1 **“Imagine if I gave up smoking ...”: A qualitative exploration of Aboriginal**  
2 **participants’ perspectives of a self-management pilot training intervention**

3  
4 ***Abstract***

5 This paper reports on a pilot qualitative study investigating Aboriginal participants’  
6 perspectives of the Flinders Living Well Smoke Free (LWSF) “training intervention”.  
7 Health workers nationally have been trained in this program, which offers a self-  
8 management approach to reducing smoking among Aboriginal clients. A component of the  
9 training involves Aboriginal clients volunteering their time in a mock care planning  
10 session providing the health workers with an opportunity to practise their newly acquired  
11 skills. During this simulation the volunteer clients receive one condensed session of the  
12 LWSF intervention imitating how the training will be implemented when the health  
13 workers have completed the training.

14 For the purpose of this study ten Aboriginal clients who had been volunteers in the mock  
15 care planning process, underwent a semi-structured interview at seven sites in Australia,  
16 including mainstream health services, Aboriginal Medical Services and remote Aboriginal  
17 communities. The study aimed to gauge their perspectives of the training intervention they  
18 experienced. Early indications suggest that Aboriginal volunteer clients responded  
19 positively to the process, with many reporting substantial health behaviour change or plans  
20 to make changes since taking part in this mock care planning exercise. Enablers of the  
21 intervention are discussed along with factors to be considered in the training program.

24 **What is known about the topic?**

- 25 • There is a paucity of research evaluating intervention programs and accompanying resources  
26 aimed at training health workers to support their Aboriginal clients to reduce smoking.

27

28 **What does this paper add?**

- 29 • This paper provides preliminary evidence that volunteer clients exposed to one condensed session  
30 of the Flinders LWSF program are positively predisposed to the intervention process.

44 ***Introduction***

45 It is widely accepted that the health status of Aboriginal people is significantly poorer than  
46 that of non-Aboriginal people, with smoking being the single most preventable cause of ill  
47 health and death (Australian Institute of Health and Welfare, 2008) in the latter group.

48 There has been a substantial reduction in daily smoking rates in the overall Australian  
49 population between 2001 and 2013: non-Aboriginal rates reducing from 24% to 16% and  
50 Aboriginal rates reducing from 51% to 41% (Australian Bureau of Statistics, 2013).

51 However, smoking rates still remain unacceptably high for Aboriginal people, with  
52 research reporting rates of up to 82% in particular communities (Robertson et al., 2013).

53 Despite recent promising signs that Aboriginal smoking rates are declining, it will be a  
54 number of years before the damage caused by smoking dissipates.

55 Despite the disproportionately high burden of smoking related harm endured by  
56 Aboriginal people, there is a notable lack of Indigenous-specific intervention programs  
57 (Ivers, 2003, Power et al., 2009) and accompanying resources (Clifford, 2010) aimed at  
58 addressing this harm. Furthermore, it is now estimated that around 75 per cent of  
59 Aboriginal smokers are thought to be trying to quit or are contemplating quitting (Clough  
60 et al., 2009) and therefore smoking intervention programs are well positioned to build up  
61 on this existing motivation for change.

62 In response to the alarmingly high rates of smoking, the Australian government announced  
63 its Indigenous Chronic Disease Package in late 2008, which included the Tackling  
64 Indigenous Smoking initiative. This has seen the roll out of Tobacco Action Workers  
65 Program nationally with Tobacco Action Workers working with Indigenous communities  
66 to reduce current smoking rates and discourage the uptake of smoking (Calma, 2011).

67 Additionally, the National Preventative Health Strategy for Tobacco suggests that tobacco

68 support should not be limited to tobacco-specific workers but extended to all health  
69 professionals in Indigenous health settings, such as nurses and Aboriginal Health Workers,  
70 to maximise the extent of influence on the Indigenous population in regards to a critical  
71 health (National Preventative Health Taskforce, 2008).

72 The Flinders Program (FP), originally based on the Coordinated Care Trials conducted  
73 between 1997-2001, teaches health practitioners the principles of self-management and  
74 motivational enhancement through semi-structured Socratic questioning to address chronic  
75 conditions and encourage behaviour change with their clients. The FP consists of care  
76 planning, coordination and coaching. The FP tools (Partners in Health scale, Cue and  
77 Response interview and Problems and Goals assessment), which underpin these skills, are  
78 based on seven principles of self-management. They guide a shared assessment between  
79 the client and health worker of the client's self-management, which results in a client  
80 centred care plan with goals and priorities determined by the client. The FP has been  
81 successfully applied to a variety of settings including substance abuse issues within  
82 Vietnam Veterans (Battersby et al., 2013), mental health (Lawn et al., 2007), diabetes in  
83 rural Aboriginal populations (Battersby et al., 2008), chronic lung disease and heart  
84 disease (Rowett, 2005) and osteoarthritis (Crotty et al., 2009). The FP has been trialled in  
85 Aboriginal communities, specifically Port Lincoln Aboriginal Medical Services and  
86 Aboriginal Health Council South Australia, through partnerships spanning 20 years (Ah  
87 Kit et al., 2003, , Harvey and McDonald, 2003, Harvey et al., 2008, Harvey, 2009, Harvey  
88 et al., 2013, Battersby et al., 2008). More recently the program was adapted with  
89 Aboriginal and Torres Strait Islander members of the National Advisory group to create  
90 the Flinders Closing the Gap Program™ (FCTGP) of Chronic Condition Management.  
91 This program is funded through the Commonwealth 'Closing the Gap: Helping Indigenous  
92 Australians Self-Manage their Chronic Disease' Program as a measure within the Council

93 of Australian Governments' (COAG) National Partnership Agreement on Closing the Gap  
94 in Indigenous Health Outcomes. FCTGP has been extended to include a specific module  
95 aimed at tackling the high rates of smoking within the Indigenous population, namely the  
96 Living Well, Smoke Free (LWSF) program. Health practitioners are provided 1-2 days  
97 training, dependent on their knowledge about smoking cessation and self-management,  
98 along with culturally-adapted resources and ongoing support with implementing the  
99 program within their practice. The training and resources were developed by Flinders  
100 Human Behaviour Health Research Unit (FHBHRU).

101 A key learning component of the current training program involves trialling the tools with  
102 volunteer clients in a mock care planning session providing the health workers with an  
103 opportunity to practise their newly acquired skills. During this simulation the volunteer  
104 clients, recruited from the health services, receive one condensed session of the LWSF  
105 intervention imitating how the training will be implemented, which in this paper is  
106 referred to as “training intervention”. It was an expectation that the “volunteer clients”  
107 would continue the process within their health service following the training intervention.  
108 When the program is implemented as intended, it is anticipated that clients will attend  
109 approximately 6-8 sessions with their health worker. Clients work through a series of  
110 exercises, such as “Conversation About Tobacco” and “Weighing It Up” (based on the  
111 Partners In Health scale and the Cue and Response interview) where they are asked open  
112 questions designed to resolve ambivalence in relation to their smoking and recognise areas  
113 where they require support. A further exercise, the My Tobacco Journey (based on the  
114 Problems and Goals assessment), is designed to capture the client’s main worry, and  
115 document how this impacts on their life. This process provides an opportunity for clients  
116 to set a specific goal that they wish to achieve in relation to their health.

117 The current project aimed to explore the experiences of the people who volunteered as  
118 clients for the training intervention and examine their thoughts and perceptions of the tools  
119 and the approach adopted by their health practitioner in relation to making changes to their  
120 tobacco smoking.

121

## 122 *Method*

123 Participating health services involved in the current research included mainstream health  
124 services, Aboriginal Medical Services and remote Aboriginal communities (seven sites in  
125 total from Victoria, Western Australia, South Australia and New South Wales). Workers  
126 (nurses and Aboriginal Health Practitioners) being trained in the LWSF program were  
127 asked to inform their clients who smoked about the training, provide information sheets  
128 and forward the details of interested clients to the trainers. Following the training, the  
129 researchers informed the volunteers about the research indicating that it would provide  
130 them an opportunity to offer feedback on the training resources and process. If they had  
131 time and interest they took part in an interview with the researcher. In total interviews  
132 were conducted with 10 participants (male,  $n=5$ ; female,  $n=5$ ), all of whom were  
133 Aboriginal and current smokers making up a sample of the volunteers who took part in the  
134 training. All interviewees provided their informed consent by way of a signing a consent  
135 form, which was read and explained to them, and received \$40 gift voucher in  
136 appreciation of their time and contribution. No-one refused to be interviewed or to have  
137 their interview recorded and no-one withdrew their involvement during or following the  
138 interview.

139 Interviews were conducted face-to-face at the participating health services or at a  
140 convenient location where requested. Most were conducted one-to-one with the exception

141 of one interview where two researchers were present and one where two participants were  
142 present. Both female interviewers were employed as researchers by Flinders University. A  
143 qualitative interview guide was developed to explore: current smoking attitudes and  
144 behaviour, what worked/did not work well in the training intervention, the level of client  
145 involvement developing their care plan, how culturally appropriate the intervention was,  
146 and general comments on barriers and enablers to smoking interventions being  
147 implemented. This interview guide was followed loosely based on broad open ended  
148 questions to allow the participant to guide the interview. The researchers attended the  
149 Flinders training in order to build rapport with participants and make them feel more  
150 comfortable about taking part in the investigation but were not involved in the delivery of  
151 the training.

152 Ethics approval for the study was received from the Aboriginal Health Research Ethics  
153 Committee in South Australia, Social and Behavioural Research Ethics Committee,  
154 Mildura Base Hospital Human Research Ethics Committee (HREC), Western Australia  
155 Aboriginal Health Ethics Committee, Gold Coast Hospital and Health Service HREC and  
156 the Department of Health and Ageing Ethics Committee. Letters of support were provided  
157 by the management of the health services involved. Flinders University also contracted an  
158 Aboriginal Research Consultant who provided culturally specific advice and support  
159 throughout the project.

160

### 161 *Data Analysis*

162 Interviews were conducted between July and December 2013, lasted on average 30 minute  
163 and were audio recorded and transcribed verbatim.

164 Thematic analysis was used to analyse the entire data set rather than each open ended  
165 question individually in order to gain an accurate reflection of commonalities across the  
166 whole data. Braun and Clarke (2006) suggest this is an appropriate approach to take when  
167 exploring an under-researched area or when working with participants whose views on the  
168 topic are unknown. The researcher followed the guidelines suggested by Braun and Clarke  
169 (2006) and therefore, initially, the researcher familiarised themselves with the data by  
170 reading and re-reading the transcribed interviews. The researcher then developed initial  
171 codes representing interesting features of the data in a systematic fashion (line-by-line).  
172 Initial codes were then used to create early themes, reflecting the entire data set. Themes  
173 were then refined and named, which required ongoing analysis. The researchers (KC and  
174 IK) met frequently to discuss themes and agreement was achieved in all cases, with only  
175 minor discrepancies occurring regarding the name of the theme, which were resolved  
176 easily through discussion. The report was then produced using participants' own words,  
177 which accurately and succinctly reflected the description of each theme, and whilst  
178 frequency was not regarded as a precipitating factor to a theme, we attempted to reflect the  
179 extent to which the theme was common across the participant responses. We took a  
180 semantic approach to the data, which attempts to create themes based purely on what the  
181 participants reported. This inductive approach led the researchers to create themes that  
182 were strongly linked to the data. The process was a recursive one, whereby the researcher  
183 moved back and forth between the data and the data analysis. Themes were documented in  
184 a table on Microsoft Word document. Creation of themes was guided by the question:  
185 what aspects of the training and resources are acting as barriers and enablers to the  
186 participants making changes to their smoking behaviour?

187

188 ***Results***

189 Analysis of the interviews revealed client perspectives, including barriers and enablers of  
190 the LWSF self-management program based on volunteer clients receiving one mock care  
191 planning session. This training intervention was an imitation of how the program will be  
192 implemented in a health care setting in future. Volunteer clients discussed their improved  
193 motivation to change following the training intervention, along with other enablers of the  
194 program (support, knowledge and culturally appropriate resources). Other themes emerged  
195 (culture, complex lives and nicotine addiction), which were discussed generally as barriers  
196 against implementation of the current self-management program.

197

198 *Motivation to Change:*

199 Although volunteers only received one condensed session of the program, all participants  
200 appeared to make a positive shift in their attitudes regarding their health in general or  
201 specific smoking behaviour change. It is not known whether this was as a result of the  
202 training intervention, although many participants indicated that the intervention directly  
203 encouraged deeper consideration of behaviour change.

204 *“I’ve always thought how am I going to do this? I’ve always thought about it but the*  
205 *opportunity never arose and I see this as an opportunity to do that”.* (Participant 3)

206 *“Before coming here, I did have thoughts about stop smoking and how it’s affecting*  
207 *people and myself...but today made me think a little bit more I guess and maybe I’ll go*  
208 *home tonight and think more intensely and...I might make the first step to do a plan or...to*  
209 *stop smoking.”* (Participant 4)

210 Although some participants admitted that the training intervention felt repetitive and could  
211 be a little confusing, generally the exercise appeared to allow participants to progress

212 within the Stages of Change (Prochaska and DiClemente, 1983), for example moving from  
213 pre-contemplation to contemplation.

214

215 *Support:*

216 The majority of participants identified the importance of support when changing  
217 behaviour, an important component of the current training intervention. Many participants  
218 had been referred to support groups after completing the training intervention. One  
219 particular participant went on to set up a smoking support group following the training  
220 intervention and many of the participants recognised the importance of having support  
221 while going through the training intervention:

222 *“It’s the person that’s there sitting with you...is trying to get a better idea of what your*  
223 *status is on the smoking level...looking at it...and talking back and forth...it gives yourself*  
224 *and that person a better understanding of where you are with it”*. (Participant 5)

225 Participants emphasised the need for building a trusting relationship with the worker  
226 before revealing confidential and personal information, with an ex-smoker often being  
227 identified as the most appropriate person to support their attempts to quit smoking.

228 Participants recognised that the training intervention made them feel listened to, involved  
229 in their care and their thoughts were acknowledged.

230

231 *Increased knowledge:*

232 A significant part of the training intervention is providing participants with knowledge  
233 around the impacts of smoking. Participants revealed that having more knowledge about  
234 smoking and how it impacts on health, made them more likely to quit smoking:

235 *“If I understand what’s going on in my body maybe I can help myself”*. (Participant 2)

236 Another participant admitted they were “blown away” by the information they received  
237 during the training intervention regarding oxygen levels and the impact this has on their  
238 health:

239 *“...because I snore really bad, and that’s associated obviously with the lack of oxygen so  
240 it’s made me really...scared, like, but in a good way, like I know I need to give up.”*

241 (Participant 9)

242

243 *Culture:*

244 Most participants found the training intervention and resources to be culturally appropriate  
245 and easy to use. Furthermore, many of the participants advocated for the intervention to be  
246 delivered in an Aboriginal Health Service where the workers have more empathy and  
247 understanding of their cultural requirements. However, it was also proposed that  
248 Aboriginal people’s distrust of non-Aboriginal people prevents them from initiating,  
249 accepting and receiving appropriate healthcare. One participant proposed that Aboriginal  
250 people and non-Aboriginal people need to learn from one another:

251 *“It’s the coming together and accepting how we’re going to accept each other...properly,  
252 honestly...somebody out bush can only give you so much information. Somebody in town  
253 can give you so much information. But together they can work...”* (Participant 5)

254 Finally, due to the sensitivity of the issues Aboriginal people faced surrounding the  
255 “Stolen Generation” it was suggested that some clients may have been reluctant to admit  
256 to their “main worry”, a question asked of them during the training intervention. Some of  
257 the participants interviewed admitted that they were reluctant to talk about their main  
258 problem, which was related to mental health issues surrounding their past. Many  
259 participants questioned how appropriately qualified the Aboriginal Health Worker was to  
260 help them, and also raised concerns about confidentiality.

261

262 *Complex Lives:*

263 An issue that was raised in all participant interviews was the complexity of people’s lives.  
264 Many were suffering with complex mental and physical health issues, such as depression,  
265 gambling addiction, schizophrenia, emphysema and sleep apnoea. Amongst the  
266 communities visited numerous other health related issues were identified, including  
267 homelessness, domestic violence, drug and alcohol abuse, grief and loss, a lack of  
268 meaningful activity and a loss of personal identity. Many participants admitted that  
269 smoking was not a priority:

270 *“Oh it relaxes me, and especially with this emphysema...I’ll have a smoke and then I’ll*  
271 *start coughing something shocking...it helps me in a way, yeah it gives me a benefit*  
272 *because I can breathe a lot better”. (Participant 2)*

273 Despite such complex issues being faced, all participants interviewed appeared to make a  
274 positive shift in their thought processes or behaviour in relation to their smoking following  
275 the training intervention.

276 After successfully tackling many mental and physical health problems, one participant  
277 perceived quitting smoking as the last hurdle:

278 *“Imagine if I gave up smoking, I’d be doing a marathon run!”* (Participant 1)

279

280 *Addiction:*

281 A major barrier to tackling smoking raised by all participants was the difficulty of quitting  
282 smoking. Participants provided many reasons why they continue to smoke, such as  
283 boredom, having a partner who smokes, smoking being part of their lifestyle, dealing with  
284 anxiety and stress, having finances available to purchase cigarettes and having to go  
285 through withdrawal, with all participants making previous quit attempts. All of the  
286 participants interviewed had been smoking for several decades; the majority of  
287 participants smoking since they were teenagers.

288 However, during the training intervention, participants were able to identify reasons to  
289 quit smoking; whether this was as a direct result of the training intervention is unclear. It  
290 also appeared that the training intervention played some role in resolving the ambivalence  
291 that the participants were facing around their smoking and helped some develop a quit  
292 smoking plan. One participant revealed that the training intervention made the challenge  
293 of quitting seem more manageable:

294 *“From all those questions it made me think, okay, I’m not so bad, like, I can, you know, I  
295 can make change”.* (Participant 9)

296

297 *Discussion*

298 There is a paucity of research investigating Indigenous health intervention programs  
299 (Ivers, 2003, Power et al., 2009) comprising complementary resources (Clifford, 2010).  
300 The Flinders LWSF intervention and training is in its infancy and this small but important  
301 analysis of the participant experiences of the training intervention suggests that despite  
302 many barriers, the Aboriginal participants we spoke to responded positively to the training  
303 intervention. Many of the respondents appeared to progress through the Stages of Change,  
304 some from pre-contemplation to contemplation, others from contemplation to action  
305 (Prochaska and DiClemente, 1983) in relation to their smoking behaviour. Furthermore,  
306 participants revealed that they were able to consider the barriers to change and proceed to  
307 formulate plans to achieve their goals. Whether this was as a result of the intervention  
308 remains unclear and requires further investigation. Nevertheless, follow-up telephone calls  
309 to a sample of the participants (n = 3) revealed that individuals had adhered to their  
310 commitments made during the training intervention. This was an unexpected outcome  
311 because the participants had only received a condensed version of the intended  
312 intervention, which would normally be 6-8 sessions involving more in-depth discussion  
313 and care planning. This important revelation provides a promising indication that the  
314 intervention can be used by health workers to support their Aboriginal clients who want to  
315 address their smoking.

316 Our study had several limitations. Researchers were time restricted, reflecting funding  
317 limitations, and therefore, only a small sample of participants was interviewed. Also, the  
318 health workers trained in the LWSF intervention all had varied backgrounds, some already  
319 possessing a strong understanding of concepts such as motivational interviewing and self-  
320 management while others had little or no understanding prior to the current training.  
321 Finally, it is assumed that the participants had volunteered to support the training because  
322 they already had an interest in addressing their smoking behaviour, and therefore the

323 current sample may be biased (Neuman, 2005). The present paper therefore demonstrates  
324 early indications of volunteer client experiences of the training intervention, which has the  
325 potential to impact positively on the large number of Aboriginal people that have been  
326 identified as motivated to quit smoking (Clough et al., 2009). Further data is required to  
327 examine client perspectives after they have received the full intervention over 6-8  
328 sessions, which includes care planning and follow up with their health worker.

329

### 330 *Implications and Conclusion*

331 This was a preliminary exploration on the perspectives of volunteers who received a mock  
332 care planning session based on a self-management approach to quitting smoking. These  
333 early positive indicators have potentially important implications for the methods that  
334 health care workers might employ to support Aboriginal smokers to manage their smoking  
335 behaviour. For instance, the worker who is responsible for delivering the LWSF program  
336 to their Aboriginal smoking clients will need to consider their clients' current  
337 circumstances, noting that although their complex lives may act as a barrier to change, it is  
338 still possible to move through the stages of change using the LWSF intervention. It may  
339 also be worth considering advising their clients to consider medication or nicotine  
340 replacement therapy to manage the physical component to reducing or quitting smoking  
341 whilst their clients complete the LWSF program. These are important considerations for  
342 any Aboriginal specific tobacco intervention programs and given the limited research in  
343 this area further research is required to evaluate the LWSF program, or a similar  
344 intervention, on a larger scale.

345

346 In conclusion, the LWSF program offers a potentially effective intervention that targets  
347 smoking among Aboriginal people. The current paper describes a pilot intervention  
348 program and perceptions of volunteer client and therefore further research is required.  
349 Health practitioners should consider the barriers and enablers of the LWSF program prior  
350 to implementation. Further research could also explore the perceptions of the workers  
351 delivering the program in order to investigate the barriers and enablers of implementing  
352 such an intervention in their workplace.

353

### 354 *Acknowledgements*

355 We wish to acknowledge the Department of Health and Ageing for funding the Flinders  
356 “Closing The Gap” Program and also thank the National Advisory Group for their  
357 contributions to the development of the resources. We also wish to extend our appreciation  
358 to the health services and clients who agreed to take part in the evaluation.
