The experiment LAZIO-Sirad was placed on board the International Space Station (ISS) with a Progress cargo on the beginning of March 2005. It was operational as part of the "Eneide" mission for 10 days from April the 17<sup>th</sup> 2005. The experiment aimed to study the radiation and magnetic environment on board the ISS with two devices: the LAZIO detector, built for the mission and the Sileye-3/Alteino telescope fitted with special multimaterial shielding tiles for the occasion. In this work we report of the preliminary results of the mission.
