CPAP in non-sleepy OSA

- Objective: To evaluate the long term effect of CPAP on blood pressure in hypertensive patients with sleep apnea and no daytime sleepiness
- Methods: RCT 374 hypertensive patients with OSA

Methods

DESIGN: Randomized prospective controlled study

POPULATION: Patients with AHI ≥ 20 and Epworth scale < 10 and hypertension

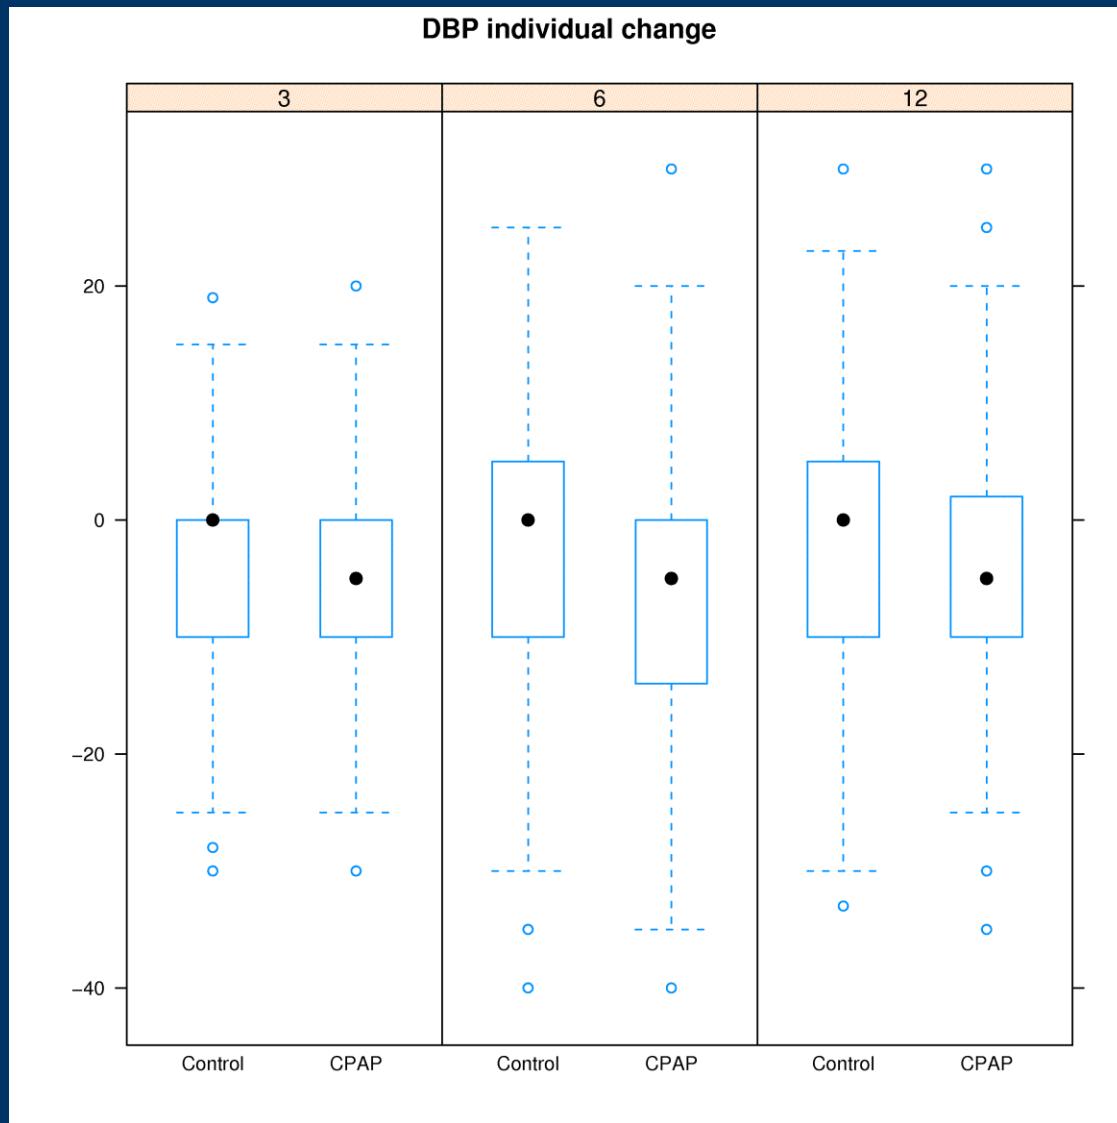

MEASUREMENTS:

- Sleep study (polysomnography or partial study)
- CPAP titration by auto-CPAP
- Office blood pressure measurement

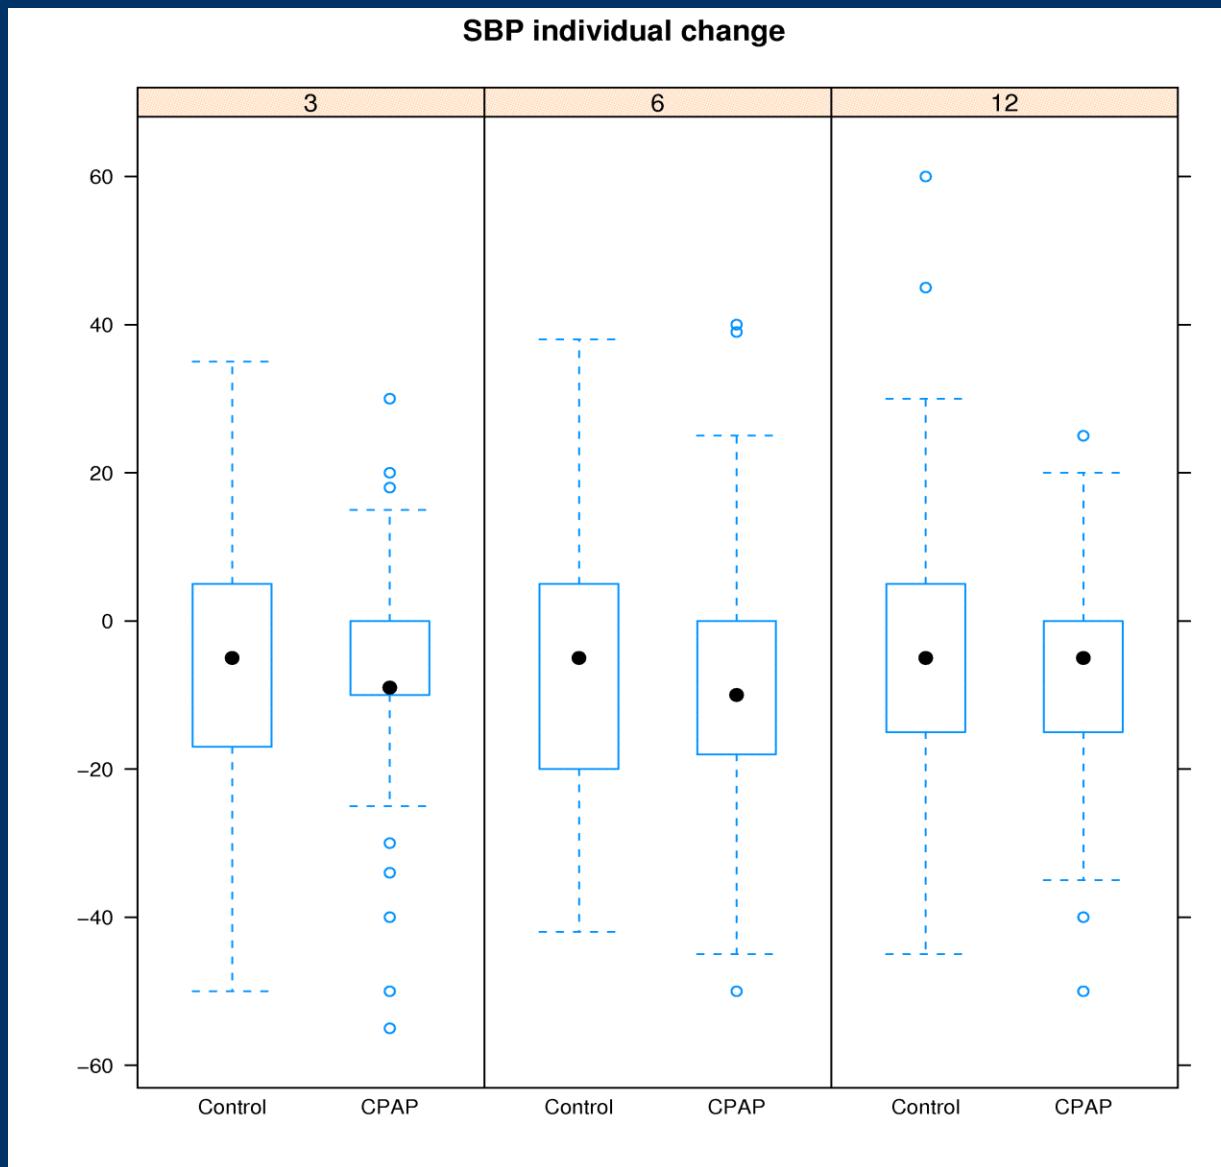

EVALUATIONS: Basal, at 3, 6 and 12 month

STATISTICS: Linear regression models

Differences diastolic blood pressure

Differences systolic blood pressure

Long-term Effect of Continuous Positive Airway Pressure in Hypertensive Patients with Sleep Apnea

AT A GLANCE COMMENTARY

Scientific Knowledge on the Subject

Continuous positive airway pressure (CPAP) is the current treatment for patients with symptomatic obstructive sleep apnea (OSA). The effects of CPAP on blood pressure are moderate and variable. Short-term studies performed in subjects with severe OSA but without daytime sleepiness failed to show any effect of CPAP on 24-hour ambulatory blood pressure. These studies infer that CPAP is not useful in nonsleepy patients.

What This Study Adds to the Field

This study shows that, in hypertensive patients with severe obstructive sleep apnea but without daytime hypersomnolence, 1 year of CPAP treatment slightly reduces blood pressure.

- Objective: To explore the effects of CPAP on systemic blood pressure in subjects with hypertension (new diagnostic) and have an apnea-hypoapnea index $>15 \text{ h}^{-1}$
- Design: RCT, placebo control

**Patients with systemic hypertension recently diagnosed by primary care physician
All of them between 18-75 yr. and habitual snorers**

Fullfill all inclusion and exclusion criteria and signed the informed consent

**Nocturnal Standard Polysomnography
If AHI ≥ 15 are included in the study**

Blood samples, questionnaires, explorations and 24 hours blood pressure monitoring

Randomization

Optimal CPAP

SHAM CPAP

**Blood samples, questionnaires, explorations and 24 hours blood pressure monitoring
At 6 and 12 weeks**

Results of 24 hr. BPM

VARIABLE	BLOOD PRESSURE		Difference	P
	Basal	3 month		
SHAM CPAP				
Diurnal SBP	133 \pm 11	132 \pm 13	-0.8 \pm 8.1	0.2
Nocturnal SBP	122 \pm 14	121 \pm 15	-0.8 \pm 9.6	0.3

en la evolución del síndrome coronario agudo. Efecto de
la intervención con presión positiva continua (CPAP).
Estudio prospectivo aleatorizado. Estudio ISAACC.**

(Clinical Trials Registration Number: NCT00738170)

Estudio ISAACC

16 centros participantes
Centro coordinador: Hospital Arnau de Vilanova de Lleida.
Fecha de inicio: 2011

Estudio ISAACC

HIPOTESIS:

El síndrome de apneas del sueño es una condición infradiagnosticada entre los pacientes con Síndrome Coronario Agudo (SCA). Las repercusiones del SAHS (episodios de hipoxia-reoxigenación, arousals, cambios en la presión intrapleural) empeoran el pronóstico clínico de los sujetos con SCA reciente. El tratamiento con presión de aire positiva continua (CPAP) revierte las repercusiones del SAHS y mejora el pronóstico del paciente con SCA.

Proyectos en curso (Ámbito internacional)

Objective: To determine the effectiveness of treatment with continuous positive airways pressure (CPAP) in addition to standard care in reducing cardiovascular (CV) morbidity and mortality in patients with co-existing CV disease and moderate-severe obstructive sleep apnea (OSA). An international, multi-centre, open, parallel group, prospective, randomised, controlled trial (Clinical Trials Registration Number: NCT00738170)

Proyectos en curso (Ámbito internacional)

Objective: The Effects of Adaptive Servo Ventilation (ASV) on Survival and Frequency of Cardiovascular (CV) Hospital Admissions in Patients with Heart Failure (HF) and Sleep Apnea (SA): (Registration Number: ISRCTN67500535)

The ADVENT-HF Trial
