Synthesis, Characterization and Reactivity of Copper(I) and Iron(II) Bis(carboxylate)Bridged Complexes
by
Daniel D. LeCloux
Submitted to the Department of Chemistry on February 11, 1998, in partial fulfillment of the requirements for the Degree of Doctor of Philosophy.

#### Abstract

\section*{Chapter 1. Synthesis and Characterization of a Novel Class of Dicopper(I) Bis(carboxylate)-Bridged Complexes}

The syntheses, spectroscopic properties, crystal and molecular structures, and bonding of several dicopper(I) bis(carboxylate)-bridged complexes are described in which the bridging dicarboxylate ligand is the dianion of $m$-xylylenediamine bis(Kemp's triacid imide) ( $\mathrm{H}_{2} \mathrm{XDK}, 1$ ). A sterically demanding benzyl derivative of $\mathrm{H}_{2}$ XDK was prepared, $\mathrm{H}_{2}$ BXDK (6). Reaction of these two ligands as well as the propyl analog, $\mathrm{H}_{2} \mathrm{PXDK}$ (2), with thallium ethoxide provided dithallium salts $\mathrm{Tl}_{2} \mathrm{~L}$ ( $\mathrm{L}=\mathrm{XDK}, 7$; PXDK, 8 ; and BXDK, 9 ). Reaction of 7,8 , or 9 with excess $\mathrm{CuBr}\left(\mathrm{Me}_{2} \mathrm{~S}\right)$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeCN}$ afforded dinuclear acetonitrile adducts $\left[\mathrm{Cu}_{2} \mathrm{~L}(\mathrm{MeCN})\right.$ ] ( $\mathrm{L}=\mathrm{XDK}, 10$; PXDK, 11; and BXDK, 12) in high yield and multigram quantities. The coordination chemistry of the $\mathrm{Cu}_{2}$ (XDK) platform was explored with a range of ancillary ligands. Treatment of $\mathbf{1 0 , 1 1}$, or 12 with an excess of the specified neutral donor ligand provided complexes $\left[\mathrm{Cu}_{2}(\mathrm{XDK})\left(\mathrm{PPh}_{3}\right)_{2}\right]$ (13), $\left[\mathrm{Cu}_{2}(\mathrm{XDK})\left(2,6-\mathrm{Me}_{2} \mathrm{PhNC}\right)_{3}\right]$ (14a), $\left[\mathrm{Cu}_{2}(\mathrm{XDK})\left(\mu-2,6-\mathrm{Me}_{2} \mathrm{PhNC}\right)\left(2,6-\mathrm{Me}_{2} \mathrm{PhNC}\right)_{2}\right](14 b),\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{NB})_{2}\right](15, \mathrm{NB}=$ norbornene), [ $\mathrm{Cu}_{2}$ (XDK)(tmeda)] (17), [Cu2(PXDK)(tmeda)] (18), [Cu2(BXDK)(tmeda)] (19), and $\left[\mathrm{Cu}\left(4,4^{\prime}-\mathrm{Me} \mathbf{e}_{2} \mathrm{bpy}\right)_{2}\right][\mathrm{Cu}(\mathrm{XDK})]$ (20). Reaction of 10 with an excess of cyclohexene resulted in the loss of the acetonitrile ligand, affording the parent unsubstituted complex [ $\mathrm{Cu}_{2}$ (XDK)] (16). Attempts to prepare anionic carbon-bridged dicopper(I) complexes with alkyl or aryl lithium compounds or cyanide reagents resulted instead in extraction of one of the $\mathrm{Cu}(\mathrm{I})$ ions, affording ( $\left.\mathrm{Et}_{4} \mathrm{~N}\right)[\mathrm{Cu}(\mathrm{PXDK})]$ (21) and [CuLi(XDK)(THF) 2 ] (22). Crystallographic chemical analysis of the complexes revealed linear two-coordinate, trigonal three-coordinate, and pseudotetrahedral four-coordinate copper(I), depending upon the composition, and variable degrees of $\mathrm{Cu}-\mathrm{Cu}$ bonding ( $\mathrm{d}_{\mathrm{Cu}}-\mathrm{Cu}$ range, $2.5697(8)-3.4211(6) \AA$ ).

## Chapter 2. Synthesis and Characterization of $\mathrm{Cu}(\mathrm{I})-\mathrm{Cu}(\mathrm{II})$ Mixed-Valence and $\mathrm{Cu}(\mathrm{I})-$ M(II) Heterodimetallic Bis(carboxylate-bridged) Complexes: Structural, Electrochemical, and Spectroscopic Investigations

The synthesis, spectroscopic, electrochemical, and structural properties of a series of $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II})$ bis(carboxylate-bridged) complexes are described, as well as
related investigations with $\mathrm{Cu}(\mathrm{I}) \mathrm{M}(\mathrm{II})$ ( $\mathrm{M}=\mathrm{Fe}$ and Zn ) analogs, utilizing the dianionic $m$-xylylenediamine bis(Kemp's triacid imide) ligand system. Treatment of previously reported $\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{MeCN})\right](1)$ or $\left[\mathrm{Cu}_{2}(\mathrm{PXDK})(\mathrm{MeCN})\right](2, \mathrm{PXDK}=$ the propyl derivative of XDK ) with one equivalent of silver $(\mathrm{I})$ triflate, trifluoroacetate, or tetrafluoroborate in THF afforded mixed valence complexes [Cu $\mathrm{Cu}_{2} \mathrm{~L}(\mu-\mathrm{X})(\mathrm{THF})_{2}$ ] (X $=$ triflate, $\mathrm{L}=\mathrm{XDK}, 4$, or PXDK, $5 ; \mathrm{X}=$ trifluoroacetate and $\mathrm{L}=\mathrm{XDK}, 6$ ); or $\left[\mathrm{Cu}_{2} \mathrm{~L}(\mathrm{THF})_{4}\right] \mathrm{X}(\mathrm{X}=$ tetrafluoroborate, $\mathrm{L}=\mathrm{XDK}, 7$, or PXDK, 8). Complex 8 was also prepared from equimolar ( $\left.\mathrm{Et}_{4} \mathrm{~N}\right)[\mathrm{Cu}(\mathrm{PXDK})]$ (3) and copper(II) triflate. Solid state structural investigations on 4,6 , and 8 revealed symmetric square pyramidal coordination environments about each copper atom and short $\mathrm{Cu}-\mathrm{Cu}$ distances ranging from 2.3988(8)-2.4246(12) $\AA$., features which taken together imply significant metal-metal bonding character. The nature of the $\mathrm{Cu}-\mathrm{Cu}$ bonding in this series of complexes was further interrogated by (a) comparative structural and ligand exchange studies with mixed-metal analogs [CuZn(PXDK)(OTf)(THF) $\left.)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]$ (9), $[\mathrm{CuFe}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{NB}) \mathrm{MeCN})]_{2}$ (10a, NB = norbornene), and CuZn(PXDK)(OTf)$(\mathrm{NB})\left(\mathrm{H}_{2} \mathrm{O}\right)(11)$, all of which exhibited longer metal-metal distances ranging from 3.294(2)-3.732(2) $\AA$ and monodentate, terminal triflate ligation; (b) by variable temperature and field EPR studies, which showed that complexes $4-8$ possess a fully delocalized electronic structure in the solid state and solution down to liquid helium temperatures; and (c) by molecular orbital calculations on simplified models of 4-8, which revealed a $\mathrm{Cu}-\mathrm{Cu}$ bonding interaction in the SHOMO and SOMO, comprised mainly of $\sigma$-type overlap between the $\mathrm{d}_{\mathrm{x} 2-\mathrm{y} 2}$ orbitals. In addition, complex 4 was shown by cyclic voltammetry to under go a chemically reversible and electrochemically quasireversible one-electron reduction that is markedly positive for a $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II})$ complex with an all-oxygen, dianionic donor set. Overall, we provide definitive evidence that, utilizing the XDK scaffold, an unusual series of class III mixed-valence dicopper complexes has been accessed. These studies should aid in understanding an electronically similar $\mathrm{Cu}-\mathrm{Cu}$ bonded system at the biological $\mathrm{Cu}_{\mathrm{A}}$ site.

## Chapter 3. Preparation of Sterically Hindered Diiron(II) Tetracarboxylate Complexes, and Their Reactivity Toward Dioxygen

A family of diferric peroxo-bridged complexes has been prepared which matches exactly the combination of carboxylate and imidazole donors of the $\mathrm{H}_{\text {peroxo }}$ intermediate in sMMO. A variety of methods including UV-Vis, EPR, Resonance Raman, and Mössbauer spectroscopies have been employed to elucidate their structures. These adducts have inequivalent iron coordination environments, a feature which is attributed either to an asymmetric peroxide bridge, a disproportionate arrangement of the ancillary carboxylate and nitrogen donor ligands about each iron center, or a combination of the two. Kinetic studies revealed that the rate of peroxo formation is first order in diiron(II) complex and $\mathrm{O}_{2}$, implicating a rate-determining bimolecular collision between the reaction components. Moreover, the rate of peroxo formation tracks inversely with the steric
demands of the carboxylate substituents, implying that a carboxylate shift is associated with the rate-determining step. The oxygenation rate is affected much more dramatically by the basicity of the N-donor ligand, however, with a difference of $>10^{5} \mathrm{~s}^{-1}$ noted for the pseudo-first-order rate constants with 1-alkylimidazole versus pyridine ligation.

## Chapter 4. Biomimetic Oxidation Studies With Discrete Diiron(III) Bis(carboxylate)Bridged Peroxo Complexes: Toward Functional Models of Oxygen Intermediates of Soluble Methane Monooxygenase

The reactivity properties of two diiron(III) peroxo complexes have been fully elucidated. These adducts behave as nucleophilic/basic peroxides, exhibiting no propensity to serve as oxygen atom donors for even potent acceptors such as triphenylphosphine. The 1-butylimidazole ligands in 1 enhance the nucleophilicity/basicity of the peroxo compared to the pyridine analog, probably because the former ligand is a superior $\sigma$-donor. This feature imparts more electron density to the iron centers, which in turn is transmitted to the peroxo ligand. Thermolysis of the peroxo adducts in a variety of media results in solvent oxidation, providing ketone and alcohol products in modest yield based on the complex. A detailed analysis of cyclopentane oxidation provided evidence for a radical chain autoxidation mechanism, a reactivity manifold which does not mimic the hydrocarbon oxidation chemistry of sMMO.

Thesis Supervisor: Stephen J. Lippard
Title: Arthur Amos Noyes Professor of Chemistry

This thesis is dedicated to my family for all your love, support and patience, and in memory of my grandfather, Roland C. LeCloux.

## Acknowledgments

I write this section of my thesis with the utmost pleasure, not only because I have saved it for last, but more importantly, it also gives me the opportunity to thank all those that have helped to make my experience at MIT so professionally and personally rewarding. First and foremost I would like to thank my advisor, Steve Lippard, for giving me virtually complete freedom to develop my research projects, while constantly instilling in me the fundamentals of scientific thinking, writing, and presentation. Former Lippard group members have reminded me how much I will value having acquired these skills once I pursue an independent career. I must say that I came to appreciate all of them when writing the thesis, and I know they will serve me well in the future, whatever that may hold.

I also must acknowledge my undergraduate advisor, William B. Tolman, at the University of Minnesota-Twin Cities. I first met Bill when taking his introductory organic chemistry course as a junior. At the time I was very committed to going to medical school, but I had enjoyed the subject immensely and wanted to obtain some practical lab experience. He enthusiastically agreed to allow me to work in his lab, and over the next two years helped to instill in me a love for chemistry which I will never relinquish. Needless to say the thought of medical school soon thereafter became a distant memory. Bill continues to provide me with much practical advice concerning all facets of my career, and he is a great friend.

There seems to be a countless number of colleagues that I need to thank for helping me professionally over the past five years. When I first arrived, fellow Subgroup 5 members Linda Doerrer, Joanne Yun, Tomoaki Tanase, and Jackie Acho helped get me started in lab. Laura Pence taught an anxious and often times overbearing young graduate student the basics of X-ray crystallography; her knowledge and patience are much appreciated. Although I never worked with him directly, Andrew Feig was always willing to answer my questions and to engage in spirited scientific debates, both of which are necessary for building the enthusiasm and confidence of a young student.

Many helped to bring together the stories described in these thesis chapters. Mike Scott and Peter Fuhrmann were always there to aid with difficult X-ray structures. Dave Coufal kindly ran liquid helium EPR samples for me, since I was always a tad too lazy to learn how to use the instrument. Maria Bautista and Linda Doerrer taught me some of the finer points of cyclic voltammetry and high vacuum line techniques. Marc Johnson and Mike Fickes of the Cummins group helped with
the MO calculations, and Mike also ran several high field, variable temperature NMR experiments for me. Kathy Franz acquired SQUID magnetic data on the copper complexes. Amy Barrios helped with many Resonance Raman studies. Jack Mizoguchi and Dongwhan Lee devoted many hours to my Mössbauer samples over at Northeastern. Ann Valentine cheerfully taught me the joys of low-temperature, stopped-flow UV-vis spectroscopy and GC-MS. Dietrich Steinhuebel always provided an extra steady pair of hands for preparing thermally unstable peroxo samples. Finally, I thank Mike Fickes, Ann Valentine, Dietrich Steinhuebel, and Justin Du Bois for a countless number of enlightening scientific discussions. I have learned much from each one of them concerning my research and chemistry in general.

Of course my personal experiences at MIT are inextricably tied to professional ones, so there will be quite a bit of repetition here. As I have preached over the years to just about anyone who will listen to me, I firmly believe single greatest attribute of MIT is one's colleagues, as they must be one of the brightest collections of people anywhere, and many in the chemistry department have become my very close friends. First I would like to thank the entire Lippard group. You are a wonderfully bright, enthusiastic, and fun-loving bunch that always seemed to put up with my intense, although good-hearted, demeanor. For this and all of the fun we had outside of the lab, I am very grateful. In addition, I must give a special thank you to Ann Valentine for being a great friend over our years at MIT, and in particular for helping me get through the thesis writing process. Everyone needs to be able to share this equally euphoric and frustrating experience with someone, lest go insane, and you certainly provided that for me. Finally, there are "the guys", as Jonas Peters has dubbed us, which includes Jonas, Mike Fickes, Robert Baumann, and Dietrich Steinhuebel. I must also throw Seble Wagaw in there as a ceremonial member, since she too has partaken in our escapades with much enthusiasm. I am confident that our paths will cross again on many occasions in the future, yet I will greatly miss our time at MIT.

## Chapter I

Synthesis and Characterization of a Novel Class of Dicopper(I) Bis(carboxylate)Bridged Complexes ${ }^{1,2}$

## Introduction

The preparation of multinuclear complexes of transition metal ions in low oxidation states for the reductive activation of small molecules is of fundamental and practical importance in bioinorganic chemistry. Many metalloenzymes utilize this strategy to achieve atom transfer reactions which pose a formidable challenge to the synthetic chemist. For example, soluble methane monooxygenase (sMMO) contains a diiron active site and catalyzes the reaction of dioxygen with methane to produce methanol and water. ${ }^{3-5}$ Particulate pMMO carries out the same reaction with a tricopper, ${ }^{6-9}$ or possibly a copper-iron, ${ }^{10}$ active site. Dopamine $\beta$-monooxygenase contains a dicopper active site and catalyzes the $\mathrm{O}_{2}$-promoted hydroxylation of a benzylic CH bond in phenethylamine derivatives. ${ }^{11,12}$ Tyrosinase utilizes a dinuclear copper active site to catalyze the orthohydroxylation of monophenols and the oxidation of catechol derivatives to orthoquinones. ${ }^{6}$ Inspired by these natural successes, we seek to prepare functional model complexes of some of the forgoing enzymes to gain a general mechanistic understanding of how two or more metal ions can work in concert to activate dioxygen reductively and harness its oxidizing equivalents for oxygen atom transfer reactions to a suitable substrate molecule. The specific reactions of interest are the hydroxylation of aliphatic, aromatic, and olefinic hydrocarbons where the oxygen atom equivalent is derived from $\mathrm{O}_{2}$. Because we are primarily concerned with exploring the basic principles of multimetal-mediated oxidation reactions, our choice of ancillary ligands is not restricted to mimic the active site residues in any particular enzyme. The target complexes for examining these reactions are required only to have discrete dinuclear units with sufficient kinetic stability toward metal ion rearrangements to avoid thermodynamically viable and catalytically inactive species along an oxidation reaction pathway.

As an initial approach to this objective we have assembled dimetallic complexes with a class of convergent bis(carboxylate) ligands derived from xylene di-
amine Kemp's triacid. ${ }^{13-20}$ Its attributes include: (a) the carboxylate functional group, which forms a host of bridged dinuclear complexes having the desired 2-5 $\AA$

$\mathrm{H}_{2}$ XDK; $\mathrm{R}=$ methyl
$\mathrm{H}_{2}$ PXDK; $\mathrm{R}=$ propyl
$\mathrm{H}_{2}$ BXDK; $\mathrm{R}=$ benzyl
metal-metal distance; ${ }^{21}$ (b) a pair of preorganized and conformationally rigid carboxylates, which tightly bind two metal ions and resist the formation of higher metal aggregates; ${ }^{19}$ and (c) variable substituents ( R ) peripheral to the metal binding sites, which provide more steric protection than simple carboxylate ligands.

The reduced metal ion pairs of particular interest to us for exploring O-atom transfer chemistry following reductive activation of dioxygen are homo- and heterodimetallic combinations of $\mathrm{Cu}(\mathrm{I})$ and $\mathrm{Fe}(\mathrm{II})$. $\mathrm{Coppr}^{22-26}$ and iron ${ }^{3,13,27-29}$ oxygenases and hydroxylases have been the subject of an enormous body of structural and functional modeling literature. We are particularly interested in the effects of the basic carboxylate ligand environment for stabilizing oxygen intermediates and for inducing oxo transfer reactivity. A program to investigate the diiron(II) chemistry of this bis(carboxylate) ligand system for the functional modeling of sMMO, in particular, is in progress. ${ }^{13,14,30}$

In the present paper, we report the preparation and characterization of a new class of dicopper(I) bis(carboxylate) complexes carried out as a prelude to an evaluation of their potential to promote hydrocarbon oxidation. The synthesis of a sterically more demanding derivative of $\mathrm{H}_{2} \mathrm{XDK},{ }^{31} \mathrm{H}_{2} \mathrm{BXDK}$, is described. Both of these
ligands as well as $\mathrm{H}_{2}$ PXDK have been used to prepare complexes with $\mathrm{Cu}(\mathrm{I})$. The reactivity of the resulting dicopper(I) XDK species with neutral ancillary ligands has been explored to elucidate fully the electronic nature of this platform and to map out its coordination chemistry. Several unprecedented copper(I) carboxylates were obtained. The dicopper(I) complexes of all three carboxylate ligands have been used in $\mathrm{O}_{2}$ reactivity studies, affording some stable peroxo intermediates at low temperature. These investigations will be described elsewhere. ${ }^{32}$

## Experimental Section

General Considerations. The $\mathrm{H}_{2}$ XDK (1) ${ }^{33}$ and $\mathrm{H}_{2} \mathrm{PXDK}(2)^{13}$ ligands were prepared according to literature procedures. All reagents were obtained from commercial sources unless otherwise noted. THF, benzene, toluene, pentane, and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from sodium benzophenone ketyl under nitrogen. Dichloromethane and chlorobenzene were distilled from $\mathrm{CaH}_{2}$ under nitrogen. Acetonitrile was predistilled from $\mathrm{CaH}_{2}$ and then from $\mathrm{P}_{2} \mathrm{O}_{5}$. The NMR solvents $\mathrm{CDCl}_{3}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$, and $\mathrm{C}_{6} \mathrm{D}_{6}$ were degassed, passed through activated basic alumina, and stored over $3 \AA$ molecular sieves prior to use. All other solvents and reagents are commercially available and were used as received. All air sensitive manipulations were carried out either in a nitrogen filled Vacuum Atmospheres drybox or by standard Schlenk line techniques at room temperature unless otherwise noted.

Physical Measurements. NMR spectra were recorded on Bruker AC-250, Varian XL-300, or Varian VXR-500 NMR spectrometers. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR chemical shifts are reported versus tetramethylsilane and referenced to the residual solvent peak. ${ }^{31} \mathrm{P}$ NMR chemical shifts are reported versus external $\mathrm{H}_{3} \mathrm{PO}_{4}$ (85\%). FTIR spectra were recorded on a BioRad FTS-135 FTIR spectrometer, and mass spectra were determined by using a Finnigan 4000 mass spectrometer with $70-\mathrm{eV}$ impact ionization. UV-vis spectra were recorded on a Cary 1E spectrophotometer.

Conductivity measurements were carried out in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at 296 K with a Fisher Scientific conductivity bridge model $9-326$ with a platinum black electrode. Elemental analyses were performed by Microlytics, South Deerfield, MA.

Synthesis. Trimethyl-cis,cis-1,3,5-tribenzylcyclohexane-1,3,5-tricarboxylate (Benzyl Kemp's Triester, 3). To a mechanically stirred solution of lithium diisopropyl amide ( 1.5 M in $\mathrm{THF}, 200 \mathrm{~mL}, 297 \mathrm{mmol}$ ) and toluene ( 400 mL ) at $0^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ was added trimethyl-1,3,5-cyclohexyltricarboxylate ( $24.0 \mathrm{~g}, 92.9 \mathrm{mmol}$ ) in toluene $(300 \mathrm{~mL})$ dropwise over 1 h . The mixture was allowed to stir an additional 0.5 h , and then benzyl bromide ( $35.4 \mathrm{~mL}, 297 \mathrm{mmol}$ ) was added via syringe in one portion. The mixture was warmed to room temperature and then refluxed for 7 h . After this time the reaction was cooled to room temperature and quenched with $\mathrm{H}_{2} \mathrm{O}(200-300 \mathrm{~mL})$. The organic phase was collected and concentrated in vacuo. The resulting oily residue was taken up in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(200 \mathrm{~mL})$ and extracted with 2 M HCl ( $2 \times 100 \mathrm{~mL}$ ) and brine ( 100 mL ). The combined organic extracts were dried with $\mathrm{MgSO}_{4}$, and the volatile components were removed in vacuo. The resulting orangebrown solid was suspended in dry $\mathrm{Et}_{2} \mathrm{O}(200-300 \mathrm{~mL})$ and then isolated by filtration to yield 3 ( $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR) as a light yellow solid ( $31.9 \mathrm{~g}, 65 \%$ ). Recrystallization from toluene/pentane provided 3 as colorless blocks. ${ }^{1} \mathrm{H}$ NMR (250 $\mathrm{MHz}, \mathrm{DMSO}, 296 \mathrm{~K}) \delta 7.32-7.20(9 \mathrm{H}, \mathrm{m}), 7.07(6 \mathrm{H}, \mathrm{d}, J=6.6 \mathrm{~Hz}), 3.43(9 \mathrm{H}, \mathrm{s}), 2.82(6 \mathrm{H}$, s), $2.41(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=14.1 \mathrm{~Hz}), 1.46(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=14.1 \mathrm{~Hz}) \mathrm{ppm} ; \operatorname{IR}(\mathrm{KBr}) 3060,3027,3000$, 2946, 2895, 1738, 1602, 1495, 1451, 1383, 1233, 1206, 1121, 1038, 993, 874, 770, 698, $549 \mathrm{~cm}^{-}$ 1. High resolution MS (FAB) Calcd for $\mathrm{C}_{33} \mathrm{H}_{36} \mathrm{O}_{6}(\mathrm{M}): m / e ~ 528.2512$. Found: 528.2505. Anal. Calcd for $\mathrm{C}_{33} \mathrm{H}_{36} \mathrm{O}_{6}$ : C, 74.98; H, 6.86. Found: C, $75.35 ; \mathrm{H}, 6.85$.
cis,cis-1,3,5-Tribenzylcyclohexane-1,3,5-tricarboxylic acid (Benzyl Kemp's Triacid, 4). To a stirred solution of $3(25.3 \mathrm{~g}, 47.8 \mathrm{mmol})$ in EtOH/THF (1:1, 500 mL total volume) was added $\mathrm{KOH}(63.0 \mathrm{~g}, 955 \mathrm{mmol})$ in a minimum amount of $\mathrm{H}_{2} \mathrm{O}$, and the mixture was refluxed for 6 h . The mixture was concentrated in vacuo to a vis-
cous oily solid. It was redissolved in $\mathrm{H}_{2} \mathrm{O}(300 \mathrm{~mL})$, cooled to $0^{\circ} \mathrm{C}$, and acidified to pH 1 with concentrated HCl . The resulting yellow precipitate was isolated by filtration, washed with $\mathrm{H}_{2} \mathrm{O}(300-400 \mathrm{~mL})$, and dried in vacuo at $110^{\circ} \mathrm{C}$ for 2 h . The powder was then suspended in dry $\mathrm{Et}_{2} \mathrm{O}$ and isolated by filtration to yield 4 ( $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR) as a white solid (18.4 g, 79\%). Recrystallization from acetone/DMSO/Et ${ }_{2} \mathrm{O}$ afforded 4 as colorless blocks. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{DMSO}, 296 \mathrm{~K}$ ) $\boldsymbol{\delta}$ $12.04(1 \mathrm{H}, \mathrm{s}), 7.29-7.14(15 \mathrm{H}, \mathrm{m}), 2.86(6 \mathrm{H}, \mathrm{s}), 2.39(3 \mathrm{H}, \mathrm{d}, J=14.7 \mathrm{~Hz}), 1.47(3 \mathrm{H}, \mathrm{d}, J=$ 13.8 Hz ) ppm; IR (KBr) 3010, 2615, 1729, 1698, 1603, 1496, 1457, 1291, 1198, 1127, 1031, 915, 767, 699, $553 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{34} \mathrm{H}_{42} \mathrm{O}_{8} \mathrm{~S}_{2}$ (4•2DMSO): C, 63.53; H, 6.59 . Found: C, $63.44 ; \mathrm{H}, 6.54$. The 4.2 DMSO stoichiometry was determined by X-ray crystallography.
cis,cis-1,3,5-Tribenzylcyclohexane-1,3-anhydride-5-acid chloride (Tribenzyl Kemp's Anhydride Acid Chloride, 5). This compound was prepared from 4 (22.3 g, $45.8 \mathrm{mmol})$ and excess $\mathrm{SOCl}_{2}(100 \mathrm{~mL})$ by a procedure analogous to one used for the synthesis of the parent trimethyl derivative ${ }^{33}$ to yield 5 ( $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR) as a white solid ( $22.3 \mathrm{~g}, 100 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $250 \mathrm{MHz}, \mathrm{CDCl}_{3}, 296 \mathrm{~K}$ ) $\delta 7.40-7.25(10 \mathrm{H}, \mathrm{m})$, 7.10-7.03 ( $5 \mathrm{H}, \mathrm{m}$ ), $3.21(2 \mathrm{H}, \mathrm{d}, J=13.6 \mathrm{~Hz}), 2.91-2.84(4 \mathrm{H}, \mathrm{m}), 2.70(2 \mathrm{H}, \mathrm{d}, J=14.4 \mathrm{~Hz})$, $1.87(1 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz}), 1.45(2 \mathrm{H}, \mathrm{d}, J=14.4 \mathrm{~Hz}), 1.16(1 \mathrm{H}, \mathrm{d}, J=13.2 \mathrm{~Hz}) \mathrm{ppm} ; \mathrm{IR}(\mathrm{KBr})$ $3062,3030,2961,2928,1803,1767,1604,1496,1455,1445,1213,1099,1057,1000,991,898$, $760,701,609,537 \mathrm{~cm}^{-1}$. Benzyl Xylene Diamine Kemp's Triacid ( $\mathbf{H}_{2}$ BXDK, 6). This compound was prepared from 5 ( $22.3 \mathrm{~g}, 45.8 \mathrm{mmol}$ ), 1,3-dimethyl-4,6-diaminobenzene ( $3.27 \mathrm{~g}, 24.0$ mmol ), and 4-dimethylaminopyridine ( $300 \mathrm{mg}, 2.40 \mathrm{mmol}$ ) by a procedure analogous to that used to prepare $\mathrm{H}_{2} \mathrm{XDK}(1) .{ }^{33}$ Recrystallization from MeOH yielded 6 ( $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR) as a white microcrystalline solid (16.6 g, 70\%). Recrystallization from $\mathrm{CHCl}_{3}$ /pentane provided 6 as colorless blocks which ap-
peared suitable for X-ray crystallography. ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}, 296 \mathrm{~K}\right) \delta 7.32-$ $7.28(4 \mathrm{H}, \mathrm{m}), 7.21-6.95(27 \mathrm{H}, \mathrm{m}), 6.54(1 \mathrm{H}, \mathrm{s}), 3.40(4 \mathrm{H}, \mathrm{d}, J=13.2 \mathrm{~Hz}), 2.75(4 \mathrm{H}, \mathrm{d}, J=$ $13.8 \mathrm{~Hz}), 2.56(4 \mathrm{H}, \mathrm{s}), 2.31(4 \mathrm{H}, \mathrm{d}, J=13.5 \mathrm{~Hz}), 2.02(2 \mathrm{H}, \mathrm{d}, J=13.0 \mathrm{~Hz}), 1.18(6 \mathrm{H}, \mathrm{s}), 1.03$ $(4 \mathrm{H}, \mathrm{d}, J=14.1 \mathrm{~Hz}), 0.89(2 \mathrm{H}, \mathrm{d}, J=13.2 \mathrm{~Hz}) \mathrm{ppm} ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(125 \mathrm{mHz}, \mathrm{CDCl}_{3}, 296\right.$ K) $\delta 181.6,173.7,136.0,135.4,135.0,133.0,132.9,131.2,130.0,128.4,128.0,127.6,126.8$, $126.2,50.2,47.3,45.0,44.4,41.8,36.9,16.0 \mathrm{ppm}$; IR (KBr) 3027, 2955, 2924, 2863, 1795, 1707, 1603, 1495, 1461, 1368, 1326, 1231, 1178, 1031, 934, 744, 700, 585, $517 \mathrm{~cm}^{-1}$. $\mathbf{T l}_{\mathbf{2}}$ (BXDK) (9). This compound was prepared from crude 6 ( $3.00 \mathrm{~g}, 2.89 \mathrm{mmol}$ ) and TIOEt ( $418 \mu \mathrm{~L}, 5.78 \mathrm{mmol}$ ) by a procedure analogous to that used to prepare 7 , affording 9 ( $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR) as a tan powder. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{Et}_{2} \mathrm{O}$ gave 9 as a white microcrystalline solid ( $3.38 \mathrm{~g}, 81 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( 300 $\left.\mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}, 296 \mathrm{~K}\right) \delta 7.88(1 \mathrm{H}, \mathrm{s}), 7.30-7.23(4 \mathrm{H}, \mathrm{m}), 7.21-6.98(26 \mathrm{H}, \mathrm{m}), 6.51(1 \mathrm{H}, \mathrm{s}), 3.48$ $(4 \mathrm{H}, \mathrm{s}, J=12.9 \mathrm{~Hz}), 2.97(4 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz}), 2.82(4 \mathrm{H}, \mathrm{s}), 2.49(4 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz}), 2.07$ $(4 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz}), 1.18(4 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz}), 1.02(2 \mathrm{H}, \mathrm{d}, J=13.2 \mathrm{~Hz}), 0.96(6 \mathrm{H}, \mathrm{s}) \mathrm{ppm} ;$ ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(75 \mathrm{mHz}, \mathrm{CDCl}_{3}, 296 \mathrm{~K}\right) \delta 180.4,176.2,138.6,136.9,135.6,133.5,133.4$, $131.8,131.3,128.8,128.6,128.4,127.2,127.1,51.0,50.5,45.9,45.4,43.5,37.9,16.6$ ppm; IR (KBr) 3083, 3027, 2916, 1731, 1681, 1559, 1453, 1357, 1187, 1031, 937, 865, 741, 700, 602, $508 \mathrm{~cm}^{-1}$. High resolution MS (FAB) Calcd for $\mathrm{C}_{68} \mathrm{H}_{62} \mathrm{~N}_{2} \mathrm{O}_{8} \mathrm{Tl}_{2}(\mathrm{M}): m / e 1444.3994$. Found: 1445.4061.
[ $\mathrm{Cu}_{\mathbf{2}}$ (XDK)(MeCN)] (10). To a stirred solution of 7 ( $3.67 \mathrm{~g}, 3.72 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeCN}(3: 1,300 \mathrm{~mL})$ under $\mathrm{N}_{2}$ was added solid $\mathrm{CuBr}\left(\mathrm{Me}_{2} \mathrm{~S}\right)(2.32 \mathrm{~g}, 11.1$ $\mathrm{mmol})$, and the mixture was rapidly stirred for 3 h . The salts were then removed by filtration through celite. The filtrate was treated with three more equiv of $\mathrm{CuBr}\left(\mathrm{Me}_{2} \mathrm{~S}\right)$ and stirred for 1 h . The solvent was removed in vacuo, and the solid residue was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(200 \mathrm{~mL})$ followed by filtration through celite. The precipitate was extracted with additional $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL})$ and filtered through celite. The combined filtrates were concentrated in vacuo to yield a solid residue. It was suspended in $\mathrm{Et}_{2} \mathrm{O}$, and the precipitate was recovered by filtration to yield 10 (> 95\% pure by ${ }^{1} \mathrm{H}$ NMR) as a white solid ( $2.50 \mathrm{~g}, 90 \%$ ). The crude powder was used without further purification for subsequent reactions. Recrystallization from $\mathrm{MeCN} / \mathrm{CH}_{2} \mathrm{Cl}_{2}-$
$/ \mathrm{Et}_{2} \mathrm{O}$ afforded 10 as colorless blocks which appeared suitable for X-ray crystallography. ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}, 296 \mathrm{~K}\right) \delta 8.47(1 \mathrm{H}, \mathrm{s}), 6.70(1 \mathrm{H}, \mathrm{s}), 2.83(4 \mathrm{H}$, $\mathrm{d}, J=13.1 \mathrm{~Hz}), 2.05(3 \mathrm{H}, \mathrm{br} \mathrm{s}), 1.77(6 \mathrm{H}, \mathrm{s}), 1.71(2 \mathrm{H}, \mathrm{d}, J=15.0 \mathrm{~Hz}), 1.20(12 \mathrm{H}, \mathrm{s}), 0.82$ $(2 \mathrm{H}, \mathrm{d}, J=13.1 \mathrm{~Hz}), 0.75(4 \mathrm{H}, \mathrm{d}, J=13.5 \mathrm{~Hz}), 0.63(6 \mathrm{H}, \mathrm{s}) \mathrm{ppm} ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}(75 \mathrm{mHz}$, $\left.\mathrm{CD}_{2} \mathrm{Cl}_{2}, 296 \mathrm{~K}\right) \delta 186.4,177.1,135.7,134.9,133.7,128.5,117.6,45.7,45.2,43.4,41.7,31.5$, 26.5, 17.5, 2.6 ppm; IR(KBr) 2963, 2921, 1738, 1704, 1568, 1463, 1403, 1357, 1176, 1086, 957, 891, 849, 759, 734, 622

[CuLi(XDK)(THF) $\mathbf{2}_{\mathbf{2}}$ (22). Method A: To a stirred solution of 10 ( $50 \mathrm{mg}, 0.067$ mmol ) and 12-crown-4 ( $43 \mathrm{~mL}, 0.27 \mathrm{mmol}$ ) in THF ( 3 mL ) was added $\mathrm{PhLi}(37 \mathrm{~mL}$, 1.8 M in cyclohexane $/ \mathrm{Et}_{2} \mathrm{O}$ ). The resulting brown mixture was stirred for 2 h , and then the volatile components were removed in vacuo. The residue was recrystallized from THF/pentane to yield a dark brown precipitate and large colorless blocks. Crystals of 22 separated from the dark residue in Paratone-N (Exxon) and were suitable for X-ray crystallography, but a large scale purification for spectroscopic and elemental analysis was unsuccessful by this method.

Method B: To a stirred solution of $10(100 \mathrm{mg}, 0.13 \mathrm{mmol})$ in THF ( 5 mL ) was added LiCN ( 0.5 M in DMF, $268 \mu \mathrm{l}, 0.13 \mathrm{mmol}$ ) via syringe in one portion. An offwhite precipitate formed immediately, and after 5 min the mixture was filtered through celite. The volatile components were removed from the filtrate in vacuo.

The resulting $\tan$ solid was washed with pentane ( $5-10 \mathrm{ml}$ ) to remove residual DMF. The dried residue was redissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{ml})$ and filtered through celite to remove a fine white precipitate. An equal volume of THF was added, and slow diffusion of pentane into this solution provided 22 as large colorless blocks. When crystalline 22 was isolated from the mother liquor, followed by drying at atmospheric pressure under $\mathrm{N}_{2}$, one of the THF molecules was lost as judged by ${ }^{1} \mathrm{H}$ NMR and elemental analysis ( $75 \mathrm{mg}, 78 \%$ ). ${ }^{1} \mathrm{H}$ NMR for $[\mathrm{CuLi}(\mathrm{XDK})(\mathrm{THF})]$ ( 300 MHz , $\left.\mathrm{CD}_{2} \mathrm{Cl}_{2}, 296 \mathrm{~K}\right) \delta 7.64(1 \mathrm{H}, \mathrm{s}), 7.14(1 \mathrm{H}, \mathrm{s}), 3.69(4 \mathrm{H}, \mathrm{t}, J=6.3 \mathrm{~Hz}), 2.72(4 \mathrm{H}, \mathrm{d}, J=13.2$ $\mathrm{Hz}), 2.08(2 \mathrm{H}, \mathrm{d}, J=13.2 \mathrm{~Hz}), 1.91(6 \mathrm{H}, \mathrm{s}), 1.87-1.80(4 \mathrm{H}, \mathrm{m}), 1.45(2 \mathrm{H}, \mathrm{d}, J=12.9 \mathrm{~Hz})$, $1.34-1.05(22 \mathrm{H}, \mathrm{m}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}, 296 \mathrm{~K}$ ) $\delta$ 185.1, 177.5, 135.6, 134.7, 133.2, 128.2, 45.7, 45.2, 43.1, 41.7, 32.3, 31.7, 26.5, 26.1, 17.6 ppm; IR(KBr) 2959, 2868, 1736, 1702, 1402, 1376, 1352, 1227, 1184, 1048, 956, 889, 760, $624 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{36} \mathrm{H}_{46} \mathrm{~N}_{2} \mathrm{O} 9 \mathrm{CuLi}(22$ minus 1THF): C, $59.95 ; \mathrm{H}, 6.43 ; \mathrm{N}, 3.88$. Found: C, $59.64 ; \mathrm{H}, 7.10$; N, 3.43.

Collection and Reduction of X-ray Data
All crystals were mounted on the tips of quartz fibers with Paratone-N (Exxon), cooled to low temperature ( $\sim-85^{\circ} \mathrm{C}$ ), and placed on Siemens CCD X-ray diffraction system controlled by a Pentium-based PC running the SMART software package. ${ }^{34}$ The general procedures for data collection and reduction follow those reported previously. ${ }^{35}$ All structures were solved by use of the direct methods programs SIR-92 ${ }^{36}$ or XS, part of the TEXSAN ${ }^{37}$ and SHELXTL ${ }^{38}$ program packages, respectively. Structure refinements were carried out with XL, part of the SHELXTL program package. ${ }^{38}$ All remaining non-hydrogen atoms were located and their positions refined by a series of least-squares cycles and Fourier syntheses. Enantiomorph checks were carried out on 17 and 21 by using the Flack parameter refinement ${ }^{39}$ in the XL program. Selection of the correct enantiomer for complex 17 was determined to be unreliable, so it was refined as a racemic twin, resulting in lower $R$ and $w \mathrm{R}^{2}$
values than were obtained when refining with either of the two enantiomers. Selection of the correct enantiomer for 21 was unambiguous. All hydrogen atoms for 6, 10, and 21 were located from difference Fourier maps and refined isotropically. For 15, the four olefinic hydrogen atoms of the coordinated norbornene molecules were located from difference maps and refined isotropically. The remaining hydrogen atoms of 15 , and all the hydrogen atoms for $13,14 a, 14 b, 16,17$, and 22 , were assigned idealized positions and given a thermal parameter 1.2 times the thermal parameter of the carbon atom to which each was attached. Empirical absorption corrections were calculated and applied for each structure using SADABS, part of the SHELXTL program package. ${ }^{38}$

The structures of $14 a, 14 b$, and 16 contain a disordered chlorobenzene molecule. The chlorine atom in each case is disordered across an inversion center positioned on the centroid of the phenyl ring. Each chlorine atom was refined with a site occupancy of 0.5 . The other chlorobenzene in 16 contains two carbon atoms with large thermal parameters. The structure of 17 contains two disordered THF molecules in which the oxygen atoms could not be determined reliably, so both were refined at partial occupancy as cyclopentane molecules. The structure of 21 contains a lattice THF molecule disordered over two positions. It was refined as a cyclopentane molecule with two of the carbon atoms at full occupancy, and the occupancy of the other three carbon atoms was distributed over two positions and refined. One of the propyl groups of 21 is disordered. The carbon atom attached to the cyclcohexyl ring was refined at full occupancy, and the occupancy of the other two carbon atoms was distributed over two positions and refined.

Important crystallographic information for each complex including refinement residuals is given in Table 1.1, along with core distances and angles in Table 1.2. Final positional and equivalent isotropic thermal parameters are provided in Tables 1.3-1.12.

## Results and Discussion

At the inception of this research, very few well characterized copper(I) carboxylate complexes had been described. The most notable work came from Floriani's lab, which reported the synthesis of carbon monoxide, ${ }^{40}$ isonitrile, ${ }^{41}$ and alkyne ${ }^{42}$ complexes incorporating $\mathrm{Cu}(\mathrm{I})$ benzoate. Copper $(\mathrm{I})$ carboxylate complexes without $\pi$ acceptor ligands, except for oligomeric homoleptic complexes, are rare owing to disproportionation to Cu metal and $\mathrm{Cu}(\mathrm{II})$ products. In addition, accounts of the reactivity toward dioxygen of any well defined $\mathrm{Cu}(\mathrm{I})$ carboxylate derivatives were nonexistent. Our initial goals were therefore to develop a facile synthesis of a discrete dicopper(I) XDK complex and ascertain its kinetic stability, and to understand the chemical properties of this bis(carboxylate)-bridged "platform" by fully elucidating its coordination chemistry with a range of ancillary ligands, ranging from $\pi$-acceptor to sigma-only donors. From these studies has emerged a detailed picture of the electronic nature of the dicopper $(\mathrm{I})$ XDK platform and a host of complexes for $\mathrm{O}_{2}$ reactivity studies.

Ligand Synthesis. Exposure of most dicopper(I) and diiron(II) complexes of XDK and PXDK to dioxygen at low temperature produces transiently stable intermediates at best. ${ }^{13,43}$ A possible decomposition pathway in these reactions is the intermolecular reaction between an $\mathrm{O}_{2}$-derived intermediate and one or more $\left\{\mathrm{M}_{2}(\mathrm{XDK})\right\}$ units. ${ }^{27,28}$ A more sterically demanding XDK derivative might block this pathway by impeding access to the intermediate or transition state. This strategy presumes that the decomposition pathway does not involve complete dissociation of the metal $\mathrm{O}_{2}{ }^{-}$ derived species from XDK, which may occur in some cases. Nevertheless it represents a reasonable starting point, and we were therefore interested to prepare a sterically more hindered XDK analog.

Derivatization of Kemp's triacid has been achieved by alkylation of trimethyl 1,3,5-cyclohexyltricarboxylate carboxylate with benzyl chloromethyl ether ${ }^{44}$ and allyl
bromide, ${ }^{45}$ both potent electrophiles. A more sterically demanding and robust substituent than the benzyloxy group was sought which would place a bulky group closer to the metal binding sites and resist oxidative cleavage. Both neopentyl and benzyl functionalities fulfill these requirements, but efforts to alkylate with neopentyl iodide failed owing to its modest electrophilicity. Reaction of trilithio trimethyl-1,3,5-cyclohexyltricarboxylate with three equivalents of benzyl bromide under relatively forcing conditions proceeded in good yield, however, affording multigram quantities of trimethyl-cis,cis-1,3,5-tribenzylcyclohexane-1,3,5-tricarboxylate (benzyl Kemp's triester, 3, Scheme 1.1). Deprotection of 3 in refluxing KOH followed by acidification with HCl provided cis,cis-1,3,5-tribenzylcyclohexane-1,3,5-tricarboxylic acid (benzyl Kemp's triacid, 4). Under identical conditions but in the absence of THF, only intractable decomposition products were obtained. The tripotassium salt of 4 precipitates out of solution when a $1: 1 \mathrm{EtOH} / \mathrm{THF}$ solvent mixture is used, and this property may protect it from further degradation. The final ether wash also proved crucial for obtaining pure product, for it removed significant quantities of partially deprotected 3 and other decomposition products. The triacid is soluble in neat DMSO or DMSO solvent mixtures. Synthesis of cis,cis-1,3,5-tribenzyl-cyclohexane-1,3-anhydride-5-acid chloride (tribenzyl Kemp's anhydride acid chloride, 5) proceeded by standard procedures ${ }^{33}$ in quantitative yield.

Condensation of 5 with 0.5 equivalents of 1,3-dimethyl-4,6-diaminobenzene followed by recrystallization from MeOH provided benzyl xylene diamine Kemp's triacid $\left(\mathrm{H}_{2} \mathrm{BXDK}, 6\right)$ in moderate yield and high purity as judged by the ${ }^{1} \mathrm{H}$ NMR spectrum of the bulk product. This spectrum also revealed that the benzyl Kemp's cyclohexyl fragments were in equivalent magnetic environments, supporting the assignment of $C_{2 v}$ symmetry for the product and confirming that the desired $U$ shaped isomer had been obtained. An X-ray structural determination of 6 confirmed this assignment (Figure 1.1). The space filling representation reveals that the
peripheral benzyl groups shroud the bis(carboxylate) oxygen plane and the metal binding sites from above, although rotation toward the outside of the molecule in solution appears facile. This flexibility would preclude steric protection from the sides of a BXDK complex. Nevertheless the benzyl groups are still forced to point up owing to the geometric constraints of the quaternary cyclohexyl carbon atoms and this property should provide added steric protection at the carboxylate binding sites compared to XDK and PXDK.

## Preparation and Reactivity of Dicopper(I) Bis(carboxylate)-Bridged Complexes:

 Synthesis of $\left[\mathrm{Tl}_{2} \mathrm{~L}\right], \mathrm{L}=\mathrm{XDK}(7), \mathrm{PXDK}(8)$, and $\mathrm{BXDK}(9)$; and $\left[\mathrm{Cu}_{2} \mathrm{~L}(\mathrm{MeCN})\right], \mathrm{L}=\mathrm{XDK}$ (10), PXDK (11), and BXDK (12). Convenient, high-yield procedures were desired for the bis(carboxylate) dicopper(I) starting materials. Other $\mathrm{Cu}(\mathrm{I})$ carboxylates have been prepared from their $\mathrm{Tl}(\mathrm{I})$ salts and a copper halide, ${ }^{46}$ so this approach was adopted (eq 1). Treatment of 1,2 , or 6 with 2 equiv of TlOEt afforded 7-9, respectively, as$$
\mathrm{L}=\begin{align*}
& \mathrm{H}_{2} \mathrm{~L}+2 \mathrm{TlOEt} \xrightarrow[-2 \mathrm{EtOH}]{\mathrm{THF}, \mathrm{rt}, \mathrm{~N}_{2}}
\end{align*} \begin{gathered}
{\left[\mathrm{Tl}_{2}(\mathrm{XDK})\right](7),\left[\mathrm{Tl}_{2}(\mathrm{PXDK})\right](8),}  \tag{1}\\
\text { or }\left[\mathrm{Tl}_{2}(\mathrm{BXDK})\right](9)
\end{gathered}
$$

white powders in quantitative yields. The ${ }^{1} \mathrm{H}$ NMR spectra of each dithallium(I) complex showed one set of cleanly shifted resonances and the disappearance of the broad singlet due to the carboxylic acid protons. Complex 7 is only slightly soluble in THF and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, whereas 8 and 9 are readily soluble.

Treatment of 7,8 or 9 with excess $\mathrm{CuBr}(\mathrm{DMS})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeCN}$ provided 1012, respectively, as crude off-white powders in $90 \%$ yield (eq 2). The ${ }^{1} \mathrm{H}$ NMR

$$
\left.[\mathrm{Tl} 2 \mathrm{~L}] \xrightarrow{\text { DK, BXDK }} \begin{array}{c}
\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeCN}  \tag{2}\\
\mathrm{rt}, \mathrm{~N}_{2} \\
-2 \mathrm{TlBr}
\end{array}\right) \xrightarrow{\text { excess } \mathrm{CuBr}(\mathrm{DMS})} \begin{gathered}
{\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{MeCN})\right](10),} \\
\left.\left[\mathrm{Cu}_{2} \mathrm{PXDK}\right)(\mathrm{MeCN})\right](11),
\end{gathered}
$$

spectrum of each product exhibited a single shifted set of dicarboxylate and MeCN ligand resonances in a 1:1 ratio. A xylene spacer aromatic proton experiences a significant downfield shift, presumably the one ortho to both imide nitrogen atoms, which is in close proximity to the metal-binding sites. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeCN} / \mathrm{Et}_{2} \mathrm{O}$ afforded colorless blocks or needles. Spectroscopic and analytical data confirm the purity of each complex. Complexes 10-12 are all non-electrolytes in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution, supporting that the metal ions are strongly coordinated by the carboxylate groups in solution. An X-ray structural determination of 10 confirmed that both Tl ions were displaced in eq 2 to form a dinuclear copper(I) carboxylatebridged complex. As illustrated in Figure 1.2, one copper atom is ligated by an acetonitrile and two carboxylate oxygen atoms in a trigonal planar geometry, and the other is coordinated in a nearly linear, two-coordinate fashion to the other two carboxylate oxygen atoms. A linear two-coordinate geometry is not uncommon for $\mathrm{Cu}(\mathrm{I}),{ }^{47}$ which appears to have the ideal ionic radius to be "skewered" by the two rigidly positioned XDK oxygen atoms. The relatively short $\mathrm{Cu} \cdots \mathrm{Cu}$ distance of 2.6287 (5) $\AA$ signifies weak metal-metal bonding, a formulation which is supported by molecular orbital calculations on a tetrameric $\mathrm{Cu}(\mathrm{I})$ trimethylsilyl complex with similar copper-copper distances. ${ }^{48}$

Reactivity of the Dicopper(I) Acetonitrile Complexes. The reactivity of 10-12 with a spectrum of reagents, weak sigma donors ( $\pi$-acceptors), basic neutral sigma donors, and anionic donors was investigated and the results are summarized in Scheme 1.2. ORTEP diagrams of the structurally characterized products are shown in Figures 1.3 and 1.4, and selected bond distances and angles are reported in Table 1.2. The coordination chemistry proved to be essentially identical for all three diacids, so only that for XDK will be described in detail.

[^0]$\left.(\mathrm{NB})_{2}\right](15),\left[\mathrm{Cu}_{2}(\mathrm{XDK})\right](16),\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\right.$ tmeda $\left.)\right](17),\left[\mathrm{Cu}_{2}(\mathrm{PXDK})(\right.$ tmeda $\left.)\right](18)$, [ $\mathrm{Cu}_{2}$ (BXDK)(tmeda)] (19), and [Cu(4,4'-Me $\left.\left.{ }_{2}{ }^{\mathrm{bpy}}\right)_{2}\right][\mathrm{Cu}(X D K)]$ (20). All of these complexes were prepared by allowing $\mathbf{1 0}$ or $\mathbf{1 1}$ to react with 2-4 equiv or an excess of the appropriate ancillary ligand, followed by washing with pentane or $\mathrm{Et}_{2} \mathrm{O}$ to remove residual free ligand. All were recrystallized to afford analytically pure material.

Treatment of $\mathbf{1 0}$ with two equivalents of triphenylphosphine followed by recrystallization afforded bis(phosphine) adduct 13 as colorless blocks. Conductivity measurements revealed 13 to be a non-electrolyte in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution. The ${ }^{1} \mathrm{H}$ NMR spectrum exhibited one set of XDK resonances and a complicated set of triphenylphosphine resonances in a $2: 1$ ratio. The proton-decoupled ${ }^{13} \mathrm{C}$ NMR spectrum showed single sets of XDK and triphenylphosphine resonances, and phosphorus coupling to three of the four phenyl ring proton resonances, as is found in free triphenylphosphine in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. The ${ }^{31} \mathrm{P}$ NMR spectrum showed one broad singlet at room temperature, shifted slightly downfield from that of free triphenylphosphine ( $\delta 5.1 \mathrm{ppm}, \Delta \mathrm{v}_{1 / 2}=24.7 \mathrm{~Hz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ). X -ray structural analysis revealed solid 13 to be composed two inequivalent trigonal planar copper atoms, with one copper displaced laterally from the four-oxygen carboxylate plane and the other lying above the plane (Figure 1.3). The copper-phosphorus bond lengths are normal for $\mathrm{Cu}(\mathrm{I})$ triphenylphosphine complexes having one phosphine ligand per copper atom. ${ }^{49}$ Simple $\mathrm{Cu}(\mathrm{I})$ carboxylate-triphenylphosphine complexes have been prepared and structurally characterized previously, with $\left[\mathrm{Cu}(\mathrm{OAc})\left(\mathrm{PPh}_{3}\right)_{2}\right]$ being a representative example. ${ }^{50}$ This mononuclear complex consists of a tetrahedrally coordinated copper atom with a chelating acetate and two triphenylphosphine ligands. The dissimilar reactivity of $\mathbf{1 0}$ is probably due to steric effects and the convergent nature of the XDK carboxylate ligands.

Exposure of 10 to excess 2,6-dimethylphenylisocyanide followed by recrystallization provided the tris(isonitrile) adduct 14 . The ${ }^{1} \mathrm{H}$ NMR spectrum exhibited
single sets of cleanly shifted XDK and isonitrile resonances in the expected ratios. The IR spectrum showed one broad isonitrile $\mathrm{C} \equiv \mathrm{N}$ stretch at $2134 \mathrm{~cm}^{-1}$. The complex is a non-electrolyte in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution. X-ray structural analysis on two different crystals, obtained under identical crystallization conditions, revealed that the tris(isonitrile) complex can exist as two isomers (Figure 1.3). In all-terminal colorless 14a, one copper is trigonal and the other tetrahedral, essentially as found in a bis(carboxylate) tris(isonitrile) complex prepared from $\mathrm{Cu}(\mathrm{I})$ benzoate and $p$-tolyl isocyanide. ${ }^{41}$ The other isomer, yellow $\mathbf{1 4 b}$, has the isonitrile ligands coordinated in a symmetrical fashion, with one bridging the two copper atoms and one terminal on each. The bridging isonitrile in $\mathbf{1 4 b}$ enforces a relatively close $\mathrm{Cu} \cdots \mathrm{Cu}$ distance of 2.7278 (9) $\AA$ compared to the value of $3.2560(5) \AA$ for 14 a. A bridging isonitrile derivative similar to $\mathbf{1 4 b}$ has not been reported for other $\mathrm{Cu}(\mathrm{I})$ carboxylates. The isomers appear to be in rapid equilibrium in solution at room temperature since only one set of ${ }^{1} \mathrm{H}$ NMR resonances is observed for the XDK and isonitrile ligands.

Treatment of 10 with excess norbornene followed by recrystallization provided bis(norbornene) adduct 15 as colorless blocks. The X-ray structure was analogous to that determined for bis(triphenylphosphine) adduct 13, with each trigonal planar copper atom ligated to XDK in a different fashion (Figure 1.3). Both norbornene ligands are coordinated via the exo face, as has been observed in other $\mathrm{Cu}(\mathrm{I})$ norbornene adducts, with characteristic $\mathrm{Cu}(\mathrm{I})$-olefin bond distances. ${ }^{51}$ When crystals of 15 are allowed to dry fully under an atmosphere of $\mathrm{N}_{2}$ at room temperature, one of the norbornene ligands is lost, as judged by ${ }^{1} \mathrm{H}$ NMR spectroscopy and elemental analysis. This complex does not lose the remaining norbornene ligand when exposed to high vacuum. It is probably composed of trigonal planar and linear two coordinate copper atoms, although an X-ray structure has not been obtained.

Treatment of 10 with excess cyclohexene, followed by evaporation of the volatile components under high vacuum, provided the desolvated parent complex
16. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and IR spectra showed no cyclohexene or acetonitrile peaks, and the product is a non-electrolyte in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution. X-ray quality crystals of 16 were grown from either $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ pentane or $\mathrm{PhCl} /$ pentane. A low resolution structure was obtained on crystals grown from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /pentane. (X-ray data for 16 from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /pentane: $\mathrm{P}_{1} / n, a=14.0015(3), b=12.8639(2), c=22.3936(3), \beta=106.621$ (1), $V=3832.8$ (1), $Z=4, T=188 K, R=0.121, w R^{2}=0.355$. This structure was not fully refined due to major disorder of the two lattice $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ molecules.) This homoleptic dinuclear complex consists of two nearly linear two coordinate copper ions with no intermolecular bonding to any neighboring $\mathrm{Cu}_{2}$ XDK (Scheme $2, \mathrm{n}=1$ ). Structural analysis of the crystals grown from $\mathrm{PhCl} /$ pentane showed that two $\left\{\mathrm{Cu}_{2} \mathrm{XDK}\right\}$ units in this isomer are linked by a bond between an XDK imide carbonyl oxygen and a neighboring copper atom (Cu2-O504, Figure 1.4). One of the \{Cu2XDK\} units consists of two linearly coordinated copper atoms with a Cu3 $\cdots \mathrm{Cu} 4$ distance of 2.6106 (9) $\AA$. Each copper atom is pulled laterally out of the four-oxygen carboxylate plane. The other $\mathrm{Cu}_{2} \mathrm{XDK}$ unit contains two- and three-coordinate copper atoms, with a slightly shorter $\mathrm{Cu} 1 \cdots \mathrm{Cu} 2$ distance of 2.5697 (8) $\AA$. Instead of being displaced in a lateral direction from the four-oxygen plane, the two-coordinate Cu 1 atom lies slightly above the plane, thus accounting for the slightly shorter $\mathrm{Cu} \cdots \mathrm{Cu}$ distance in this $\left\{\mathrm{Cu}_{2}\right.$ (XDK) \} unit. These structures may be contrasted to those of polymeric $\mathrm{Cu}(\mathrm{I})$ acetate ${ }^{52}$ and tetrameric $\mathrm{Cu}(\mathrm{I})$ benzoate, ${ }^{53}$ where oligomerization via the bridging carboxylate oxygen atoms occurs, presumably because of the greater conformational flexibility of these ligands. Apparently the convergent nature of the XDK ligand coupled with the chelate effect cause the carboxylate ligands to bind the copper ions more tightly compared to simple $\mathrm{Cu}(\mathrm{I})$ carboxylates, thus inhibiting oligomerization.

Exposure of $\mathbf{1 0}$ to CO in THF or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution followed by solvent removal afforded no product, as judged by IR and NMR spectroscopy. These results are in contrast to the stable CO adducts obtained with $\mathrm{Cu}(\mathrm{I})$ benzoate and other simple car-
boxylates. ${ }^{40,46}$ Carbon monoxide is a very poor sigma donor, and the $\mathrm{Cu}(\mathrm{I})$ ions in the $\left\{\mathrm{Cu}_{2}\right.$ (XDK\} platform must also be unable to engage in $\pi$ backbonding with this ligand. Both factors preclude stable adduct formation.

Reaction of $\mathbf{1 0}, \mathbf{1 1}$, or $\mathbf{1 2}$ with excess tmeda followed by recrystallization from THF/pentane provided mono(tmeda) adducts 17-19 as colorless blocks or needles. These reactions do not occur for $\mathrm{Cu}(\mathrm{I})$ acetate or benzoate, which upon exposure to excess tmeda under identical conditions immediately disproportionates to Cu metal and uncharacterized $\mathrm{Cu}(\mathrm{II})$ products. An X-ray structure was obtained for 17. This complex is composed of one linear two-coordinate copper, analogous to that observed for acetonitrile complex 10, and a tetrahedrally ligated copper with a chelating tmeda molecule. The $\mathrm{Cu} \cdots \mathrm{Cu}$ distances in 10 and 17 are also nearly identical.

Because tmeda adducts 17-19 react with dioxygen at low temperature to afford stable peroxo intermediates in some cases, ${ }^{43}$ detailed knowledge of their solution properties was desired. Of particular interest was to determine whether the $\mathrm{Cu}(\mathrm{I})$ ions remained coordinated to the XDK ligand in solution, and whether the tmeda ligand exhibited fluxional behavior. All of the tmeda adducts are non-electrolytes in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution, even in the presence of a 20 -fold excess of tmeda, confirming that the $\mathrm{Cu}(\mathrm{I})$ ions remain coordinated to the carboxylates in solution. The ${ }^{1} \mathrm{H}$ NMR spectrum of each of the tmeda adducts exhibits a single set of XDK resonances, suggesting that the approximate $C_{S}$ symmetry of the solid state structure of 17 may not be maintained in solution. If it were, the pair of four-proton doublets assigned to the XDK methylene groups ( $\mathrm{H}_{\mathrm{ax}}$ and $\mathrm{H}_{\mathrm{eq}}$, below) might split into four, two-proton doublets. This phenomenon has been observed for other asymmetrically ligated $\mathrm{M}_{2}$ XDK and heterodimetallic $\mathrm{MM}^{\prime}(\mathrm{XDK})$ complexes, when one of the mirror planes of the $C_{2 \mathrm{v}}$-symmetric XDK ligand is lost. ${ }^{43}$ The psuedo $C_{2 \mathrm{v}}$-symmetric spectral pattern observed for 17 suggests that the tmeda ligand exchanges between the two copper sites
in $\mathrm{Cu}_{2}$ (XDK) by an intra- and/or intermolecular fashion, resulting in one set of averaged $\mathrm{H}_{\mathrm{ax}}$ and $\mathrm{H}_{\mathrm{eq}}$ resonances.

Additional ${ }^{1} \mathrm{H}$ NMR experiments were carried out to help elucidate the nature of this exchange process. The ${ }^{1} \mathrm{H}$ NMR spectrum of recrystallized 17 in the presence of one additional equiv of tmeda still displayed a single set of tmeda and XDK resonances, slightly shifted from those in 17, suggesting that free and coordinated tmeda exchange rapidly on the ${ }^{1} \mathrm{H}$ NMR timescale. To determine whether the tmeda ligand in 17 could be exchanging intermolecularly between different $\left\{\mathrm{Cu}_{2}\right.$ (XDK) \} units, a ${ }^{1} \mathrm{H}$ NMR spectrum of an equimolar mixture of 17 and parent complex 16 was recorded at room temperature. The spectrum exhibited one set of XDK and tmeda resonances, and the chemical shifts of the XDK resonances were the average of those observed for pure 16 and 17. A variable temperature (VT) ${ }^{1} \mathrm{H}$ NMR spectroscopic study was carried out on pure 17. As the temperature was decreased, the two sharp tmeda singlets (methyl and methylene protons) broadened and overlapped one another. The tmeda resonances appeared to coalesce between -70 and -80 ${ }^{\circ} \mathrm{C}$. Below this temperature one broad singlet was observed for the tmeda methyl groups, and the tmeda methylene resonances appeared to be split into two broad singlets in an approximately $3: 1$ ratio. One sharp set of XDK resonances was observed down to $-85^{\circ} \mathrm{C}$, accompanied by small changes in their chemical shifts. A more detailed interpretation of the VT data was hampered by overlap of the tmeda resonances with each other and with the XDK resonances. Although no detailed mechanistic information could be gleaned from the VT experiments, the broadening and shifting of the tmeda resonances with decreasing temperature does support the occurrence of some fluxional tmeda exchange process(es), perhaps involving copper-nitrogen bond breaking and/or different conformations of the five-membered tmeda chelate ring. Taken together, these additional ${ }^{1} \mathrm{H}$ NMR experiments
support the conclusion that the tmeda ligands in complexes 17-19 are exchanging rapidly between copper sites, but do not reveal the mechanism.

Treatment of 10 with two equiv of 4,4'-dimethyldipyridine afforded 20 as a dark brick-red solid. This color is characteristic of the $\left[\mathrm{Cu}(\mathrm{bpy})_{2}\right]^{+}$cation, ${ }^{54}$ and immediately suggested that one of the copper ions had been extracted from the bis(carboxylate) platform. Neutral and ionic species may be in equilibrium, as indicated by eq 3. A similar equilibrium was suggested to explain the solution

$$
\begin{equation*}
\left[\mathrm{Cu}_{2}(\mathrm{XDK})\left(4,4^{\prime}-\mathrm{Me}_{2} \mathrm{bpy}\right)_{2}\right] \rightleftharpoons\left[\mathrm{Cu}\left(4,4^{\prime}-\mathrm{Me}_{2} \mathrm{bpy}\right)_{2}\right][\mathrm{Cu}(\mathrm{XDK})] \tag{3}
\end{equation*}
$$

behavior of $\left[\mathrm{Cu}(\mathrm{phen})_{2}\right]_{2}\left[\mathrm{Cu}(\mathrm{OAc})_{2}\right]$, specifically based on its crystal structure and solution conductivity properties. ${ }^{54,55}$ Determination of the molar conductivity from a plot of the measured conductivity versus concentration for complex 20 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (Figure 1.5) gave approximately the same value as those obtained for $\mathrm{Bu}_{4} \mathrm{NPF}_{6}$ and $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{ClO}_{4}$, consistent with the equilibrium in eq 3 lying completely to the right. Suitable crystals of 20 could not be obtained for X-ray crystallography. Based on the similarity of its UV-vis spectral features to those of $\left[\mathrm{Cu}(\text { phen })_{2}\right]_{2}\left[\mathrm{Cu}(\mathrm{OAc})_{2}\right]$ and its conductivity properties, 20 is probably composed of a bis(dipyridyl) cation and a linear two coordinate $\mathrm{Cu}(\mathrm{XDK})$ anion.

## Anionic Donors: Preparation of $\left(\mathrm{Et}_{4} \mathrm{~N}\right)[\mathrm{Cu}(\mathrm{PXDK})](21)$ and $\left[\mathrm{CuLi}(\mathrm{XDK})(\mathrm{THF})_{2}\right]$

(22). We attempted to prepare a class of anionic-bridged dicopper(I) XDK complexes in order to explore further the chemistry of this system. Attempts to synthesize thio-late- or cyanide-bridged $\left\{\mathrm{Cu}_{2}(\mathrm{XDK})\right\}$ complexes from $\mathrm{Et}_{4} \mathrm{~N}(\mathrm{SR})(\mathrm{R}=\mathrm{Ph}, \mathrm{Me})$ and $\mathrm{Et}_{4} \mathrm{~N}(\mathrm{CN})$, respectively, were unsuccessful. The former reagents invariably yielded copper(I) sulfide and intractable XDK-containing products. Reaction of acetonitrile adduct 11 with tetraethylammonium cyanide in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ immediately resulted in precipitation of $\mathrm{Cu}(\mathrm{I})$ cyanide and formation of 21 , as judged by IR and ${ }^{1} \mathrm{H}$ NMR
spectroscopic analyses. The solid state structure of 21 is composed of two crystallographically independent clusters which differ only in the orientation of the peripheral propyl groups. Each contains linear two-coordinate copper ligated by cis-carboxylate oxygen atoms. This mononuclear complex is unreactive toward additional cyanide, attesting to the effectiveness of the XDK ligand for retaining the remaining copper atom in the "skewered" two coordinate arrangement.

Alkyl- and aryl-bridged cuprate complexes of XDK were sought for studies of conjugate addition and other $\mathrm{R}^{-}$transfer reactions. The only structurally characterized $\mathrm{Cu}(\mathrm{I})$ carboxylate-alkyl or aryl complex reported to date is $\left[\mathrm{Cu}_{3}(\mu-\mathrm{Mes})(\mu-\right.$ $\left.\mathrm{O}_{2} \mathrm{CPh}\right)_{2}$ ], a neutral trinuclear cluster isolated upon exposure of $\mathrm{Cu}(\mathrm{I})$ benzoate to pentameric mesitylcopper(I). ${ }^{56}$ No well characterized $\mathrm{Cu}(\mathrm{I})$ carboxylate alkyl or aryl cuprates have been described. Treatment of $\mathbf{1 0}$ with one equiv of PhLi in THF afforded heterodimetallic complex 22 as the only XDK-containing product isolated, even when a large excess of 12 -crown- 4 was added. Much difficulty was experienced in trying to purify 22 from the phenylcopper(I) coproduct and large amounts of an intractable brown material. As in the preparation of mononuclear 21, this complex was obtained more conveniently from 10 and lithium cyanide. The solid state structure consists of a linear two coordinate copper atom and a tetrahedrally ligated lithium atom bridged by XDK. Crystals of 22 lose one of the coordinated THF molecules upon isolation and drying, as judged by integration of the ${ }^{1} \mathrm{H}$ NMR spectrum and elemental analysis, presumably to afford [ $\mathrm{CuLi}(\mathrm{XDK})(\mathrm{THF})]$. The solid state structure is unknown, but by analogy to other heterodimetallic alkali metal XDK complexes, ${ }^{57}$ the lithium ion is probably coordinated to one or more of the XDK imide carbonyl oxygens. Compounds 21 and 22 provided the ideal kinetic stability for the preparation of a host of $\mathrm{Cu}(\mathrm{I}) / \mathrm{Cu}(\mathrm{II})$ mixed valent and $\mathrm{Cu}(\mathrm{I}) \mathrm{M}$ (II) heterodimetallic bis(carboxylate)-bridged complexes, which are the subject of a separate report. ${ }^{32}$

## Conclusions

A more sterically demanding version of XDK and PXDK has been prepared in multigram quantities and high purity. The kinetic stability imparted by the convergent nature of the XDK ligand system provides an excellent template for the synthesis of discrete dinuclear $\mathrm{Cu}(\mathrm{I})$ complexes. All three XDK derivatives afford complexes, some heretofore unknown for $\mathrm{Cu}(\mathrm{I})$ carboxylates, of $\pi$ acceptor and sigma donor ligands. Disproportionation reactions which occur with the simple $\mathrm{Cu}(\mathrm{I})$ carboxylates are not observed with XDK. Attempts to prepare anionic-bridged $\mathrm{Cu}_{2} \mathrm{XDK}$ complexes resulted instead in extrusion of one $\mathrm{Cu}(\mathrm{I})$ ion and formation of monocopper(I) XDK products.

Numbers in parentheses are estimated standard deviations of
the last significant figure. $b_{U}(\mathrm{eq})$ is defined as one third
of the trace of the orthogonalized Uij tensor.

## Chapter II

Synthesis and Characterization of $\mathbf{C u}(\mathrm{I})-\mathbf{C u}$ (II) Mixed-Valence and $\mathrm{Cu}(\mathrm{I})-\mathrm{M}(\mathrm{II})$ Heterodimetallic Bis(carboxylate-bridged) Complexes: Structural, Electrochemical, and Spectroscopic Investigations

## Introduction

The ubiquitous cellular respiratory protein cytochrome $c$ oxidase $(\mathrm{CcO})$ couples the catalytic reduction of dioxygen to water with the production of a proton electrochemical gradient across a cell membrane, providing the energy essential for ATP synthesis from ADP and inorganic phosphate. ${ }^{1}$ Another respiratory protein, nitrous oxide reductase ( $\mathrm{N}_{2} \mathrm{OR}$ ), plays an analogous role in denitrifying bacteria by catalyzing the reduction of $\mathrm{N}_{2} \mathrm{O}$ to $\mathrm{N}_{2}$ and water. ${ }^{2}$ A common feature of both of these enzymes is their use of a unique electron transfer center, $\mathrm{Cu}_{\mathrm{A}}$. Recent spectroscopic ${ }^{3-8}$ and $X$-ray structural ${ }^{9-11}$ studies have provided compelling evidence that $\mathrm{Cu}_{\mathrm{A}}$ is a fully delocalized mixed-valence "class $\mathrm{III"12}$ dicopper center. The X-ray structural analyses revealed that each copper ion is ligated by two bridging thiolates and a terminal histidine nitrogen, with weaker contacts occurring between a methionine thioether and one copper and between a glutamate carboxylate oxygen atom and the other (Table 2.1). Most remarkably, the $\mathrm{Cu}_{\mathrm{A}}$ site possesses an intermetal distance of $2.5 \AA$, which is consistent with the presence of a genuine metalmetal bond. This feature is unprecedented in biological systems and is undoubtedly connected intimately with the highly unusual electronic properties and the function of the center. ${ }^{13}$

The recent identification of the $\mathrm{Cu}_{\mathrm{A}}$ site has spawned interest in the structural and spectroscopic properties of well-defined complexes to model its electron transfer properties. Many mixed-valence dicopper complexes are known, but most are fully localized class I systems, with no electronic exchange between the $\mathrm{d}^{9}$ and $\mathrm{d}^{10}$ metal centers. ${ }^{12,14}$ A small number of class II dicopper complexes have been characterized. ${ }^{12,15-19}$ Some have been shown to exhibit temperature dependent electronic exchange phenomena, whereby the unpaired electron becomes spintrapped upon cooling, as judged primarily by EPR spectroscopy. ${ }^{15-17}$ Fully
delocalized, type III mixed-valence copper complexes which remain delocalized at liquid helium temperatures are rare.

The two types of class III dicopper complexes described to date employ a tridentate $\mathrm{N}_{2} \mathrm{~S}$ ligand, LiPrdacoS, ${ }^{20,21}$ or octaazacryptand macrobicyclic ligands, L1-L ${ }^{3}$ (Table 2.1). ${ }^{22-24}$ In addition to having different bridging properties, the two ligands afford complexes with very different $\mathrm{Cu} \cdots \mathrm{Cu}$ distances and metal ion geometries. The $\mathrm{N}_{2} \mathrm{~S}$ ligand provides a $\mathrm{Cu}(1.5) \mathrm{Cu}(1.5)$ complex of overall $\mathrm{C}_{\mathrm{i}}$-symmetry, each Cu having a distorted trigonal pyramidal geometry. The $\mathrm{Cu} \cdots \mathrm{Cu}$ distance of 2.9306(9) $\AA$ is long and there is presumably no metal-metal bond. Ligands $\mathrm{L}^{1}-\mathrm{L}^{3}$ afford $D_{3 \mathrm{~d}}{ }^{-}$ symmetric complexes with trigonal bipyramidal Cu centers and $\mathrm{Cu}-\mathrm{Cu}$ distances of 2.448(1), 2.415(1), and 2.419(1) $\AA$, respectively. The identical coordination environments about the two copper ions within each complex suggest delocalized mixed-valence formulations for all in the solid state. The delocalization origins of these two classes of compounds is revealed by their frozen solution EPR ( $T=4-20 \mathrm{~K}$ ) and electronic absorption spectral properties, summarized in Table 2.1. The $\mathrm{N}_{2} \mathrm{~S}-$ derived complex exhibits a rhombic EPR spectrum with a seven-line hyperfine splitting of the two lower field components due to spin delocalization over both $\mathrm{I}=$ $3 / 2 \mathrm{Cu}$ ions. In contrast, EPR spectra obtained for complexes with the octazacryptands are axial and display seven-line hyperfine coupling on the lower field, $A_{\|}$component, indicating substantial $d_{z 2}$ character in the ground state. The electronic absorption spectra of all these complexes exhibit relatively intense ( $\varepsilon>$ $1000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ) features in the near-infrared (NIR) region, but the absorption maxima differs substantially for the two different types of complexes, again suggesting different electronic states.

Recently in two independent studies, ${ }^{25-27}$ detailed descriptions of the electronic structures of the $\mathrm{Cu}_{\mathrm{A}}$ center and its models have been put forth based on thorough analyses of UV-vis, NIR, MCD, EPR, EXAFS, and X-ray structural data,
coupled with molecular orbital calculations. The singly occupied molecular orbital (SOMO) for the $\mathrm{N}_{2}$ S-derived mixed-valence complex is partly composed of weakly participating, $\pi$-bonding $\mathrm{d}_{\mathrm{x} 2-\mathrm{y} 2}$ metal orbitals. It is dominated by the antibonding sulfur p-orbitals, however, as might be expected in this case since the Cu ions are too far apart for direct d-orbital overlap. ${ }^{25,26}$ At the other extreme, in the octazacryptand systems the $\sigma^{*}$ SOMO is dominated by $d_{z 2}-d_{z 2}$ out-of-phase overlap afforded by the short metal-metal distance and lack of an efficient superexchange pathway through the four-atom bridging groups. ${ }^{26}$ The $\sigma^{*}$ SOMO for $\mathrm{Cu}_{\mathrm{A}}$ was assigned to be a composite of those deduced for these two models, with significant metal $\mathrm{d}_{\mathrm{x} 2}-\mathrm{y} 2-\mathrm{d}_{\mathrm{x} 2}-$ $y^{2}$ out-of-phase and sulfur $p_{\pi}-p_{\pi}$ in-phase overlap. ${ }^{25,26}$ Taken together, these studies suggest that the superexchange pathway in this set of class III mixed-valence complexes is comprised of overlap between metal d- or ligand p-orbitals, or both, depending on the energetic accessibility of a metal-metal compared to a bridging exchange pathway.

The above examples notwithstanding, the paucity of small molecule analogs of the $\mathrm{Cu}_{\mathrm{A}}$ center hampers efforts to develop general principles that govern the assembly of dicopper mixed-valence cores and their class III behavior. For example it would be of interest to know (1) what spectrum of ligands will assemble the mixedvalence core and protect it from decomposition pathways such as disproportionation; (2) how the superexchange pathway is affected by $\mathrm{Cu}-\mathrm{Cu}$ distance, and number and donor properties of bridging ligands, metal ion geometries, and the overall complex symmetry; and (3) how these properties affect the ease with which the mixed-valence core can cycle reversibly between the $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ and $\mathrm{Cu}(1.5) \mathrm{Cu}(1.5)$ oxidation states with minimal ligand reorganization and at biologically relevant potentials. An efficient approach to exploring these questions is to utilize a readily modified ligand system that will stabilize the $\mathrm{Cu}(1.5) \mathrm{Cu}(1.5)$ and $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ units, while leaving open coordination sites for
docking ancillary ligands with variable donor properties to perturb incrementally the overall electronic structure. This strategy will facilitate the construction of a family of closely related complexes from which the relative importance of the above factors can be evaluated.

In the present investigation, we have approached this goal by using the $m$ xylylenediamine bis(Kemp's triacid imide) ( $\mathrm{H}_{2} \mathrm{XDK}$ ) ligand system, ${ }^{28-30}$ previously demonstrated to be an ideal platform for binding a variety of metal fragments with labile coordination sites in both bioinorganic ${ }^{29,31-37}$ and organometallic ${ }^{38}$ applications. Previously we reported the synthesis and characterization of several bis(carboxylate)-bridged dicopper(I) complexes derived from XDK and $\pi$-acceptor and $\sigma$-donor ligands. ${ }^{28}$ In these complexes the copper atoms have linear two-coordinate, trigonal three-coordinate, or pseudo four-coordinate geometries, and variable Cu Cu distances ranging from $2.5697(8)$ to $3.4211(6) \AA$. Here we report a series of dicopper mixed-valence complexes having variable ancillary ligands which facilitate the analysis of the factors that influence their electronic behavior. The synthesis, solid state and solution characterization, and electrochemical behavior of these complexes and related $\mathrm{Cu}(\mathrm{I})$ heterodimetallic complexes are described, the latter serving to enhance our understanding of the electronic properties of the mixedvalence system.

## Experimental Section

General Considerations. The complexes $\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{MeCN})(1)$, $\mathrm{Cu}_{2}$ (PXDK)(MeCN) (2), and ( $\left.\mathrm{Et}_{4} \mathrm{~N}\right)[\mathrm{Cu}(\mathrm{PXDK})]$ (3) were prepared according to literature procedures. ${ }^{28}$ The compound $\left[\mathrm{Fe}(\mathrm{OTf})_{2}(\mathrm{MeCN})_{2}\right]$ was prepared according to a procedure used to obtain the Mn (II) analog. ${ }^{39}$ All other reagents were procured from commercial sources and used as received unless otherwise noted. THF, benzene, toluene, pentane, and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from sodium benzophenone
ketyl under nitrogen. Dichloromethane and 1,2-dichloroethane were distilled from $\mathrm{CaH}_{2}$ under nitrogen. The NMR solvent $\mathrm{C}_{6} \mathrm{D}_{6}$ was degassed, passed through activated basic alumina, and stored over $3 \AA$ molecular sieves prior to use. All air sensitive manipulations were carried out either in a nitrogen filled Vacuum Atmospheres drybox or by standard Schlenk line techniques at room temperature unless otherwise noted.

Physical Measurements. NMR spectra were recorded on a Bruker AC-250 or Varian XL-300 spectrometer. ${ }^{1} \mathrm{H}$ NMR chemical shifts are reported versus tetramethylsilane and referenced to the residual solvent peak. FTIR spectra were recorded on a BioRad FTS-135 FTIR spectrometer. UV-vis-NIR spectra were recorded on a Cary 5E reference spectrophotometer. Conductivity measurements were carried out in THF or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at 296 K with a Fisher Scientific conductivity bridge, model 9-326, outfitted with a platinum black electrode. Elemental analyses were performed by Microlytics, South Deerfield, MA.

Electrochemistry. Cyclic voltammetric measurements were carried out in a Vacuum Atmospheres drybox under $\mathrm{N}_{2}$ with an EG\&G Model 263 potentiostat. A three electrode configuration was used consisting of a $1.75 \mathrm{~mm}^{2}$ platinum working electrode, a $\mathrm{Ag} / \mathrm{AgNO}_{3}$ ( 0.1 M in MeCN ) reference electrode, and a coiled platinum wire auxiliary electrode. A 0.5 M solution of $\mathrm{Bu}_{4}\left(\mathrm{NPF}_{6}\right)$, triply recrystallized from acetone, was used as supporting electrolyte. Solute samples were typically 1-2 mM. Scan rate profiles were conducted for each sample, at scan speeds of $50-500 \mathrm{mV} / \mathrm{s}$, and compared to that obtained for $\mathrm{Cp}_{2} \mathrm{Fe}$ under identical conditions. All cyclic voltammograms were externally referenced to $\mathrm{Cp}_{2} \mathrm{Fe}$, for which $\mathrm{E}_{1 / 2}=+143 \mathrm{mV}$ in THF $\left(\Delta \mathrm{E}_{\mathrm{p}}=68 \mathrm{mV}\right.$, scan rate $\left.=50 \mathrm{mV} / \mathrm{s}\right)$.

EPR Spectroscopy. For measurements at 9 K , data were collected on a Bruker Model 300 ESP X-band spectrometer operating at 9.47 GHz . For measurements at 77 K, data were collected on a Varian E104 X-band spectrometer operating at 9.14 GHz .

The Q-band measurements were performed at 2 K with a modified Varian E109 spectrometer operating at 35 GHz . Liquid helium temperatures were maintained with an Oxford Instruments EPR 900 cryostat, and liquid nitrogen temperatures with an EPR finger dewar. For all measurements 1 mM frozen solutions were prepared in 2-methyltetrahydrofuran, a solvent in which the samples glassed well. Solid samples ( $\sim 1 \mathrm{mg}$ ) were prepared as finely ground powders. Simulations were carried out with the WINEPR SimFonia program package. ${ }^{40}$ The fits incorporated coupling of the unpaired spin simultaneously to each $\mathrm{I}=3 / 2$ copper center.

Extended Hückel Molecular Orbital Calculations. These computations ${ }^{41}$ were carried out with the program YAeHMOP, ${ }^{42}$ operating on a Silicon Graphics Indy computer. Simplified models of the mixed-valence complexes 7 and 8 were implemented, $\left[\mathrm{Cu}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{OMe}_{2}\right)\right]^{+}$and $\left[\mathrm{Cu}_{2}(\mathrm{OH})_{2}\left(\mathrm{OH}_{2}\right)\left(\mathrm{OMe}_{2}\right)_{4}\right]^{+}$, and used the core crystallographic coordinates determined for 8.

Preparation of Compounds. [ $\left.\mathrm{Cu}_{2}(\mathrm{XDK})(\mu-\mathrm{OTf})(\mathrm{THF})_{2}\right]$ (4). To a stirred solution of $\mathbf{1}(300 \mathrm{mg}, 0.402 \mathrm{mmol})$ in THF ( 5 mL ) was added a solution of AgOTf ( 105 mg , 0.402 mmol ) in THF ( 1 mL ) in one portion. The colorless solution immediately turned dark purple and an off-white precipitate formed. The mixture was filtered through Celite, and the filtrate was evaporated to dryness. Recrystallization from THF/pentane at $-30^{\circ} \mathrm{C}$ provided 4 as thin purple blocks which appeared suitable for X-ray crystallography ( $386 \mathrm{mg}, 96 \%$ ). IR ( KBr ) 2962, 2935, 2875, 1734, 1691, 1460, 1362, 1297, 1264, 1182, 1024, $868,760,637 \mathrm{~cm}^{-1}$; UV-vis (THF, $\left.\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 542$ (1200), 768 (sh, 300), 956 (630). Anal. Calcd for $\mathrm{C}_{45} \mathrm{H}_{62} \mathrm{~N}_{2} \mathrm{O}_{14} \mathrm{Cu}_{2} \mathrm{~F}_{3} \mathrm{~S}_{1}$ (4. 1THF): C, 50.46; H, 5.83; N, 2.62. Found: C, 50.45; H, 6.08; N, 2.47.
$\left[\mathrm{Cu}_{2}(\right.$ PXDK $\left.)(\mu-\mathrm{OTf})(\mathrm{THF})_{2}\right]$ (5). Method A. This compound was prepared from 2 ( $50 \mathrm{mg}, 0.055 \mathrm{mmol}$ ) and AgOTf ( $14 \mathrm{mg}, 0.055 \mathrm{mmol}$ ) by an analogous procedure to that used to prepare 4. Recrystallization from pentane and a trace amount of THF at $-30^{\circ} \mathrm{C}$ afforded 5 as purple needles ( $29 \mathrm{mg}, 45 \%$ ).

Method B. To a stirred suspension of 3 ( $50 \mathrm{mg}, 0.053 \mathrm{mmol}$ ) in THF ( 2 mL ) was added $\mathrm{Cu}(\mathrm{OTf})_{2}(19.6 \mathrm{mg}, 0.053 \mathrm{mmol})$ in THF $(1 \mathrm{~mL})$ in one portion. Complex 3 was immediately consumed and the solution turned dark purple. After 15 min the THF was removed in vacuo. The solid residue was taken up in $\mathrm{Et}_{2} \mathrm{O}(2-3 \mathrm{~mL})$ and then filtered through Celite to remove the precipitated $\mathrm{Et}_{4} \mathrm{~N}$ (OTf). Solvent removal in vacuo followed by recrystallization provided 5 as purple needles. ( $25 \mathrm{mg}, 40 \%$ ). IR (KBr) 2962, 2935, 2875, 1733, 1691, 1534, 1460, 1362, 1296, 1182, 1024, 868, $637 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{53} \mathrm{H}_{78} \mathrm{~N}_{2} \mathrm{O}_{13} \mathrm{Cu}_{2} \mathrm{~F}_{3} \mathrm{~S}_{1}$ : C, $54.53 ; \mathrm{H}, 6.73 ; \mathrm{N}, 2.40$. Found: C, $54.34 ; \mathrm{H}$, 6.54; N, 2.61.
$\left[\mathrm{Cu}_{2}(\mathrm{XDK})\left(\mu-\mathrm{O}_{2} \mathrm{CCF}_{3}\right)(\mathrm{THF})_{2}\right]$ (6). This compound was prepared from $\mathbf{1}$ (150 $\mathrm{mg}, 0.201 \mathrm{mmol}$ ) and $\mathrm{AgO}_{2} \mathrm{CCF}_{3}(44 \mathrm{mg}, 0.20 \mathrm{mmol})$ by an analogous procedure to that used to prepare 4. Recrystallization from THF/pentane provided 6 as purple blocks which appeared suitable for X-ray crystallography ( $152 \mathrm{mg}, 79 \%$ ). IR ( KBr ) 2980, 2933, 2878, 1734, 1695, 1662, 1500, 1467, 1421, 1381, 1353, 1336, 1230, 1183, 1141, $1035,838,761,667,477 \mathrm{~cm}^{-1}$; UV-vis (THF, $\left.\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 563$ (2000), 806 (sh, 320), 942 (sh, 360), 1250 (500). Anal. Calcd for $\mathrm{C}_{42} \mathrm{H}_{54} \mathrm{~N}_{2} \mathrm{O}_{12} \mathrm{Cu}_{2} \mathrm{~F}_{3}: \mathrm{C}, 52.39 ; \mathrm{H}, 5.65 ; \mathrm{N}$, 2.91. Found: C, 52.17; H, 5.63; N, 2.89.
$\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{THF})_{4}\right]\left(\mathrm{BF}_{4}\right)$ (7). This compound was prepared from 1 (100 mg, 0.134 mmol ) and $\mathrm{AgBF}_{4}(26 \mathrm{mg}, 0.13 \mathrm{mmol})$ by an analogous procedure to that used to prepare 4. Recrystallization from THF/pentane provided 7 as purple plates ( 120 mg, 82\%). IR (KBr) 2969, 2927, 2875, 1734, 1698, 1540, 1462, 1423, 1353, 1230, 1028, 957, 864, 759, 676, $523 \mathrm{~cm}^{-1}$; UV-vis (THF, $\left.\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 536$ (1600), 923 (1200). Anal. Calcd for $\mathrm{C}_{48} \mathrm{H}_{70} \mathrm{~N}_{2} \mathrm{O}_{12} \mathrm{Cu}_{2} \mathrm{~B}_{1} \mathrm{~F}_{4}$ : C, 51.29; $\mathrm{H}, 5.81$; N, 2.99. Found: C, 50.98; H , 5.92; N, 3.04.
$\left[\mathrm{Cu}_{2}\right.$ (PXDK)(THF) $\left.\mathbf{4}_{4}\right]\left(\mathrm{BF}_{4}\right)$ (8). This compound was prepared from $2(121 \mathrm{mg}$, 0.132 mmol ) and $\mathrm{AgBF}_{4}(26 \mathrm{mg}, 0.132 \mathrm{mmol})$ by an analogous procedure to that used to prepare 4. Recrystallization from THF/pentane provided 8 as purple needles
which appeared suitable for X-ray crystallography ( $101 \mathrm{mg}, 61 \%$ ). IR ( KBr ) 2962, 2933, $2869,1734,1692,1540,1459,1362,1314,1264,1182,1034,866,759,673,586 \mathrm{~cm}^{-1}$; UV-vis (THF, $\left.\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 527$ (1700), 878 (1200). Anal. Calcd for $\mathrm{C}_{60} \mathrm{H}_{94} \mathrm{~N}_{2} \mathrm{O}_{12} \mathrm{Cu}_{2} \mathrm{~B}_{1} \mathrm{~F}_{4}$ : C, 57.68; H, 7.58; N, 2.24. Found: C, $56.84 ; \mathrm{H}, 7.25 ; \mathrm{N}, 2.42$.
$\left[\mathrm{CuZn}(\mathrm{PXDK})(\mathrm{OTf})(\mathbf{T H F})_{\mathbf{2}}\left(\mathbf{H}_{\mathbf{2}} \mathbf{O}\right)\right](9)$. This compound was prepared from $\mathbf{3}$ (200 $\mathrm{mg}, 0.213 \mathrm{mmol}$ ) and $\mathrm{Zn}(\mathrm{OTf})_{2}(94 \mathrm{mg}, 0.21 \mathrm{mmol})$ by a procedure analogous to method $B$ used to prepare 5 , except that the reaction mixture was allowed to stir for 12 h . Recrystallization from pentane with a trace of THF provided 9 as colorless blocks which appeared suitable for X-ray crystallography. ( $154 \mathrm{mg}, 61 \%$ ). ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}, 296 \mathrm{~K}\right) \delta 7.31(1 \mathrm{H}, \mathrm{s}), 6.63(1 \mathrm{H}, \mathrm{s}), 3.83(8 \mathrm{H}, \mathrm{br} \mathrm{s}), 2.90-2.60(4 \mathrm{H}, \mathrm{m})$, $2.30-1.92(6 \mathrm{H}), 1.83(6 \mathrm{H}, \mathrm{s}), 1.68-1.03(34 \mathrm{H}, \mathrm{m}), 1.03-0.80(16 \mathrm{H}, \mathrm{m}), 0.75(4 \mathrm{H}, \mathrm{d}, J=12.6$ Hz); IR (KBr) 3451, 2963, 2933, 2874, 1734, 1676, 1577, 1459, 1365, 1309, 1184, 1027, 918, $761,637 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{53} \mathrm{H}_{80} \mathrm{~N}_{2} \mathrm{O}_{14} \mathrm{Cu}_{1} \mathrm{Zn}_{1} \mathrm{~F}_{3} \mathrm{~S}_{1}$ : C, 53.62; H, 6.79; N, 2.36. Found: C, 54.22; H, 6.55; N, 2.34.
$[\mathrm{CuFe}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{NB})(\mathrm{MeCN})]_{2}(\mathbf{1 0 a})$. To a stirred suspension of $3(200 \mathrm{mg}$, $0.213 \mathrm{mmol})$ in THF $(3 \mathrm{~mL})$ was added $\left[\mathrm{Fe}(\mathrm{OTf})_{2}(\mathrm{MeCN})_{2}\right](106 \mathrm{mg}, 0.243 \mathrm{mmol})$ in THF ( 1 mL ) in one portion. After 15 min the THF was removed in vacuo. The solid residue was taken up in $\mathrm{Et}_{2} \mathrm{O}(2-3 \mathrm{~mL})$ and then filtered through Celite. Solvent removal in vacuo followed by recrystallization from 1,2dichloroethane/norbornene (NB, 1:1, v:w) and pentane afforded 10a as small colorless blocks ( $146 \mathrm{mg}, 60 \%$ ) which appeared suitable for X-ray crystallography. IR (KBr) 3049, 2871, 2742, 1737, 1699, 1594, 1502, 1412, 1368, 1315, 1181, 1033, 926, 862, 762, $637 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{54} \mathrm{H}_{75} \mathrm{~N}_{3} \mathrm{O}_{11} \mathrm{Cu}_{1} \mathrm{Fe}_{1} \mathrm{~F}_{3} \mathrm{~S}_{1}$ : C, 56.47; $\mathrm{H}, 6.57 ; \mathrm{N}, 3.65$. Found: $\mathrm{C}, 55.58 ; \mathrm{H}, 6.80 ; \mathrm{N}, 3.38$. This sample was heated in vacuo at $90^{\circ} \mathrm{C}$ for 6 h in an attempt to remove completely the two lattice dichloroethane molecules, which were identified by X-ray crystallography. Apparently only partial elimination was
achieved, and subsequent heating at higher temperatures resulted in decomposition of the complex.
[ $\left.\mathrm{CuZn}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{NB})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]$ (11). Compound 9 was prepared in situ from 3 ( $38 \mathrm{mg}, 0.040 \mathrm{mmol}$ ) and $\mathrm{Zn}(\mathrm{OTf})_{2}(15 \mathrm{mg}, 0.040 \mathrm{mmol})$ and then recrystallized from benzene/norbornene ( $1: 1, \mathrm{v}: \mathrm{v}$ ) and pentane to afford 11 as colorless blocks which appeared suitable for X -ray crystallography ( $27 \mathrm{mg}, 57 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $250 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$, $296 \mathrm{~K}) \delta 7.35(1 \mathrm{H}, \mathrm{s}), 6.61(1 \mathrm{H}, \mathrm{s}), 5.22(2 \mathrm{H}, \mathrm{s}), 3.82(4 \mathrm{H}, \mathrm{br} \mathrm{s}), 2.95-2.72(6 \mathrm{H}, \mathrm{m}), 2.30-1.90$ ( $8 \mathrm{H}, \mathrm{m}$ ), 1.79 ( $6 \mathrm{H}, \mathrm{s}$ ), 1.68-0.60 (46H, m); IR (KBr) 3314, 2964, 2933, 2875, 1737, 1682, 1603, 1505, 1459, 1410, 1367, 1334, 1236, 1201, 1018, 926, 762, $637 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{52} \mathrm{H}_{74} \mathrm{~N}_{2} \mathrm{O}_{12} \mathrm{Cu}_{1} \mathrm{Zn}_{1} \mathrm{~F}_{3} \mathrm{~S}_{1}: \mathrm{C}, 54.92 ; \mathrm{H}, 6.55 ; \mathrm{N}, 2.46$. Found: C, 55.63; H, 6.78; N, 2.42.

Collection and Reduction of X-ray Data. All crystals were mounted on the tips of quartz fibers with Paratone-N (Exxon), cooled to low temperature ( $\sim-85^{\circ} \mathrm{C}$ ), and placed on Siemens CCD X-ray diffraction system controlled by a Pentium-based PC running the SMART software package. ${ }^{43}$ The general procedures for data collection and reduction follow those reported previously. ${ }^{44}$ All structures were solved with the direct methods programs SIR- $92^{45}$ or XS, part of the TEXSAN ${ }^{46}$ and SHELXTL ${ }^{47}$ program packages, respectively. Structure refinements were carried out with XL, part of the SHELXTL program package. ${ }^{47}$ All remaining non-hydrogen atoms were located and their positions refined by a series of least-squares cycles and Fourier syntheses. Hydrogen atoms were assigned idealized positions and given a thermal parameter 1.2 times the thermal parameter of the carbon atom to which each was attached. Empirical absorption corrections were calculated and applied for each structure by using SADABS, part of the SHELXTL program package. ${ }^{47}$

In the structure of 4, each coordinated THF molecule as well as one of the two lattice THF molecules contain a carbon atom disordered over two positions. In each case the atom was distributed over two positions and refined. In the structure of 6 each coordinated THF molecule was disordered over two positions. In one
molecule, two of the carbon atoms and the oxygen atom were refined at full occupancy, and the occupancy of the remaining two carbon atoms was distributed over two positions and refined. In the other, the occupancy of one carbon atom was distributed over two positions and refined, and the remaining atoms were refined at full occupancy. The lattice THF molecule in 6 contains large thermal parameters, so each atom was refined at a site occupancy of 0.5 . Two of the coordinated THF molecules in the structure of 8 were disordered over two positions. Two of the carbon atoms and the oxygen atom were refined at full occupancy, whereas the remaining carbon atoms were distributed over two positions and refined. The structure of 9 contains a coordinated THF molecule disordered over two positions, and it was refined in similar fashion to those described for the structure of 4. Finally, in the structure of 11 the copper atom and norbornene ligand are disordered. The site occupancy of this fragment was distributed over two positions and refined. Bond distances and angles for each orientation of 11 are reported in Table 2.3. For both structures 9 and 11, the assignment of the metal atom positions as Cu or Zn was based on chemically reasonable presumptions that (a) the overall neutral charge of each complex necessitates the assignment of one mono- and divalent metal ion; (b) the three-coordinate geometry for the metal coordinated to the norbornene ligand in 11 is quite common for $\mathrm{Cu}(\mathrm{I})$ but not for $\mathrm{Zn}(\mathrm{II})$; and (c) the $\mathrm{Cu}-\mathrm{C}$ distances in 11 are nearly identical to those observed for $\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{NB})_{2}\right] .{ }^{28}$

Important crystallographic information for each complex, including refinement residuals, is available in Table 2.2. Selected bond distances and angles for the coordination spheres of each structurally characterized complex are displayed in Table 2.3, and final positional and equivalent isotropic displacement parameters are listed in Tables 2.4-2.8.

## Results and Discussion

Preparation and Structural Characterization of Mixed-Valence Complexes
 $\left.\left.\mathrm{O}_{2} \mathrm{CCF}_{3}\right)(\mathrm{THF})_{2}\right](6),\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{THF})_{4}\right]\left(\mathrm{BF}_{4}\right)(7)$, and $\left.\left[\mathrm{Cu}_{2} \text { (PXDK)(THF) }\right)_{4}\right]\left(\mathrm{BF}_{4}\right)$ (8). Each of these complexes was prepared by one electron oxidation of acetonitrile adducts 1 or 2 with the appropriate silver(I) salt in THF (Scheme 2.1). Removal of the resulting solids followed by recrystallization afforded $4-8$ as deep purple compounds in moderate to excellent yield. Recovery of 5 and 8 was limited by their significant solubility under the recrystallization conditions. The products appeared to be stable in the presence of excess $\mathrm{Ag}^{+}$, suggesting that these mixed-valence complexes are resistant to disproportionation followed by further $\mathrm{Ag}^{+}$oxidation of the remaining equivalent of $\mathrm{Cu}(\mathrm{I})$. By contrast, oxidation of $\mathbf{1}$ or 2 with $\mathrm{Ag}^{+}$salts of more basic anions, such as benzoate, led to mixtures of intractable blue-green products. This result indicates that ancillary ligands more donating than trifluoroacetate are incompatible with the dicopper-XDK mixed-valence framework. The triflate adduct 5 could also be prepared from mononuclear PXDK complex 3 and $\mathrm{Cu}(\mathrm{OTf})_{2}$. Because of the propyl groups in PXDK, 5 is readily soluble in $\mathrm{Et}_{2} \mathrm{O}$, allowing the $\mathrm{Et} \mathrm{t}_{4} \mathrm{~N}(\mathrm{OTf})$ byproduct to be removed conveniently by filtration.

The IR spectra of compounds 4-8 display new features attributable to their respective anions. In addition, the XDK carboxylate stretch in the dicopper(I) starting materials 1 and $\mathbf{2}$ is shifted by $5-15 \mathrm{~cm}^{-1}$ to lower energy for each product, indicating a change in Cu geometry. The UV-vis spectra of each product exhibit a relatively sharp and intense ( $\varepsilon=1200-2000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ) feature with a maximum at $\sim 545 \mathrm{~nm}$ (Figures 2.1-2.3). For the three XDK complexes, this band is most intense for the trifluoroacetate derivative. In the visible/near-infrared region, all the complexes show broad absorptions between 700 and 1500 nm . Based on the peak shapes, this feature appears to arise from a single transition for the $\mathrm{BF}_{4}{ }^{-}$complexes, but is made up of overlapping components for the OTf ${ }^{-}$and $\mathrm{O}_{2} \mathrm{CCF}_{3}{ }^{-}$adducts. A similarly
intense ( $\varepsilon>500 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ) feature at low energy has been observed in other class II and III mixed-valence copper complexes. In the class II systems it has been assigned as an intervalence charge transfer, ${ }^{16,17}$ and in the class III complexes as a $\psi \rightarrow \psi^{*}$ transition within the $\mathrm{Cu}(1.5) \mathrm{Cu}(1.5)$ manifold. ${ }^{25,26}$ The relatively sharp transition observed for the $\mathrm{BF}_{4}{ }^{-}$adduct parallels those observed for the class III octaazacryptand complexes, ${ }^{24,26}$ but the multiple bands appearing in the spectrum of the triflate and $\mathrm{O}_{2} \mathrm{CCF}_{3}{ }^{-}$derivatives are currently not understood. In the absence of additional information such as MCD or single crystal data, we choose neither to assign the NIR transitions nor make a definitive class II or III designation based on these spectra.

The solution stability of the mixed-valence complexes was assessed by UV-vis spectroscopic and conductivity measurements. In all cases, the optical spectra remained unchanged after standing in THF, benzene, or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ for several days under $\mathrm{N}_{2}$. Upon addition of a strongly coordinating solvent such as MeCN, however, the solutions immediately turned pale blue-green and absorption spectra typical of mononuclear $\mathrm{Cu}(\mathrm{II})$ were observed. The conductivity behavior of 4-8 similarly remained unchanged over the same time period in THF solution. The triflate and $\mathrm{O}_{2} \mathrm{CCF}_{3}{ }^{-}$adducts are non-electrolytes, whereas the $\mathrm{BF}_{4}{ }^{-}$adducts are 1:1 electrolytes as judged by a comparison of conductivity vs. concentration plots for 7 and $\mathrm{Bu}_{4} \mathrm{~N}\left(\mathrm{PF}_{6}\right)$ (Figures 2.4 and 2.5). These results demonstrate that the $\left[\mathrm{Cu}_{2}(\mathrm{XDK})\right]^{+}$ mixed-valence core is highly resistant to disproportionation, even in the absence of excess THF, provided only weak field ligands are present.

The structures of 4,6, and 8, as determined by X-ray crystallography, are displayed in Figures 2.6-2.8. Selected bond distances and angles, atomic coordinates, and equivalent isotropic displacement parameters are listed in Tables 2.3 and 2.4-2.8, respectively. The structure of the triflate adduct 4 consists of two slightly distorted square pyramidal copper atoms, each ligated by two XDK carboxylate oxygens, a THF molecule, and an oxygen atom of a bridging triflate ion. The bond distances and
angles about each Cu atom are almost identical, and the dinuclear complex has idealized $C_{2 v}$ geometry, although no symmetry is crystallographically imposed on the molecule. Both copper atoms are nestled slightly above ( $0.241(2) \AA$ ) the rigidly disposed and coplanar XDK carboxylate oxygen atoms, with nearly identical OXDK-$\mathrm{Cu}-\mathrm{OXDK}_{\mathrm{XD}}$ angles. The fifth coordination site is filled by the adjacent copper fragment, the $\mathrm{Cu}-\mathrm{Cu}$ distance being $2.4093(8) \AA$. This value is significantly smaller than the $2.6287(5) \AA$ distance in the dicopper(I) in starting material 1 or in homoleptic $\mathrm{Cu}_{2}$ (XDK), where the average $\mathrm{Cu} \cdots \mathrm{Cu}$ distance is 2.5901 (9) $\AA .{ }^{28} \mathrm{The} \mathrm{Cu}-$ Cu bond in $\mathbf{4}$ is slightly shorter than that observed for the octaazacryptand class III mixed-valence complexes (Table 2.1). ${ }^{27}$ The longest $\mathrm{Cu}-\mathrm{O}$ distance is that to the triflate oxygen atom, which is $\sim 0.2 \AA$ longer than the $\mathrm{Cu}-\mathrm{O}$ bond involving THF, which identifies the triflate as the axial ligand of the square pyramid. Because the ligand fields presented by the three different type donor atoms, the carboxylates, THF and copper, differ widely, the true symmetry at each metal center is rhombic, as reflected by EPR spectroscopy (vide infra).

The solid state structure for trifluoroacetate analog 6 (Figure 2.7) is quite similar to that of 4 , with a few important distinctions. Firstly, the $\mathrm{Cu}-\mathrm{Cu}$ bond in 6 is $2.3988(8) \AA$, the shortest distance thus far observed for any dicopper mixed-valence complex. Secondly, the axial $\mathrm{Cu}-\mathrm{O}$ bonds to the trifluoroacetate ligand have shortened by $\sim 0.1 \AA$. Thirdly, the $\mathrm{OXDK}^{-C u}-\mathrm{OXDK}$ angles have contracted by $\sim 10^{\circ}$, reflecting displacement of the copper atoms by $0.363(3) \AA$ from the plane of the XDK carboxylate oxygen atoms. In addition, the $\mathrm{Cu}-\mathrm{OXDK}_{\mathrm{XD}}$ bond lengths are slightly longer in 6 versus 4. All of these differences reflect the superior donor properties of the trifluoroacetate ligand compared to the triflate, their relative pK a values being $0.3^{48}$ and $-5.9,49$ respectively. Trifluoroacetate provides a greater share of the overall electron density required by each copper ion, diminishing the bonding interaction to the XDK carboxylate oxygens in 6. Overall the tris(carboxylate-bridged) motif
comprises a superior set of bridging ligands, however, a feature which accounts for the slightly shorter $\mathrm{Cu}-\mathrm{Cu}$ distance in 6 compared to 4 .

In the structure of 8 , the bridging anion has been displaced in favor of THF ligands, due to the poor donor properties of the $\mathrm{BF}_{4}{ }^{-}$anion and its even rarer inclination to behave as a bridging ligand (Figure 2.8). Without the third bridge, the $\mathrm{Cu}-\mathrm{Cu}$ distance in 8 has lengthened slightly compared to that in 4 . The axial $\mathrm{Cu}-$ $O_{T H F}$ bond lengths and the $\mathrm{O}_{\text {XDK }}-\mathrm{Cu}-\mathrm{OXDK}_{\text {X }}$ angles are quite similar to the analogous values in 4, however.

## Preparation and Structural Characterization of Heterodimetallic Complexes $\left[\mathrm{CuZn}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{THF})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right](9),[\mathrm{CuFe}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{NB})(\mathrm{MeCN})]_{2}(10 \mathrm{a})$, and

 [ $\left.\mathrm{CuZn}(\mathrm{PXDK})(\mathrm{OTf})(\mathrm{NB})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]$ (11). Heterodimetallic complexes containing $\mathrm{Cu}(\mathrm{I})$ and divalent non-copper ions were sought to help delineate the significance of metal-metal bonding in the dicopper mixed-valence derivatives. If the close contact between copper atoms in the latter was only a consequence of the bridging XDK ligand, then a similar metal $\cdots$ metal distance might be expected for analogous $\mathrm{Cu}(\mathrm{I}) \mathrm{M}(\mathrm{II})(\mu-\mathrm{XDK})$ complexes. Although it is difficult to duplicate exactly the ligand composition of the $\mathrm{Cu}(\mathrm{II})$ fragment in 4-8 to make such a comparison most relevant, the successful preparation of triflate complex 5 from mononuclear 3 and $\mathrm{Cu}(\mathrm{OTf})_{2}$ by Method B (Experimental Section) suggested a route to the desired mixed-metal complexes by substituting $\mathrm{M}(\mathrm{OTf})_{2}$ starting materials for copper(II) triflate under identical reaction conditions. Heterodimetallic $\mathrm{Cu}(\mathrm{I})$ complexes with $\mathrm{Zn}(\mathrm{II})$ and Fe (II) were of particular interest because these occur in the copper-iron active site in $\mathrm{CcO}^{1}$ and the copper-zinc site in $\mathrm{Cu}, \mathrm{Zn}$ superoxide dismutase. ${ }^{50}$ Although neither active site complex involves carboxylate ligands, structurally characterized $\mathrm{Cu}(\mathrm{I}) \mathrm{Fe}(\mathrm{II})$ and $\mathrm{Cu}(\mathrm{I}) \mathrm{Zn}(\mathrm{II})$ complexes are virtually nonexistent, ${ }^{51}$ so their structures and reactivity are of intrinsic interest in the present context.Exposure of 3 to a suspension of $\mathrm{Zn}(\mathrm{OTf})_{2}$ in THF resulted in gradual consumption of both reagents over 12 h (Scheme 2.1). As was the case for 5 , the purification of $\mathrm{Cu}(\mathrm{I}) \mathrm{Zn}(\mathrm{II})$ complex 9 was facilitated by its solubility in ether, which allowed insoluble $\mathrm{Et}_{4} \mathrm{~N}(\mathrm{OTf})$ to be filtered off. The analogous reaction with the XDK analog of 3 yielded an identical product, as judged by ${ }^{1} \mathrm{H}$ NMR spectroscopy, but it could not be separated from the byproduct salt. The water ligand in 9 might be derived from a trace amount of water in the $\mathrm{Zn}(\mathrm{OTf})_{2}$ reagent or the etheral solvents; the synthesis proved to be quite reproducible, however.

The ${ }^{1} \mathrm{H}$ NMR spectrum of 9 displays a single set of XDK and THF resonances in a 1:1 ratio. Some of the upfield XDK resonances corresponding to protons adjacent to the metal binding sites, and the two THF resonances, were broadened at room temperature. We ascribe this behavior to dynamic exchange process(es) involving the THF ligand. A resonance that could be ascribed to water was presumably obscured by the ligand resonances, but the identity of this ligand was confirmed by X-ray crystallography, elemental analysis, and IR spectroscopy.

Complex 10a was prepared from 3 and $\left[\mathrm{Fe}(\mathrm{OTf})_{2}(\mathrm{MeCN})_{2}\right]$ in a similar fashion. The THF complex analogous to 9 did not afford crystalline material until excess norbornene was added, which presumably displaces the THF ligand bound to $\operatorname{copper}(\mathrm{I})$ in the precursor complex. A similar transformation was accomplished with the $\mathrm{Cu}(\mathrm{I}) \mathrm{Zn}(\mathrm{II})$ complex by recrystallizing it in the presence of excess norbornene to provide 11. Triflate complex 4 was unreactive toward excess norbornene under similar conditions, as judged by UV-vis spectroscopy. This result suggests that delocalization in this complex may mask any reactivity as a copper(I) species, and that a $\mathrm{Cu}(1.5) \mathrm{Cu}(1.5)$ oxidation state assignment is more appropriate for 4-8. Alternatively, kinetic factors may explain the inertness of 4 towards norbornene.

To elaborate further the chemistry of the Cu (I) Fe (II) system, attempts were made to prepare an analog of the tris(carboxylate-bridged) complex 6. Compound 10a
was treated with 1 equivalent of $\mathrm{Me}_{4} \mathrm{~N}\left[\mathrm{O}_{2} \mathrm{C}(4\right.$-tert- $\left.\mathrm{Bu}-\mathrm{Ph})\right]$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, affording a white solid presumed to be $\left[\mathrm{CuFe}(\mathrm{PXDK})\left(\mathrm{O}_{2} \mathrm{C}(4-\text { tert }-\mathrm{Bu}-\mathrm{Ph})(\mathrm{NB})(\mathrm{MeCN})\right]_{\mathrm{n}}(10 \mathrm{~b}, \mathrm{n}=1\right.$ or 2), once extracted with $\mathrm{Et}_{2} \mathrm{O}$ to remove the salt byproduct. Attempts to recrystallize this complex for X-ray analysis were thwarted by its facile disproportionation to $\mathrm{Fe}(\mathrm{III})$ products and copper metal upon standing in solution for $>2 \mathrm{~h}$. The crude material was characterized by FTIR spectroscopy. A difference spectrum of 10 b and 10 a is consistent with displacement of the triflate ligand by the carboxylate (Figure 2.9). The increased basicity of the carboxylate compared to the triflate ligand must render the iron(II) center more reducing, thus accounting for the difference in stability of the two complexes.

The solid state structures of 9 and 11 are presented in Figures 2.10 and 2.11, respectively. The structure of 9 consists of a trigonal copper atom ligated by a THF and two carboxylate oxygen atoms. The zinc atom is trigonal bipyramidally coordinated by five oxygen atoms contributed by two from PXDK, a monodentate, terminal triflate, a THF, and a water molecule. The water is hydrogen bonded to the imide carbonyls of the PXDK ligand, a common feature in XDK complexes when water or alcohol ligands are present. ${ }^{32-34,36}$ The triflate ligand displays no affinity for $\mathrm{Cu}(\mathrm{I})$, and the metal-metal distance in this complex has lengthened to 2.8810 (8) $\AA$, compared to $2.4093(8) \AA$ for the triflate analog 4. The X-ray structure of 11 is somewhat analogous to that determined for 9 in that the copper atom is trigonal, the triflate ligand is coordinated in the same fashion, and the metal ions are well separated from one another. The copper-norbornene fragment is disordered over two positions with equal site occupancies in each orientation. These two binding modes were also observed within the same molecule of $\left[\mathrm{Cu}_{2}(\mathrm{XDK})(\mathrm{NB})_{2}\right],{ }^{28}$ and are judged to be energetically similar.

The structure of 10 a was of only modest quality, ${ }^{52}$ but it served to identify the overall geometry and is depicted in Scheme 2.1. The complex dimerizes in the solid
state via bridging triflate groups, the two halves of the dimer being related by a center of inversion. Qualitatively, the $\mathrm{Cu}-\mathrm{Fe}$ separation of $3.492(2) \AA$ is similar to the $\mathrm{Cu}-\mathrm{Zn}$ distances in 11. Thus replacement of the $\mathrm{Cu}(\mathrm{II})$ ion in 5 with Zn (II) or Fe(II) provided complexes with reasonably similar composition but of different structures, particularly with respect to the metal $\cdots$ metal separation. Collectively, these structural and copper(I) ligand exchange studies lend credence to the supposition that the short $\mathrm{Cu}-\mathrm{Cu}$ distances and approximate $C_{2 v}$ symmetry observed for 4-8 are a consequence of metal-metal bonding and valence delocalization, and not a function of the ligand architecture.

Electrochemical Properties of the Mixed-Valence Complexes. With the mixedvalence solvento complex 7 and the dicopper(I) analog ${ }^{28}$ in hand, we were interested to determine whether they could be electrochemically interconverted. It was anticipated a priori that quasireversible behavior might be observed owing to molecular reorganization, since the copper ion geometries in 7 and $\mathrm{Cu}_{2}$ (XDK) differ significantly. Moreover, it was of additional interest to determine whether the reduction potential of the $\left[\mathrm{Cu}_{2}(\mathrm{XDK})\right]^{+} / \mathrm{Cu}_{2}(\mathrm{XDK})$ couple deviates significantly from known trends for copper complexes because of the valence delocalized character of the mixed-valence form. ${ }^{53}$

The homoleptic dicopper(I) complex exhibited a chemically reversible ( $\mathrm{i}_{\mathrm{pa}} / \mathrm{i}_{\mathrm{pc}}$ ~1) and electrochemically quasireversible ( $\Delta \mathrm{E}_{\mathrm{p}}=105 \mathrm{mV}$, scan rate $=50 \mathrm{mV} / \mathrm{s}$ ) cyclic voltammogram, with $\mathrm{E}_{1 / 2}=-214 \mathrm{mV}$ vs. $\mathrm{Cp}_{2} \mathrm{Fe}^{+} / \mathrm{Cp}_{2} \mathrm{Fe}$ (Figure 2.12). Plots of $\mathrm{i}_{\mathrm{pa}}$ and $i_{p c}$ vs. the square root of the scan rate are linear (Figure 2.13), as would be expected for a (nearly) reversible couple. The same electrochemical couple was observed for the oxidized complex 7 (Figures 2.14 and 2.15: $\mathrm{E}_{1 / 2}=-222 \mathrm{mV}, \Delta \mathrm{E}_{\mathrm{p}}=132 \mathrm{mV}$, scan rate $=50 \mathrm{mV} / \mathrm{s}, \mathrm{i}_{\mathrm{pa}} / \mathrm{i}_{\mathrm{pc}} \sim 1$ ), confirming the one-electron nature of the process. An identical couple was also observed for the triflate complex 4 (Figures 2.16 and 2.17: $E_{1 / 2}=-218 \mathrm{mV}, \Delta \mathrm{E}_{\mathrm{p}}=147 \mathrm{mV}$, scan rate $=50 \mathrm{mV} / \mathrm{s}, \mathrm{i}_{\mathrm{pa}} / \mathrm{i}_{\mathrm{pc}} \sim 1$ ), suggesting that
triflate is dissociated upon dissolution in the electrolyte media, or upon reduction to the $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ species. At higher potentials an oxidation wave was detected, possibly signaling formation of a $\mathrm{Cu}(\mathrm{II}) \mathrm{Cu}$ (II) species, with $\mathrm{E}_{\mathrm{pa}}=443 \mathrm{mV}$ (Figure 2.18). This feature could not be made reversible, even at high scan speeds ( $>500 \mathrm{mV} / \mathrm{s}$ ). Unlike the behavior noted for the more weakly coordinating triflate anion, the trifluoroacetate ligand in 6 might remain associated with the $\mathrm{Cu}_{2}$ (XDK)+ fragment during cyclic voltammetry, because the analogous $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ reduction wave is completely irreversible (Figure 2.19).

In order to place the electrochemical data presented in a more general context, $\mathrm{E}_{1 / 2}$ values for a variety of $\mathrm{Cu}(\mathrm{I})$ and $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ complexes are compiled in Table 2.9. In each case the redox couple was chemically reversible and electrochemically reversible, or nearly so ( $\Delta \mathrm{E}_{\mathrm{p}}<150 \mathrm{mV}$ ). The mononuclear complexes listed contain ligands ranging from a dianionic $\mathrm{N}_{2}$-bis(phenoxide) species (a) to neutral ${ }^{54}$ or cationic ${ }^{55-57}$ donors with all nitrogen ligands (complexes $\mathbf{d}, \mathbf{g}, \mathbf{h}-\mathbf{j}$ ). For comparison to the results obtained for 7 , class I (e), ${ }^{58} \mathrm{II}(\mathrm{b}),{ }^{17}$ and III (g) ${ }^{23}$ mixed-valence systems with well behaved electrochemistry were included. For $c$, the mixed-valence form has not been isolated and characterized, but the dicopper(II) form undergoes two sequential one-electron steps at the same potential. ${ }^{59}$ To make the comparison more meaningful, potentials for each couple were referenced to the $\mathrm{Cp}_{2} \mathrm{Fe}^{+} / \mathrm{Cp}_{2} \mathrm{Fe}$ couple in THF. Scaling was accomplished with the aid of literature data relating SHE to $\mathrm{SCE},{ }^{60} \mathrm{AgCl} / \mathrm{Ag}$ to $\mathrm{SCE},{ }^{60}$ and SCE to $\mathrm{Cp}_{2} \mathrm{Fe}^{+} / \mathrm{Cp}_{2} \mathrm{Fe}$ (in THF) ${ }^{61}$. These normalized $\mathrm{E}_{1 / 2}$ values can be used as a rough approximation only, since the potentials for each complex depend on experimental conditions, including choice of solvent, electrolyte and electrolyte concentration, solvation, and ion pairing.

As expected from previous electrochemical studies of a large series of copper complexes, ${ }^{53}$ the compounds in Table 2.9 display the general trend that more negative reduction potentials occur as the ligand set becomes increasingly more
basic, with ligands which favor square planar or tetragonal over tetrahedral geometries, and with decreasing positive charge on the complex. From this standpoint all of the mixed-valence systems from the literature are unremarkable in in the sense that their redox potentials are not anomalously affected by electronic coupling between adjacent copper atoms, except for $\mathbf{c}$. Given the tetraanionic charge on the ligand and the rigidly planar structure of the dicopper(II) form, the $\mathrm{E}_{1 / 2}$ values for this complex should more closely resemble that of a. Since little is known about the electronic and solid state structures of the mixed-valence and dicopper(I) forms of $c$, however, it is difficult to rationalize these findings.

For the $\mathrm{Cu}_{2}(\mathrm{XDK}) / \mathrm{Cu}_{2}$ (XDK) ${ }^{+}$couple, two competing factors unique to this system can be identified which tend to shift the reduction potential in opposite directions. One is the stability of the mixed-valence form due to its delocalized electronic structure, and the other is the resistance of the dicopper(I) variant to deviate from its linear, two-coordinate copper geometries. Judging from the large positive deviation of the redox potential from its expected position in the series of complexes (Table 2.9), the latter feature seems to predominate. Our previous studies of ligand substitution reactions with the $\mathrm{Cu}_{2}$ (XDK) scaffold revealed one of the $\operatorname{copper}(\mathrm{I})$ ions to be unreactive towards $\sigma$-donors. Even when exposed to excess tetramethylethylenediamine (tmeda, eq 1), it preferred to retain a

linear, two-coordinate "skewered" geometry. We suggest that the electrochemical oxidation of $\mathrm{Cu}_{2}$ (XDK) reaction involves coordination of two THF ligands to each copper ion, thus making it more difficult to oxidize compared to the other copper complexes with anionic oxygen donors which do not have the geometrical
constraints of XDK. In much the same way that ligands such as $\mathbf{i}$ and $\mathbf{j}$ prefer copper(I) by favoring a tetrahedral geometry, the XDK ligand enforces a linear, twocoordinate copper(I) structure. The magnitude of the positive $\mathrm{E}_{1 / 2}$ shift appears to be much greater for 7 , however, since the all-oxygen $\mathrm{Cu}_{2}$ (XDK) donor set should place its $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{I})$ potential near those found for a-c.

It is interesting that the $\mathrm{E}_{1 / 2}$ value for $\mathrm{Cu}_{2}$ (XDK) falls approximately in the range found for blue copper proteins, $\sim+200$ to +800 mV vs. NHE, or $\sim-600$ to 0.0 mV vs. $\mathrm{Cp}_{2} \mathrm{Fe}+/ \mathrm{Cp}_{2} \mathrm{Fe}$ in THF, which employ a soft, monoanionic $\mathrm{N}_{2} \mathrm{~S}_{2}$ ligand donor set while imposing a geometry intermediate between square planar and tetrahedral. Unlike our system, however, the rate of electron transfer is maximized at these biological electron transfer centers by requiring minimal ligand reorganization when cycling between the +1 and +2 oxidation states. Here we have achieved biologically relevant redox potentials through geometric constraints, at the cost of imparting a significant degree of reorganizational energy. Since these properties could readily be achieved in a protein matrix, the carboxylate-bridged dicopper(1.5) center would be a viable biological redox center.

EPR Studies of $\left[\mathrm{Cu}_{\mathbf{2}}(\mathrm{XDK})(\mathbf{T H F})_{\mathbf{4}}\left(\mathrm{BF}_{4}\right)\right]$ (7). EPR spectroscopy is a key tool for characterizing electronic exchange in mixed-valence copper complexes because seven-line hyperfine coupling of the unpaired electron to a pair of $I=3 / 2$ copper nuclei is diagnostic of spin delocalization. ${ }^{15-17,20,23}$ In class II systems, electron exchange is typically mediated by population of vibrationally excited states, which imparts sufficient kinetic energy for the electron to pass over the barrier separating the electronic ground states of the two metal ions. Thus the rate of electron transfer in these systems is temperature-dependent, and valence delocalization is observed when the rate exceeds the time scale of the EPR experiment. In contrast, class III mixed valence systems exhibit temperature independent delocalization behavior, at least on the EPR time scale and over the temperature range to which the sample
may be cooled. In this case the electronic structure is best defined by a single wavefunction encompassing both metal ions in which the unpaired electron resides. EPR studies of the present system were therefore undertaken in both the solid state and solution in order to probe the extent of electron delocalization, its temperature dependence, and the similarities between structures in the two different states.

A survey of the X-band frozen solution EPR spectra of 4, 6 and 7 obtained at liquid helium temperature proved them to be quite similar, so a detailed investigation was undertaken with the solvento adduct 7.62 EPR spectra for 7 are presented in Figures 2.20 and 2.21 for frozen solution and powdered samples, respectively, together with a simulation for each case, from which $g$ values and copper hyperfine coupling constants were derived. The spectra of 7 at 9 and 77 K exhibited nearly identical rhombic signals with a readily discernible seven-line copper hyperfine coupling pattern on the lowest field component and overlapping hyperfine features on the two higher field components (Table 2.10). The X-band EPR spectra of powdered samples acquired at the same temperatures were extremely similar, albeit slightly broader, suggesting that the delocalized solid state structure is retained in solution. A frozen solution Q-band spectrum acquired at 2 K also exhibited seven distinct hyperfine lines on the lowest field component (Figure 2.22). Furthermore, power dependence saturation studies on both the frozen solution and powdered samples revealed that each spectrum corresponded to a single species. Taken together, the EPR studies provide compelling evidence that the $\mathrm{Cu}_{2}(\mathrm{XDK})^{+}$ mixed-valence series should be classified as a fully delocalized, class III system in both the solid state and solution. Moreover, these studies represent the first report of full delocalization for a dicopper mixed-valence species at 2 K , reinforcing its class III designation.

The rhombic signal and distinct hyperfine coupling constants at each $g$ value were anticipated based on the approximate $C_{2 v}$ symmetry of the mixed-valence complexes and the significantly different ligand fields presented by the three types of ligands to each copper, the two carboxylate oxygens, the two THF oxygens, and the adjacent copper fragment. ${ }^{63}$ The spectra may be compared with the rhombic spectra obtained for the $\mathrm{Cu}_{\mathrm{A}}$ site ${ }^{6}$ and for $\left(\mathrm{CuL}^{\text {iPrdacoS }}\right)_{2}{ }^{+},{ }^{20}$ each of which showed similar g values to those obtained for 7 , but the bis( $\mu$-thiolato) model complex exhibited substantially smaller copper hyperfine coupling constants (Table 2.1). The larger copper hyperfine interactions in $\mathbf{7}$ may be explained in part by a greater amount of spin density residing at the metal centers because of the short $\mathrm{Cu}-\mathrm{Cu}$ interaction and the absence of a superexchange pathway through bridging ligands. In contrast to these rhombic systems, the octazacryptand ligands afforded mixed-valence complexes with axial EPR spectra arising from its trigonal ligand field.

Molecular Orbital Calculations. An extended Hückel molecular orbital treatment of 7 was undertaken to elucidate its frontier molecular orbitals. The parameters of interest are the bonding and antibonding molecular orbitals responsible for the $\mathrm{Cu}-\mathrm{Cu}$ interactions, their relative energies, and their copper orbital components. Net stabilization imparted to the dinuclear structure by $\mathrm{Cu}-\mathrm{Cu}$ bonding was assessed by analyzing the interaction of the two mononuclear fragments as a function of $\mathrm{Cu}-\mathrm{Cu}$ distance. Two simplified models were implemented, $\left[\mathrm{Cu}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$ and $\left[\mathrm{Cu}_{2}(\mathrm{OH})_{2}\left(\mathrm{OH}_{2}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$, each derived from the crystallographic coordinates of the dicopper core in 8 . The $\mathbf{z}$-axis was taken along the apical copper- $\mathrm{OMe}_{2}$ bond of one of the copper atoms, and the x - and y -axes along the copper-copper and copper-carboxylate (hydroxide/water) oxygen vectors, respectively.

Figures 2.23-2.24 display contour plots of the SOMO and second highest occupied molecular orbital (SHOMO) for $\left[\mathrm{Cu}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$. The SOMO has
considerable $\mathrm{Cu} \mathrm{d}_{\mathrm{x} 2-\mathrm{y} 2} / \mathrm{Cu}_{\mathrm{x} 2-\mathrm{y} 2} \sigma$-antibonding character ( $\sim 60 \%$ for each copper), with a lobe from each metal pointed toward the other along the x-axis. The $4 \mathrm{~s}(\sim 11 \%$ for each copper) and $\mathrm{d}_{\mathrm{z} 2}$ ( $\sim 8 \%$ for each copper) orbitals also contribute significantly to the SOMO, having the same phases as the $\mathrm{d}_{\mathrm{x} 2}-\mathrm{y}^{2}$ orbital on the two metals. In addition, the p orbital contribution from each ligand is out-of-phase with respect to the adjacent copper orbital lobe. The SHOMO in effect represents the bonding counterpart of the anti-bonding SOMO, but has more $d_{z 2}(32 \%)$ and $4 \mathrm{~s}(22 \%)$ character at the expense of the $d_{x 2-y 2}(36 \%)$. Again the ligand p orbitals are out-ofphase with respect to the adjacent copper orbital lobe, and in neither the SOMO nor the SHOMO are the carboxylate carbon atoms participating. An exchange pathway for electron delocalization therefore appears to be accessible only through the $\mathrm{Cu}-\mathrm{Cu}$ interaction and not through the carboxylate ligands. Additional support for a net $\mathrm{Cu}-\mathrm{Cu}$ bonding interaction is obtained from a reduced Mulliken overlap population analysis, which revealed that the overall $\mathrm{Cu}-\mathrm{Cu}$ overlap population to be +0.1495 at the crystallographic $\mathrm{Cu}-\mathrm{Cu}$ distance of $2.40 \AA$. This value may be compared to the average overlap population of +0.5362 for $\mathrm{C}-\mathrm{O}$ single bonds in the same structure. Hence the short $\mathrm{Cu}-\mathrm{Cu}$ distance in the mixed-valence complexes is indicative of a weak metal-metal bond.

A fragment molecular orbital (FMO) analysis was carried out on $\left[\mathrm{Cu}_{2}(\mathrm{OH})_{2}\left(\mathrm{OH}_{2}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$, a simpler model which permits the two copper fragments to be separated without breaking any carbon-oxygen bonds (Figure 2.25). The frontier molecular orbitals for this model had essentially identical energies and orbital contributions as those obtained for $\left[\mathrm{Cu}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$. The FMO analysis revealed that a significant bonding/antibonding interaction results between the highest occupied molecular orbital (HOMO) of the $\mathrm{Cu}(\mathrm{I})$ and Cu (II) fragments when the two are brought together. This interaction is also observed in a Walsh diagram, where the molecular orbital energy is plotted as a function of the $\mathrm{Cu}-\mathrm{Cu}$
distance (Figure 2.25). The orbitals perturbed most dramatically are the SHOMO and SOMO, those suspected to play the greatest role in $\mathrm{Cu}-\mathrm{Cu}$ bonding. The energy gap between the SOMO and SHOMO of $\left[\mathrm{Cu}_{2}(\mathrm{OH})_{2}\left(\mathrm{OH}_{2}\right)_{2}\left(\mathrm{OMe}_{2}\right)_{4}\right]$ is maximized at $\sim 2.2$ $\AA$, reasonably close to the crystallographically determined distance of $2.40 \AA$. A minimum for the total energy of the molecular orbitals is reached at a $\mathrm{Cu}-\mathrm{Cu}$ distance of $\sim 2.9 \AA$. Greater error for this latter parameter is to be expected, since the total energy is made up of the individual energies of the 65 occupied molecular orbitals. Nevertheless, both the FMO and Walsh analyses support the idea that net stabilization is imparted to these mixed-valence complexes through $\mathrm{Cu}-\mathrm{Cu}$ bonding. Furthermore, the bonding interaction principally utilizes the $\mathrm{Cu} \mathrm{d}_{\mathrm{x} 2-\mathrm{y} 2}$ orbitals. This outcome does not support a previous assertion that strong $\mathrm{Cu}-\mathrm{Cu}$ bonding can only be mediated by $\mathrm{Cu} \mathrm{d}_{\mathrm{z} 2} / \mathrm{Cu} \mathrm{d}_{\mathrm{z} 2}$ overlap, and that $\left(\mathrm{d}_{\mathrm{x} 2}-\mathrm{y} 2\right)^{1}$ dimers are always held together exclusively as a consequence of their ligand structures. ${ }^{22}$ Instead, we conclude that the only strict requirement for $\mathrm{Cu}-\mathrm{Cu}$ bonding in these dimers is reasonable $\sigma$-type overlap between two adjacent metal orbitals and, depending on the geometry, this interaction can be achieved with $\mathrm{d}_{\mathrm{x} 2-\mathrm{y} 2}$ orbitals.

## Conclusions

A series of dicopper mixed-valence complexes have been assembled with the XDK ligand system. Their fully delocalized, class III behavior has been demonstrated experimentally through (a) X-ray crystallographic studies which show that the coordination environments about each copper atom are identical, and (b) solid state and solution EPR studies which demonstrate that the unpaired spin is coupled simultaneously to both $I=3 / 2$ copper ions down to 2 K . Support for a stabilizing $\mathrm{Cu}-\mathrm{Cu}$ bonding interaction in these complexes was provided by (a) the synthesis of $\mathrm{Cu}(\mathrm{I})$ heterodimetallic complexes with other divalent metal ions which are of similar composition but have much longer $\mathrm{Cu}(\mathrm{I}) \cdots \mathrm{M}(\mathrm{II})$ distances; (b) the lack of
reactivity of the mixed-valence complexes with norbornene, which reacts quantitatively with the $\mathrm{Cu}(\mathrm{I})$ fragment of the heterodimetallic complexes; and (c) extended Hückel molecular orbital calculations, which show a $\mathrm{Cu}-\mathrm{Cu}$ interaction in
 overlap. Cyclic voltammetric studies revealed an electrochemically quasireversible $\mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II}) / \mathrm{Cu}(\mathrm{II}) \mathrm{Cu}(\mathrm{II})$ wave with a very positive $\mathrm{E}_{1 / 2}$ value, tentatively attributed to the geometrical constraints imposed by the XDK ligand, which favors the linear two-coordinate $\mathrm{Cu}(\mathrm{I})$ geometry. In the aggregate, these studies significantly enhance our understanding of the assembly, stability, and electronic structure of class III mixed-valence $\mathrm{Cu}-\mathrm{Cu}$ bonded systems. We suggest that this new structural and redox active motif would serve well as a biological electron transfer center in carboxylate-bridged environments.

(19) $\mathrm{A} \mathrm{Cu}(\mathrm{I}) \mathrm{Cu}(\mathrm{II})$ mixed-valence "acetate/methanol" complex has been reported, and support for a delocalized structure at room temperature and at 77 K was acquired by EPR. This complex was never isolated, however, and it disproportionated to a large extent upon cooling below $\sim-50^{\circ} \mathrm{C}$ as judged by the presence of a significant mononuclear $\mathrm{Cu}(\mathrm{II})$ impurity in the EPR spectrum. ## Chapter III

Modeling the $\mathbf{H}_{\text {peroxo }}$ Intermediate of Soluble Methane Monooxygenase:
Preparation of Sterically Hindered Diiron(II) Tetracarboxylate Complexes, and Their Reactivity Toward Dioxygen

## Introduction

Over the last few decades, a class of carboxylate-bridged diiron proteins has been discovered that utilizes dioxygen for a variety of functions, ranging from $\mathrm{O}_{2}$ transport to the selective catalytic oxidation of organic substrates by hydroxylation, epoxidation, or hydrogen atom abstraction processes. ${ }^{1-5}$ This diversity is aptly represented in three of the most intensively studied of these proteins, hemerythrin, ribonucleotide reductase, and methane monooxygenase. Hemerythrin ( Hr ) is the dioxygen carrier protein in marine invertebrates. The reduced protein has a $\left[\mathrm{Fe}_{2}(\mu-\right.$ $\left.\mathrm{OH})\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2}(\mathrm{His})_{5}\right]^{+}$donor set, and in the oxidized form $\mathrm{O}_{2}$ is bound as a terminal $\eta^{1}$-hydroperoxide, hydrogen bonded to the oxo bridge (eq 1).

Ribnucleotide reductases are essential for reducing ribonucleotides to deoxyribonucleotides, which are used in DNA biosynthesis. The $E$. coli form of this enzyme houses a diiron active site in the R2 subunit (RNR-R2). Here $\mathrm{O}_{2}$ is activated and one of its oxidizing equivalents is used to generate a tyrosyl radical, which in turn transfers an electron from the R1 subunit, where the ribonucleotide reduction is catalyzed. Methane monooxygenase (MMO) is used by obligate methanotrophic bacteria to oxidize methane selectively to methanol. These bacteria use methane as their sole source of carbon and energy. This mixed function oxidase incorporates one of the oxygen atoms from dioxygen into methanol and the other into water (eq 2). The soluble form (sMMO) contains a diiron center in the hydroxylase component (MMOH), the site of methane oxidation.

$$
\begin{equation*}
\mathrm{CH}_{4}+\mathrm{O}_{2}+\mathrm{NADH}+\mathrm{H}^{+} \longrightarrow \mathrm{CH}_{3} \mathrm{OH}+\mathrm{H}_{2} \mathrm{O}+\mathrm{NAD}^{+} \tag{2}
\end{equation*}
$$

Unlike hemerythrin, the RNR-R2 and MMOH enzymes contain oxygen-rich coordination environments at their diiron active sites. In each protein four carboxylate and two imidazole ligands are distributed about the two iron atoms. The remainder of coordination sites are occupied by a variable number of water, hydroxide, or oxo ligands, depending on the enzyme and its position in the catalytic cycle. Depicted in Figure 3.1 are the active site structures of the diiron(II) forms of RNR-R2 and MMOH, and the oxidized diiron(III) form of MMOH, each deduced from X-ray crystal structural analyses. ${ }^{6-8}$

A detailed mechanistic picture of the $\mathrm{O}_{2}$ activation process in RNR-R2, ${ }^{2,9,10}$ and $\mathrm{sMMO}{ }^{2,4,9,10}$ is emerging as a result of the detection and spectroscopic characterization of transient oxygen intermediates (Figure 3.2). For RNR-R2, the first intermediate forms and decays within 35 milliseconds. ${ }^{11}$ Based on the similarity of its Mössbauer and UV-vis spectra to those observed for a model complex and an analogous intermediate in MMOH (vide infra), this species has been tentatively assigned as a diiron(III) peroxo complex, the product of $\mathrm{O}_{2}$ binding to the fully reduced diiron center combined with two-electron reduction. Intermediate $X$, which forms subsequently after the peroxo, has Mössbauer, ${ }^{12}$ Q-band ENDOR, ${ }^{13}$ and EXAFS ${ }^{14}$ spectra consistent with an antiferromagnetically coupled Fe (III) Fe (IV) center with at least one oxo bridge and a terminal water or hydroxide ligand. In addition, X has an $\mathrm{Fe} \cdots \mathrm{Fe}$ separation of $2.5 \AA$ and at least one $\mathrm{Fe}-\mathrm{O}$ distance of $1.8 \AA$. The EXAFS parameters are consistent with the presence of two or three single atom bridges. This high-valent intermediate X is the direct precursor to catalytically active RNR-R2 ( $R R_{\text {act }}$ ) and generates the active enzyme possibly by hydrogen atom abstraction from Tyr-122, to afford an oxo-bridged diiron(III) center and the tyrosyl radical. Presumably X is the product of peroxide $\mathrm{O}-\mathrm{O}$ bond cleavage, but it is not clear whether injection of an extra electron must accompany O-O bond scission or,
alternatively, whether a yet unobserved dioxodiiron(IV) species might be initially generated. ${ }^{10}$

For MMOH, a metastable diiron(III) peroxo intermediate ( $\mathrm{H}_{\mathrm{peroxo}}$ ) has also been identified as an early product of the $\mathrm{O}_{2}$ reaction chemistry, ${ }^{15}$ but it forms and decays more slowly than its RNR-R2 analog. ${ }^{11} \mathrm{H}_{\text {peroxo }}$ converts to a diiron(IV) species termed Q (or MMOH-Q). ${ }^{15,16}$ This intermediate, or a closely related derivative, is believed to be the active substrate oxidant since Q is the last ironoxygen species detected prior to methane oxidation, and its decomposition is accelerated by the presence of substrate. The structure of $Q$ has been interrogated by EXAFS, which revealed quite similar parameters to those observed for intermediate X in RNR-R2. ${ }^{17}$ The EXAFS data do not provide unique structural infomation about either high-valent intermediate, however, particularly regarding the coordination of the oxygen ligands derived from $\mathrm{O}_{2}$.

Recent experiments on RNR-R2 and MMOH reveal that the two systems share common oxygen intermediates, the fate of which is exquisitely regulated according to their different oxidative functions. In one study, an RNR-R2 mutant was prepared in which an aspartate residue in the active site was replaced with glutamate, affording an MMOH-like coordination environment. ${ }^{18}$ With this modest change in the flexibility of a single carboxylate ligand, the D84E mutant remarkably afforded a diiron(III) peroxo that formed and decayed at rates comparable to those of MMOH- $\mathrm{H}_{\text {peroxo, }}$, proceeding to form a stoichiometric amount of a stable tyrosyl radical, most likely via intermediate $X$. These results lend credence to the assignment of the initial $\mathrm{O}_{2}$ intermediate in native RNR-R2 as a diiron(III) peroxo species, and reveal that the stability of the peroxo intermediates in RNR-R2 and MMOH can be regulated by tuning the active site ligands.

In the other study, intermediate Q in MMOH was reduced radiolytically at low temperature, while keeping the active site structure conformationally fixed in a
frozen solution. ${ }^{19}$ This procedure provided a new spectroscopically distinct species, termed Qx , having Mössbauer parameters essentially identical to those of R2-X. This result, coupled with the EXAFS studies of $Q$, suggests that R2-X and $Q$ have very similar structures, and that R2-X is derived from a Q-like analog by reduction with an external electron. In this manner, the extra oxidizing equivalent in a dioxodiiron(IV) intermediate could be quickly sequestered in RNR-R2 by an outer sphere reduction, so that R2-X can generate a tyrosyl radical stable towards further degradation by a metal-based oxidant. In contrast, both oxidizing equivalents of $\mathrm{MMOH}-\mathrm{Q}$ are retained for methane oxidation.

Considerable effort has been expended to prepare synthetic models for the dioxygen intermediates described above for RNR-R2 and sMMO. The goals have been to mimic their spectroscopic and structural features, and utimately their oxidation chemistry. ${ }^{1,5}$ The most notable systems reported to date include three well characterized diiron(III) peroxo complexes and an Fe (III) Fe (IV) bis( $\mu$-oxo) species, the properties of which are summarized in Table 3.1. The peroxo complexes were all prepared by exposure of the ferrous precursor to $\mathrm{O}_{2}$ at low temperature. ${ }^{20-22}$ They have UV-vis spectra characterized by a broad charge-transfer band centered at $\sim 600$ $\mathrm{nm}\left(\varepsilon \sim 2000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right.$ ), and resonance Raman O-O stretches at $\sim 900 \mathrm{~cm}^{-1}$. In addition, X-ray structural studies revealed the peroxide to be bound symmetrically in an eclipsed or gauche $\mu-1,2$ bridging mode for each complex.

The $\mathrm{Fe}($ III $) \mathrm{Fe}(\mathrm{IV})$ bis( $\mu$-oxo) model was prepared from hydrogen peroxide and a diiron(III) bis( $\mu$-oxo) "diamond core" precursor, possibly via a diiron(III)( $\mu$-oxo) $(\mu$ peroxo) intermediate. ${ }^{23,24}$ It has an antiferromagnetically coupled, valence localized, $\mathrm{S}=1 / 2$ ground state and distinct Mössbauer quadrapole doublets for the Fe (III) and $\mathrm{Fe}(\mathrm{IV})$ ions. The electronic structure of the metal ions matches well with analogous spectroscopic data accumulated for Qx and X , but it is not yet clear whether the arrangement of oxo ligands in each system is the same.

Despite these recent advances, there are many deficiencies in the models for RNR-R2 and sMMO. Most importantly, in no system where a peroxo has been derived from the reaction of an iron(II) precursor with $\mathrm{O}_{2}$ has conversion to a high valent Q - or X -like species been demonstrated, nor has hydrocarbon oxidation chemistry been achieved. These shortcomings may stem from the fact that the present model systems do not reproduce the ligand composition found at the RNRR2 and sMMO active sites; their soft, nitrogen-rich coordination environments more closely resemble the active site residues in hemerythrin. The widely different fates of the peroxo ligands in Hr, RNR-R2, and sMMO may be due in part to the ability of the latter two systems, owing to their more basic, oxygen-rich donor sets, to support higher iron oxidation states required for O-O bond cleavage. With this hypothesis in mind, we were interested to investigate a carboxylate-rich model system in the hope that it would more closely mimic the RNR/sMMO systems from the dioxygen binding through $\mathrm{O}-\mathrm{O}$ bond cleavage and substrate oxidation steps.

Recently, carboxylate-bridged diiron(II) complexes having the xylylenediamine bis(Kemp's triacid imide) ( $\mathrm{H}_{2} \mathrm{XDK}$ ) ligand system were described, and their reactivity towards dioxygen explored in a preliminary manner. ${ }^{25}$ A family of diferrous tris(carboxylate-bridged) complexes was obtained which matched the composition of amino acid ligands at the MMOH active site. When one of these derivatives was exposed to $\mathrm{O}_{2}$ at low temperature in THF, the solution flashed deep purple, but quickly decayed to a red-orange color in less than 30 s (eq 3). Monitoring this reaction by stopped-flow UV-vis spectroscopy revealed the build-up and

decay over 10 s of an intermediate with an optical band centered at 650 nm . This species was tentatively assigned as a diiron(III) peroxo, but its inherent instability precluded any further characterization or functional reactivity studies.

In previous investigations from this laboratory, we have focused on the thermal decomposition of well defined diiron(III) peroxo complexes. ${ }^{26,27}$ Kinetic studies revealed the decay to have second order behavior in the peroxo, resulting in the extrusion of 0.5 equivalents of $\mathrm{O}_{2}$ and cleanly yielding diiron(III) oxo-bridged derivatives. Since bimolecular decay pathways are typically retarded by implementing sterically more hindered ligands, we modified the diiron XDK ligand system with bulkier $R$ groups with the aim of stabilizing the incipient peroxo intermediate. Presented here are the synthesis and characterization of sterically

hindered diiron(II) tetracarboxylate complexes and studies of their reactivity toward $\mathrm{O}_{2}$ to form stable peroxo adducts. A detailed account of their reactivity toward electrophilic, nucleophilic, and hydrocarbon substrates is in the following chapter. ${ }^{28}$

## Experimental Section

General Considerations. The compounds $\mathrm{H}_{2} \operatorname{XDK}(1),{ }^{29} \mathrm{H}_{2} \operatorname{PXDK}(2),{ }^{25}$, $\mathrm{H}_{2}$ BXDK (3), ${ }^{30}$ 1-phenylcyclohexanecarboxylic acid, ${ }^{31}$ and $\left[\mathrm{FeTp}^{3,5-i P r}{ }^{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{2} \mathrm{Ph}\right)\right]^{20}$ were prepared according to literature procedures. The thallium(I) salts of the carboxylic acid ligands were obtained as described in the literature or by analogous procedures, ${ }^{30,32}$ and each was identified by ${ }^{1} \mathrm{H}$ NMR spectroscopy as the desolvated thallium salt of high purity ( $>95 \%$ ). Ligands 1 -methylimidazole and 1butylimidazole were degassed and stored over $3 \AA$ molecular sieves for several days
prior to use. Dioxygen ( $99.994 \%$, BOC Gases) was dried by passing the gas stream through a column of Drierite. Labeled dioxygen ( $50 \%{ }^{18} \mathrm{O}_{2}$ and $95 \%{ }^{18} \mathrm{O}_{2}$ ) reagents were purchased from Cambridge Isotope Laboratories, Inc., and used without further purification. All other reagents were procured from commercial sources and used as received unless otherwise noted. THF, benzene, toluene, pentane, and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from sodium benzophenone ketyl under nitrogen. Dichloromethane, 1,2dichloroethane, and pyridine were distilled from $\mathrm{CaH}_{2}$ under nitrogen. The NMR solvent $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ was degassed, passed through activated basic alumina, and stored over $3 \AA$ molecular sieves prior to use. All air sensitive manipulations were carried out either in a nitrogen filled Vacuum Atmospheres drybox or by standard Schlenk line techniques at room temperature unless otherwise noted.

Synthesis. [Fe(XDK)(py) $\mathbf{2}_{2}$ (4). To a rapidly stirred suspension of $\mathrm{Tl}_{2}$ (XDK) (2.00 g, 2.02 mmol ) and pyridine ( $1.64 \mathrm{ml}, 20.2 \mathrm{mmol}$ ) in THF ( 15 mL ) was added a solution of $\mathrm{FeBr}_{2}(446 \mathrm{mg}, 2.02 \mathrm{mmol})$ in THF ( 5 mL ). After 6 h , the precipitated TlBr was removed by filtration through Celite, and the filtrate was evaporated to dryness. The crude residue was washed with pentane ( 20 mL ) to remove any residual pyridine, isolated by filtration, and dried fully in vacuo to afford 4 as a light yellow powder ( $1.44 \mathrm{~g}, 90 \%$ ). This crude material was used for subsequent reactions without further purification. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /pyridine/ $\mathrm{Et}_{2} \mathrm{O}$ afforded 4 as yellow blocks which appeared suitable for X-ray crystallography: IR (KBr) 3068, 2961, $2929,1735,1696,1602,1404,1463,1358,1334,1218,1195,1087,1039,958,835,760,626$ $\mathrm{cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 364$ (580). Anal. Calcd for $\mathrm{C}_{42} \mathrm{H}_{48} \mathrm{~N}_{4} \mathrm{O}_{8} \mathrm{Fe}_{1}$ : C, 63.64; H, 6.10; N, 7.07. Found: C, 61.33; H, 6.26; N, 6.60.
[Fe(BXDK)(py) ${ }_{2}$ ] (5). This compound was prepared as a light yellow powder from $\mathrm{Tl}_{2}$ (BXDK) ( $2.33 \mathrm{~g}, 1.61 \mathrm{mmol}$ ), pyridine ( $560 \mu \mathrm{l}, 6.92 \mathrm{mmol}$ ), and $\mathrm{FeBr}_{2}$ ( 354 mg , $1.61 \mathrm{mmol})$ by a procedure analogous to that used to prepare $4(1.55 \mathrm{~g}, 77 \%)$. The crude material was used for all subsequent reactions. Recrystallization from
$\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{Et}_{2} \mathrm{O}$ provided 5 as opaque yellow needles. IR ( KBr ) $3062,3027,2921,2857$, 1734, 1693, 1603, 1495, 1446, 1352, 1191, 1040, 935, 761, 700, 593, $526 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 361$ (690). Anal. Calcd for $\mathrm{C}_{78} \mathrm{H}_{72} \mathrm{~N}_{4} \mathrm{O}_{8} \mathrm{Fe}_{1}: \mathrm{C}, 74.97$; H, 5.81; N, 4.49. Found: C, 74.45; H, 5.80; N, 4.34.
[ $\left.\mathrm{Fe}_{\mathbf{2}}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{Ct}-\mathrm{Bu}\right)\left(\mathrm{O}_{2} \mathrm{Ct}-\mathrm{Bu}\right)(\mathrm{py})_{2}\right]$ (6). To a stirred solution of $\mathrm{TlO}_{2} \mathrm{Ct}$ - Bu ( $147 \mathrm{mg}, 0.480 \mathrm{mmol}$ ) and pyridine ( $116 \mu \mathrm{l}, 1.44 \mathrm{mmol}$ ) in THF ( 3 mL ) was added $\mathrm{FeBr}_{2}$ ( $53 \mathrm{mg}, 0.24 \mathrm{mmol}$ ) in THF ( 1 ml ). After 10 min this mixture was added in one portion to a stirred solution of $5(300 \mathrm{mg}, 0.240 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$. The resulting mixture was allowed to stir for 0.5 h , after which time the precipitated TlBr was removed by filtration through Celite, and the volatile components were removed in vacuo. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{Et}_{2} \mathrm{O}$ afforded 6 as yellow blocks ( $265 \mathrm{mg}, 73 \%$ ) which appeared suitable for X-ray crystallography. IR ( KBr ) 3062, 3028, 2959, 2923, 2863, 1734, 1693, 1602, 1541, 1486, 1407, 1365, 1221, 1189, 1042, 937, 763, 701, $608,528 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 355$ (920). Anal. Calcd for $\mathrm{C}_{88.5} \mathrm{H}_{91} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2} \mathrm{Cl}\left(6 \cdot 0.5 \mathrm{CH}_{2} \mathrm{Cl}_{2}\right): \mathrm{C}, 68.71 ; \mathrm{H}, 5.90 ; \mathrm{N}, 3.60$. Found: C, 68.45; H, 6.06; N, 3.48. One lattice dichloromethane was identified by X-ray crystallography, and apparently it was not removed completely by pumping on the sample in vacuo for one day. When this procedure was repeated with heating, sample decomposition was observed.
[ $\mathrm{Fe}_{2}$ (XDK) $\left.\left(\mu-\mathrm{O}_{2} \mathrm{CPhCy}\right)\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)(\mathrm{py})_{2}\right]$ (7). This compound was prepared from $\mathrm{Tl}\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)(308 \mathrm{mg}, 0.757 \mathrm{mmol})$, pyridine ( $184 \mu \mathrm{l}, 2.27 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}$ ( $83 \mathrm{mg}, 0.378$ mmol ) and $4(300 \mathrm{mg}, 0.378 \mathrm{mmol})$ as described for 6. Recrystallization from benzene/pentane afforded 7 as pale yellow blocks which appeared suitable for X-ray crystallography ( $291 \mathrm{mg}, 61 \%$ ). IR (KBr) 3063, 2960, 2928, 2862, 1737, 1699, 1614, 1448, $1405,1355,1221,1187,1069,957,851,760,698,637 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}(\varepsilon\right.$, $\mathrm{M}^{-1}, \mathrm{~cm}^{-1}$ )) 354 (840). Anal. Calcd for $\mathrm{C}_{68} \mathrm{H}_{78} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}$ : C, 65.08; H, 6.26; N, 4.46. Found: C, 64.09; H, 6.63; N, 4.08.
[ $\left.\mathrm{Fe}_{\mathbf{2}}(\mathrm{XDK})\left(\mu-\mathrm{O}_{\mathbf{2}} \mathbf{C A r}\right)\left(\mathrm{O}_{\mathbf{2}} \mathbf{C A r}\right)(\mathrm{py})_{2}\right]$ (8). This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CAr}$ ( $342 \mathrm{mg}, 0.757 \mathrm{mmol}$ ), pyridine ( $184 \mu \mathrm{l}, 2.27 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}(83 \mathrm{mg}, 0.378$ $\mathrm{mmol})$, and $4(300 \mathrm{mg}, 0.378 \mathrm{mmol})$ as described for 6. Recrystallization from THF/pentane provided 8 as yellow blocks ( $285 \mathrm{mg}, 56 \%$ ). IR ( KBr ) 2960, 2870, 1736, 1699, 1611, 1536, 1464, 1412, 1357, 1220, 1192, 1069, 958, 841, 760, 698, $511 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 353$ (790). Anal. Calcd for $\mathrm{C}_{72} \mathrm{H}_{96} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}$ : C, 65.45; H, 7.32; N, 4.24. Found: C, 66.17; H, 7.01; N, 3.80.
[ $\left.\mathrm{Fe}_{\mathbf{2}}(\mathrm{XDK})\left(\mu-\mathrm{O}_{\mathbf{2}} \mathrm{CAr}\right)\left(\mathrm{O}_{\mathbf{2}} \mathrm{CAr}\right)(3-\mathrm{Fpy})_{2}\right]$ (9). This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CAr}$ ( $342 \mathrm{mg}, 0.757 \mathrm{mmol}$ ), 3-fluoropyridine ( $157 \mu \mathrm{l}, 1.82 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}$ ( 83 mg , $0.378 \mathrm{mmol})$, and $4(300 \mathrm{mg}, 0.378 \mathrm{mmol})$ as described for 6. Recrystallization from THF/pentane provided 9 as yellow blocks ( $246 \mathrm{mg}, 48 \%$ ). IR ( KBr ) 2962, 2931, 2870, $1735,1697,1608,1463,1409,1359,1233,1197,1101,959,761,537 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ ( $\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)$ ) 361 (790). Anal. Calcd for $\mathrm{C}_{72} \mathrm{H}_{96} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2} \mathrm{~F}_{2}$ : C, 63.72; H , 6.98; N, 4.13. Found: C, 63.95; H, 6.96; N, 3.53.
[ $\left.\mathrm{Fe}_{\mathbf{2}}(\mathbf{B X D K})\left(\mu-\mathrm{O}_{2} \mathrm{Ci}-\mathrm{Pr}\right)\left(\mathrm{O}_{2} \mathrm{Ci}-\mathrm{Pr}\right)(\mathrm{py})_{2}\right]$ (10). This compound was prepared from $\mathrm{TlO}_{2} i-\mathrm{Pr}(70 \mathrm{mg}, 0.24 \mathrm{mmol})$, pyridine ( $60 \mu \mathrm{l}, 0.72 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}(26 \mathrm{mg}, 0.12 \mathrm{mmol})$, and $5(150 \mathrm{mg}, 0.120 \mathrm{mmol})$ as described for 6 . Recrystallization from THF/pentane provided 10 as yellow needles ( $135 \mathrm{mg}, 76 \%$ ). IR ( KBr ) 3062, 3028, 2965, 2923, 2869, 1733, 1693, 1602, 1546, 1495, 1446, 1364, 1190, 1034, 850, 763, 701, $528 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 357(920)$. Anal. Calcd for $\mathrm{C}_{86} \mathrm{H}_{86} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}: \mathrm{C}, 69.82$; H, 5.86; N, 3.79. Found: C, 69.34; H, 6.05; N, 3.50 .
$\left[\mathrm{Fe}_{2}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{CH}_{2} t-\mathrm{Bu}\right)\left(\mathrm{O}_{2} \mathrm{CH}_{2} t-\mathrm{Bu}\right)(\mathrm{py})_{2}\right]$ (11). This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CH}_{2} t$ - $\mathrm{Bu}\left(77 \mathrm{mg}, 0.24 \mathrm{mmol}\right.$ ), pyridine ( $60 \mu \mathrm{l}, 0.72 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}$ ( $26 \mathrm{mg}, 0.12 \mathrm{mmol}$ ), and 5 ( $150 \mathrm{mg}, 0.120 \mathrm{mmol}$ ) as described for 6. Recrystallization from THF/pentane provided 11 as yellow blocks ( $130 \mathrm{mg}, 71 \%$ ). IR ( KBr ) 3062, 3028, $2952,2866,1733,1693,1603,1548,1447,1364,1190,1041,936,744,701,528 \mathrm{~cm}^{-1}$; UV-vis
$\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 358$ (960). Anal. Calcd for $\mathrm{C}_{90} \mathrm{H}_{94} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}: \mathrm{C}, 70.40$; H, 6.17; N, 3.65. Found: C, 70.20; H, 6.60; N, 3.26.
$\left[\mathrm{Fe}_{\mathbf{2}}(\mathbf{B X D K})\left(\mu-\mathrm{O}_{\mathbf{2}} \mathbf{C P h}\right)\left(\mathrm{O}_{\mathbf{2}} \mathbf{C P h}\right)(\mathbf{p y})_{2}\right](12)$. This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CPh}(78 \mathrm{mg}, 0.24 \mathrm{mmol})$, pyridine ( $60 \mu \mathrm{l}, 0.72 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}(26 \mathrm{mg}, 0.12 \mathrm{mmol})$, and 5 ( $150 \mathrm{mg}, 0.120 \mathrm{mmol}$ ) as described for 6. Recrystallization from THF/ $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /pentane provided 12 as yellow blocks ( $132 \mathrm{mg}, 71 \%$ ) which appeared suitable for X-ray crystallography. IR (KBr) 3061, 3028, 2952, 2920, 2865, 1733, 1694, $1604,1543,1495,1447,1364,1189,1069,1042,937,853,762,720,701,588,528 \mathrm{~cm}^{-1}$; UVvis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 351$ (1400). Anal. Calcd for $\mathrm{C}_{93} \mathrm{H}_{84} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2} \mathrm{Cl}_{2}$ ( $\mathbf{1 2} \cdot 1 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ): C, $68.43 ; \mathrm{H}, 5.19 ; \mathrm{N}, 3.43$. Found: C, $68.84 ; \mathrm{H}, 5.21 ; \mathrm{N}, 3.13$.
$\left[\mathrm{Fe}_{\mathbf{2}}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{\mathbf{2}} \mathrm{CPhCy}\right)\left(\mathrm{O}_{\mathbf{2}} \mathrm{CPhCy}\right)(\mathrm{py})_{2}\right]$ (13). This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CPhCy}(391 \mathrm{mg}, 0.960 \mathrm{mmol})$, pyridine ( $233 \mu \mathrm{l}, 2.88 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}(106 \mathrm{mg}$, 0.480 mmol ), and 5 ( $600 \mathrm{mg}, 0.480 \mathrm{mmol}$ ) as described for 6. Recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{THF} /$ pentane provided 13 as yellow blocks ( $623 \mathrm{mg}, 76 \%$ ) which appeared suitable for X-ray crystallography. Anal. Calcd for $\mathrm{C}_{104} \mathrm{H}_{102} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}: \mathrm{C}, 72.98 ; \mathrm{H}, 6.01 ; \mathrm{N}$, 3.27. Found: C, 72.73; H, 6.09; N, 3.02.
[ $\mathrm{Fe}_{2}$ ( BXDK ) $\left.\left(\mu-\mathrm{O}_{2} \mathrm{CAr}\right)\left(\mathrm{O}_{2} \mathrm{CAr}\right)(\mathrm{py})_{2}\right]$ (14). This compound was prepared from $\mathrm{TlO}_{2} \mathrm{CAr}\left(108 \mathrm{mg}, 0.240 \mathrm{mmol}\right.$ ), pyridine ( $60 \mu \mathrm{l}, 0.72 \mathrm{mmol}$ ), $\mathrm{FeBr}_{2}(26 \mathrm{mg}, 0.12$ $\mathrm{mmol})$, and $5(150 \mathrm{mg}, 0.120 \mathrm{mmol})$ as described for 6. Recrystallization from benzene/pentane provided 14 as yellow blocks ( $144 \mathrm{mg}, 67 \%$ ) which appeared suitable for X-ray crystallography. IR (KBr) 3068, 3028, 2960, 2928, 2868, 1733, 1693, $1605,1462,1406,1362,1190,1070,937,762,701,730,528 \mathrm{~cm}^{-1}$; UV-vis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\lambda_{\max }\right.$, $\left.\mathrm{nm}\left(\varepsilon, \mathrm{M}^{-1}, \mathrm{~cm}^{-1}\right)\right) 352$ (870). Anal. Calcd for $\mathrm{C}_{108} \mathrm{H}_{120} \mathrm{~N}_{4} \mathrm{O}_{12} \mathrm{Fe}_{2}$ : $\mathrm{C}, 72.96 ; \mathrm{H}, 6.80 ; \mathrm{N}$, 3.15. Found: C, 72.96; H, 7.10; N, 3.03.
[ $\mathrm{Fe}_{\mathbf{2}} \mathbf{( X D K )}$ ( $\left.\left.\mu-\mathrm{O}_{\mathbf{2}} \mathbf{C P h C y}\right)\left(\mathrm{O}_{\mathbf{2}} \mathbf{C P h C y}\right)(\mathbf{M e - I m})_{2}\right]$ (15). To a stirred suspension of $\mathrm{Tl}_{2}$ (XDK) ( $420 \mathrm{mg}, 0.425 \mathrm{mmol}$ ) and Me-Im ( $71 \mu \mathrm{l}, 0.89 \mathrm{mmol}$ ) in THF ( 5 mL ) was added $\mathrm{FeBr}_{2}(187 \mathrm{mg}, 0.851 \mathrm{mmol})$ in THF ( 2 mL ) followed by $\mathrm{TlO}_{2} \mathrm{CPhCy}$ ( 347 mg , 0.851 mmol ) in THF ( 2 mL ). After 12 h the mixture was allowed to settle and the majority of the precipitated TlBr was removed by filtration through Celite. The resulting cloudy filtrate was evaporated to dryness and taken up in benzene. Filtration through Celite afforded a clear filtrate. The Celite/TIBr filter cakes were extracted two additional times with THF ( 5 mL ) to obtain additional product. The combined filtrates were evaporated to dryness to yield a crude white residue. This material was suspended in pentane ( 10 mL ), and the resulting white powder was isolated by filtration. Recrystallization from THF/pentane afforded 15 as colorless needles ( $386 \mathrm{mg}, 72 \%$ ). IR ( KBr ) 2959, 2929, 2859, 1734, 1695, 1609, 1535, 1462, 1405, $1357,1228,1192,1087,958,852,762,697,628 \mathrm{~cm}^{-1}$. Anal. ## Collection and Reduction of X-ray Data

All crystals were mounted on the tips of quartz fibers with Paratone-N (Exxon), cooled to low temperature ( $\sim-85{ }^{\circ} \mathrm{C}$ ), and placed on Siemens CCD X-ray diffraction system controlled by a Pentium-based PC running the SMART software
package. ${ }^{33}$ The general procedures for data collection and reduction follow those reported previously. ${ }^{34}$ All structures were solved by use of the direct methods programs SIR- $92^{35}$ or XS, part of the TEXSAN ${ }^{36}$ and SHELXTL ${ }^{37}$ program packages, respectively. Structure refinements were carried out with XL, part of the SHELXTL program package. ${ }^{37}$ All remaining non-hydrogen atoms were located and their positions refined by a series of least-squares cycles and Fourier syntheses. Hydrogen atoms were assigned idealized positions and given a thermal parameter 1.2 times the thermal parameter of the carbon atom to which each was attached. Empirical absorption corrections were calculated and applied for each structure using SADABS, part of the SHELXTL program package. ${ }^{37}$

The structure of 7 contains a lattice benzene molecule which was refined at partial occupancy. Two of the three lattice benzene molecules in the structure of 13 have large thermal parameters. The structure of 12 contains a lattice THF molecule disordered over two positions, where an inversion center passes through the center of a carbon-carbon bond. It was refined as a cyclopentane molecule with one of the carbon atoms at full occupancy, and the occupancy of the other three carbon atoms was distributed over two positions per atom and refined. The butyl group of one of the Bu-Im ligands in the structure of $\mathbf{1 6}$ is disordered. The occupancy of the carbon atom $\beta$ to the imidazole nitrogen was distributed over two positions and refined. The other carbon atoms of the butyl group were refined at full occupancy.

Pertinent crystallographic information for each complex including refinement residuals is available in Table 3.2. Selected bond distances and angles, as well as atomic coordinates and equivalent isotropic displacement parameters, are provided Tables 3.3 and 3.4-3.8, respectively.

Physical Measurements. NMR spectra were recorded on a Varian Unity-300 NMR spectrometer. ${ }^{1} \mathrm{H}$ NMR chemical shifts are reported versus tetramethylsilane and referenced to the residual solvent peak. FTIR spectra were recorded on a BioRad

FTS-135 FTIR spectrometer. Room-temperature UV-vis spectra were recorded on a Cary 1E spectrophotometer. Low-temperature spectra were recorded on a HP8452A diode array spectrophotometer using a custom manufactured immersion dewar, equipped with a 3 mL cell ( 1 cm pathlength) with quartz windows connected to a $14 / 20$ female joint via a 10 cm long glass tube. A temperature of $-77^{\circ} \mathrm{C}$ was maintained with a dry ice/acetone bath and monitored with a Sensortek Model BAT-12 thermocouple thermometer. Conductivity measurements were carried out in THF or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with a Fisher Scientific conductivity bridge, model 9-326, outfitted with a platinum black electrode. Manometric experiments were carried out according to literature procedure, ${ }^{38}$ using Vaska's complex or $\left[\mathrm{Fe}\left(\mathrm{Tp}{ }^{3,5-}\right.\right.$ $\left.\left.{ }^{\mathrm{iPr} 2}\right)_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{2} \mathrm{Ph}\right)\right]^{20}$ as authentic standards, which form $1: 1$ and $2: 1$ complex:dioxygen adducts, respectively. Elemental analyses were performed by Microlytics, South Deerfield, MA.

EPR Spectroscopy. Spectra were recorded at 4.5 K on a Bruker Model 300 ESP X-band spectrometer operating at 9.47 GHz . Liquid helium temperatures were maintained with an Oxford Instruments EPR 900 cryostat. For all measurements 1 mM frozen solutions were prepared in 2-methyltetrahydrofuran, a solvent in which the samples glassed well.

Resonance Raman Spectroscopy. Raman data were acquired by using a Coherent Innova 90 argon laser with an excitation wavelength of 647.1 nm and 65 mW of power. A $0.6-\mathrm{m}$ single monochromator ( 1200 grooves/nm grating), with an entrance slit of $100 \mu \mathrm{~m}$, and a liquid nitrogen cooled-CCD detector (Princeton Instruments, Inc.) were used in a standard backscattering configuration. A holographic notch filter (Kaiser Optical Systems) was used to attenuate Rayleigh scattering. Spectra of all samples were collected in toluene or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution at -77 ${ }^{\circ} \mathrm{C}$ with the same custom-manufactured dewar used to acquire low-temperature UV-vis spectra. Solute concentrations were made as high as possible depending on
the solubility of the reduced sample, $\sim 20 \mathrm{mM}$ in the best cases, to ensure an optimal signal to noise ratio. A total of 1000 scans each with a three second exposure time were collected for each sample. Raman shifts were calibrated with toluene or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as an internal standard. The data were processed by using CSMA software (Princeton Instruments, Inc. Version 2.4A) on a Gateway 2000 computer, and the resulting ASCII files were processed with Kaleidagraph (Abelbeck Software). Spectra are displayed in Figures 3.13-3.15, and $\mathrm{O}-\mathrm{O}$ and $\mathrm{Fe}-\mathrm{O}$ stretching frequencies are listed in Table 3.11.

Mössbauer Spectroscopy. Solid samples were prepared by suspending $\sim 0.04$ mol of powdered material in Apiezon N grease, and then packing the mixture into a nylon sample holder. Frozen solution samples of diferrous complexes 13 or 15 were prepared in THF in a drybox. In each case 1 mL of the $\sim 40 \mathrm{mM}$ solution was syringed into a nylon sample holder, that was then sealed with Apiezon $\mathbf{N}$ grease, brought out of the drybox, and rapidly cooled to 77 K . Peroxo sample $13 . \mathrm{O}_{2}$ was prepared in a round bottom flask at $-77^{\circ} \mathrm{C}$ by exposing 1 mL of a THF solution of $13(40 \mathrm{mM})$ to excess $\mathrm{O}_{2}(1 \mathrm{~atm})$ for 2 h . The sample was quickly transferred (< 5 s ) to a nylon sample holder, immersed in liquid nitrogen, by means of a glass syringe equipped with a 4 cm stainless steel needle, and precooled to $-77^{\circ} \mathrm{C}$. All data were collected at 77 K with a ${ }^{57} \mathrm{Co}$ source in a Rh matrix at room temperature and fit to Lorentzian line shapes. Spectra are illustrated in Figures 3.16-3.18, and parameters derived from fits are listed in Table 3.12.

UV-Vis Kinetics. Experiments were carried out by using the custom dewar mentioned above. Reduced samples in freshly distilled THF solution, typically 0.5 mM , were loaded in a drybox and the dewar was fitted with a rubber septum. The apparatus was brought out, placed under a positive $N_{2}$ pressure, and cooled to $-77{ }^{\circ} \mathrm{C}$ with a dry ice acetone bath. The samples were subjected to an $\mathrm{O}_{2}$ purge at atmospheric pressure for 5.0 min at a flow rate of 10 standard cubic centimeters per
minute (SCCM), maintained with a Matheson Dyna-Blender Model 8280 oxygen/nitrogen constant flow mixing system. Purging for this time length and at this flow rate resulted in highly reproducible rate constants, thus assuring that the entire sample solution and vessel headspace were completely purged with the desired gas mixture. For dioxygen dependent kinetic studies, the mole fraction of $\mathrm{O}_{2}$ was controlled by diluting pure $\mathrm{O}_{2}$ with dinitrogen, while retaining a total flow rate of 10 SCCM. Oxygen concentrations were calculated using eq 4 , where $X=$ mole fraction of $\mathrm{O}_{2}, \mathrm{~L}=$ Ostwald coefficient ( 0.245 for THF), $\mathrm{P}_{(\mathrm{g})}=$ partial pressure, and $\mathrm{V}^{\circ}{ }_{(1)}=$ molar volume. ${ }^{39}$ All experiments were carried out under pseudo -first -order oxygen concentrations, ranging from $3.07-15.4 \mathrm{mM}$, while keeping the initial

$$
\begin{equation*}
X=\left(\frac{R T}{P_{(g)} L V_{(I)}^{\circ}}+1\right)^{-1} \tag{4}
\end{equation*}
$$

concentration of diferrous complex constant for each run. Scans were acquired at 600 nm and points were taken every $2-10 \mathrm{sec}$, depending on the rate at which the reaction proceeded. Reactions were followed to at least four half lives in all cases. Data were analyzed with Kaleidagraph (Abelbeck Software) and fit to modeldependent equations by using nonlinear least squares regression. In all cases the data were fit unambiguously to a first order exponential buildup, defined in eq 5 , where $A_{t}$ is the absorbance at time $t, \Delta A$ is the change in absorbance during the reaction,

$$
\begin{gather*}
\mathrm{A}_{\mathrm{t}}=\mathrm{A}_{\infty}+(\Delta \mathrm{A})\left(1-\exp \left(-k_{\mathrm{obs}} \mathrm{t}\right)\right)  \tag{5}\\
\text { rate }=k\left[\mathrm{Fe}_{2}^{2+}\right]\left[\mathrm{O}_{2}\right] \tag{6}
\end{gather*}
$$

$A_{\infty}$ is the absorbance at infinite time, and $k_{\text {obs }}\left(\equiv k_{\psi}\right)$ is the observed psuedo first order rate constant. All plots of $\ln \left(k_{\mathrm{obs}}\right)$ vs $\ln \left(\left[\mathrm{O}_{2}\right]\right)$ were linear with a slope close to 1.0, implying that an overall second order rate law applies, eq 6 . Second order rate constants, tabulated in Table 3.13, were derived from the slopes of $\mathrm{k}_{\mathrm{obs}}$ vs. [ $\mathrm{O}_{2}$ ] plots.

Standard errors in these rates are based on linear regression analyses of the slopes, and are reported at the $95 \%$ confidence level. Plots of $\mathrm{A}_{600}$ vs. time, $k_{\psi}$ vs. [ $\mathrm{O}_{2}$ ], and $\ln \left(k_{\Psi}\right)$ vs. $\ln \left(\left[\mathrm{O}_{2}\right]\right)$ for complexes $6,7,13$, and 14 are illustrated in Figures 3.19-3.22.

## Results and Discussion

Preparation and Characterization of $\left[\mathrm{Fe}(\mathrm{XDK})(\mathrm{py})_{2}\right](4)$ and $\left[\mathrm{Fe}(\mathrm{BXDK})(\mathrm{py})_{2}\right]$ (5). In order to develop an efficient route to a family of diiron(II) complexes incorporating the XDK ligand system and ancillary carboxylates of variable steric properties, the synthesis of pure mononuclear precursors in large quantities was desired. Treatment of $\mathrm{Tl}_{2}(\mathrm{XDK})$ or $\mathrm{Tl}_{2}$ (BXDK) with 1 equiv of iron(II) bromide and excess pyridine provided yellow bis(pyridine) adducts 4 and 5, respectively, in multigram quantities and high yield (eq 7). An X-ray structural analysis on the XDK

derivative revealed the iron atom to be coordinated by three XDK oxygen and two pyridine nitrogen atoms. ${ }^{40}$ The structure is essentially identical to that determined for the $\mathrm{Zn}(\mathrm{II})$ analog, ${ }^{41}$ with one long XDK Fe-O interaction at 2.326(5) $\AA$ and the other two at an average distance of $2.080(3) \AA$. In contrast, the analogous reaction with 1-methyl- or 1-butylimidazole led to a mixture of intractable products, even when exactly two equivalents were used.

Preparation and Characterization of Dinuclear [ $\mathrm{Fe}_{2}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{C} t-\mathrm{Bu}\right)\left(\mathrm{O}_{2} \mathrm{C} t-\right.$
 $\left.\left.\mathrm{O}_{2} \mathrm{CAr}\right)\left(\mathrm{O}_{2} \mathrm{CAr}\right)(\mathrm{py})_{2}\right](8),\left[\mathrm{Fe}_{2}(\mathrm{XDK})\left(\mu-\mathrm{O}_{2} \mathrm{CAr}\right)\left(\mathrm{O}_{2} \mathrm{CAr}\right)(3-\mathrm{Fpy})_{2}\right](9),\left[\mathrm{Fe}_{2}(\mathrm{BXDK})(\mu-\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{Ci}-\mathrm{Pr}\right)\left(\mathrm{O}_{2} \mathrm{Ci}-\mathrm{Pr}\right)(\mathrm{py})_{2}\right](10),\left[\mathrm{Fe}_{2}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{CH}_{2} t-\mathrm{Bu}\right)\left(\mathrm{O}_{2} \mathrm{CH}_{2} t-\mathrm{Bu}\right)(\mathrm{py})_{2}\right]$ (11),
$\left[\mathrm{Fe}_{\mathbf{2}}\right.$ ( BXDK$\left.)\left(\mu-\mathrm{O}_{2} \mathrm{CPh}\right)\left(\mathrm{O}_{2} \mathrm{CPh}\right)(\mathrm{py})_{2}\right]$ (12), $\left[\mathrm{Fe}_{\mathbf{2}}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{\mathbf{2}} \mathrm{CPhCy}\right)\left(\mathrm{O}_{\mathbf{2}} \mathbf{C P h C y}\right)(\mathrm{py})_{2}\right]$ (13), $\left[\mathrm{Fe}_{2}(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{CAr}\right)\left(\mathrm{O}_{2} \mathrm{CAr}\right)(\mathrm{py})_{2}\right](14),\left[\mathrm{Fe}_{2}(\mathrm{XDK})\left(\mu-\mathrm{O}_{2} \mathrm{CPhCy}\right)\left(\mathrm{O}_{\mathbf{2}} \mathrm{CPhCy}\right)(\mathrm{Me}-\right.$ $\mathrm{Im})_{2}$ ] (15), and $\left[\mathrm{Fe}_{2}(\mathrm{PXDK})\left(\mu-\mathrm{O}_{2} \mathrm{CPhCy}\right)\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)(\mathrm{Bu}-\mathrm{Im})_{2}\right]$ (16). The diferrous bis(pyridine) complexes $\mathbf{7 - 1 4}$ were conveniently prepared from 4 or 5 and " $\left[\mathrm{Fe}\left(\mathrm{O}_{2} \mathrm{CR}\right)(\mathrm{py})_{n}\right]$ ", the latter being generated in situ from iron(II) bromide, the

appropriate ancillary carboxylate, and excess pyridine (eq 8). The 3 -fluoropyridine derivative 9 and imidazole adducts 15-16 were prepared in one-pot reactions from the thallium carboxylic acid reagents, two equiv of iron(II) bromide, and two equiv of 3-fluoropyridine or 1 -alkylimidazole. In the preparation of 15 and 16, removal of the TlBr precipitate was aided by allowing the reaction mixtures to stand overnight prior to filtration through Celite. Additional extractions of the resulting Celite/TlBr filter cake were required to recover substantial quantities of additional product. All complexes were obtained in high yield and purity following recrystallization at room temperature. Despite repeated attempts in each case, elemental analysis samples of $4,7,8$ and 16 deviated $1-2 \%$ from calculated carbon values. It is unclear whether these complexes have poor combustion properties and/or they contain minor impurities, but other closely related derivatives have analyzed correctly. Schematic representations of all complexes 4-16 are provided in Scheme 3.1.

The IR spectra of complexes 7-16 displayed a new C-O stretch at 1605-1615 $\mathrm{cm}^{-1}$, and another centered at $1693 \mathrm{~cm}^{-1}$ was more intense and broadened compared to the dithallium(I) and/or mononuclear iron(II) precursors. Both of these differences are attributed to the two additional carboxylate ligands in the products.

The UV-vis spectra of the pyridine adducts 5-14 all exhibited an absorbance at 350$360 \mathrm{~nm}\left(\varepsilon=500-1000 \mathrm{~cm}^{-1}\right)$, tentatively assigned as a metal-to-ligand charge transfer, which was absent in the colorless 1-alkylimidazole derivatives. Complexes 4-16 are all non-elctrolytes, so most are soluble in solvents as non-polar as THF. Where aliphatic groups have been incorporated into the XDK and 1-alkylimidazole ligands, for example 16, complexes are readily soluble in diethyl ether and cyclopentane.

Because 6, 7, 12-13, and 16 represent the spectrum of steric hindrance and electronic differences within this series of complexes, X-ray structures were acquired to ascertain how each ligand component might influence the iron coordination geometries and dioxygen reactivity. ORTEP and space-filling diagrams are displayed in Figures 3.3-3.10, and selected bond distances and angles are listed in Table 2.3. Each structure consists of a four- or five-coordinate iron atom (Fe1) ligated by two syn-syn bidentate bridging XDK oxygen atoms and one or two monodentate bridging ancillary carboxylate oxygen atoms. ${ }^{42}$ The number of latter donor atoms depends on the choice of N -donor ligand and the steric properties of the XDK and ancillary carboxylate substituents. The Fe 2 atoms in 6 and 12 are best described as distorted trigonal bipyramidal, whereas those in 7,13 , and 16 are distorted tetrahedral. The other iron atom ( Fe 1 ) has a coordinatively saturated octahedral geometry in all cases, and it is ligated by two syn-syn bidentate bridging XDK carboxylate oxygen atoms, two symmetric chelating ancillary carboxylate atoms, and a N -donor nitrogen atom.

The most significant difference in these structures is the orientation of the bridging ancillary carboxylate ligand relative to the rest of the complex framework. Five metrical parameters change significantly within the series: $\mathrm{Fe} 2-\mathrm{O} 402$, Fe 2O401, Fe1-O402-Fe2, Fe1-O402-C401, Fe2-O401-C401, and Fe2-O402-C401. These changes are all related to the tilt angle, $\tau$, of this monodentate bridging carboxylate ligand toward the center of the complex, as defined in Figure 3.11.42 Within the
subset of pyridine complexes 6,7 , and 12-13, a repulsive interaction between the two ancillary carboxylate substituents decreases $\tau$. In complexes 12 and $\mathbf{1 3}, \tau$ is also affected in the same sense by a steric interaction between the bridging ancillary carboxylate and the XDK benzyl substituents. As the Fe2-O402 distance (B) lengthens the Fe2-O401 distance (D) shortens, resulting in no change in the Fe1-O402 distance (A) across the series. Similarly, an increase in the Fe2-O401-C401 angle $(\gamma)$ is accompanied by a decrease in the $\mathrm{Fe} 1-\mathrm{O} 402-\mathrm{Fe} 2(\Theta), \mathrm{Fe} 1-\mathrm{O} 402-\mathrm{C} 401(\alpha)$, and $\mathrm{Fe} 2-$ O402-C401 ( $\beta$ ) angles. Based on these parameters, the order of increasing steric repulsion between the carboxylate substituents for this subset of pyridine complexes is: $12<6<7<13$, corresponding to $\Delta \tau=-7^{\circ}$, proceeding from $12 \rightarrow 13$. By contrast, $\tau$ is much smaller for the butyl-imidazole adduct 16 compared to all the pyridine adducts, apparently due to the more basic character of the 1-alkylimidazole donor compared to pyridine which increases the electron density at Fe2, thereby disrupting the Fe2-O402 interaction entirely. Hence, for 16 these steric and electronic factors have the combined effect of nearly inducing a complete carboxylate shift ${ }^{42}$ from the monodentate bridging observed for the pyridine adducts to syn syn bidentate bridging.

Reactions of the Diferrous Complexes Toward Dioxygen. UV-Vis and Manometry. As mentioned in the introduction, previous studies revealed the presence of a short-lived intermediate generated when $\left[\mathrm{Fe}_{2}\right.$ (PXDK) $\left(\mu-\mathrm{O}_{2}\right.$ Ctert$\mathrm{Bu})\left(\mathrm{O}_{2} \mathrm{Ctert}\right.$ - Bu$)(\mathrm{Me}-\mathrm{Im})_{2}$ ] was exposed to excess $\mathrm{O}_{2}$ at $-77^{\circ} \mathrm{C}$ in THF solution. As an initial approach toward stabilizing this species, we implemented the more sterically demanding BXDK ligand, while holding the other steric properties constant, and changed the N -donor ligand to pyridine. Space-filling diagrams of the previously reported complex and 6 are displayed in Figure 3.4. From these representations, it is apparent that the BXDK benzyl substituents proximal to its carboxylate oxygen donor atoms shroud the iron coordination sites to a greater extent than do PXDK propyl
groups. Furthermore, the benzyl substituents appear to enforce a single approach for $\mathrm{O}_{2}$ to the unsaturated metal center along the $\mathrm{Fe}-\mathrm{Fe}$ vector.

Exposure of 6 to $\mathrm{O}_{2}$ under identical conditions to those previously reported resulted in a much slower color change to deep midnight blue over the course of 2-3 $h$. The buildup of this species was monitored by UV-vis spectroscopy, revealing a broad absorption centered at $\sim 580 \mathrm{~nm}\left(\varepsilon \sim 1200 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right.$, Figure 3.12A). This feature is characteristic of an iron(III)-peroxo ligand-to-metal charge transfer band, ${ }^{1,5}$ and it immediately suggested that a family of peroxo complexes having steric and electronic properties similar to 6 could be accessed. The oxygenation is irreversible, since application of high vacuum / Ar purge cycles to the solution at $-77{ }^{\circ} \mathrm{C}$ resulted in no diminution of the charge transfer band. Warming above $-65^{\circ} \mathrm{C}$ under excess $\mathrm{O}_{2}$ or Ar , or under high vacuum, caused rapid peroxo decomposition within five minutes, as judged by a color change to light brown. A similar decomposition was noted if the peroxo solution is allowed to stand at $-77^{\circ} \mathrm{C}$ for $12-24 \mathrm{~h}$.

The other diiron(II) tetracarboxylate complexes were then screened for their ability to form stable peroxo complexes, the results of which are summarized in Table 3.9. The $\mathrm{O}_{2}$ reactions either resulted in rapid decomposition to form roomtemperature stable Fe (III) products, or afforded an intermediate very similar to that observed for 6. For BXDK derivatives with pyridine, ancillary carboxylate ligands smaller than pivolate (10-12) reacted with $\mathrm{O}_{2}$ at a similar rate, but none of these reactions resulted in the buildup of the 580 nm charge-transfer band. The less sterically encumbering XDK ligand formed stable peroxo adducts when significantly more hindered ancillary carboxylates were implemented, such as 1-phenylcyclohexyl- (PhCy) or 2,4,6-triisopropyl (Ar) carboxylic acid (7-8, Figure 3.12B). Similarly, these hindered carboxylates afforded stable peroxo adducts with 3fluoropyridine or 1-alkylimidazole donors ( $9,15-16$, Figure $3.12 C$ ). The rate of peroxo formation is considerably faster for the 1 -alkylimidazole complexes compared to all
the pyridine analogs, however, with 15-16 reacting with $\mathrm{O}_{2}$ to completion within seconds versus $0.25-2 \mathrm{~h}$ for 6-14, as judged by UV-vis spectroscopy. The energy and intensity of the peroxo-to-iron(III) charge transfer band in these derivatives were the same as for the pyridine analogs. This result is not surprising because other diiron(III) peroxo complexes with widely varying ligand sets possess essentially an identical transition. ${ }^{1,5}$ Furthermore, equivalent irreversible $\mathrm{O}_{2}$ binding and thermal stability behavior was noted for all peroxo derivatives irrespective of their steric and electronic properties.

Oxygen uptake experiments were carried out on pyridine adduct 13 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and 1-butylimidazole adduct 16 in THF and $\mathrm{Et}_{2} \mathrm{O}$ (Table 3.10). Vaska's complex and $\left[\mathrm{FeTp}^{3,5-\mathrm{Pr} 2}\left(\mathrm{O}_{2} \mathrm{CCH}_{2} \mathrm{Ph}\right)\right]^{20}$ were used as authentic $\mathrm{O}_{2}$ uptake standards in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and the ethereal solvents, respectively. Complexes 13 and 16 consumed $1.0 \pm 0.1$ equivalents of dioxygen, consistent with a discrete diiron(III) peroxide formulation for each. When the peroxo adducts were allowed to decay by warming to room temperature, additional $\mathrm{O}_{2}$ consumption was observed for those manometric experiments carried out in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ or THF, whereas no further uptake was noted for the diethyl ether trials. All of this decay behavior is in stark contrast to that noted for another diiron(III) peroxo system, ${ }^{27}$ where 0.5 equivalents of $\mathrm{O}_{2}$ was released upon peroxo decay, and suggests that the peroxide ligand is retained in the decomposition products and/or ligand or solvent oxidation is occurring concomitant with peroxo decay. A detailed analysis of this chemistry will be discussed elsewhere. ${ }^{28}$

The oxygen adducts exhibited the greatest stability toward decomposition in the least polar solvents, such as THF and toluene. By contrast, dichloromethane could be utilized with the more sterically demanding pyridine derivatives 7-8 and 13-14, but the peroxo adducts derived from less hindered 6 or the 1 -alkylimidazole derivatives 15-16 were observed to decompose in this solvent within seconds. The higher dielectric constant ${ }^{43}$ of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (9.08) compared to THF (7.58) and toluene
(2.379) may lead to fluxional ligand exchange processes in the chlorinated solvent, possibly involving a carboxylate shiff ${ }^{42}$ of the ancillary donors, which could result in dissociation of a carboxylate oxygen ligand. The preference for mondentate over chelating carboxylate ligation is accentuated in increasingly polar media, ${ }^{41,44}$ and such a process here could compromise the steric pocket surrounding the peroxide, leading to bimolecular decay. The highly sterically demanding $R$ substituents in 7-9 and 13-14 may shroud the peroxide sufficiently to prevent decay by this mechanism. Rapid degradation of the peroxos derived from complexes 15-16 may be due to the greater basicity of the 1 -alkylimidazole ligand compared to pyridine, which may render the carboxylate donors even more labile. Alternatively, decay of the peroxo adducts may occur by direct reaction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, since 1,2 -dichloroethane is detected by GC-MS in the solvent mixture upon warming. ${ }^{28}$ Taken together, this survey of steric, electronic, and solvent polarity studies demonstrates that oxygen adducts can be stabilized with this ligand system provided the carboxylate substituents form a sufficiently hindered array about the peroxide ligand.

EPR and ${ }^{1} \mathbf{H}$ NMR Studies. The peroxo adducts are EPR silent at 4.5 K , a feature which is consistent with an antiferromagnetically coupled, $\mathrm{S}=0$ ground state. Similar to other diiron(III) peroxides, including the sMMO $\mathrm{H}_{\text {peroxo }}$ intermediate, ${ }^{15}$ this coupling is most likely mediated by a bridging peroxide. ${ }^{45,46} \mathrm{~A}$ ${ }^{1} \mathrm{H}$ NMR spectrum for the peroxo adducts formed in this study was not observed at $-80^{\circ} \mathrm{C}$, however, suggesting low lying paramagnetic excited states are accessed thermally at higher temperatures, inducing fast relaxation of the ligand protons. By contrast, a paramagnetically shifted but reasonably sharp ${ }^{1} \mathrm{H}$ NMR spectrum was observed for a diiron (III) peroxo complex with a hindered hydrotris(pyrazolyl)borate ligand. ${ }^{45}$

Resonance Raman Studies of the Peroxo Adducts. Raman spectra were acquired for peroxo adducts derived from complexes 6-8,13-14, and 16 in fluid
solution at $-77^{\circ} \mathrm{C}$. The results of these experiments are summarized in Table 3.11, and the spectra acquired for $16 \cdot \mathrm{O}_{2}$ are displayed in Figures 3.13-3.14. The pyridine and 1-butylimidazole derivatives all give rise to a $\left.v^{16} \mathrm{O}-16 \mathrm{O}\right)$ band at $864 \mathrm{~cm}^{-1}$ in toluene solution. When ${ }^{18} \mathrm{O}_{2}$ was used to prepare $16 . \mathrm{O}_{2}$ this band shifts to $818 \mathrm{~cm}^{-1}$, in good agreement with the theoretically predicted shift of $50 \mathrm{~cm}^{-1}$ for a diatomic O O harmonic oscillator. The peak shifts slightly to $861 \mathrm{~cm}^{-1}$ for $13.16 \mathrm{O}_{2}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution. $\mathrm{Av}(\mathrm{Fe}-\mathrm{O})$ band was detected at $484 \mathrm{~cm}^{-1}$ for $13 \cdot \mathrm{O}_{2}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, but a negligible shift was noted for this feature upon ${ }^{18} \mathrm{O}_{2}$ substitution. The band was obscured entirely in toluene solution due to the intense solvent background peaks in this spectral region. The observed $v(O-O)$ frequencies of $861-864 \mathrm{~cm}^{-1}$ are typical of diiron( $\mu$-1,2-peroxo) complexes. Although these values are $15-40 \mathrm{~cm}^{-1}$ lower than other complexes with this ligating motif, ${ }^{1,5}$ they are $50-60 \mathrm{~cm}^{-1}$ higher in energy than those reported for mononuclear iron(III) $\eta^{2}$-peroxo adducts. ${ }^{1}$ We therefore tentatively assign $\mu$-1,2-peroxo coordination mode for $13 \cdot \mathrm{O}_{2}$ and $16 \cdot \mathrm{O}_{2}$.

Raman spectroscopy was also used to measure the exchange of peroxide with free $\mathrm{O}_{2}$. Such an exchange process could either be a dissociative (eq 9), implying

$$
\begin{align*}
& {\left[\mathrm{Fe}^{I I I} 2\left({ }^{(18} \mathrm{O}_{2}\right) \mathrm{L}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{~N}_{2}\right] \stackrel{-18 \mathrm{O}_{2}}{\rightleftharpoons}\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{~L}\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)\left(\mathrm{O}_{2} \mathrm{CR}\right) \mathrm{N}_{2}\right] \stackrel{+{ }^{16} \mathrm{O}_{2}}{\rightleftharpoons}\left[\mathrm{Fe}^{I I I}\left({ }^{16} \mathrm{O}_{2}\right) \mathrm{L}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{~N}_{2}\right]}  \tag{9}\\
& {\left[\mathrm{Fe}^{I I I}\left({ }^{(18} \mathrm{O}_{2}\right) \mathrm{L}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{~N}_{2}\right] \stackrel{+{ }^{16} \mathrm{O}_{2}}{=}\left[\mathrm{Fe}^{111} \mathrm{I}_{2}\left({ }^{18} \mathrm{O}_{2}\right)\left({ }^{(16} \mathrm{O}_{2}\right)\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{~N}_{2}\right] \stackrel{-18 \mathrm{O}_{2}}{\rightleftharpoons}\left[\mathrm{Fe}^{111}\left({ }^{16} \mathrm{O}_{2}\right) \mathrm{L}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{~N}_{2}\right](10)}
\end{align*}
$$

reversible $\mathrm{O}_{2}$ binding, or associative, mediated by a bis $\left(\mathrm{O}_{2}\right)$ intermediate (eq 10). The former mechanism is unlikely because $\mathrm{O}_{2}$ is not liberated when a solution of the peroxo adduct is placed under a dynamic vacuum. A sample of ${ }^{16.18} \mathrm{O}_{2}$ was prepared by exposing a 20 mM solution of 16 in toluene to $\sim 0.25 \mathrm{~atm}$ of excess ${ }^{18} \mathrm{O}_{2}$ for 1 h , and Raman spectra were recorded prior to and following a vigorous, five-minute ${ }^{16} \mathrm{O}_{2}$ purge. The $v\left({ }^{16} \mathrm{O}-16 \mathrm{O}\right)$ feature appeared in the spectrum immediately following the purge, but not at the expense of the intensity of the $v\left({ }^{18} \mathrm{O}-{ }^{18} \mathrm{O}\right)$ band. Moreover, the
$v\left({ }^{16} \mathrm{O}-16 \mathrm{O}\right)$ peak continued to grow in intensity when the solution was allowed to stir under 1 atm of ${ }^{16} \mathrm{O}_{2}$ over two hours, but again the $\left.v^{18} \mathrm{O}-{ }^{18} \mathrm{O}\right)$ band did not diminish. These results suggest that oxygenation of the reduced complex is slow under the concentrated conditions of the Raman experiment, and that peroxide does not exchange with free $\mathrm{O}_{2}$ by any mechanism, at least over several hours.

We attempted to obtain structural information about the orientation of peroxide binding by carrying out a labeling experiment with a 1:2:1 statistical mixture of ${ }^{18} \mathrm{O}_{2},{ }^{16} \mathrm{O}^{18} \mathrm{O}$, and ${ }^{16} \mathrm{O}_{2}$ (Figure 3.15). If the peroxide oxygen atoms are distributed asymmetrically about the Fe (III) ions, then two ${ }^{16} \mathrm{O}^{18} \mathrm{O}$ peroxide peaks should be observed, with a 1:1:1:1 relative intensity ratio for the ${ }^{18} \mathrm{O}_{2},{ }^{16} \mathrm{O}^{18} \mathrm{O}$, ${ }^{18} \mathrm{O}^{16} \mathrm{O}$, and ${ }^{16} \mathrm{O}_{2}$ isotopomers. Alternatively, equivalent ${ }^{16} \mathrm{O}^{18} \mathrm{O}$ and ${ }^{18} \mathrm{O}^{16} \mathrm{O}$ peroxide stretching frequencies would give rise to three peaks in a 1:2:1 ratio. Interpretation of resulting Raman spectrum proved to be difficult, however, because of the difficulty of resolving the ${ }^{16} \mathrm{O}^{18} \mathrm{O}$ peroxide peak(s) and the fact that their intensity relative to the ${ }^{18} \mathrm{O}_{2}$ and ${ }^{16} \mathrm{O}_{2}$ bands were obscured by a coincidental toluene peak, even after considerable effort was expended to subtract the solvent background.

Mössbauer Spectroscopy. Zero-field Mössbauer studies were carried out to gain additional information concerning the iron environments in the reduced and peroxo complexes. The results of these experiments are summarized in Table 3.12, and spectra with overlaid fits are illustrated in Figures 3.16-3.18. Spectra were recorded for 13 in the solid state, and for 13 and 15 in frozen THF solution. Each spectrum consists of two overlapping quadrupole doublets of equal intensity, indicating inequivalent iron sites. Pairing of the four peaks derived from a fitting protocol is ambiguous, so both combinations for each complex are listed in Table 3.12. Consistent with our previous assignments in similar complexes, ${ }^{25}$ we tentatively attribute the doublet with the higher quadrupole splitting parameter $\left(\Delta E_{Q}\right)$ to the four-coordinate iron(II) center, since it has a more asymmetric
coordination environment compared to the octahedral metal ion. The iron(II) isomer shifts ( $\delta$ ) and $\Delta \mathrm{E}_{\mathrm{Q}}$ values for 13 are slightly different in the solid state and solution, in contrast to the previous study where a less hindered analog exhibited the nearly identical parameters in the two different phases. ${ }^{25}$ In the present system it is neither known how the solid and solution structures differ nor what magnitude of change would be required to yield slightly altered Mössbauer spectra. Nevertheless, the equal integrated intensity of the two quadrupole doublets is consistent with the dinuclear structure remaining intact in solution.

A Mössbauer spectrum of $\mathbf{1 3} \cdot \mathrm{O}_{2}$ in THF is displayed in Figure 3.18. A modest amount ( $20 \%$ ) of the diiron(II) starting material is apparent in this sample, as judged by the identical isomer shift of the most positive feature compared to that observed for 13 (Figure 3.18, Top). This result is consistent with the Raman experiment mentioned above, where it was determined that oxygenation of extremely concentrated diiron(II) samples ( 20 mM ) is slow relative to the rate in more dilute solutions, such as that used for the UV-vis protocol. It is difficult to know a priori how long to permit the reduced complexes to react with $\mathrm{O}_{2}$ before quenching the sample in liquid nitrogen. Given the thermal instability of the peroxo complexes, which decompose significantly within $12-24 \mathrm{~h}$ at $-77^{\circ} \mathrm{C}$, and the fact that the spectroscopic properties of the reduced complexes are well known, we chose not to allow any of these concentrated reactions to proceed beyond $\sim 2 \mathrm{~h}$. The bottom portion of Figure 3.18 displays the experimental data with the dirion(II) component subtracted out, together with a fit of the peroxo spectrum.

Like the iron(II) complexes, the peroxo consists of two overlapping quadrupole doublets of equal integrated intensity. Both possible pairings of the four simulated peaks are listed in Table 3.12, along with the Mössbauer parameters for oxyhemerythrin ${ }^{47}$ and MMO- $\mathrm{H}_{\text {peroxo. }} .^{15}$ The isomer shifts and $\Delta \mathrm{E}_{\mathrm{Q}}$ values are both in the range typical of high spin $\mathrm{Fe}(\mathrm{III}),{ }^{48}$ and these parameters bear considerable
resemblance to those determined for the phenoxo-bridged peroxo complex in Table 3.1. ${ }^{21}$ These results indicate either that the peroxo sample is composed of one dinuclear complex with inequivalent iron centers, or of two different dinuclear peroxo complexes with equivalent iron centers within the same molecule. Since a 1:1 ratio of two different peroxo isomers is highly improbable, we conclude the former alternative best describes the makeup of $13 \cdot \mathrm{O}_{2}$.

Kinetic Studies of the Reaction of the Diferrous Complexes With $\mathbf{O}_{\mathbf{2}}$ and a Proposed Mechanism for Peroxo Formation. The UV-vis, manometric, EPR, resonance Raman, and Mössbauer spectroscopic data collectively point to the formation of a discrete ( $\mu$-1,2-peroxo) diiron(III) complex with inequivalent metal centers. With these results in hand, we decided to investigate the mechanism of peroxo formation by time-resolved UV-vis kinetic studies to determine the reaction order with respect to the diferrous complex and $\mathrm{O}_{2}$. Moreover, X-ray structural investigations demonstrated that the coordination number of one of the starting diiron(II) centers could be modulated as a function of intramolecular steric repulsions (vide supra), and we were interested to determine whether this effect might play a role in the kinetics of oxygenation.

Kinetic runs were carried out at $-77^{\circ} \mathrm{C}$ on pyridine adducts $6,7,13$, and 14 using a custom-made immersion dewar. All experiments were performed under pseudo-first-order conditions, with the iron complex as the limiting reagent. Dioxygen concentrations were varied over a range of $3.1-15.4 \mathrm{mM}$. The buildup of the peroxo charge transfer band was monitored at 600 nm as a function of time (Figures 3.19-3.22, Top). These plots could be fit to a first order exponential buildup for each complex. Plots of $\ln \left(k_{\psi}\right)$ vs. the $\ln \left[\mathrm{O}_{2}\right]$ afforded straight lines with slopes near 1.0, indicating that the oxygenation reaction is first order in this reagent (Figures 3.19-3.22, Bottom). Second order rate constants were obtained for the four iron complexes from the slopes derived from plots of $k_{\psi}$ vs. the [ $\mathrm{O}_{2}$ ] (Figures 3.19-
3.22, Middle). These rate constants are provided in Table 3.13 along with metrical data from the crystal structures of 6, 7, and 13 describing the orientation of each bridging ancillary carboxylate. Activation parameters could not be obtained because the peroxo adducts decompose quite rapidly above $-65{ }^{\circ} \mathrm{C}$, thus limiting the temperature for aquisition to only a $15^{\circ}$ range.

The first-order dependence in each reagent indicates that the rate limiting step in these oxygenation reactions is a bimolecular collision between the diiron(II) complex and dioxygen. Within the series, the rate constants increase modestly over a four-fold range as the steric demands of the carboxylate substituents are enhanced. This kinetic trend correlates well with lengthening of the $\mathrm{Fe} 2-\mathrm{O} 402$ bond and decrease in $\tau$ as a function of the same steric parameters and may indicate that, in the transition state, cleavage of this bond is required to open a coordination site for $\mathrm{O}_{2}$ binding to Fe 2 . This event corresponds to a rate limiting carboxylate shift from mondentate bridging to syn syn bidentate bridging. Such structural/kinetic comparisons must be viewed with caution, however, since the Mössbauer studies on the diiron(II) complexes showed that the solid and solution structures may not be identical. Nevertheless, the trend does suggest that bond cleavage is involved in the rate limiting step and argues against a mechanism where passage of the $\mathrm{O}_{2}$ molecule to an iron center is impeded by the sterically encumbering carboxylate substituents. The latter mechanism was observed for the oxygenation of a series of iron(II) hydrotris(pyrazolyl)borate-carboxylate complexes, where exceedingly bulky carboxylate substituents shut down the reaction entirely. ${ }^{45}$ By contrast, space-filling models of 6-16 show that the pathway to the four- or five-coordinate iron center is unobstructed, regardless of the carboxylate substituents (Figures 3.4 and 3.6, for example).

The 1 -alkylimidazole adducts 15 and 16 react to completion with $\mathrm{O}_{2}$ in the time of mixing of the two reagents $(<1 \mathrm{~s})$, much more rapidly than the oxygenation
rates observed for the pyridine complexes. Neither could be studied by these conventional kinetics methods. The less hindered analog $\left[\mathrm{Fe}_{2}\right.$ (PXDK) $\left(\mu-\mathrm{O}_{2} \mathrm{C}\right.$ tert$\mathrm{Bu})\left(\mathrm{O}_{2} \mathrm{C}\right.$ tert- Bu$)(\mathrm{Me}-\mathrm{Im})_{2}$ ], was previously analyzed by stopped-flow UV-vis spectroscopy under very similar experimental conditions: $\left[\mathrm{Fe}_{2}{ }^{2+}\right]=0.8 \mathrm{mM}$ (after mixing) in THF, $\mathrm{T}=-76{ }^{\circ} \mathrm{C}$, excess $\mathrm{O}_{2} \cdot{ }^{25}$ These studies revealed a pseudo-first-order rate constant of $300 \mathrm{~s}^{-1}$, a value $>10^{5}$ faster than the pseudo-first-order rate constants observed for the pyridine adducts. The dramatically enhanced rates could be due in part to the minimal bonding interaction between the Fe 2 and O 402 in this complex. Because changes in this parameter have only a modest effect on the rate constants, however, we attribute most of the rate difference instead to the greater basicity of the 1-alkylimidazole ligand compared with pyridine. This electronic factor should lead to a significantly more negative midpoint potential for the diiron(II)/diron(III) couple with 1-alkylimidazole, thereby enhancing the thermodynamic driving force for the $\mathrm{O}_{2}$ reaction, and consequently accelerating the rate.

A mechanism for peroxo formation is presented in Scheme 3.2. Although peroxo buildup exhibits clean first order dependence in each reaction component, the kinetics do not reveal if the rate limiting event leads to peroxo formation directly. Alternatively, very fast electron transfer and/or ligand rearrangement steps may occur after $\mathrm{O}_{2}$ binding, thereby preceding final peroxo assembly. Consequently, if the final peroxo formation event is beyond the rate limiting step, then prior intermediates could involve a diiron(II) $-\mathrm{O}_{2}$ adduct, an Fe (II) Fe (III) superoxide complex, and/or several plausible isomers based on the arrangement of the carboxylate and nitrogen donors. Two likely possibilities are structures $\mathbf{a}$ and $\mathbf{b}$ in Scheme 3.2. For the final structure, the spectroscopic data are consistent with a bridged peroxo arrangement with inequivalent iron sites. To accommodate the latter feature, the mirror plane and rotational symmetry of the diiron-XDK framework must be removed. Structures c-e incorporate these properties through
the orientation of the peroxide (c) or the other ligands (d and e). We consider these or closely related isomers as viable candidates for the structures of the peroxo complexes presented here.

## Conclusions

A family of diferric peroxo-bridged complexes has been prepared which matches exactly the combination of carboxylate and imidazole donors of the $\mathrm{H}_{\text {peroxo }}$ intermediate in sMMO. A variety of methods including UV-Vis, EPR, Resonance Raman, and Mössbauer spectroscopies have been employed to elucidate their structures. These adducts have inequivalent iron coordination environments, a feature which is attributed either to an asymmetric peroxide bridge, a disproportionate arrangement of the ancillary carboxylate and nitrogen donor ligands about each iron center, or a combination of two. Kinetic studies revealed that the rate of peroxo formation is first order in diiron(II) complex and $\mathrm{O}_{2}$, implicating a rate-determining bimolecular collision between the reaction components. Moreover, the rate of peroxo formation tracks inversely with the steric demands of the carboxylate substituents, implying that a carboxylate shift is associated with the rate-determining step. The oxygenation rate is affected much more dramatically by the basicity of the N -donor ligand, however, with a difference of $>10^{5} \mathrm{~s}^{-1}$ noted for the pseudo-first-order rate constants with 1-alkylimidazole versus pyridine ligation. In sum, these studies have spawned the most accurate compositional models of the $\mathrm{H}_{\text {peroxo }}$ intermediate reported to date, and their steric and electronic tunability have allowed us to explain many factors which affect their formation, structure, and stability.

## Chapter IV

The Reactivity of Well Defined Diiron(III) Peroxo Complexes Towards Substrates:

## Addition to Electrophiles and Hydrocarbon Oxidation

## Introduction

The selective and efficient catalytic oxidation of hydrocarbon substrates under mild conditions continues to be a formidable goal for the synthetic chemist. ${ }^{1,2}$ In Nature, obligate methanotrophic bacteria carry out one of the most challenging types of these reactions, the conversion of methane to methanol under ambient conditions (eq 1), utilizing a soluble ${ }^{3-5}$ or particulate ${ }^{6,7}$ methane monooxygenase

$$
\begin{equation*}
\mathrm{CH}_{4}+\mathrm{O}_{2}+\mathrm{NADH}+\mathrm{H}^{+} \longrightarrow \mathrm{CH}_{3} \mathrm{OH}+\mathrm{H}_{2} \mathrm{O}+\mathrm{NAD}^{+} \tag{1}
\end{equation*}
$$

(sMMO or pMMO). The soluble form houses a diiron center in its hydroxylase component $(\mathrm{MMOH})$, the site of methane oxidation. This protein is a member of a class of non-heme diiron enzymes which carry out a variety of selective hydrocarbon oxidative processes. ${ }^{3,5}$ A closely related enzyme is ribonucleotide reductase, which uses $\mathrm{O}_{2}$ at a diiron center in its R 2 subunit ( RNR -R2) to generate a tyrosyl radical which in turn assists in the catalytic reduction of ribonuleotides. We seek to prepare functional synthetic models of these systems, with the goals of aiding in the elucidation of the biological $\mathrm{O}_{2}$-activation mechanisms, and to develop practical hydrocarbon oxidation catalysts.

The current state of knowledge regarding these systems, including their structural, spectroscopic, and mechanistic ties, was described in detail in Chapter 3; therefore, only a brief review will be provided here. Metal-oxygen intermediates have been characterized for $s \mathrm{SMO}^{4,8,9}$ and RNR-R2 ${ }^{10-12}$ by coupling stopped-flow and rapid freeze quench methods to a variety of spectroscopies. Both proteins react with $\mathrm{O}_{2}$ in their diferrous forms to afford a diiron(III) peroxo complex as the first detected intermediate. For sMMO, this species converts to a diiron(IV) species, Q, which is believed to be the active substrate oxidant. In RNR-R2, the peroxo converts to a diiron(III)(IV) complex, X , possibly through a diiron(IV) intermediate like
sMMO-Q. Intermediate $X$ reacts with an adjacent tryrosine, formally by hydrogen atom abstraction, to yield a catalytically viable tyrosyl radical.

Much effort has been expended to mimic the oxidation chemistry of nonheme enzymes with iron(III) complexes with either hydrogen peroxide ${ }^{13-16}$ or tertbutylhydro peroxide ${ }^{17-19}$ as the oxidant. By contrast, the reactivity of discrete, well defined diiron(III) peroxo complexes derived from iron(II) precursors and $\mathrm{O}_{2}$ is essentially unexplored. Given that sMMO utilizes a reductive $\mathrm{O}_{2}$ activation pathway, it is desirable to track an oxidation reaction in a model system from the dioxygen binding step, to formation of a high valent oxidant, and finally through the substrate oxidation event. Such a study would provide invaluable insight into the enzymatic mechanism, and as well as spawn the development of practical oxidation catalysts. Here we provide a complete analysis of the reactivity of diiron(III) peroxo complexes derived from the $m$-xylylenediamine bis(kemp's triacid)imide $\left(\mathrm{H}_{2} \mathrm{XDK}\right)$ ligand system. ${ }^{20}$

## Experimental Section

General Considerations. The complexes $\left[\mathrm{Fe}_{2}\left(\mu-\mathrm{O}_{2}\right)\right.$ (PXDK) $(\mu-$ $\left.\left.\mathrm{O}_{2} \mathrm{CPhCy}\right)\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)(\mathrm{Bu}-\mathrm{Im})_{2}\right](1)$ and $\left[\mathrm{Fe}_{2}\left(\mu-\mathrm{O}_{2}\right)(\mathrm{BXDK})\left(\mu-\mathrm{O}_{2} \mathrm{CPhCy}\right)\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)(\mathrm{py})_{2}\right]$ (2) were prepared from $\mathrm{O}_{2}$ and the diiron(II) precursors at $-77^{\circ} \mathrm{C}$ according to an established procedure. ${ }^{20}$ Authentic samples of $3,3^{\prime}, 5,5^{\prime}$-tetra-tert-butyl-1, $1^{\prime}$-bi-2,2'phenol, ${ }^{21}$ cyclopentylhydroperoxide, ${ }^{22}$ and 2-hydroxytetrahydrofuran, ${ }^{23}$ were synthesized according to the literature methods, and their purity was confirmed by ${ }^{1}$ H NMR and/or GC and GC/MS analyses. Dioxygen (99.994\%, BOC Gases) was dried by passing the gas stream through a column of Drierite. Labeled dioxygen $\left(95 \%{ }^{18} \mathrm{O}_{2}\right)$ toluene, and THF reagents were purchased from Cambridge Isotope Laboratories, Inc. The solvents were vacuum transferred from Na /benzophenone ketyl. All other reagents were procured from commercial sources and used as received unless otherwise noted. THF, cyclopentane, toluene, pentane, and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from
sodium benzophenone ketyl under nitrogen. Pentane, cyclopentane, isopentane, 1hexene, and cyclohexene were distilled from sodium under nitrogen. Dichloromethane, 1,2-dichloroethane, and pyridine were distilled from $\mathrm{CaH}_{2}$ under nitrogen. All air sensitive manipulations were carried out either in a nitrogen filled Vacuum Atmospheres drybox or by standard Schlenk line techniques at room temperature unless otherwise noted.

Physical Measurements. NMR spectra were recorded on a Bruker AC-250 or Varian XL-300 spectrometer. ${ }^{1} \mathrm{H}$ NMR chemical shifts are reported versus tetramethylsilane and referenced to the residual solvent peak. FTIR spectra were recorded on a BioRad FTS-135 FTIR spectrometer.

GC and GC/MS. Analyses were carried out on a HP-5970 gas chromatograph connected to a HP-5971 mass analyzer. Alltech Econo-cap EC-WAX capillary columns of dimensions ( $15 \mathrm{~m} \times 0.53 \mathrm{~mm} \times 1.2 \mu \mathrm{~m}$ ) and ( $30 \mathrm{~m} \times 0.25 \mathrm{~mm} \times 0.25 \mu \mathrm{~m}$ ) were used for GC and GC/MS studies, respectively, except for triphenylphosphine and triphenylphosphine oxide, which were assayed with a HP-101 ( $12 \mathrm{~m} \times 0.2 \mathrm{~mm} \times$ 0.2 mm ) capillary column. The following method was used to effect nearly all separations: initial temperature $=50^{\circ} \mathrm{C}$, initial time $=10 \mathrm{~min}$, and a temperature ramp of $50-200^{\circ} \mathrm{C}$ at $10 \mathrm{deg} / \mathrm{min}$. The products were identified by comparing their retention times and mass spectral patterns to those of authentic standards. Integrations were acquired by FID detection run in parallel to mass spectrometry by using an HP-3393 integrator. FID response calibration constants were measured by running calibration curves with authentic samples and an internal standard, either cyclopentanone or cyclohexanone.

For kinetic isotope or ${ }^{18} \mathrm{O}_{2}$ labeling studies, the ratio of isotopomers was determined by mass spectral integration of each parent ion. The integration response was assumed to be identical for the isotopomers.

Low-Temperature UV-vis Spectroscopy. Spectra were recorded on a HP8452A diode array spectrophotometer by using a custom manufactured immersion dewar, equipped with a 3 mL cell ( 1 cm pathlength) with quartz windows connected to a $14 / 20$ female joint via a 10 cm long glass tube. A temperature of $-77^{\circ} \mathrm{C}$ was maintained with a dry ice/acetone bath and monitored with a Sensortek Model BAT-12 thermocouple thermometer.

Resonance Raman Spectroscopy. Raman data were acquired by using a Coherent Innova 90 argon laser with an excitation wavelength of 647.1 nm and 65 mW of power. A $0.6-\mathrm{m}$ single monochromator (1200 grooves/nm grating), with an entrance slit of $100 \mu \mathrm{~m}$, and a liquid nitrogen cooled-CCD detector (Princeton Instruments, Inc.) were used in a standard backscattering configuration. A holographic notch filter (Kaiser Optical Systems) was used to attenuate Rayleigh scattering. Spectra of all samples were collected in toluene solution at $-77^{\circ} \mathrm{C}$ with the same custom-manufactured dewar used to acquire low-temperature UV-vis spectra. Solute concentrations were made as high as possible depending on the solubility of the reduced sample, $\sim 20 \mathrm{mM}$ in the best cases, to ensure an optimal signal-to-noise ratio. High vacuum line techniques were used to transfer ${ }^{18} \mathrm{O}_{2}$ and to manipulate the resulting samples. A total of 1000 scans each with a three second exposure time were collected for each sample. Raman shifts were calibrated with toluene as an internal standard. The data were processed by using CSMA software (Princeton Instruments, Inc. Version 2.4A) on a Gateway 2000 computer, and the resulting ASCII files were processed with Kaleidagraph (Abelbeck Software).

Synthetic Methods. General Procedures for Stoichiometric Reactions of 1 or 2 at $-77^{\circ} \mathrm{C}$. All reactions were monitored by low-temperature UV-vis spectroscopy. The dewar was equipped with a stir bar and loaded in the drybox with 5.0 mL of a $0.50-1.0 \mathrm{mM}$ solution of the diiron(II) precursors of 1 or 2 . The apparatus was topped with a rubber septum, brought out of the box, placed under a positive $\mathrm{N}_{2}$ pressure,
and cooled to $-77^{\circ} \mathrm{C}$ with a dry ice acetone bath. A spectrum was recorded, and then the sample was subjected to a gentle purge of $\mathrm{O}_{2}$ at atmospheric pressure for 15 s , after which time the peroxo complex 1 or 2 had formed to completion, as judged by the blue color which had developed. Excess $\mathrm{O}_{2}$ was removed with a 5 min Ar purge of the solution. Another spectrum was recorded, and then $200 \mu \mathrm{l}$ of the test reagent solution was added dropwise to a stirred solution of the peroxo complex, taking care not to allow the peroxo solution to warm above $-77^{\circ} \mathrm{C}$. For the $\mathrm{CO}_{2}$ reactions, the gas was bubbled gently through the solution of the peroxo complex over $\sim 30 \mathrm{~s}$. Note: Owing to the low temperature, this procedure introduces a large excess of $\mathrm{CO}_{2}$ to the solution, and therefore considerable caution should be taken when venting the solution upon warming so as to not build up a dangerous pressure level. The resulting mixture was allowed to stir for $15-30 \mathrm{~s}$, by which time a homogenous solution had formed. Additional spectra were recorded, and the reaction was monitored to completion, as judged by the complete decay of the peroxo charge transfer band. The quantities of reagents and solvent used for each reaction are listed in Table 4.1. UV-vis spectra are displayed in Figures 4.1-4.5 and 4.8-4.4.12.

General Procedures for Solvent Oxidation Studies. Samples were prepared in the immersion dewar described above or in a round bottom flask sealed with a rubber septum. All sample volumes were 5.0 mL . Peroxo complex 1 was generated in the usual manner at $-77^{\circ} \mathrm{C}$. It was stable for at least several hours at this temperature, as judged by UV-vis spectroscopy, which afforded identical traces in all the solvents. For thermolysis reactions carried out under argon, the peroxo solution was degassed by carrying out three vacuum/Ar purge cycles and three freeze-pumpthaw cycles with liquid nitrogen, and then backfilled with 1 atm of Ar prior to warming. Warming to room temperature over five min was accomplished by removing the dry ice/acetone bath from the stirred solution. Warming over 2 h was carried out by removing the excess dry ice while keeping the flask or UV-vis cell in
contact with the bath. Solutions incubated at low temperature for longer time periods were placed in a $-85^{\circ} \mathrm{C}$ refrigerator. After addition of an internal standard, the crude reaction mixtures were examined directly by GC and GC/MS analyses.

Intermolecular Kinetic Isotope Measurements. Peroxo complex samples (1.0 mM ) were prepared in equimolar quantities of perdeutero or protio solvents, to a total volume of 5.0 mL . Thermolyses were carried out over 5 min as described above, and the crude reaction mixtures were analyzed by GC/MS.

## Results and Discussion

Reactions of Peroxide Complexes 1 and 2 with Various Reagents at $-77^{\circ} \mathrm{C}$. The electronic spectra of the 1 -alkylimidazole and pyridine complexes 1 and 2 were used to monitor their reactivity toward three classes of substrates: oxygen-atom acceptors, electrophiles/acids, and weak H -atom donors. Such a comparative analysis has been used previously to characterize transition metal peroxo complexes, where the reactivity pattern of the peroxide ligand depends on the Lewis acidity of the metal ion and the mode of peroxo coordination. ${ }^{24-26}$ In general, early transition metal ions in high oxidation states render coordinated peroxide ligands electron deficient such that they typically undergo oxygen-atom transfer reactions to acceptors such as phosphines and olefins. These reactions become more favored thermodynamically as the substituents bound to the reacting substrate functionality are more electron releasing. By contrast, low-valent, late-metal peroxo adducts usually behave as nucleophiles, undergoing addition reactions to electrophiles such as $\mathrm{CO}_{2}$, acyl chlorides, or electron-deficient olefins. In addition, these electron rich peroxo adducts will react with acids to afford hydroperoxo complexes or they may react with an additional acid equivalent to liberate $\mathrm{H}_{2} \mathrm{O}_{2}$. Peroxo complexes may also display radical character and react with weak hydrogen atom donors such as isopropyl C$\mathrm{H}^{27,28}$ and phenolic $\mathrm{O}-\mathrm{H}^{24,25}$ bonds. Peroxo $\mathrm{O}-\mathrm{O}$ bond cleavage may occur prior to
hydrogen atom abstraction in these reactions, as has been demonstrated in a related bis( $\mu$-oxo) dicopper system. 29-31 Moreover, the distinction between nucleophilic/basic versus radical peroxo character can be probed with phenols since deprotonation usually leads to phenoxide coordination, ${ }^{26}$ whereas hydrogen atom abstraction provides a phenoxyl radical. With the appropriate aryl substitution, such a species can be identified as the $2,2^{\prime}$-biphenol-coupled product. ${ }^{24,32}$

Stoichiometric reactions were conducted by generating peroxo complex 1 or 2 in solution at $-77{ }^{\circ} \mathrm{C}$, followed by thorough removal of excess $\mathrm{O}_{2}$ with Ar purge/dynamic vacuum cycles and then addition of the reagent. Reactions were monitored by UV-vis spectroscopy. These studies are summarized in Scheme 4.1. No reaction was observed for peroxo adducts 1 or 2 with triphenylphosphine or 2-cyclohexen-1-one, an outcome which suggests that this class of peroxo complexes has no electrophilic character, even toward electron-poor olefins. Similarly, exposure of either peroxo complex to the weak H -atom donor dimethylbenzylamine afforded no reaction.

Treatment of the 1-butylimidazole peroxo complex 1 with 1.0 equiv of 2,4-di-tert-butylphenol resulted in a color change from purple to deep royal blue within 30 s. By contrast, peroxo 2 did not react with the phenol under similar conditions. UVvis spectral studies of both of these reactions were carried out, the results of which are displayed in Figure 4.1-4.2. The product spectrum for $1+$ phenol persists for $>2 \mathrm{~h}$ at $-77^{\circ} \mathrm{C}$, but decays rapidly upon warming to room temperature. No 2,2'-biphenol coupled product was detected by GC/MS, as judged by comparison of the product chromatogram to that of pure $2,2^{\prime}$-biphenol, but $\mathrm{H}_{2} \mathrm{O}_{2}$ was detected qualitatively. These facts, coupled with the metastable nature of the product and the resemblance of its UV-vis spectrum to that of 1 suggested that a diiron(III) phenoxidehydroperoxide complex might have been formed through deprotonation of the phenol with the diiron(III)-bound peroxide. The resulting charge transfer band at
$620 \mathrm{~nm}\left(\varepsilon=1400 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ is considerably blue-shifted from those of known hydroperoxo complexes, however, $\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{N} 4 \mathrm{Py})(\mathrm{OOH})(\mathrm{MeCN})\right]\left(\mathrm{ClO}_{4}\right)_{2}\left(\lambda_{\max }=458\right.$ $\left.\mathrm{nm}, \varepsilon=1100 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)^{33}$ and $\left.[\mathrm{Fe}(\mathrm{TPA})(\mathrm{OOH})]\left(\mathrm{ClO}_{4}\right)\right]^{2+}\left(\lambda_{\max }=538 \mathrm{~nm}\right) .{ }^{13}$ Moreover, reactions with less electron-rich phenols such as the parent compound and pentafluorophenol exhibited UV-vis bands blue shifted of that obtained for the 2,4-di-tert-butylphenol product (Figures 4.3-4.4). Both of these facts make it more likely that the product UV-vis feature is due to a phenoxide-to-iron(III) charge transfer.

Resonance Raman studies were conducted to probe further the fate of the peroxide complex 1 upon treatment with 2,4-di-tert-butylphenol. Peroxo species were prepared with ${ }^{16} \mathrm{O}_{2}$ or ${ }^{18} \mathrm{O}_{2}$, and each was treated with 1.1 equiv of the phenol. Spectra before and after the reaction are displayed in Figures 4.5 and 4.6. For the ${ }^{16} \mathrm{O}_{2}$ sample, the $v\left({ }^{16} \mathrm{O}-16 \mathrm{O}\right)$ band at $864 \mathrm{~cm}^{-1}$ disappears almost entirely upon addition of the phenol, and two new bands appear at 750 and $913 \mathrm{~cm}^{-1}$. The $v\left({ }^{18} \mathrm{O}-18 \mathrm{O}\right)$ band also diminishes when phenol is added, as judged by the narrowing and shifting of the peak at $\sim 825 \mathrm{~cm}^{-1}$, which is composed of the peroxo band and one assigned to toluene (see Chapter 3, Figures 3.13-3.14). The same two new peaks that were observed when phenol was added to the ${ }^{16} \mathrm{O}_{2}$ sample also appear in the ${ }^{18} \mathrm{O}_{2}$ spectrum, indicating that neither can be ascribed to a hydroperoxide or peroxide species. These features are therefore assigned to phenol vibrations which are resonance enhanced by the phenoxide-to-iron charge transfer band. A new $v(\mathrm{O}-\mathrm{O})$ band may be obscured by the toluene peaks, but none was observed after carrying out solvent subtraction routines.

Irrespective of the identity of the products, this set of experiments shows that 1 behaves as a basic, as opposed to a hydrogen atom abstracting, peroxo species. The fact that 2 does not react at all with 2,4-di-tert-butylphenol further supports this conclusion. Compared to pyridine, the more basic 1-alkylimidazole groups impart additional electron density to the iron centers, which is in turn transmitted to the
peroxide. The large discrepancy in the $\mathrm{pK}_{\mathrm{a}}$ values for 1-butylimidazole ( $\sim 6.8$ ) compared to phenol $(\sim 10.0)^{34}$ makes proton transfer to the 1 -alkylimidazole ligand highly improbable.

Two other proton donors were investigated to probe further the character of the peroxide ligands in 1 and 2. Treatment of 1 with 1.1 equiv of 2,4,6-tri-tertbutylphenol provided no reaction, as judged by UV-vis spectroscopy (Figure 4.7). Apparently proton transfer does not occur in this case because the sterically encumbered phenol blocks access to the peroxide ligand. Alternatively, the deprotonated phenol may be too hindered to bind to the iron center(s). A carboxylic acid was used to determine whether a hydroperoxo complex could be stabilized by an additional hindered carboxylate ligand and to see if the less basic pyridine peroxo complex 2 could be protonated. Treatment of peroxo complex 1 with 1.1 equiv of 1 phenylcyclohexylacetic acid was accompanied by decomposition at $-77^{\circ} \mathrm{C}$ within $15-$ 30 s (Figure 4.8), yielding intractable products following workup at room temperature. Like all the phenol reactions, $\mathrm{H}_{2} \mathrm{O}_{2}$ was detected qualitatively in the crude decomposed mixtures. Peroxo 2 was completely unreactive toward the carboxylic acid, an outcome which further illustrates the vastly different electronic properties that are imparted to the two peroxo ligands solely by the choice of N donor ligand.

Electrophilic reagents were examined to probe the nucleophilicity of the peroxo complexes. Exposure of $1-77^{\circ} \mathrm{C}$ to a large excess of $\mathrm{CO}_{2}$ resulted in decay of the peroxide-to-iron charge transfer band at within 15 s (Figure 4.9). As with other peroxo complexes that react with $\mathrm{CO}_{2}$, this reaction probably generates a peroxycarbonate species which decomposes to an iron(III) carbonate complex(es), although nothing tractable was isolated from the reaction mixture. Consistent with the protonolysis studies, 2 was unreactive toward $\mathrm{CO}_{2}$ over the course of 2 h of monitoring the reaction by UV-vis spectroscopy (Figure 4.10).

Finally, the behavior of 1 toward reductants was examined to obtain an estimate of its reduction potential. No reaction was observed with ferrocene or pentamethylferrocene (Figure 4.11), but treatment with cobaltocene induced a rapid decay of the peroxo UV-vis band (Figure 4.12). The cobaltocenium cationic product could not be identified because intense features in the higher energy visible region dominated the spectrum. Assuming this compound donates an electron to the peroxo complex in a $1: 1$ stoichiometry, then the reduction potential of 1 is estimated to be between that of $\mathrm{Cp} 2^{*} \mathrm{Fe}$ and cobaltocene, -0.59 and -1.33 mV , respectively vs. $\mathrm{Cp}_{2} \mathrm{Fe}^{+} / \mathrm{Cp}_{2} \mathrm{Fe} .{ }^{35}$ This value attests to the stability of the diiron(III) peroxo species toward hydrogen atom donors and dioxygen dissociation, since both processes would require reduction of one or both $\mathrm{Fe}(\mathrm{III})$ ions. In particular, it provides at least a partial explanation as to why peroxo species 1 deprotonates 2,4-di-tert-butylphenol instead of abstracting a hydrogen atom from this reagent.

Thermolysis Reactions Leading to Solvent Oxidation. Solutions of peroxo complexes 1 or 2 rapidly decay when warmed above $\sim 5^{\circ} \mathrm{C}$, changing from purple and midnight blue, respectively, to an orange brown color which is characteristic of $\mu$-oxodiiron(III) complexes. Several mechanisms could account for this decay. The most well documented of such a reaction in diiron(III) peroxo chemistry is a bimolecular decomposition accompanied by extrusion of 0.5 equiv of $\mathrm{O}_{2}$ per diiron complex, affording oxo-bridged Fe (III) products. ${ }^{36,37}$ This process could not account for the entire decomposition of 1 or 2 because manometric studies indicated either that $\mathrm{O}_{2}$ was not released during decay or that in solvents such as THF and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, up to an additional equiv of dioxygen was consumed. ${ }^{20}$ Such a result might be explained a priori by ligand oxidation, but a thorough ${ }^{1} \mathrm{H}$ NMR and GC/MS analysis of the organic components revealed no oxidized ligands following acid dissociation and extraction of the decomposition products. Instead, solvent oxidation products were identified in the reaction mixtures for several different solvents. A detailed
analysis of those reactions for 1 was undertaken because its butyl and propyl groups make it soluble in a wide variety of hydrocarbons. Table 4.2 summarizes the results of this initial survey.

These studies defined the scope of the oxidation process. Substrates with particularly weak C-H bonds ${ }^{34}$ such as T.HF ( $92 \mathrm{kcal} / \mathrm{mol}$ ), cyclohexene (allylic C-H $=85 \mathrm{kcal} / \mathrm{mol}$ ), and toluene ( $85 \mathrm{kcal} / \mathrm{mol}$ ) afforded $\gamma$-butyrolactone and 2 hydroxytetrahydrofuran, 2-cyclohexen-1-ol, 2-cyclohexen-1-one, and cyclohexene oxide, and benzaldehyde, respectively, in modest yields based on 1. Dichloroethane, identified qualitatively as a product of peroxo decay in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solutions, was formed by $\mathrm{C}-\mathrm{Cl}$ bond homolysis. Solvents with high $\mathrm{C}-\mathrm{H}$ bond strengths such as isopentane ( $95 \mathrm{kcal} / \mathrm{mol}$ ), and pentane ( $98 \mathrm{kcal} / \mathrm{mol}$ ) were completely unreactive. Cyclopentane, with an intermediate C-H bond strength ( $94.5 \mathrm{kcal} / \mathrm{mol}$ ), provided a small amount of product.

A key to understanding this chemistry is provided by the product distribution for each substrate. For cyclohexene, only allylic oxidation products were produced in appreciable quantities. This result contrasts with that for sMMO, early transition metal peroxo complexes, and many terminal oxo complexes, which all afford the epoxide as the major or exclusive product. For oxidations at saturated C-H bonds, ketones are favored over alcohol products, whereas sMMO affords alcohols exclusively.

To investigate the mechanism in more detail, we chose to focus on cyclopentane oxidation. This solvent is readily purified and not susceptible to autoxidation in air for months at room temperature. Cyclohexene and THF, on the other hand, autoxidize after $\sim 12 \mathrm{~h}$ in air, judging by GC/MS. From a practical standpoint its higher $\mathrm{C}-\mathrm{H}$ bond strength makes cyclopentane a more attractive target.

Table 4.3 lists a series of conditions designed to probe the oxidation mechanism of cyclopentane. Entries 1-3 reveal that yields of ketone and alcohol are unaffected by the warming rate, or reaction atmosphere, or peroxo concentration, providing in each case the same small quantities of ketone and alcohol in a 2.5 ratio. When decomposed reaction mixtures were allowed to stand in air for extended periods of time (entries 6-8), however, a slow but steady production of additional product resulted, as determined by analyzing aliquots of the reaction mixture by GC/MS on a daily basis. After three weeks the total yield of oxidized products based on the original [1] was $250 \%$, but the ketone:alcohol ratio remained invariant over this time period. The latter observation suggests that the entire oxidation process proceeds through a common mechanism, from the initial warming of the peroxo solution and throughout prolonged incubation in air at room temperature. An aliquot of the long-term reaction was removed after 1 day (entry 8) and treated with a 50-fold excess of 2,4,6-tert-butylphenol, which complete quenched product formation. Moreover, when solutions of 1 were warmed in the presence 1.0 equiv of this phenol, with which it does not react at $-77^{\circ} \mathrm{C}$ (vide supra), no oxidized products were observed either immediately after the reaction or upon standing in air for several days.

An intermolecular kinetic isotope effect (KIE) was not measured for cyclopentane oxidation because the perdeutero isotopomer is prohibitively expensive. Alternatively, we carried out measurements using THF and toluene as solvents, which afforded $k_{\mathrm{H}} / k_{\mathrm{D}}$ values of 6.2 and 7.8 , respectively (Figures 4.15-4.16). These values may be compared to the intramolecular KIE values of 2-3 for Gif cyclohexane and adamantane oxidations, ${ }^{38}$ and 1.0 for sMMO. ${ }^{39}$

The ability of phenol to quench product formation indicates that a free radical, non-metal based autoxidation mechanism is most likely occurring for this system. An example of such a mechanism is illustrated by eqs $2-5$ for oxidation at a
secondary carbon atom. . ${ }^{26}$ This well known hydrocarbon oxidation

\end{align*}
$$

process is initiated by hydrogen atom abstraction to generate an alkyl radical, which is trapped with dioxygen. The resulting alkyl peroxy radical then reacts with another equivalent of substrate, and the chain is propagated. Chain termination occurs when two alkyl peroxy radicals combine, and this resulting species then rearranges to afford dioxygen, ketone, and alcohol. Decomposition of the resulting alkyl hydroperoxide to ketone and alcohol can be catalyzed by iron salts via the HaberWeiss cycle (eqs 6-7)..$^{40,41}$ The resulting alkoxy radical reacts with substrate to yield alcohol (eq 8), and the alkyl peroxy radical can decompose as indicated in eq 5.

$$

\mathrm{RO} \cdot+\mathrm{R}_{2} \mathrm{CH}_{2} \longrightarrow \mathrm{R}_{2} \mathrm{CH} \cdot+\mathrm{ROH} \tag{8}
\end{gather*}
$$

The reaction mixtures were analyzed by ${ }^{1} \mathrm{H}$ NMR and GC/MS to determine whether a significant concentration of cyclopentylhydroperoxide builds up over the course of the extended reactions. No ${ }^{1} \mathrm{H}$ NMR resonances or GC/MS peaks attributable to this species were identified upon comparing the data to that obtained for a pure sample prepared independently. A peroxo sample was also warmed in the presence of 10 equiv of $\mathrm{PPh}_{3}$ to trap any intermediate cyclopentylhydroperoxide, which would afford triphenylphosphine oxide and alcohol. This procedure neither changed the overall yield nor altered the ketone:alcohol ratio, suggesting that if the hydroperoxide is formed it decomposes exceedingly rapidly.

Perhaps the most interesting issue for this system is the role of 1 in the autoxidation chemistry. For reactions conducted under Ar, the peroxo is presumably the source of free $\mathrm{O}_{2}$, whereby some is released from the peroxo upon warming. In addition, it is highly probable that a metal-bound oxygen species is involved in the initiation step. This reaction involves direct hydrogen atom abstraction by the diiron(III) peroxide, affording a $\mathrm{Fe}(\mathrm{II}) \mathrm{Fe}(\mathrm{III})$ hydroperoxo complex and an alkyl radical (eq 8). The former could then eliminate a hydroxyl radical

$$
\begin{align*}
& {\left[\mathrm{Fe}^{\mathrm{II} \mathrm{\prime}}{ }_{2}\left(\mu-\mathrm{O}_{2}\right)(\mathrm{XDK})\left(\mathrm{O}_{2} \mathrm{CPhCy}\right)_{2}(\mathrm{Bu}-\mathrm{Im})_{2}\right]+\mathrm{C}_{5} \mathrm{H}_{10} \longrightarrow} \\

\end{align*}
$$

and a ( $\mu$-oxo)diiron(III) product (eq 9). This particular sequence of events is unlikely, however, since 1 displays no propensity to abstract a hydrogen atom from even weak H -atom donors such as phenol $(\mathrm{O}-\mathrm{H} \text { bond strength }=88 \mathrm{kcal} / \mathrm{mol})^{34}$. Alternatively, the peroxo complex may convert to a new intermediate that is capable of the hydrogen atom abstraction reaction. One possibility is a dioxodiiron(IV) species having the same metal oxidation states as sMMO-Q but exhibiting a much different pattern of reactivity (eq 11). Another possibility is a bimolecular decay, whereby some of the peroxo complex decays by releasing $\mathrm{O}_{2}$ upon

$$
\begin{align*}

\end{align*}
$$

warming, and the resulting reducing equivalents are then used at a diiron(III) peroxide to effect Fenton chemistry, perhaps with trace water serving as a proton source to generate a hydroxyl radical (eq 12).

An important conclusion to be drawn from the cyclopentane oxidation studies is that we have not accessed the manifold of reactivity used by the diiron centers in sMMO in terms of substrate scope, product selectivity, or the oxidation mechanism. Studies of the enzyme with radical clock substrate probes and chiral ethane have provided evidence against a discrete radical intermediate, having a lifetime greater than $\sim 10^{-13} \mathrm{~s} .{ }^{42,43}$ For a functional model system to duplicate the enzymatic chemistry, metal-based oxidants which formally abstract a hydrogen atom from a substrate molecule must be avoided. Not only might such a reaction lead to undesired radical chain autooxidation chemistry, but also because it would simply that the model has not matched the composition and structure of the key enzymatic oxidant.

Recent X-ray studies of resting state MMOH and EXAFS studies on intermediate Q provide some insight into why the diiron XDK system may not be able to mimic the enzymatic chemistry and suggest new design strategies for improved functional models. In the resting enzyme, only one carboxylate ligand bridges the diiron center. The short $\mathrm{Fe} \cdots \mathrm{Fe}$ distance of $2.5 \AA$ observed for intermediate $Q$ cannot be accommodated by a synsyn bidentate bis(carboxylate)bridged core, and it is unlikely that the rigid XDK ligand system possesses the flexibility to undergo the carboxylate shift ${ }^{44}$ required to convert peroxo adducts 1 or 2 into Q-like diiron(IV) complexes. Alternatively, ligands which provide a single syn syn bidentate carboxylate bridge while maintaining a rigid dinucleating framework may provide ideal balance for converting a peroxo adduct into a Q-like species. Efforts to prepare such complexes are currently underway in this laboratory.

## Conclusions

The reactivity properties of diiron(III) peroxo complexes 1 and 2 have been fully elucidated. These adducts behave as nucleophilic/basic peroxides, exhibiting no propensity to serve as oxygen atom donors, even for potent acceptors such as triphenylphosphine. The 1-butylimidazole ligands in 1 enhance the nucleophilicity/basicity of the peroxo compared to the pyridine analog, probably because the former ligand is a superior $\sigma$-donor. This feature imparts more electron density to the iron centers, which in turn is transmitted to the peroxo ligand. Thermolysis of the peroxo adducts in a variety of media results in solvent oxidation, providing ketone and alcohol products in modest yield based on the complex. A detailed analysis of cyclopentane oxidation provided evidence for a radical chain autoxidation mechanism, a reactivity manifold which does not mimic the hydrocarbon oxidation chemistry of sMMO. Future efforts are aimed at preparing diiron(III) peroxo complexes with mono(carboxylate)-bridged structures, a design aspect which may facilitate conversion to a Q-mimic and allow access to the enzymatic hydroxylation pathway.

## Biographical Note

The author was born in Madison, WI on April 6, 1970. After spending a short amount of time there and in Illinois, California, and Ohio, he resided in Racine, WI for the remainder of his primary and all of his secondary education, which culminated in graduation from J. I. Case High School in 1988. From there he went on to the University of Minnesota-Twin Cites, where Professor William B. Tolman provided him with such remarkable undergraduate research opportunities in chemistry that he decided to pursue his doctorate in this field instead of medicine. Following his graduate studies at MIT, the author plans to work as a postdoctoral fellow with Professor Erick M. Carreira at the California Institute of Technology.
