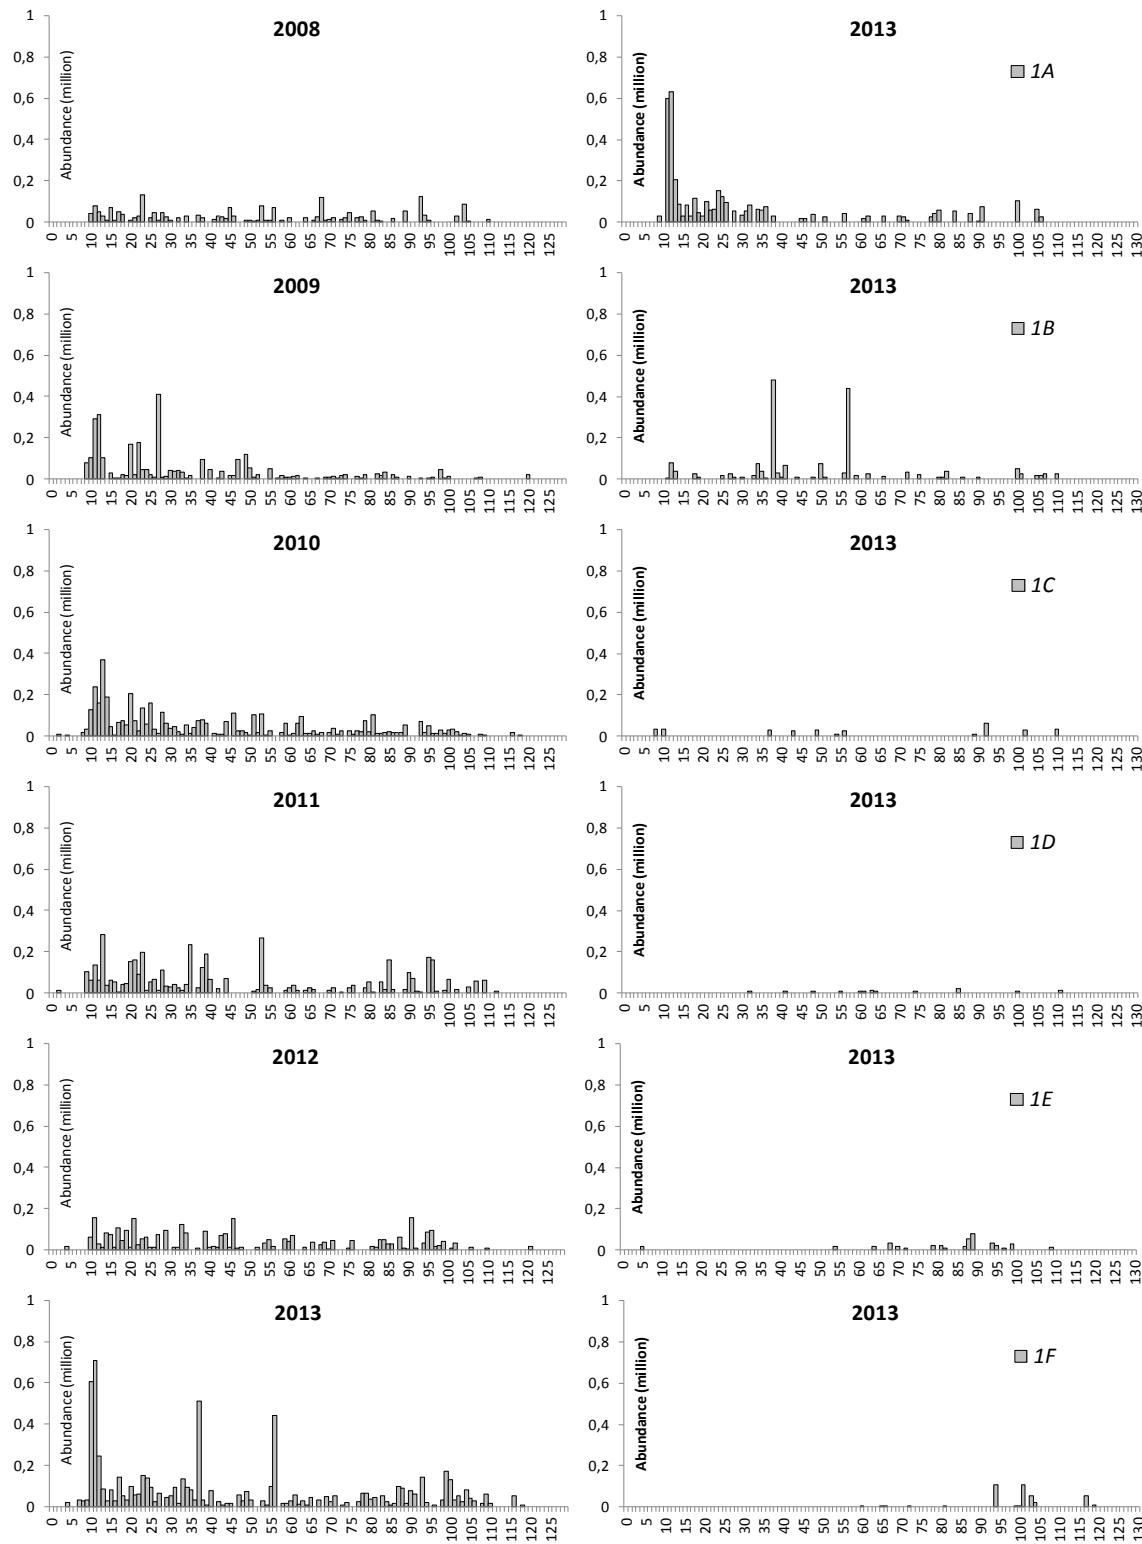

Fig. 19. Spotted wolfish (*Anarhichas lupus*). Length frequencies for West Greenland 2008-2013 (left) and length frequencies per division in 2013 (right).

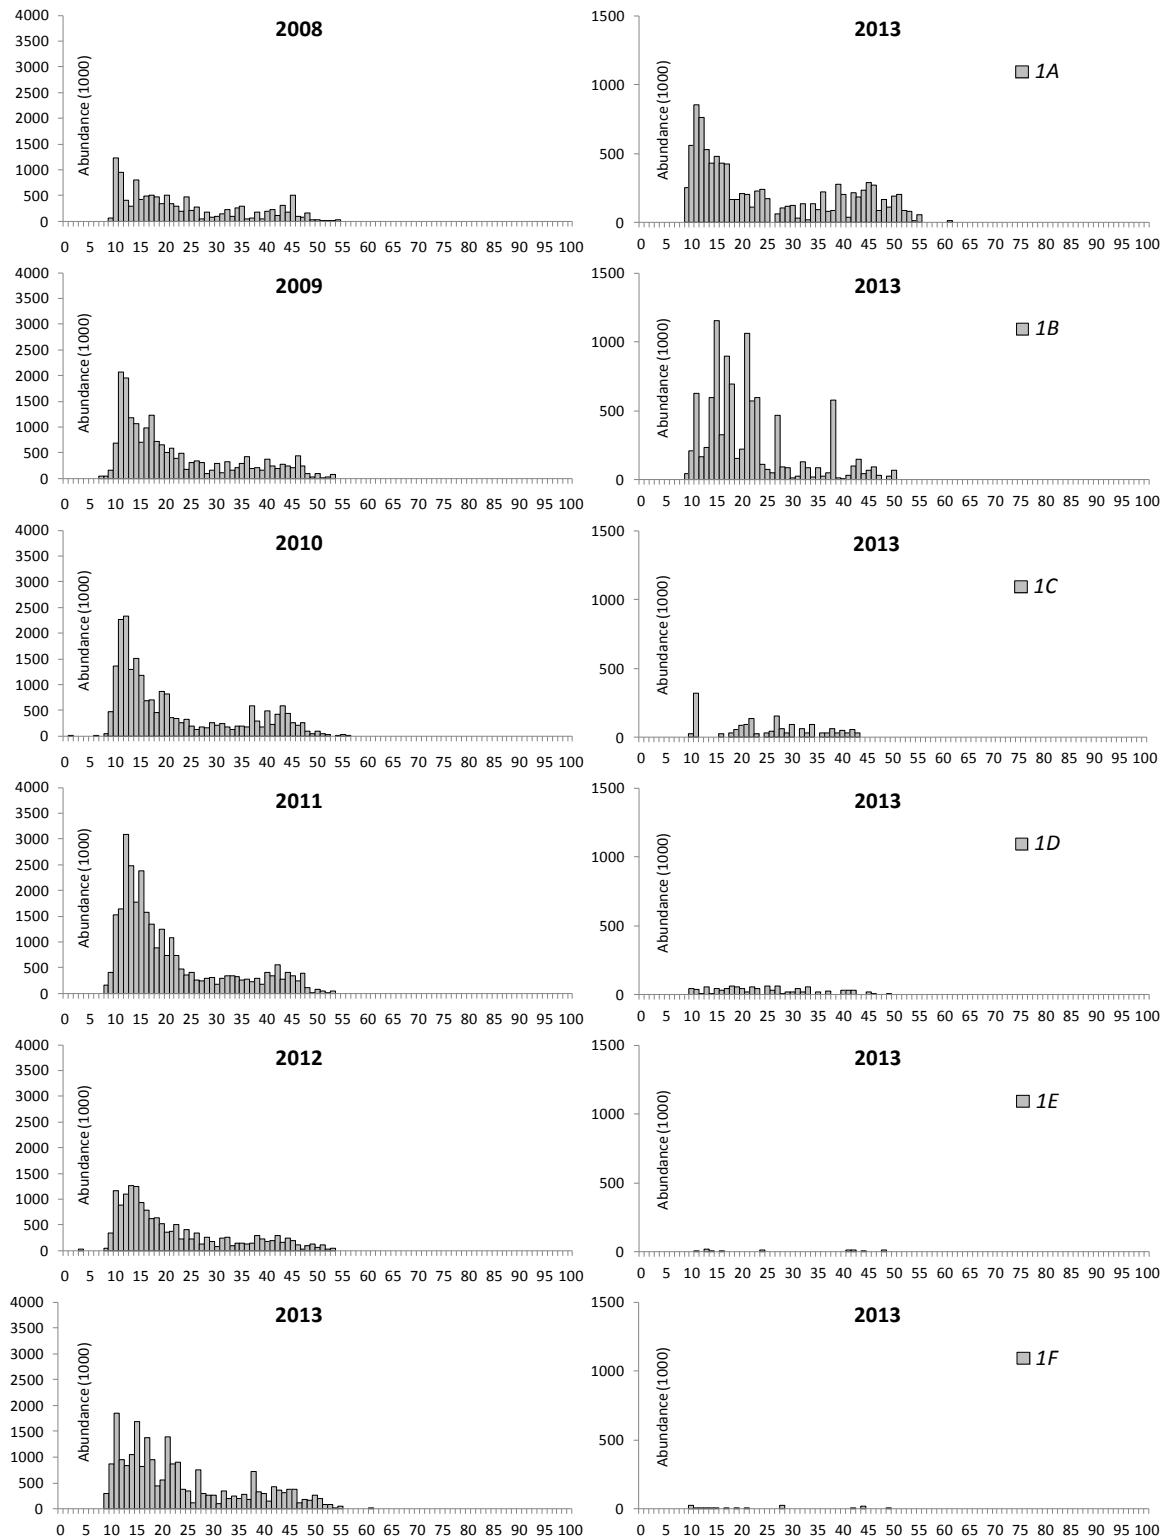

Fig. 20. Thorny skate (*Amblyraja radiata*) length frequencies for West Greenland 2008-2013 (left) and length frequencies per division in 2013 (right).
