

# The Efficient Computation of Bounds for Functionals of Finite Element Solutions in Large Strain Elasticity

J. Bonet , A. Huerta and J. Peraire

**Abstract**— We present an implicit a-posteriori finite element procedure to compute bounds for functional outputs of finite element solutions in large strain elasticity. The method proposed relies on the existence of a potential energy functional whose local minima, over a space of suitably chosen continuous functions, corresponds to the problem solution. The output of interest is cast as a constrained minimization problem over an enlarged discontinuous finite element space. A Lagrangian is formed where the multipliers are an adjoint solution, which enforces equilibrium, and hybrid fluxes, which constrain the solution to be continuous. By computing approximate values for the multipliers on a coarse mesh, strict upper and lower bounds for the output of interest on a suitably refined mesh, are obtained. This requires a minimization over a discontinuous space, which can be carried out locally at low cost. The computed bounds are uniformly valid regardless of the size of the underlying coarse discretization. The method is demonstrated with two applications involving large strain plane stress incompressible neo-hookean hyperelasticity.

## I. INTRODUCTION

Engineering applications require the prediction of certain quantities of interest, or outputs – such as compliance, stresses, flow rates, heat transfer. These outputs are functionals of field variables – such as displacement, velocity or, temperature – which, in turn, are solutions of partial differential equations that need to be approximated numerically. Engineering decisions are thus based on approximations to the desired outputs that are generated from computed approximations to the field variables. It is often difficult to determine a-priori the size of the discretization that would yield the outputs at a required level of accuracy. In fact, it is well known that for a given field solution, different outputs can be predicted at varying levels of accuracy. The situation is further complicated in a real design, or optimization, setting where one may require multiple appeals to the PDE solver to evaluate solutions for different values of the design parameters. In this case, using a conservative fine discretization for every solution, in an attempt to guarantee a prescribed accuracy, may prove prohibitive.

In this paper, we consider the non-linear equations describing the large strain deformation of a hyperelastic material. We propose a finite element a-posteriori method to compute inexpensive upper and lower bounds for engineering outputs of in-

terest. The proposed method requires the solution of non-linear local Neumann sub-problems and is therefore referred to as an implicit method [2]. When compared to the simpler less expensive a-posteriori explicit methods, which only require residual evaluations (e.g. [3]), implicit methods offer the potential for quantitative constant-free bounds. The original implicit methods [8], [1], [4] were developed, for linear self-adjoint problems, to provide bounds for the energy norm of the error. In reality however, it is not the error in the energy norm which is of interest, but the error in the quantities on which an engineering decision will be based – for instance deflection or stress. The first attempts at developing a-posteriori error estimation for functional outputs were carried out in the context of explicit error estimation [5]. It turns out that the error in the quantities of interest can be related to a weighted norm of the residual where the specific weights are determined by the solution of an adjoint problem. Unfortunately, the explicit nature of the procedure means that these estimates contain unknown constants, which severely limit its quantitative value.

The development of an implicit procedure yielding a-posteriori constant-free bounds for linear-functional outputs of partial differential equations was presented in [10], [11], [12]. The method is applicable to elliptic coercive problems including non-symmetric terms. The approach is based on a finite element domain decomposition technique and the construction of an augmented Lagrangian, in which the objective is a “quadratic” energy re-formulation of the desired output, and the constraints are the finite element equilibrium equations and inter-subdomain continuity requirements. Bounds for the output, on a suitably refined “truth” mesh, are then obtained by appealing to a dual min-max relaxation, evaluated for lagrange multipliers computed on a coarse “working” mesh. One attractive feature of this approach is its natural extension to non-linear problems and outputs. Previous a-posteriori error estimation methods for non-linear partial differential equations, are based on a linearized problem, and hence, only provide meaningful estimates once the computed solution is in the asymptotic convergence range. The proposed approach, on the other hand, is formulated directly in the non-linear context. Although the bounds are uniformly valid, they are found to converge to the true output at the optimal rate when the asymptotic regime is reached. To our knowledge, this is the first time that a procedure that yields a-posteriori strict bounds for outputs of engineering interest, in the context of large strain fully non-linear hyperelastic materials, has been proposed. The procedure is illustrated

J. Bonet is a Professor in the Department of Civil Engineering, University of Wales Swansea, Swansea SA2 8PP, UK

A. Huerta is a Professor in the Departamento de Matematica Aplicada III, Universitat Politecnica de Catalunya, 08034 Barcelona, Spain

J. Peraire is a Professor in the Department of Aeronautics and Astronautics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA

for a two dimensional, incompressible neo-hookean hyperelastic material under plane stress, but it is generally applicable to general three dimensional finite strain models.

The focus of this paper is on computing bounds, but the method presented provides naturally a local indicator that can be used to drive a mesh adaptive procedure as shown in [12].

The paper is organized as follows. First, we introduce the model problem and formulation that will be used as vehicle to illustrate our method. We describe the necessary preliminaries and present a bound procedure for the total potential energy. Next, we develop the extension to arbitrary functional outputs. We present numerical results for two examples commonly studied in the literature, and conclude with a discussion on the advantages and drawbacks of the proposed approach.

## II. PROBLEM FORMULATION

Consider the finite deformation of a 2D body under the action of a distributed traction on its boundary as illustrated in figure 1. Let  $\Omega$  represent the two dimensional domain corresponding to the undeformed configuration, and  $\mathbf{X} = (X_1, X_2) \in \Omega$ , denote the material coordinates of a given point. The boundary of  $\Omega$  is denoted by  $\Gamma = \overline{\Gamma_D^1} \cup \overline{\Gamma_N^1} = \overline{\Gamma_D^2} \cup \overline{\Gamma_N^2}$ . Here,  $\Gamma_D^i, i = 1, 2$  is the portion of the boundary where the motion in the  $i$ -th direction is prescribed to be  $g_i$ , whereas  $\Gamma_N^i, i = 1, 2$  is the portion of the boundary where the  $i$ -th component of the traction,  $\mathbf{t} = (t_1, t_2)$ , per unit of undeformed length and thickness,  $t_i$ , is specified.

A motion is described by a mapping  $\mathbf{x} = \varphi(\mathbf{X}) \in \Omega'$ , which gives the final position,  $\mathbf{x}$ , of any material particle  $\mathbf{X}$ . We define the space of allowable motions,  $\mathcal{X}$ , as the subset of functions in  $(H^1(\Omega))^2$  satisfying the prescribed boundary conditions. We also identify the space of variations,  $\mathcal{V}$ , as the tangent space to  $\mathcal{X}$  [9]. Thus,

$$\mathcal{X} = \{\varphi = (\varphi_1, \varphi_2) \in (H^1(\Omega))^2 \mid \varphi_i|_{\Gamma_D^i} = g_i \text{ for } i = 1, 2\}, \quad (1)$$

$$\mathcal{V} = \{\mathbf{v} = (v_1, v_2) \in (H^1(\Omega))^2 \mid v_i|_{\Gamma_D^i} = 0 \text{ for } i = 1, 2\}. \quad (2)$$

The body is considered to be sufficiently thin so that a constant strain can be assumed throughout its thickness. In this case, the plane stress incompressible neo-Hookean strain energy function per unit initial area,  $\psi$ , can be expressed, in terms of the deformation gradient tensor,  $\mathbf{F} = \partial\varphi/\partial\mathbf{X}$ , as [6]:

$$\psi(\mathbf{F}) = \frac{1}{2} \mu H(\mathbf{F} : \mathbf{F} + (\det \mathbf{F})^{-2} - 3), \quad (3)$$

where  $\mu$ , is the initial shear modulus and  $H$ , the initial thickness.

Finally, the total energy potential,  $\Pi : \mathcal{X} \rightarrow \mathbb{R}$ , is given by,

$$\Pi(\varphi) = \int_{\Omega} \psi(\mathbf{F}) d\Omega - \sum_{i=1}^2 \int_{\Gamma_N^i} t_i \varphi_i H dS. \quad (4)$$

Fig. 1. 2D body in plane stress

### A. Minimization Statement

The equilibrium configuration is given by the motion  $\phi \in \mathcal{X}$  that minimizes the total potential energy,

$$\Pi(\phi) = \inf_{\varphi \in \mathcal{X}} \Pi(\varphi). \quad (5)$$

We note that, in general,  $\Pi$  will not be convex and may have either none or multiple minima. This issue will be further discussed below, but, for current purposes, we shall assume that  $\Pi$  has a unique minimum.

Thus, if we define the residual  $R : \mathcal{V} \times \mathcal{X} \rightarrow \mathbb{R}$ , as

$$R(\mathbf{v}; \varphi) = \lim_{\epsilon \rightarrow 0} \frac{\Pi(\varphi + \epsilon \mathbf{v}) - \Pi(\varphi)}{\epsilon}, \quad (6)$$

a variational statement for the problem, expressing equilibrium, is given as: find  $\phi \in \mathcal{X}$  such that

$$R(\mathbf{v}; \phi) = 0, \quad \forall \mathbf{v} \in \mathcal{V}. \quad (7)$$

In most situations, we are not ultimately interested in  $\phi$ , but in specific outputs that depend on  $\phi$ . Such are, for instance, the motion of a point, or the average stress over a certain portion of the body. To this end, we introduce the output functional  $\mathcal{S}(\varphi) : \mathcal{X} \rightarrow \mathbb{R}$ , and express our output of interest,  $s$ , as

$$s = \mathcal{S}(\phi). \quad (8)$$

In principle,  $\mathcal{S}$  can be a non-linear functional as discussed later, although at present we have only applied the proposed technology to linear outputs.

We define, for future use the tangent form  $K : (\mathcal{V})^2 \times \mathcal{X} \rightarrow \mathbb{R}$ , as

$$K(\mathbf{v}_1, \mathbf{v}_2; \varphi) = \lim_{\epsilon \rightarrow 0} \frac{R(\mathbf{v}_2; \varphi + \epsilon \mathbf{v}_1) - R(\mathbf{v}_2; \varphi)}{\epsilon}, \quad (9)$$

and the Hessian form  $DK : (\mathcal{V})^3 \times \mathcal{X} \rightarrow \mathbb{R}$ , as

$$DK(\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3; \varphi) = \lim_{\epsilon \rightarrow 0} \frac{K(\mathbf{v}_2, \mathbf{v}_3; \varphi + \epsilon \mathbf{v}_1) - K(\mathbf{v}_2, \mathbf{v}_3; \varphi)}{\epsilon}. \quad (10)$$

We point out that, by construction, the form  $R$  is linear with respect to its first argument; and  $K$  and  $DK$  are linear and symmetric with respect to their two, and three, first arguments, respectively.

Fig. 2. Illustration of  $\mathcal{X}_H(\mathcal{V}_H)$ ,  $\mathcal{X}_h(\mathcal{V}_h)$ ,  $\hat{\mathcal{X}}_H(\hat{\mathcal{V}}_H)$ ,  $\hat{\mathcal{X}}_h(\hat{\mathcal{V}}_h)$ .

### III. FINITE ELEMENT SPACES

We consider two triangulations of the computational domain  $\Omega$ : a working or design  $H$ -mesh,  $\mathcal{T}_H$ , consisting of  $n_H$  elements,  $T_H$ ; and the fine  $h$ -mesh,  $\mathcal{T}_h$ , consisting of  $n_h$  elements  $T_h$ . We assume that  $\mathcal{T}_h$  can be obtained by uniform refinement of  $\mathcal{T}_H$ . To each of these meshes we associate piecewise linear continuous finite element subspaces,

$$\mathcal{X}_H = \{\varphi \in \mathcal{X} \mid \varphi|_{T_H} \in (\mathbf{P}_1(T_H))^2, \forall T_H \in \mathcal{T}_H\}, \quad (11)$$

$$\mathcal{X}_h = \{\varphi \in \mathcal{X} \mid \varphi|_{T_h} \in (\mathbf{P}_1(T_h))^2, \forall T_h \in \mathcal{T}_h\}, \quad (12)$$

where  $\mathbf{P}_1(T)$  denotes the space of linear polynomials over  $T$ . We have that, by construction,  $\mathcal{X}_H \subset \mathcal{X}_h \subset \mathcal{X}$ .

The algorithms to be presented require that our forms be expressed as sums of contributions over  $H$ -elements  $T_H$ . Towards this end, we introduce the “broken” spaces  $\hat{\mathcal{X}}_H$  and  $\hat{\mathcal{X}}_h$ ,

$$\hat{\mathcal{X}}_H = \{\varphi \in L_2(\Omega) \mid \varphi|_{T_H} \in (\mathbf{P}_1(T_H))^2, \forall T_H \in \mathcal{T}_H\}, \quad (13)$$

$$\hat{\mathcal{X}}_h = \{\varphi \in L_2(\Omega) \mid \varphi|_{T_h} \in \mathcal{Z}_h(T_h), \forall T_h \in \mathcal{T}_h\}. \quad (14)$$

Here,  $L_2(\Omega)$  is the space of square-integrable functions over  $\Omega$ , and  $\mathcal{Z}_h(T_h)$  is defined as

$$\mathcal{Z}_h(T_h) = \{\varphi \in (H^1(T_h))^2 \mid \varphi|_{T_h} \in (\mathbf{P}_1(T_h))^2, \forall T_h \in \mathcal{R}_{T_h}\}, \quad (15)$$

where  $\mathcal{R}_{T_h}$  denotes the set of  $h$ -elements contained in  $T_h$ . The above described meshes and associated spaces are illustrated in figure 2, for a simple square domain. It is apparent that, by construction,  $\mathcal{X}_H \subset \hat{\mathcal{X}}_H$ ,  $\mathcal{X}_h \subset \hat{\mathcal{X}}_h$ , and  $\hat{\mathcal{X}}_H \subset \hat{\mathcal{X}}_h$ .

We can also define the tangent finite element spaces  $\mathcal{V}_H$ ,  $\mathcal{V}_h$ ,  $\hat{\mathcal{V}}_H$  and  $\hat{\mathcal{V}}_h$  in an analogous manner.

Finally, the forms  $\Pi$ ,  $R$ ,  $K$ ,  $DK$  and  $S$ , are extended to accept discontinuous functions in the “broken” spaces by redefining these forms as a sum of  $H$ -element contributions. For instance,  $K$  is now written as

$$K(\mathbf{v}_1, \mathbf{v}_2; \varphi) = \sum_{T_H \in \mathcal{T}_H} K_{T_H}(\mathbf{v}_1|_{T_H}, \mathbf{v}_2|_{T_H}; \varphi|_{T_H}); \quad (16)$$

with similar expressions for  $\Pi$ ,  $R$ ,  $DK$  and  $S$ .

#### A. Continuity Form

Let  $\mathcal{E}(\mathcal{T}_H)$  (respectively,  $\mathcal{E}(\mathcal{T}_h)$ ) denote the set of open edges in the triangulation  $\mathcal{T}_H$  (respectively,  $\mathcal{T}_h$ ). We introduce a space of functions over the element edges  $\gamma_H \in \mathcal{E}(\mathcal{T}_H)$ ,

$$\mathcal{Q}_H = \{\mathbf{q} = (q_1, q_2) \mid q_1 \in (\mathbf{P}_1(\gamma_H))^2, \forall \gamma_H \in \mathcal{E}(\mathcal{T}_H) \mid q_1|_{\Gamma_N^1} = 0, q_2|_{\Gamma_N^2} = 0\}; \quad (17)$$

analogously, for edges  $\gamma_h \in \mathcal{E}(\mathcal{T}_h) \cap \mathcal{E}(\mathcal{T}_H)$ ,

$$\mathcal{Q}_h = \{\mathbf{q} = (q_1, q_2) \mid q_1 \in (\mathbf{P}_1(\gamma_h))^2, \forall \gamma_h \in \mathcal{E}(\mathcal{T}_h) \cap \mathcal{E}(\mathcal{T}_H) \mid q_1|_{\Gamma_N^1} = 0, q_2|_{\Gamma_N^2} = 0\}. \quad (18)$$

It follows that  $\mathcal{Q}_H \subset \mathcal{Q}_h \subset L_2(\mathcal{E}(\mathcal{T}_H))$ , and the functions in these spaces can, of course, be discontinuous.

Next, we introduce the “jump” bilinear form  $b : \hat{\mathcal{X}} \times \mathcal{Q}_h \rightarrow \mathbb{R}$ .

$$b(\varphi, \mathbf{q}) = \sum_{\gamma_H \in \mathcal{E}(\mathcal{T}_H)} \int_{\gamma_H} [\varphi]_{\gamma_H} \cdot \mathbf{q}|_{\gamma_H} H dS, \quad (19)$$

where  $[\varphi]_{\gamma_H}$  is the jump in  $\varphi$  across  $\gamma_H$ , when  $\gamma_H$  is an interior edge, and takes the value of  $\varphi$  on  $\gamma_H$ , when  $\gamma_H$  is on the boundary  $\Gamma$ . Interior edges are given an arbitrary orientation so that the sign of  $[\varphi]_{\gamma_H}$  is uniquely defined. The form (19), can be used to enforce continuity on functions in  $\hat{\mathcal{X}}_H$  and  $\hat{\mathcal{X}}_h$ ; in particular,

$$\hat{\mathcal{X}}_H \equiv \{\varphi \in \hat{\mathcal{X}}_H \mid b(\varphi, \mathbf{q}) = 0, \forall \mathbf{q} \in \mathcal{Q}_H\} \quad (20)$$

$$\hat{\mathcal{X}}_h \equiv \{\varphi \in \hat{\mathcal{X}}_h \mid b(\varphi, \mathbf{q}) = 0, \forall \mathbf{q} \in \mathcal{Q}_h\} \quad (21)$$

We note that the form  $b(\cdot, \cdot)$  places no restriction on  $\varphi$  on natural boundaries.

### IV. BOUND PROCEDURE FOR THE TOTAL POTENTIAL ENERGY

#### A. The coarse mesh problem

The coarse mesh solution  $\phi_H$  is obtained by considering the minimization statement (5) over the functions in  $\mathcal{X}_H$ . If  $\Pi_H$ , denotes the attained minimum, we have,

$$\Pi_H \equiv \Pi(\phi_H) = \inf_{\varphi \in \mathcal{X}_H} \Pi(\varphi). \quad (22)$$

The minimizer,  $\phi_H$ , satisfies the following equilibrium condition,

$$R(\mathbf{v}; \phi_H) = 0, \quad \forall \mathbf{v} \in \mathcal{V}_H. \quad (23)$$

This statement represents a set of nonlinear coupled algebraic equations which can be conveniently solved using an iterative

Newton-Raphson procedure [6]. More specifically, the following recursive expression can be used to determine the  $i+1$ -th iterate,  $\phi_H^{i+1}$ , given  $\phi_H^i$ : find  $\phi_H^{i+1} \in \mathcal{X}_H$  such that

$$K(\mathbf{v}, \phi_H^{i+1} - \phi_H^i; \phi_H^i) = -R(\mathbf{v}; \phi_H^i), \quad \forall \mathbf{v} \in \mathcal{V}_H. \quad (24)$$

A fine mesh solution  $\phi_h$ , corresponding to the minimizer of (5) over  $\mathcal{X}_h$ ,

$$\Pi_h \equiv \Pi(\phi_h) = \inf_{\varphi \in \mathcal{X}_h} \Pi(\varphi), \quad (25)$$

could, in principle, be computed in an analogous manner. Since  $\mathcal{X}_H \in \mathcal{X}_h$ , it follows that  $\Pi_H$  is automatically an upper bound for the total potential energy at  $\phi_h$ ,  $\Pi_h$ ; i.e.  $\Pi_h \leq \Pi_H \equiv \Pi_h^+$ .

For linear elements, we expect the  $H^1$ -norm of the solution error to be  $\mathcal{O}(H)$ , that is  $\|\phi - \phi_H\|_1 \sim \mathcal{O}(H)$ , and  $|\Pi - \Pi_H| \sim \mathcal{O}(H^2)$ . Hence, if we assume  $h$  sufficiently small so that  $\phi_h \sim \phi$ , then we have  $\Pi_h^+ - \Pi \sim \mathcal{O}(H^2)$ .

### B. Lagrangian formulation

Our objective now is to compute a lower bound for  $\Pi_h$ , without requiring the solution of an expensive fine mesh problem. In principle, a lower bound for  $\Pi_h$ , will be obtained whenever the minimization in (5) is done over a space which contains  $\mathcal{X}_h$ . We recall that one such space would be  $\hat{\mathcal{X}}_h$ . Unfortunately, direct minimization over  $\hat{\mathcal{X}}_h$  would lead to a larger problem than that of calculating  $\Pi_h$  exactly, and worst yet, lead to a minimum which, in general, would be  $-\infty$ .

In order to overcome this difficulty we proceed as follows. Given (21), we can rewrite (25) as a constrained minimization problem over  $\hat{\mathcal{X}}_h$ ,

$$\Pi_h = \inf_{\varphi \in \hat{\mathcal{X}}_h} \Pi(\varphi) = \begin{cases} \inf & \Pi(\varphi). \\ \varphi \in \hat{\mathcal{X}}_h & \\ b(\varphi, \mathbf{q})=0, \forall \mathbf{q} \in \mathcal{Q}_h & \end{cases} \quad (26)$$

An augmented Lagrangian  $\mathcal{L} : \hat{\mathcal{X}} \times \mathcal{Q}_h \rightarrow \mathbb{R}$ , can now be defined as

$$\mathcal{L}(\varphi, \mathbf{q}) = \Pi(\varphi) + b(\varphi, \mathbf{q}), \quad (27)$$

where  $\mathbf{q}$ , plays the role of a lagrange multiplier and will be referred to as a hybrid flux [7]. The solution of the constrained minimization problem (26),  $\phi_h \in \hat{\mathcal{X}}_h$ , and  $\mathbf{p}_h \in \mathcal{Q}_h$ , can thus be expressed as a saddle point of  $\mathcal{L}$ ,

$$\begin{aligned} \Pi_h \equiv \mathcal{L}(\phi_h, \mathbf{p}_h) &= \inf_{\varphi \in \hat{\mathcal{X}}_h} \sup_{\mathbf{q} \in \mathcal{Q}_h} \mathcal{L}(\varphi, \mathbf{q}) \\ &\geq \sup_{\mathbf{q} \in \mathcal{Q}_h} \inf_{\varphi \in \hat{\mathcal{X}}_h} \mathcal{L}(\varphi, \mathbf{q}). \end{aligned} \quad (28)$$

where the last inequality follows from simple duality theory [13]. Since we are interested in a lower bound, the problem can be further relaxed by setting the hybrid flux to a fixed, but at this stage arbitrary, value  $\bar{\mathbf{q}}$ , thus,

$$\Pi_h \geq \inf_{\varphi \in \hat{\mathcal{X}}_h} \mathcal{L}(\varphi, \bar{\mathbf{q}}), \quad \forall \bar{\mathbf{q}} \in \mathcal{Q}_h. \quad (29)$$

which defines the lower bound  $\Pi_h^-(\bar{\mathbf{q}})$  as:

$$\Pi_h^-(\bar{\mathbf{q}}) \equiv \mathcal{L}(\hat{\phi}_h, \bar{\mathbf{q}}) = \inf_{\varphi \in \hat{\mathcal{X}}_h} \mathcal{L}(\varphi, \bar{\mathbf{q}}) \quad (30)$$

The important point here is that, whereas the problem (29) is large and expensive to solve, the minimization (29) is carried out over the ‘‘broken’’ space  $\hat{\mathcal{X}}_h$  and therefore can be solved for each  $H$ -macroelement in a decoupled manner as shown in the Appendix I.

The accuracy of the lower bound will depend on the duality gap in (29), and on the choice of hybrid fluxes  $\bar{\mathbf{q}}$ . In principle, we expect the duality gap to be zero provided that sufficient regularity conditions are met. An inexpensive choice of hybrid fluxes which is based on the coarse grid solution  $\phi_H$ , and yields optimal bound convergence (i.e.  $\Pi_h - \Pi_h^- \sim \mathcal{O}(H^2)$ ) is presented below.

### C. Hybrid Fluxes

In order to determine suitable approximations to the hybrid fluxes  $\bar{\mathbf{q}}$ , we look for the saddlepoint of the Lagrangian (27), in the coarse grid subspaces  $\hat{\mathcal{X}}_H \subset \hat{\mathcal{X}}_h$  and  $\mathcal{Q}_H \subset \mathcal{Q}_h$ . In particular, we look for  $\phi_H$  and  $\mathbf{p}_H$  such that

$$\Pi_H \equiv \mathcal{L}(\phi_H, \mathbf{p}_H) = \inf_{\varphi \in \hat{\mathcal{X}}_H} \sup_{\mathbf{q} \in \mathcal{Q}_H} \mathcal{L}(\varphi, \mathbf{q}), \quad (31)$$

and then set  $\bar{\mathbf{q}} = \mathbf{p}_H$ . It is now clear that, the solution  $\phi_H$  to the above problem can be obtained directly by solving the coarse grid problem (22) over  $\mathcal{X}_H$ . Once  $\phi_H$  is known, the hybrid fluxes can be determined. First, we note that stationary point of the Lagrangian, will satisfy

$$R(\mathbf{v}; \phi_H) + b(\mathbf{v}, \mathbf{p}_H) = 0, \quad \forall \mathbf{v} \in \hat{\mathcal{X}}_H. \quad (32)$$

The above equation represents a solvable but indeterminate system. The solution of this problem is known as the equilibration problem. From the physical point of view, these hybrid fluxes represent tractions that must be applied so that the each  $H$ -macroelement is in equilibrium when considered in isolation. We follow here the approach proposed in [8], [4], [1], which requires solving an indeterminate system at each vertex of the  $\mathcal{T}_H$  grid, the size of which is given by the number of edges that meet at the vertex.

## V. BOUND PROCEDURE FOR AN ARBITRARY OUTPUT

### A. Lagrangian formulation

We consider now the evaluation of upper and lower bounds for an arbitrary output  $s_h = \mathcal{S}(\phi_h)$ . For this purpose, we note first that  $s_h$  is the solution of the following constrained minimization problem

$$s_h = \begin{cases} \inf & \mathcal{S}(\varphi), \\ \varphi \in \hat{\mathcal{X}}_h & \\ R(\mathbf{v}; \varphi)=0, \forall \mathbf{v} \in \mathcal{V}_h & \\ b(\varphi, \mathbf{q})=0, \forall \mathbf{q} \in \mathcal{Q}_h & \end{cases} \quad (33)$$

where the chosen constraints simply force  $\varphi$ , to be continuous and satisfy equilibrium thus being equal to  $\phi_h$  and hence,  $\mathcal{S}(\varphi)$  becomes  $\mathcal{S}(\phi_h)$ . It is now possible to re-write the above constrained minimization problem as a saddle point problem as

$$\gamma s_h = \inf_{\varphi \in \hat{\mathcal{X}}_h} \sup_{\substack{\mathbf{v} \in \mathcal{V}_h \\ \mathbf{q} \in \mathcal{Q}_h}} \mathcal{L}_h^\gamma(\varphi, \mathbf{v}, \mathbf{q}), \quad (34)$$

where the Lagrangian functional is now

$$\mathcal{L}_h^\gamma(\varphi, \mathbf{v}, \mathbf{q}) = \Pi(\varphi) - \Pi(\phi_h) + \gamma S(\varphi) + R(\mathbf{v}; \varphi) + b(\varphi, \mathbf{q}), \quad \forall \gamma \in \mathbb{R}^+. \quad (35)$$

Note that the first two terms in the above expression will cancel each other when  $\varphi = \phi_h$ . In addition, the positive factor  $\gamma$  in the above equation, although arbitrary at this stage, has the function of scaling the physical dimensions of the output  $s$  to equal those of energy, thus matching other terms in the expression for  $\mathcal{L}_h^\gamma$ . Finally, the last two terms in equation (36) contain the Lagrange multipliers,  $\mathbf{v}$  and  $\mathbf{q}$ , known as the adjoint and hybrid fluxes respectively, which enforce the required constraints.

Duality and a relaxation of the constraints, by choosing fixed but arbitrary adjoint,  $\mathbf{v} = \bar{\mathbf{v}}$ , and hybrid fluxes,  $\mathbf{q} = \bar{\mathbf{q}}$ , in equation (34), gives a lower bound expression for the output  $s_h$  as

$$s_h \geq \frac{1}{\gamma} \inf_{\varphi \in \mathcal{X}_h} \mathcal{L}_h^\gamma(\varphi, \bar{\mathbf{v}}, \bar{\mathbf{q}}), \quad \forall \bar{\mathbf{q}} \in \mathcal{Q}, \quad \forall \bar{\mathbf{v}} \in \mathcal{V}_h, \quad \forall \gamma \in \mathbb{R}^+. \quad (36)$$

The presence of the unknown potential  $\Pi(\phi_h)$  in the above Lagrangian  $\mathcal{L}_h^\gamma$  can be remedied by noting that  $\Pi(\phi_H)$  is indeed an upper bound for  $\Pi(\phi_h)$ . Consequently, the final desired lower bound to the output  $s$  is obtained by replacing  $\Pi(\phi_h)$  by  $\Pi(\phi_H)$  to give,

$$s_h \geq \frac{1}{\gamma} \inf_{\varphi \in \mathcal{X}_H} \mathcal{L}_H^\gamma(\varphi, \bar{\mathbf{v}}, \bar{\mathbf{q}}) \equiv s_h^-(\bar{\mathbf{v}}, \bar{\mathbf{q}}, \gamma), \quad \forall \bar{\mathbf{q}} \in \mathcal{Q}_h, \quad \forall \bar{\mathbf{v}} \in \mathcal{V}_h, \quad \forall \gamma \in \mathbb{R}^+ \quad (37)$$

where  $\mathcal{L}_H^\gamma$  is now

$$\mathcal{L}_H^\gamma(\varphi, \mathbf{v}, \mathbf{q}) = \Pi(\varphi) - \Pi(\phi_H) + \gamma S(\varphi) + R(\mathbf{v}; \varphi) + b(\varphi, \mathbf{q}). \quad (38)$$

Note that the above minimization is again carried out in the broken space  $\mathcal{X}_h$  and hence can be solved in an un-coupled manner on each macro-element. Once appropriate multipliers have been selected, as described in the section below, the minimizer,  $\hat{\phi}_h^\gamma$ , is obtained by solving the problem

$$\mathcal{L}_H^\gamma(\hat{\phi}_h^\gamma, \bar{\mathbf{v}}, \bar{\mathbf{q}}) = \inf_{\varphi \in \mathcal{X}_h} \mathcal{L}_H^\gamma(\varphi, \bar{\mathbf{v}}, \bar{\mathbf{q}}), \quad (39)$$

and satisfies the following equilibrium condition

$$R(\mathbf{w}, \hat{\phi}_h^\gamma) + \gamma DS(\mathbf{w}, \hat{\phi}_h^\gamma) + K(\mathbf{w}, \bar{\mathbf{v}}; \hat{\phi}_h^\gamma) + b(\mathbf{w}, \bar{\mathbf{q}}) = 0, \quad \forall \mathbf{w} \in \mathcal{V}_h. \quad (40)$$

Here,  $DS$  denotes the first variation of the output, that is

$$DS(\mathbf{w}; \varphi) = \lim_{\epsilon \rightarrow 0} \frac{S(\varphi + \epsilon \mathbf{w}) - S(\varphi)}{\epsilon}. \quad (41)$$

The non-linear set of equations (41), can now be solved separately for each element with a procedure analogous to that of Appendix I.

Finally, in order to obtain an upper bound for  $s_h$ , it is only necessary to derive a lower bound  $\hat{s}_h^-$  for  $\hat{s} = -S(\phi_h)$ , following the procedure just outlined, and then set  $s_h^+ = -\hat{s}_h^-$  [10],

Fig. 3. Square block problem

[11], [12]. It turns out that, if we are interested in computing both upper and lower bounds, the coarse mesh adjoint can be re-used, thus gaining some computational efficiency. We also point out that, provided the minimization problem (39) is well defined and bounded infimum exists, non-linear functionals of the solution can be considered without any changes to the described procedure.

### B. Evaluation of the adjoint and the hybrid fluxes

The adjoint and the hybrid fluxes are found by solving the constrained minimization problem (34) formulated in the coarse mesh spaces,  $\mathcal{X}_H \subset \mathcal{X}_h$ ,  $\mathcal{V}_H \subset \mathcal{V}_h$ , and  $\mathcal{Q}_H \subset \mathcal{Q}_h$ . These will lead to inexpensive choices of  $\bar{\mathbf{q}} = \mathbf{p}_H$  and  $\bar{\mathbf{v}} = \mathbf{u}_H$  which are found to yield optimum bound convergence. For this purpose, we re-write problem (34), in the coarse mesh,

$$\gamma s_H = \inf_{\varphi \in \mathcal{X}_H} \sup_{\substack{\mathbf{v} \in \mathcal{V}_H \\ \mathbf{q} \in \mathcal{Q}_H}} \mathcal{L}_H^\gamma(\varphi, \mathbf{v}, \mathbf{q}). \quad (42)$$

Setting the variation of the Lagrangian functional  $\mathcal{L}_H^\gamma$ , with respect to  $\mathbf{v}$  and  $\mathbf{q}$ , to zero, gives

$$R(\mathbf{w}; \phi_H) = 0 \quad \forall \mathbf{w} \in \mathcal{V}_H, \quad (43)$$

$$b(\phi_H, \mathbf{q}) = 0 \quad \forall \mathbf{q} \in \mathcal{Q}_H, \quad (44)$$

where, by construction,  $\phi_H$  is the solution of the coarse grid problem (22). Considering now variations with respect to the first argument  $\varphi$  at  $\varphi = \phi_H$  gives

$$R(\mathbf{w}; \phi_H) + \gamma DS(\mathbf{w}; \phi_H) + K(\mathbf{w}, \mathbf{u}_H; \phi_H) + b(\mathbf{w}, \mathbf{p}_H) = 0 \quad \forall \mathbf{w} \in \mathcal{V}_H. \quad (45)$$

If we first restrict this expression to variations  $\mathbf{w}$  that belong to the unbroken tangent space  $\mathcal{V}_H$ , the first and last terms of the above equation vanish and a linear set of equations for the adjoint  $\mathbf{u}_H$  emerges as,

$$\gamma DS(\mathbf{w}; \phi_H) + K(\mathbf{w}, \mathbf{u}_H; \phi_H) = 0 \quad \forall \mathbf{w} \in \mathcal{V}_H \quad (46)$$

Equation (46) can now be used to evaluate the hybrid fluxes  $\mathbf{p}_H$  by solving an equilibration procedure analogous to that encountered in section IV-C. Finally, the free parameter  $\gamma$ , is chosen according to the procedure presented in Appendix II.

Fig. 5. Square block problem - intermediate meshes  $H/2$  and  $H/8$

## VI. EXAMPLES

Two simple examples are used to demonstrate the procedures presented above: a simple extension of a square block and the deflection of a short cantilever (Cook's membrane).

### A. Square block

A square block of hyperelastic material is pulled along one side as shown in figure 3. Dimensions, boundary conditions and material properties are defined in the figure. In addition to the energy, the average displacement of the right vertical boundary of the block, will be used as the desired output for the problem.

The coarse discretization consists of 32 equal linear triangles and it is shown, together with its corresponding deformed shape, in figure 4. The starting solution,  $\phi_H^0$ , to initiate the Newton-Raphson iteration (24), is taken to be simply  $\phi_H^0 = \mathbf{X}$ . The fine mesh is obtained by subdividing each triangle into  $16^2$  smaller elements in a regular pattern, so that  $h = H/16$ . In order to check the convergence of the bounds obtained with  $H$ , the solution of the problem and output bounds have also been obtained using intermediate meshes with sizes  $H/2$ ,  $H/4$  and  $H/8$ . Two typical intermediate meshes  $H/2$  and  $H/8$  are shown in figure 5.

The results obtained for the energy bounds are summarized in numeric form in table I, and graphically in figure 6. It is clear that the convergence of bound gap is quadratic with  $H$ .

The bounds obtained for the average displacement are shown in table II. The same results are illustrated graphically in figure 7. Again the convergence of the bound gap is clearly quadratic.

### B. Cook's membrane

The second example relates to the bending of a short cantilever. This is a well-known problem in solid mechanics. The

Mesh size	$\Pi_h^+$	$\Pi_h^-$	$\Delta_\Pi = \Pi_h^+ - \Pi_h^-$
$H$	-20.887	-21.295	0.408
$H/2$	-21.004	-21.136	0.132
$H/4$	-21.044	-21.081	0.037
$H/8$	-21.056	-21.063	0.007

TABLE I  
SQUARE BLOCK - ENERGY BOUNDS

Fig. 6. Square block - energy bounds

geometry, loads, and boundary conditions are shown in figure 8.

As in the previous example, a series of meshes has been used to investigate the bound convergence. These range from the coarse mesh  $\mathcal{X}_H$ , comprising 34 elements, to the fine mesh  $\mathcal{X}_h$  with  $16^2 \times 34$  elements shown in figure 9. In between, intermediate meshes with spacings  $H/2$ ,  $H/4$  and  $H/8$  have also been used. Figure 10 shows the final deformations obtained using the coarse mesh  $\mathcal{X}_H$  and a finer mesh with spacing  $H/2$ . In all cases, the Newton-Raphson iteration (24) used to obtain the coarse solution has been started with  $\phi_H^0 = \mathbf{X}$ .

The upper and lower bounds obtained for the energy are listed in table III and depicted figure 11. We note that the lower bounds for the energy, despite still converging quadratically to the exact value when  $H$  is sufficiently small, are significantly less sharp than the upper bounds, or indeed poorer than the lower bounds obtained in the previous example. The reason for the increased gap is due to the fact that many more modes of deformation are present in the broken fine mesh, which permit the local buckling of those macro-elements that are in compression. These local buckling modes, however, do not satisfy continuity across element edges and hence are not present in the unbroken solution. Under such conditions, the broken and unbroken solu-

Mesh size	$s$	$s_h^+$	$s_h^-$	$\Delta_s = s_h^+ - s_h^-$

tions are qualitatively dissimilar and hence will have markedly different energy values. A clearer illustration of this problem can be seen by re-running the previous square block problem in compression rather than in tension. The deformed solutions of some local problems are shown for both the tension and compression cases in figure 12. It is clear that, for the compression case, premature local buckling is taking place well before any global buckling occurs.

Mesh size	$\Pi_h^+$	$\Pi_h^-$	$\Delta_\Pi = \Pi_h^+ - \Pi_h^-$

TABLE III  
COOK'S MEMBRANE - ENERGY OUTPUT

## VII. CONCLUDING REMARKS

We have presented an efficient method for the computation of bounds for functional outputs of solutions in finite strain elasticity problems. The method has been described in detail for the simple case of two dimensional plane stress but, in principle, the procedures presented can be easily extended to three

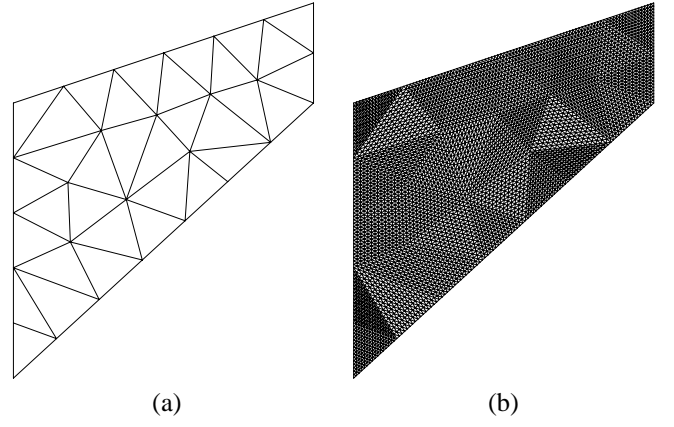

Fig. 9. Cook's membrane - (a) coarse and (b) fine meshes

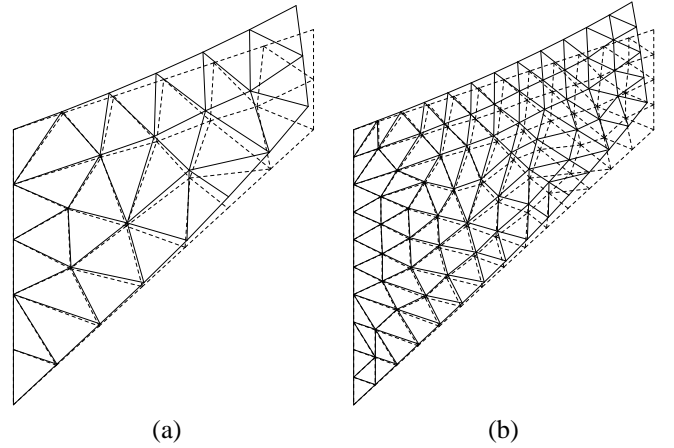

Fig. 10. Cook's membrane - (a) course mesh deformation and (b) H/2 deformation

Fig. 11. Cook's membrane - energy bounds

Fig. 12. Local solutions for the square block in (a) tension and (b) compression

dimensions. We have only considered linear functional outputs, but under some restrictions more general non-linear outputs can also be dealt with.

Unlike previous error estimation procedures for non-linear problems, the approach presented is fully non-linear and the computed bounds are uniformly valid regardless of the size of the underlying discretization. In addition, optimal bound convergence, with effectivities of order one, are obtained when the coarse grid solution is in the asymptotic convergence range.

The method presented can be extended in a number of ways. Adaptive mesh refinement, to efficiently modify an existing discretization in order to tighten the bound gap, can be incorporated in a straightforward manner [12]. Approaches that enrich the functional spaces by increasing the polynomial order (p-methods), rather than subdividing the elements (h-methods), can also be considered without complication.

Perhaps, the most severe drawback of the present approach is that of the premature buckling of the local problems. This is mostly encountered when solving problems subject to strong compression and, as previously mentioned, is due to the excessive freedom introduced by our relaxation. We are currently investigating procedures to alleviate this problem which will be the subject of a future communication.

#### APPENDIX I : SOLUTION OF THE LOCAL PROBLEMS

The minimization problem expressed in (30), can be carried out over each macro-element independently so that the lower bound for the energy is given by the sum of individual macro-element contributions. Thus if  $\mathcal{L}_{T_H}$  denotes the restriction of  $\mathcal{L}$  over  $T_H$ , we have

$$\Pi_h^-(\mathbf{p}_H) = \sum_{T_H \in \mathcal{T}_H} \mathcal{L}_{T_H}(\hat{\phi}_h|_{T_H}, \mathbf{p}_H). \quad (47)$$

The local minimizers  $\phi_{T_H} \equiv \hat{\phi}_h|_{T_H}$  are determined by solving the local problems

$$\begin{aligned} \mathcal{L}_{T_H}(\phi_{T_H}, \mathbf{p}_H) &= \inf_{\varphi \in \mathcal{Z}_h(T_H)} \Pi_{T_H}(\varphi, \mathbf{t}_{T_H}); \\ \Pi_{T_H}(\varphi, \mathbf{t}_{T_H}) &\equiv \Pi_{T_H}^{\text{int}}(\varphi) + \Pi_{T_H}^{\text{ext}}(\varphi, \mathbf{t}_{T_H}). \end{aligned} \quad (48)$$

Here, the internal elastic strain energy potential is given by

$$\Pi_{T_H}^{\text{int}}(\varphi) = \int_{T_H} \psi(\mathbf{F}) d\Omega \quad (49)$$

and the ‘‘external’’ energy potential, which contains the effect of the hybrid fluxes and any externally applied traction on the boundaries of  $T_H$ ,  $\mathbf{t}|_{\gamma_H}$ , is given by

$$\begin{aligned} \Pi_{T_H}^{\text{ext}}(\varphi, \mathbf{t}_{T_H}) &= \sum_{\gamma_H \in \mathcal{E}(T_H)} \int_{\gamma_H} \mathbf{t}_{T_H}|_{\gamma_H} \cdot \varphi|_{\gamma_H} H dS; \\ \mathbf{t}_{T_H}|_{\gamma_H} &= \mathbf{t}|_{\gamma_H} + \sigma_{\gamma_H} \mathbf{p}|_{\gamma_H}, \end{aligned} \quad (50)$$

where  $\mathcal{E}(T_H)$ , denotes the set of edges belonging to the macro-element  $T_H$ , and  $\sigma_{\gamma_H}$  is either 1 or  $-1$ , depending on the orientation associated to  $\gamma_H$  (see [2], [12] for further details).

Fig. 13. Local minimization problem

Fig. 14. Illustration of solution non-uniqueness

The stationarity conditions corresponding to problem (49) are: find  $\phi_{T_H} \in \mathcal{Z}_h(T_H)$  such that

$$\begin{aligned} R_{T_H}(\mathbf{v}; \phi_{T_H}) &\equiv T_{T_H}(\mathbf{v}; \phi_{T_H}) + \Pi_{T_H}^{\text{ext}}(\mathbf{v}, \mathbf{t}_{T_H}) = 0, \\ \mathbf{v} &\in \mathcal{Z}_h(T_H), \end{aligned} \quad (51)$$

where  $R_{T_H}$ , denotes the local problem residual, and the internal equivalent forces  $T_{T_H}(\mathbf{v}; \varphi)$ , are defined by the the first variation of the internal strain energy potential as

$$T_{T_H}(\mathbf{v}; \varphi) = \lim_{\epsilon \rightarrow 0} \frac{\Pi_{T_H}^{\text{int}}(\varphi + \epsilon \mathbf{v}) - \Pi_{T_H}^{\text{int}}(\varphi)}{\epsilon}. \quad (52)$$

In general, the solution of the above local problems will only be defined up to rigid body translations. The exception will be for those macro-elements with one or more edges on a Dirichlet boundary. However, provided that the external forces,  $\mathbf{t}_{T_H}$ , are in equilibrium, as guaranteed by the equilibration procedure employed to compute the hybrid fluxes, the potential to be minimized is independent of rigid body translations and hence the displacement of one point can be arbitrarily set to zero as illustrated in figure 13.

In the linear, small strain regime, rigid body rotations need to be removed from the solution space by choosing one additional suitable boundary condition. In the large strain regime, however, the external strain energy is not independent of rigid body rotations and hence the amount of rotation is solely determined by the external loads. Moreover, for any given set of self balanced external loads, one can typically find two equilibrium configurations, one in tension and one in compression, as shown in figure 14 for a simple one dimensional bar. The solution in tension represents a global minimum, whereas the solution in compression represents a minimum of the total energy with respect to all possible incremental motions except for a rigid body rotation, for which it is in fact a local maximum. This is illustrated in figure 15, which shows the shape of the total potential energy for the simple bar problem.

It is clear that the relevant local solution will be determined by the global problem. For instance, we would expect that if the H-macroelement corresponding to the global coarse solution is in compression, the local relevant solution would be that which is also in compression. For such case, the possible traction solution is artificially added by the relaxation of the continuity requirements in the space of local solutions.

From a practical point of view, it is found that a simple Newton-Raphson solution process does not generally converge

Fig. 15. Total energy potential for one dimensional bar

to the desired solution in compression. In order to resolve this difficulty a simple strategy has been devised, which is effective for the two dimensional problem considered here (a similar procedure can be devised in three dimensions). In particular, the degrees of freedom that describe the space of local configurations  $\mathcal{Z}_h(T_H)$  are re-defined to include explicitly a rotation angle  $\vartheta$ . For this purpose, a restricted space  $\tilde{\mathcal{Z}}_h(T_H)$  is defined by introducing an additional support condition to remove rigid body rotations of the macro-element  $T_H$ , as:

$$\tilde{\mathcal{Z}}_h(T_H) = \{\tilde{\varphi} \in \mathcal{Z}_h(T_H) \mid (\varphi(\mathbf{X}_2) - \varphi(\mathbf{X}_1)) \cdot \boldsymbol{\nu} = 0\} \quad (53)$$

where  $\mathbf{X}_1$  and  $\mathbf{X}_2$  are the material coordinates of the first two macro-element vertices, and  $\boldsymbol{\nu}$  is a suitable fixed vector not parallel to the side joining these two nodes.

In order to recover the original solution space, one additional rotational degree of freedom  $\vartheta$  is now introduced as the angle by which an arbitrary motion  $\varphi$  needs to be rotated to belong to  $\tilde{\mathcal{Z}}_h$ . This rotation is illustrated in figure 16 and defines the rotation operator  $\mathbf{R}_\vartheta$  such that  $\tilde{\varphi} = \mathbf{R}_\vartheta \varphi$ . It is clear that the total energy of the macro-element will remain unchanged if the external forces are similarly rotated, that is,

$$\Pi_{T_H}(\varphi, \mathbf{t}_{T_H}) = \Pi_{T_H}(\tilde{\varphi}, \mathbf{R}_\vartheta \mathbf{t}_{T_H}) \quad (54)$$

The shape of the modified potential expressed as a function of the rotation angle and the restricted local motion is illustrated in figure 17 for the simple bar problem. It can be qualitatively observed that much of the severe non-linearity of the original problem with respect to rigid body rotations has disappeared.

Finding the stationary points with respect to both  $\tilde{\varphi}$  and  $\vartheta$  leads to the following set of nonlinear equilibrium equations for  $\theta_{T_H}$  and  $\tilde{\phi}_{T_H} = \mathbf{R}_{\theta_{T_H}} \phi_{T_H}$ :

$$T_{T_H}(\mathbf{v}; \tilde{\phi}_{T_H}) + \Pi_{T_H}^{\text{ext}}(\mathbf{v}, \mathbf{R}_{\theta_{T_H}} \mathbf{t}_{T_H}) = 0, \quad \forall \mathbf{v} \in \tilde{\mathcal{Z}}_h(T_H), \quad (55)$$

$$\Pi_{T_H}^{\text{ext}}(\tilde{\phi}_{T_H}, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}} \mathbf{t}_{T_H}) = 0, \quad (56)$$

where  $\mathbf{k}$  is the unit vector normal to the plane of motion. We note that equation (56), expresses moment equilibrium and implies that the reaction in the additional support, introduced to define  $\tilde{\mathcal{Z}}_h(T_H)$ , is zero.

Starting from initial guesses  $\theta_{T_H}^0 = 0$  and  $\tilde{\phi}_{T_H}^0 = \phi_H|_{T_H}$ , an iterative Newton-Raphson procedure is now implemented to obtain linear equations for the increments  $\Delta \tilde{\phi} = \tilde{\phi}_{T_H}^{i+1} - \tilde{\phi}_{T_H}^i$

Fig. 16. Modified local minimization problem

Fig. 17. Total energy potential for one dimensional bar in transformed solution space

and  $\Delta \theta = \theta_{T_H}^{i+1} - \theta_{T_H}^i$  as,

$$K_{T_H}(\mathbf{v}, \Delta \tilde{\phi}; \tilde{\phi}_{T_H}^i) + \Pi_{T_H}^{\text{ext}}(\mathbf{v}, \Delta \theta \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}) = (57)$$

$$-R_{T_H}(\mathbf{v}; \tilde{\phi}_{T_H}^i) \quad \forall \mathbf{v} \in \tilde{\mathcal{Z}}_h(T_H),$$

$$\Pi_{T_H}^{\text{ext}}(\Delta \tilde{\phi}, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}) - \Pi_{T_H}^{\text{ext}}(\tilde{\phi}_{T_H}^i, \Delta \theta \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}) = (58)$$

$$-\Pi_{T_H}^{\text{ext}}(\tilde{\phi}_{T_H}^i, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}).$$

The solution of the above linear system can be facilitated by decomposing  $\Delta \tilde{\phi}$  as,

$$\Delta \tilde{\phi} = \Delta \tilde{\phi}_R + \Delta \theta \Delta \tilde{\phi}_\theta, \quad (59)$$

where,

$$K_{T_H}(\mathbf{v}, \Delta \tilde{\phi}_R; \tilde{\phi}_{T_H}^i) = -R_{T_H}(\mathbf{v}; \tilde{\phi}_{T_H}^i) \quad (60)$$

$$\forall \mathbf{v} \in \tilde{\mathcal{Z}}_h(T_H),$$

$$K_{T_H}(\mathbf{v}, \Delta \tilde{\phi}_\theta; \tilde{\phi}_{T_H}^i) = -\Pi_{T_H}^{\text{ext}}(\mathbf{v}, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}) \quad (61)$$

$$\forall \mathbf{v} \in \tilde{\mathcal{Z}}_h(T_H).$$

Substituting the decomposition (59) into equation (59) gives the angle increment after simple algebra as,

$$\Delta \theta = - \frac{\Pi_{T_H}^{\text{ext}}(\tilde{\phi}_{T_H}^i + \Delta \tilde{\phi}_R, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H})}{\Pi_{T_H}^{\text{ext}}(\Delta \tilde{\phi}_\theta, \mathbf{k} \times \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H}) - \Pi_{T_H}^{\text{ext}}(\tilde{\phi}_{T_H}^i, \mathbf{R}_{\theta_{T_H}^i} \mathbf{t}_{T_H})}. \quad (62)$$

The above angle increment can now be substituted back into equation (59) to give the iterative increment  $\Delta \tilde{\phi}$  in  $\phi_{T_H}$ .

Finally, we set

$$\Pi_{T_H}(\phi_{T_H}, \mathbf{t}_{T_H}) = \Pi_{T_H}(\tilde{\phi}_{T_H}, \mathbf{R}_{\theta_{T_H}} \mathbf{t}_{T_H}). \quad (63)$$

We have found that the above artifice proves effective to give the appropriate local solution in the presence of moderate compression.

## APPENDIX II : EVALUATION OF THE PARAMETER $\gamma$

The parameter  $\gamma$  was introduced in equation (39) as a device to harmonize the physical units in the Lagrangian functional. This has the inevitable consequence of making output bound  $s_h^-$  depend on the chosen value for this factor. Ideally, one should find the value of  $\gamma$  which leads to the highest lower bound. In fact, it is possible to solve for  $\gamma$  as an additional unknown by maximizing the expression for  $s_h^-$  with respect to  $\gamma$ , thus obtaining one additional equation that permits the evaluation of the optimum  $\gamma$ . This equation, however, is highly nonlinear and cumbersome to solve, as it links the solution of the local problems.

A much simpler alternative is obtained by assuming small values of  $\gamma$  and taking a truncated Taylor series expansion of the potential  $\mathcal{L}_H$  about the point  $\gamma = 0$ , which coincides with the case discussed in section (6), where the bounds for the total potential energy were evaluated. For this purpose, it is first useful to re-write equation (38) as,

$$\begin{aligned} s_h^-(\mathbf{u}_H, \mathbf{p}_H, \gamma) &= \frac{f(\gamma)}{\gamma}, \\ f(\gamma) &= \Pi(\hat{\phi}_h^\gamma) - \Pi(\phi_H) + \gamma \mathcal{S}(\hat{\phi}_h^\gamma) + \\ &R(\mathbf{u}_H; \hat{\phi}_h^\gamma) + b(\hat{\phi}_h^\gamma, \mathbf{p}_H). \end{aligned} \quad (64)$$

Using a truncated Taylor series expansion of  $f(\gamma)$  about  $\gamma = 0$ , taking linear and quadratic terms, an approximate optimum value of  $\gamma$  is easily found as,

$$\gamma_{\text{opt}} = \sqrt{\frac{2f(0)}{f''(0)}}. \quad (65)$$

The value of  $f(0)$  is simply,

$$f(0) = \Pi(\hat{\phi}_h^0) - \Pi(\phi_H) + b(\hat{\phi}_h^0, \mathbf{p}_H^0). \quad (66)$$

where  $\hat{\phi}_h^0$  and  $\mathbf{p}_H^0$  coincide with the local solution  $\hat{\phi}_h$  and hybrid fluxes  $\mathbf{p}_H$  obtained in section (6).

The first and second derivatives of  $f(\gamma)$ , are readily evaluated from equation (65) and with the help of equilibrium statement (41) to give,

$$f'(\gamma) = \mathcal{S}(\hat{\phi}_h^\gamma) + R\left(\frac{d\mathbf{u}_H}{d\gamma}; \hat{\phi}_h^\gamma\right) + b\left(\hat{\phi}_h^\gamma, \frac{d\mathbf{p}_H}{d\gamma}\right) \quad (67)$$

$$\begin{aligned} f''(\gamma) &= DS\left(\frac{d\hat{\phi}_h}{d\gamma}; \hat{\phi}_h^\gamma\right) + K\left(\frac{d\mathbf{u}_H}{d\gamma}, \frac{d\hat{\phi}_h^\gamma}{d\gamma}; \hat{\phi}_h^\gamma\right) \\ &+ b\left(\frac{d\hat{\phi}_h^\gamma}{d\gamma}, \frac{d\mathbf{p}_H}{d\gamma}\right), \end{aligned} \quad (68)$$

where the derivatives  $d\mathbf{u}_H/d\gamma$  and  $d\mathbf{p}_H/d\gamma$  are obtained by differentiating with respect to  $\gamma$  equations (46) and (46) respectively, to give,

$$-DS(\mathbf{w}; \phi_H) + K\left(\mathbf{w}, \frac{d\mathbf{u}_H}{d\gamma}; \phi_H\right) = 0, \quad \forall \mathbf{w} \in \mathcal{V}_H, \quad (69)$$

$$-DS(\mathbf{w}; \phi_H) + K\left(\mathbf{w}, \frac{d\mathbf{u}_H}{d\gamma}; \phi_H\right) + \quad (70)$$

$$b\left(\mathbf{w}, \frac{d\mathbf{p}_H}{d\gamma}\right) = 0, \quad \forall \mathbf{w} \in \hat{\mathcal{V}}_H.$$

Similarly, the derivative of  $\hat{\phi}_h^\gamma$  with respect to  $\gamma$  can be evaluated by differentiating equation (41), which at  $\gamma = 0$  yields,

$$K\left(\mathbf{w}, \frac{d\hat{\phi}_h^\gamma}{d\gamma}; \hat{\phi}_h^0\right) + DS(\mathbf{w}, \hat{\phi}_h^0) + \quad (71)$$

$$K\left(\mathbf{w}, \frac{d\mathbf{u}_H}{d\gamma}; \hat{\phi}_h^0\right) + b\left(\mathbf{w}, \frac{d\mathbf{p}_H}{d\gamma}\right) = 0, \quad \forall \mathbf{w} \in \hat{\mathcal{V}}_h.$$

Finally, note that this equation enables the expression for  $f''(0)$  from equation (71) to be simplified to,

$$f''(0) = -K\left(\frac{d\hat{\phi}_h}{d\gamma}, \frac{d\hat{\phi}_h}{d\gamma}; \hat{\phi}_h^0\right). \quad (72)$$

The above procedure provides a simple mechanism for evaluating a reasonable value of  $\gamma$ . It must be emphasized, however, that the lower and upper bounds of  $s$  are, not only valid for any value of  $\gamma$ , but also the bound gap converges quadratically to zero regardless of  $\gamma$ .

## ACKNOWLEDGEMENTS

This work was partially carried out while J. Peraire was on sabbatical leave at the Universitat Politecnica de Catalunya, Barcelona. The authors would like to acknowledge the support provided by the Ministry of Spanish Education, the Singapore-MIT Alliance and Sandia National Laboratories for supporting the work reported here. The authors would also like to acknowledge fruitful discussions and collaboration with Professors A.T. Patera from MIT, and Y. Maday from Paris VI.
