## Acknowledgements

Firstly I must thank Emma. Without your support and understanding this work would have not been possible. To George and Oliver, I promise to stay at home on the weekends from now on. A big thank you also goes to my Mum who has been a constant support throughout my time at university.

I would also like to thank Professors Edwards and Cavell, and Dr Graham Eastham for their support, constant encouragement and advice throughout this project. Thanks must also go to Dr Malik for determination of the crystal structures in this thesis, and Dr Tom Skelton for the catalytic work undertaken at Wilton.

Special thanks must go to Woody and Vanessa for their proof reading skills and advice in writing this thesis.

Thanks must also go to the following for keeping me entertained throughout my three years in Cardiff. Thank you Ben, Gimp, Sam, Jules, Bob, Marcus, Stu, Rhian, Nick, Emyr, Huw, Mike, Hello Dave and the folks from the local shop (Saas Grund) who's photo kept me entertained for hours at a time.

Thanks must also go to the staff of the chemistry department, without you it simply wouldn't have been possible. Thank you Gaz, Robin, Alun, Ricky, Rob Jenks and Carl.

#### Abstract

## Abstract

Several novel $o$-xylene bridged diphosphine ligands have been synthesised, and their activity tested in the palladium catalysed methoxycarbonylation of ethylene. Particular interest has been paid to the synthesis of phosphine ligands with tertiaryalkyl groups pendant to the phosphorus atoms.

Results obtained from catalysis compare favourably with ligand systems described in the chemical literature, with 1,2-bis(di-1-adamantylphosphinomethyl)benzene and 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene providing highly active catalyst systems, with selectivity towards methylpropionate.

Alternative synthetic strategies are described, which have provided novel routes to the phosphines of interest. These methodologies having increased the scope of phosphine ligand synthesis with di-tertiary-alkyl substituted species.

Several complexes of the new ligands have been prepared and characterised, giving insight into the properties of the novel ligands.

## Introduction

### 1.1.1 The phosphine; electronic and steric properties

Many properties of phosphine ligands make them desirable species to use and study in complexation chemistry and homogeneous catalysis. The synergic nature of a phosphine-metal bond means that a phosphine ligand can act as a $\sigma$-base, whilst also having $\pi$-acid characteristics. These property allows phosphine ligands to assist in the stabilisation of metal complexes in low oxidation states.

The $\sigma$-basic character of a phosphine-metal bond is derived from $\sigma$ donation of the phosphorus loan pair of electrons. The $\pi$-acidic character being due to back donation of electron density from the metal to the phosphine. The back donation is thought to be into either $\sigma^{*}$ antibonding molecular orbitals on the phosphine or empty d-orbitals on the phosphorus atom (Figure 1). ${ }^{1,2,3,4}$

Figure 1.

A second desirable feature of phosphine ligands is that they may be "tuned" for a particular purpose. Groups pendant on the phosphorus atom giving differing electronic as well as steric properties to the phosphine.

The steric properties of a coordinated monodentate phosphine are often defined by the cone angle, a parameter first described by Tolman. ${ }^{5}$ The cone angle is measured by drawing a cone such that the lines touch the outer most part of the groups bonded to the phosphorus atom, and the lines intersect at the centre of the metal atom (Figure 2).

## Chapter 1

Figure 2. Tolman cone angle

A simple measure of the $\sigma$-basicity of a phosphine is to take the pKa of the conjugate acid (i.e. the phosphonium salt), a high pKa indicating a more basic phosphine (Table 1). This method is not a true reflection of just $\sigma$-basicity, but rather a measure of the overall characteristics of the phosphine.

| Phosphine | pKa |
| :---: | :---: |
|  |  |
| $\mathrm{P}(t-\mathrm{Bu})_{3}$ | 11.40 |
| $\mathrm{P}(\mathrm{Et})_{3}$ | 8.69 |
| $\mathrm{P}(\mathrm{Ph})_{3}$ | 2.73 |

Table 1. Relative pKa of selected phosphines.

Tolman ${ }^{6}$ also devised a now widely accepted methodology to measure the relative $\pi$ acidity of a particular phosphine ligand. The $\pi$-acidity of a phosphine ligand has an effect upon other $\pi$-acidic co-ligands coordinated to a metal atom. Because a phosphine with high $\pi$-acidity will accept more of the electron density from the metal, this lessens the available electron density shared between the other coordinated ligands bound to the same d orbital. Synthesis of a number of phosphine metalcarbonyl species allowed Tolman ${ }^{6}$ to compare the relative $\pi$-acidity of the phosphine ligands by comparison of their IR spectra. As the electron density is removed from the metal by the phosphine ligand, the carbonyl ligands receive less back bonding from the metal. This has the effect of strengthening the C-O bond (the acceptor orbitals of

## Chapter 1

CO are antibonding) shifting the $\mathrm{A}_{1}$ band in the IR to a lower wave number in the IR spectrum. By comparison of the wavelength at which the $A_{1}$ band is observed, comparison of the relative $\pi$-acidity of different phosphine ligands can be made.

### 1.2 Phosphines in homogeneous catalysis

Because of the properties described in section 1.1, phosphine ligands have become widely associated with homogeneous catalytic reactions. Phosphines can be used to stabilise reactive, coordinatively unsaturated intermediates, impart chirality on a reaction or stabilise a particular oxidation state of the metal complex.

### 1.2.1 Bidentate phosphine ligands

Bidentate phosphine ligands have become increasingly important in homogeneous catalysis. This is particularly apparent in reactions where the catalyst is a four coordinate species. In these cases the tethering of the two phosphine donors often restricts the phosphine to coordinate with the two donor phosphorus atoms mutually cis to one another. This arrangement leaves the two other possible coordination sites trans to the phosphine available for coordination of the reacting substrates. This arrangement of ligands being the most favourable for reaction between coordinated substrates.

Bidentate ligands may also be used to help stabilise the metal in a particular oxidation state, through careful control of ligand bite angle. ${ }^{7,8,9}$ A pertinent example being the nickel catalysed hydrocyanation of styrene (Figure 3) described by van Leeuwen. ${ }^{10}$

Figure 3. Hydrocyanation of styrene

The rate limiting step in the reaction is known to be the reductive elimination of the product from a $\mathrm{Ni}($ II ) phosphine species. A significant influence upon the yield of the
reaction is observed as the bite angle of the bidentate phosphine (Figure 4) ligand employed is altered (Table 2). The bite angle of the phosphine ligand also influences a side reaction where excess HCN can poison the catalyst by displacing the coordinated styrene substrate, to give a catalytically inactive $\mathrm{Ni}(I I)$ species.

Figure 4. Structure of bidentate phosphine ligands used in the hydrocyanation reactions. ${ }^{10}$

The largest yields are observed with ligands that give a bite angle of $105-106^{\circ}$. The effect can be attributed to the stabilisation of the tetrahedral $\mathrm{Ni}(0)$ species by the phosphine ligand aiding the reductive elimination of the product. The bite angle of the phosphine can also disfavour the formation of the catalytically inactive square planar $\mathrm{Ni}(\mathrm{II})$ species and retards catalyst poisoning.

| X | R | Natural bite angle | Yield (\%) |
| :---: | :---: | :---: | :---: |
| $\mathrm{H}, \mathrm{H}$ | H | $101^{\circ}$ | $35-41$ |
| $\mathrm{SiMe}_{2}$ | H | $105^{\circ}$ | $94-95$ |
| S | Me | $106^{\circ}$ | $69-92$ |
| CMe | 2 | $109^{\circ}$ | $27-75$ |
| Direct bond | H | $131^{\circ}$ | 0.7 |
| $\mathrm{PPh}_{3}$ | H | - | 0 |
| $\mathrm{Ph}_{2} \mathrm{P}(\mathrm{CH})_{2} \mathrm{PPh}_{2}$ |  | $78^{\circ}$ | 51 |
| $\mathrm{Ph}_{2} \mathrm{P}(\mathrm{CH})_{3} \mathrm{PPh}_{2}$ |  | $87^{\circ}$ | $4-11$ |
| $\mathrm{Ph}_{2} \mathrm{P}(\mathrm{CH})_{4} \mathrm{PPh}_{2}$ |  | $98^{\circ}$ | $3-8$ |
| BINAP |  | $85^{\circ}$ | 4 |

Table 2.

### 1.2.2 Methoxycarbonylation of ethylene

Much of the work carried out in this area has concentrated upon the efficient synthesis of polyketones (Figure 5). The polymer being highly valued for its thermoplastic

## Chapter 1

properties and the ease with which they may be derivatised to form further functionalised polymers.

Figure 5. Structure of polyketones.

Polyketones were first synthesised (non catalytically) by Brubaker at Du pont during the 1950's. ${ }^{11}$ Using free radical initiation and extreme pressure (500-1500 bar) it was possible to produce polyketone. However, the molecular weight of the product was low, and the incorporation of carbon monoxide into the polymer chain was irregular.

During subsequent years many attempts have been made to synthesis polyketones catalytically, to control both CO incorporation and to increase the molecular weight of the polymer produced, these attempts have been based around several different transition metal catalyst systems.

The first was reported by Reppe and Magin in 1951. ${ }^{12}$ The system was based on the nickel complex $\mathrm{K}_{2} \mathrm{Ni}(\mathrm{CN})_{4}$. The catalyst gave low molecular weight polyketone along with substantial proportions of diethylketone and propionic acid.

Further work with Nickel based systems has more recently been undertaken by Klabunde et al (Figure 6). ${ }^{13}$ The complexes employed contained bidentate phosphorus - oxygen ligands similar to those found in Shells SHOP process used for the oligomerisation of alkenes. However, the yield of polymer per gram of catalyst remained low.

## Chapter 1

Figure 6. Complexes studied by Klabunde

Rhodium carbonyls have also been reported as catalysts for ethylene carbonylation. ${ }^{14}$ However, yields of high molecular weight polymer were generally low and only formed along with significant amounts of di/triketones.

The first palladium-based catalysts (bis(phosphine)palladiumdichloride) were reported by Gough at ICI in $1957 .{ }^{15}$ The synthesis of polyketone proceeded at reasonable rates $\left(300 \mathrm{~g} \mathrm{~g}^{-1}(\mathrm{Pd}) \mathrm{h}^{-1}\right)$ but required harsh reaction conditions $\left(250^{\circ} \mathrm{c}\right.$, 2000 bar) for this rate to be achieved. Also, yields of polymer (gram polymer / grams Pd cat) were low.

Not until the early 1980's was it reported that related palladium complexes (e.g. cationic [bis(triphenylphosphine)palladium(II)tetraflouroborate] in aprotic solvents could be used to give polyketone under mild reaction conditions. However the above catalytic system, employed by Sen and co workers still suffered from low reaction rates and only produced low molecular weight polymer. ${ }^{16}$

Around the same period, related cationic palladium phosphine complexes with weakly/non co-ordinating anions were being used for the alkoxycarbonylation of ethene to give methylpropionate by Shell in Amsterdam with $98 \%$ selectivity. ${ }^{17}$

Upon replacement of the monodentate triphenylphosphine ligands used in methyl propionate synthesis, with a bidentate tertiary phosphine ligand (e.g. 1,3-
bis(diphenylphosphino)propane) a change in catalyst selectivity (from methyl propionate to polyketone) was observed. Under identical conditions to those used for the synthesis of methyl propionate $\left(85^{\circ} \mathrm{c}, 45 \mathrm{bar}\right)$, the bidentate ligands gave high molecular weight polyketones at very high rates $\left(6000 \mathrm{~g} \mathrm{~g}^{-1}(\mathrm{Pd}) \mathrm{h}^{-1}\right)$, turnovers of around $10^{6}$ could be achieved. ${ }^{17}$

The polymerisation catalysts developed by Drent ${ }^{17}$ at Shell are believed to operate according to the following catalytic mechanism, where two catalytic cycles operate in tandem (Figure 7).

Figure 7. Catalytic cycle for methoxycarbonylation of ethylene

It is thought that the selectivity of the catalyst can be determined by how the two phosphorus donors are arranged around the metal atom. ${ }^{17,18}$ The bidentate ligands being constrained so that the two phosphine donors are mutually cis to one another, this being the most favourable arrangement for propagation of the growing polymer chain. Two monodentate ligands are able to isomerise from cis to trans (and trans to cis). This process is believed to be responsible for preventing chain growth, with the phosphine ligands blocking the sites required for coordination of further substrate molecules by isomerisation.

## Chapter 1

From this hypothesis Drent made the generalisation that all monodentate phosphine ligands gave cationic palladium catalysts with selectivity towards methyl propionate and bidentate ligands change the selectivity of this system to polyketones. ${ }^{18}$ This observation has subsequently been proved to be untrue.

Simply by changing the substituents on the phosphorus atoms in the bidentate phosphine ligand to bulkier groups, the selectivity of the catalyst can be change back to methylpropionate.

This phenomenon was observed by replacement of the phenyl groups in ligands such as dppp (used by Drent for polyketone catalysis) to tertiary butyl groups to yield the ligand 1,3-bis(di-tert-butylphosphino)propane, which gave a selectivity to methyl propionate of $99.6 \%{ }^{19}$

Further improvement in selectivity ( $99.8 \%$ ) has been observed at ICI with the ligand 1,2-bis(di-tert-butylphosphinomethyl)benzene. ${ }^{20}$

Whilst these new bidentate ligands also co-ordinate around the palladium center in a similar fashion to those described by Drent (i.e. with phosphorus atoms cis to one another), it is suggested that the steric bulk of the substituent groups on the phosphorus atoms have a detrimental effect upon the selectivity of the catalyst.

This can be rationalised by consideration of the steric environment created by the substituent groups on each phosphorus atom around the active metal center. The idea of "pocket angle" (Figure 8) may be used to describe the relationship between the steric bulk of the phosphines and the subsequent size of the active metal center available for the co-ordination of further groups (e.g. CO, ethene, solvent, anion).

## Chapter 1

Figure 8. The "pocket angle".

It has been suggested that there is an optimum size for the active site in $\mathrm{CO} /$ ethene polymerisation catalysts. ${ }^{21}$ It is the size of the pocket angle in the plane of the ligands around the metal center that has a significant effect on selectivity in the case of methyl propionate formation with bidentate ligands.

This observation may be explained when it is considered that the most sterically crowded species formed during the catalytic cycle is the acyl complex, which is formed as an intermediate prior to alkene insertion. In order for chain propagation to occur (in the case of polyketones), it is necessary for ethene to co-ordinate to the metal so that insertion (and therefore propagation) can take place. However, it is apparent that the size of the pocket angle created by the steric bulk of the bidentate phosphine ligand can retard such a reaction. Hence, propagation of the polymer chain becomes unfavourable and methanolysis to give methyl propionate (and regenerate the active catalyst) is observed. Pocket angle and activity data for several o-xylene diphosphine ligands with different substituents are collected in Table 3. ${ }^{22}$

## Chapter 1

L) $\operatorname{Pd}(\mathrm{DBA})]$ complex. ${ }^{22}$

Table 3.

The catalytic cycle for the synthesis of methylpropionate with sterically bulky bidentate phosphine ligands is believed to be different from that shown in Figure 7 for the synthesis of polyketones. Work by Eastham has studied the mechanism via variable temperature NMR spectroscopy, and implies that only one half of the catalytic cycle depicted in Figure 7, is active in MEP synthesis. It is thought that only the hydride cycle is active in these systems (Figure 9). ${ }^{23}$

Figure 9. The Hydride cycle

## Chapter Two

## Chapter 2

### 2.1 Introduction.

### 2.1.1 Tertiary-butyl substituted phosphines.

Phosphines substituted with the tertiary-butyl functionality have proven to be remarkably successful ligands in a variety of homogeneous catalytic reactions. A pertinent example being the use of tris(t-butyl)phosphine in the palladium catalysed Heck coupling of arylchlorides with methyl acrylate. ${ }^{1}$ Part of the reason for the high reactivity of catalysts derived from this phosphine is the activating effect of the phosphine's high basicity. This criterion can in turn be attributed to the $t$-butyl functionality.

Sterically demanding spectator ligands may also play an important role in the stabilisation of reactive intermediates during catalytic or indeed any other organometallic reaction. The phosphine ligand described in this chapter, namely 1,2-bis(di-t-butylphosphinomethyl)benzene 1 , has previously been shown to stabilise reactive palladium alkyl and palladium hydride species important in the alkoxycarbonylation of ethylene. ${ }^{2}$

### 2.1.2 Ligand synthesis.

The first example of the synthesis of an ortho-xylene bridged alkyl diphosphine was described by Moulton and Shaw. ${ }^{3}$

In this example, the phosphonium bromide salt of 1,2-bis(di-tbutylphosphinomethyl)benzene 1 was synthesised via the nucleophilic addition of two equivalents of di-t-butylphosphine 2 to $\alpha, \alpha$ 'dibromo-ortho-xylene (Scheme 1). The phosphine was liberated upon subsequent treatment with base.

Scheme 1. Shaw's synthesis of 1,2-bis(di-t-butylphosphinomethyl)benzene ${ }^{3}$

## Chapter 2

This strategy, although providing convenient access to these compounds, has limited potential due to its poor yield (typically $<40 \%$ ). The low yield of phosphonium salt is explained by the formation of a second product, where the singly substituted intermediate in the reaction cyclises to give an iso-phosphindolinium salt (Figure 1).

Figure 1. 2,2 di-t-butyl iso-phosphindolinium bromide
Subsequently, it has become desirable to develop a higher yielding route to 1 and other related ortho-xylene bridged diphosphine ligands.

Edwards et al (scheme 2) ${ }^{4}$ have previously described such a strategy for the synthesis of 1 . A hexane solution of $o$-xylene, ${ }^{n} \mathrm{BuLi}$ and $\mathrm{KO}^{t} \mathrm{Bu}$ was heated under reflux to afford $\alpha, \alpha^{\prime}$ dipotassio-ortho-xylene as a red pyrophoric solid. Subsequent reaction of the organopotassium with two equivalents of di-t-butylchlorophosphine ${ }^{5} 2$ in diethyl ether afforded 1 in $85 \%$ yield.

Scheme 2. An alternative synthesis of $1 .{ }^{4}$

The chemistry described by Edwards et al provides an efficient and high yielding route to ortho-xylene bridged alkyl diphosphine ligands. However, the synthesis is only applicable to ortho-xylene and requires the desired chlorophosphine to be readily available.

### 2.1.3 Phosphine borane adducts.

Borane adducts of primary and secondary phosphines have proven to be useful in the synthesis of new tertiary phosphine ligands. Their chemistry has recently been reviewed. ${ }^{6}$

Commonly the tertiary phosphines that have previously been synthesised via a borane adduct carry the diphenyl functionality. ${ }^{7}$ Examples of alkyl phosphines synthesised from their borane adducts are less common. Imamoto et al ${ }^{8}$ have recently described the synthesis of (S,S)-1,2-bis(t-butylmethylphosphinotrihydroboronmethyl)benzene from the corresponding optically active secondary phosphine-borane adduct (Scheme 3). However, there are no examples in the chemical literature of the synthesis of a tertiary phosphine-borane adduct, where the phosphorus carries two tertiary-alkyl substituents.

The deprotonation, alkylation procedure described by Imamoto $^{7}$ and previous workers, ${ }^{9,10,11}$ seemed a pertinent methodology to extend to the ligands of interest in this work.

Scheme 3. Imamoto's synthesis

The chemistry of the borane functionality is such that it aids the deprotonation of the secondary phosphine-borane adduct by inductively removing some of the electron
density from the phosphorus atom to render the P-H proton more acidic. This effect is particularly important in tertiary-alkyl substituted species where these groups cause the phosphorus to be particularly electron rich. A second effect of the borane group is that the deprotonated phosphide is less basic than its borane free counterpart. Therefore, their application is advantageous if base catalysed elimination and other undesirable side reactions are to be avoided. ${ }^{6}$

This chapter describes a novel, alternative synthesis of 1 . The methodology is applicable to a wide variety of substrates (both in terms of organophosphorus starting material and backbone) and potentially provides an effective strategy for the synthesis of a wider variety of new tertiary-alkyl substituted phosphine ligands. Some novel metal complexes of 1 are also described.

### 2.2 Results and discussion.

### 2.2.1 Ligand synthesis.

Di-tertiary-butylchlorophosphine 2 was synthesised by the known literature methodology. ${ }^{5}$ Di-tertiary-butylphosphine 3 was synthesised via the reduction of 2 with $\mathrm{LiAlH}_{4}$ in diethyl ether.

### 2.2.1.1 Di-tertiary-butylphosphinetrihydroboron 4.

Reaction of di-tertiary-butylphosphine 3 with an excess of borane-THF adduct afforded di-tertiary-butylphosphinetrihydroboron 4 as a white solid in quantitative yield. It was noted that the solid readily sublimed when warmed under vacuum. The structure of 4 was confirmed by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum displayed a broad quartet with a chemical shift of 48.55 ppm ( ${ }^{1} J_{\mathrm{P}-\mathrm{B}} 44.65 \mathrm{~Hz}$ ) as expected for coupling to a nuclei with a spin of $3 / 2$. The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a doublet with a chemical shift of -43.31 ppm .

The ${ }^{1} H$ NMR Spectrum is dominated by the doublet assigned to the eighteen tertiarybutyl protons ( $\delta_{\mathrm{H}} 1.25 \mathrm{ppm}$ ). A smaller doublet of quartets centred at $\delta_{\mathrm{H}} 4.07 \mathrm{ppm}$ is also observed for the proton directly bound to the phosphorus atom, the AMX pattern observed being consistent with coupling to both phosphorus and boron. The coupling constant was found to be ${ }^{1} J_{\mathrm{H}-\mathrm{P}} 430.74 \mathrm{~Hz}$.

## Chapter 2

### 2.2.1.2 1,2-bis(di-tertiary-butylphosphinotrihydroboronmethyl)benzene 5.

1,2-bis(di-tertiary-butylphosphinotrihydroboronmethyl)benzene 5 was synthesised by the method described by Inamoto et al ${ }^{8}$ for the synthesis of the related compound (S,S)-1,2-bis(tertiary-butylmethylphosphinotrihydroboronmethyl)benzene (scheme 3).

A variety of bases and conditions were investigated for the deprotonation of 4.
When the reaction was carried out with ${ }^{n} \mathrm{BuLi}$ as the base, 5 was obtained in only poor yield ( $<20 \%$ ). ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy performed after the addition of the base revealed that 4 was only partially deprotonated with 1.2 equivalents of ${ }^{\mathrm{n}} \mathrm{BuLi}$. Indeed, after the reaction mixture was left to stand at room temperature, the small amount of lithium phosphide in solution rapidly reprotonated to reform 4.

Further experiments revealed that a stronger base is required to fully deprotonate 4. The most effective and reproducible was found to be $\sec$ - BuLi . The dropwise addition of $\sec -\mathrm{BuLi}$ to a cooled $\left(-78^{\circ} \mathrm{C}\right)$ THF solution of 4 affords an intensely coloured (yellow) solution of lithium di-tertiary-butylphosphidetrihydroboron. The reaction can be followed by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ or ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy. The lithium di-tertiarybutylphosphidetrihydroboron was observed as a broad quartet with a chemical shift of $\delta_{\mathrm{P}} 5.73 \mathrm{ppm}$ in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum and as a doublet at $\delta_{\mathrm{B}}-36.59 \mathrm{ppm}$ in its ${ }^{11} B\left\{{ }^{1} H\right\}$ NMR spectrum.

After stirring the solution at room temperature for 2 hrs and then recooling $\left(-78^{\circ} \mathrm{C}\right)$, a THF solution of $\alpha, \alpha^{\prime}$ dichloro-ortho-xylene was added dropwise to afford 5 (Scheme 4) in $93 \%$ yield.

Scheme 4. Synthesis of 5.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra of 5 are fully consistent with the proposed structure. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consists of a broad quartet, with a
chemical shift of $\delta_{\mathrm{P}} 55.42 \mathrm{ppm}\left({ }^{1} J_{\mathrm{P}-\mathrm{B}} 68.48 \mathrm{~Hz}\right.$ ). As would be expected the quartet has shifted downfield by 6.87 ppm upon alkylation of the secondary phosphine-borane adduct $\mathbf{4}$ to form the tertiary phosphine-borane adduct 5 . The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows the expected doublet at $\delta_{\mathrm{B}}-42.30 \mathrm{ppm}$.

The ${ }^{1} \mathrm{H}$ NMR spectrum is again dominated by the tertiary-butyl protons that are observed as a doublet centred at $\delta_{\mathrm{H}} 1.24 \mathrm{ppm}\left({ }^{3} J_{\mathrm{H}-\mathrm{P}} 12.30 \mathrm{~Hz}\right)$. The methylene protons are also observed as a doublet ( $\delta_{\mathrm{H}} 3.37 \mathrm{ppm},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 11.88 \mathrm{~Hz}$ ). Two complex resonances are also observed for the two sets of equivalent aromatic protons ( $\delta_{\mathrm{H}} 7.14$ and $\left.\delta_{\mathrm{H}} 7.59 \mathrm{ppm}\right)$. Colourless crystals of 5 were obtained from a concentrated chloroform solution that was layered with methanol.

The solid-state structure of $\mathbf{5}$ has been determined by X-ray diffraction (figure 2) and is consistent with the solution structure as determined by NMR spectroscopy. Selected bond lengths and angles are given in Table 1.

Figure 2. Crystal structure of 5. Hydrogen atoms have been omitted for clarity. Thermal ellipsoids are drawn at $50 \%$ probability.

## Chapter 2

| Bond | Distance $(\AA)$ | Group | Angle ( ${ }^{\circ}$ ) |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}_{1}-\mathrm{P}_{1}$ | $1.843(3)$ | $\mathrm{C}_{7}-\mathrm{C}_{8}-\mathrm{P}_{2}$ | $118.69(19)$ |
| $\mathrm{C}_{8}-\mathrm{P}_{2}$ | $1.854(3)$ | $\mathrm{C}_{2}-\mathrm{C}_{1}-\mathrm{P}_{1}$ | $119.12(19)$ |
| $\mathrm{P}_{1}-\mathrm{B}_{1}$ | $1.939(4)$ | $\mathrm{C}_{8}-\mathrm{P}_{2}-\mathrm{B}_{2}$ | $114.93(14)$ |
| $\mathrm{P}_{2}-\mathrm{B}_{2}$ | $1.939(4)$ | $\mathrm{C}_{1}-\mathrm{P}_{1}-\mathrm{B}_{1}$ | $116.27(15)$ |
| $\mathrm{P}_{2}-\mathrm{C}_{21}$ | $1.873(3)$ | $\mathrm{C}_{21}-\mathrm{P}_{2}-\mathrm{B}_{2}$ | $109.54(15)$ |
| $\mathrm{P}_{2}-\mathrm{C}_{17}$ | $1.877(3)$ | $\mathrm{C}_{8}-\mathrm{P}_{2}-\mathrm{C}_{21}$ | $107.81(13)$ |
| $\mathrm{P}_{1}-\mathrm{C}_{13}$ | $1.867(3)$ | $\mathrm{C}_{17}-\mathrm{P}_{2}-\mathrm{C}_{21}$ | $112.10(14)$ |
| $\mathrm{P}_{1}-\mathrm{C}_{9}$ | $1.866(3)$ | $\mathrm{C}_{17}-\mathrm{P}_{2}-\mathrm{B}_{2}$ | $109.96(15)$ |
|  |  | $\mathrm{C}_{9}-\mathrm{P}_{1}-\mathrm{B}_{1}$ | $109.40(19)$ |
|  |  | $\mathrm{C}_{1}-\mathrm{P}_{1}-\mathrm{C}_{9}$ | $106.71(13)$ |
|  | $\mathrm{C}_{13}-\mathrm{P}_{1}-\mathrm{B}_{1}$ | $110.04(19)$ |  |
|  | $\mathrm{C}_{9}-\mathrm{P}_{1}-\mathrm{C}_{13}$ | $112.03(13)$ |  |

Table 1. Selected bond lengths and angles for 1,2-bis(di-tertiarybutylphosphinotrihydroboronmethyl)benzene 5.

The two phosphorus atoms can be seen to take the anti conformation (figure 2), in order to minimise steric interactions between the four bulky tertiary-butyl groups. The mean C-P-C and C-P-B angles were found to be $110.43^{\circ}(15)$ close to the expected ideal angle of $109.5^{\circ}$ for a non-constrained tertiary-phosphine-borane adduct. The C$P$ bond lengths compare favorably to those previously reported for the free phosphine. ${ }^{12}$ The mean C-P bond length being $1.884 \AA$ in the free phosphine and slightly shorter at $1.863(3) \AA$ for 5.

### 2.2.1.3 1,2-bis(di-tertiary-butylphosphinomethyl)benzene 1.

In order to remove the protective borane group from the phosphine, there are a number of protocols suggested by the chemical literature. The most common is the exchange of the borane group from the phosphine-borane to an alternative lewis base. ${ }^{7,8}$ Although phosphine-boranes are more stable than amine-borane adducts, equilibria allow the borane group to migrate to the amine. For this reason and their availability, amines have commonly been employed in deprotection reactions. ${ }^{9}$

To effect deprotection in a "one pot" procedure it is necessary to heat the phosphineborane under reflux in the presence of a strongly basic amine ( $N, N, N, N-$ tetramethyldiaminoethane (TMEDA), morpholine, triethylamine) (Scheme 5).

Scheme 5. De-protection of phosphine-borane adducts

Deprotection following this methodology can also be carried out in the presence of "catalytically active" metals, in a deprotection/complexation procedure. The precatalyst Rh (DIOP) has been prepared in this way without loss of activity in subsequent asymmetric hydrogenation reactions when compared to the catalyst precursor prepared by the conventional route. ${ }^{10}$

Samples of 5 were heated under reflux in toluene in the presence of an excess of several different amines (triethylamine, TMEDA, 1,4-diazabicyclo[2.2.2]octane \{DABCO\}). However, it was found that in all cases this methodology did not afford the complete deprotection of the phosphine (determined via ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy). Complete exchange of the borane function from 5 was only achieved after several cycles with fresh amine, which was found to be rather inconvenient and gave much-reduced yields of 1 .

In common with Livinghouse et al ${ }^{11}$ it was found that deprotection of more electron rich phosphine-boranes such as 5 were better achieved via treatment with several equivalents of a strong acid $\left(\mathrm{MeSO}_{3} \mathrm{H}\right.$ or $\left.\mathrm{HBF}_{4} . \mathrm{OMe}_{2}\right)$ to form a phosphonium salt of 1. The phosphine was then liberated on addition of an excess of base $(\mathrm{NaOH}$, $\mathrm{NaHCO}_{3}$ ). This work highlights one of the limitations of the borane exchange chemistry, where more basic phosphines such as 1 hold the equilibrium towards the left-hand side (Scheme 5), often preventing complete deprotection of the phosphineborane adduct. It may be for this reason that examples of borane deprotection in the literature via the borane exchange methodology are limited to aryl and less basic alkyl phosphines. ${ }^{7}$

## Chapter 2

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR Spectra are fully consistent with the proposed structure of 1 and with that previously reported ${ }^{3,4,12}$ As expected the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows a singlet with a chemical shift of $\delta_{\mathrm{P}} 28.06 \mathrm{ppm}$ indicative of the fact that the two phosphorus atoms are chemically equivalent. Again, as observed with the previously described compounds 4 and 5, the ${ }^{1} \mathrm{H}$ NMR spectrum is dominated by the resonance assigned to the $t$-butyl protons, which are observed as a sharp doublet with a chemical shift of $\delta_{\mathrm{H}} 1.14 \mathrm{ppm}\left({ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.77 \mathrm{~Hz}\right.$ ). As with 5 the methylene protons are also observed as a doublet, and have a chemical shift of $\delta_{\mathrm{H}} 3.03 \mathrm{ppm}\left({ }^{2} J_{\mathrm{H}-\mathrm{P}} 2.85 \mathrm{~Hz}\right)$. Two multiplets observed at $\delta_{\mathrm{H}} 7.05$ and 7.53 ppm were assigned to the aromatic protons of the $o$-xylene moiety.

### 2.2.2 Complexation chemistry.

### 2.2.2.1 [chloro (1,2-bis(di-tertiary-butylphosphinomethyl)benzene) silver (I)] 6.

The title compound was synthesised via the reaction of 1.5 equivalents of 1 with silver trifluoromethanesulphonate, and subsequently sodium chloride in dichloromethane to afford 6 as a colourless solid.

The particular interest in the silver (I) system lies in the fact that it can adopt a range of coordination numbers from 2 to 4 , and the preference for a particular geometry with chelating ligands is largely ligand dependent and influenced by the length and rigidity of the moiety connecting donor atoms as well as the steric size of other substituents. These parameters are of course, of interest in homogeneous catalysis.

Coordination studies with silver (I) halide ions and chelating diphosphines have previously been performed and a range of structures are observed (Figure 3). ${ }^{13}$

B

C

D

Figure 3. Range of observed structures. (The zig-zag lines represent a range of bridging groups).

Commonly, diphosphine ligands with long chains between the phosphorus atoms and small to medium sized substituents (e.g. phenyl) at phosphorus e.g. 1,5bis(diphenylphosphino) pentane give complexes of type $B$ with the diphosphine bridging two metal centres to give a dimer. ${ }^{14}$ The dimer also has two bridging halide ligands.

When the length of the chain between phosphine donors is shortened, structural type C is usually observed. In this case the diphosphine chelates a single metal atom and the dimer is supported only by the bridging halide ions. Interestingly, when the phenyl analogue of 1 (1,2-bis(diphenylphosphinomethyl) benzene) is used as the phosphine ligand the structural type observed is $\mathrm{C}^{13}$ The dimeric silver atoms are held in a tetrahedral environment with two halide ions bridging between the two metal ions.

The effect of steric bulk from the $t$-butyl groups in 1 is neatly demonstrated by the fact that the silver chloride complex derived from this ligand falls into the trigonal planar motif, A. This appears to be consistent with other bulky tertiary-butyl substituted diphosphine ligands (e.g.2,11-bis[(di-tert-butylphosphino)methyl]
benzophenanthrene) which also gives $\mathrm{Ag}(\mathrm{I})$ complexes with the trigonal planar arrangement of ligands. ${ }^{15}$ A similar structure is also observed for the related 3coordinate $d^{10}$ palladium(0) complex described by Bellabarba and Tooze where the same chelating phosphine ligand 1 is coordinated (Figure 4). ${ }^{31}$

Figure 4. [1,2-bis(di-t-butylphosphinomethyl)benzene carbonyl palladium (0)] ${ }^{31}$ The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra of 6 are consistent with the assigned structure of 6 . The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum displays the expected two doublets (P-Ag coupling) both having a chemical shift of $\delta_{\mathrm{P}} 79.80 \mathrm{ppm}$. Each doublet can be distinguished due to the difference in coupling constant between phosphorus and the two spin $1 / 2$ isotopes of silver, $\mathrm{Ag}^{107}$ and $\mathrm{Ag}^{109}\left({ }^{1} J_{\mathrm{P}-\mathrm{Ag}} 407.42 \mathrm{~Hz}\right.$ and ${ }^{1} J_{\mathrm{P}-\mathrm{Ag}} 541.88 \mathrm{~Hz}$ respectively). Again, as observed with the free ligand 1 the ${ }^{1} \mathrm{H}$ NMR spectrum is dominated by the doublet assigned to the tertiary-butyl protons ( $\delta_{\mathrm{H}} 1.32 \mathrm{ppm},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 6.37 \mathrm{~Hz}$ ). A doublet observed at $\delta 3.25 \mathrm{ppm}$ can be assigned to the methylene protons, and two multiplets assigned to the aromatic protons $\delta_{\mathrm{H}} 6.92$ and 7.20 ppm .

### 2.2.2.2 [(1,2-bis(di-tertiary-butylphosphinomethyl)benzene)tetracarbonyl molybdenum (0)] 7

The title compound 7 was synthesised via the reaction of one equivalent of 1 with cisbis(piperidine)tetracarbonylmolybdenum(0) ${ }^{16} 8$ in warm dichloromethane. Initially upon addition of the dichloromethane solution of 1 to 8 , an orange coloured suspension was obtained. Upon heating, the orange solid 8 dissolved to afford a yellow coloured solution. After the solution was allowed to cool, no precipitation of 8 was observed, indicating the reaction had taken place.

Colourless X-ray quality crystals of 7 were grown from a chloroform solution layered with methanol. The X-ray crystal structure of 7 is shown in Figure 5. Selected bond distances and angles are given in Table 2.

Figure 5. Crystal structure of 7. Hydrogen atoms have been omitted for clarity.
Thermal ellipsoids are drawn at $50 \%$ probability.

| Bond | Length $(\AA)$ | Group | Angle $\left({ }^{\circ}\right)$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{P}_{1}-\mathrm{Mo}_{1}$ | $2.658(6)$ | $\mathrm{P}_{1}-\mathrm{Mo}_{1}-\mathrm{P}_{2}$ | $94.161(18)$ |
| $\mathrm{P}_{2}-\mathrm{Mo}_{1}$ | $2.658(6)$ | $\mathrm{C}_{5}-\mathrm{P}_{1}-\mathrm{C}_{9}$ | $109.82(11)$ |
| $\mathrm{P}_{1}-\mathrm{C}_{13}$ | $1.879(2)$ | $\mathrm{C}_{25}-\mathrm{P}_{2}-\mathrm{C}_{21}$ | $109.97(10)$ |
| $\mathrm{P}_{2}-\mathrm{C}_{20}$ | $1.869(2)$ | $\mathrm{C}_{13}-\mathrm{P}_{1}-\mathrm{C}_{5}$ | $96.19(11)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{1}$ | $2.035(2)$ | $\mathrm{C}_{20}-\mathrm{P}_{2}-\mathrm{C}_{25}$ | $97.05(10)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{2}$ | $1.964(2)$ | $\mathrm{C}_{1}-\mathrm{Mo}_{1}-\mathrm{C}_{3}$ | $160.79(10)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{3}$ | $2.035(2)$ | $\mathrm{C}_{2}-\mathrm{Mo}_{1}-\mathrm{C}_{4}$ | $86.15(10)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{4}$ | $1.969(2)$ |  |  |
| $\mathrm{C}_{1}-\mathrm{O}_{1}$ | $1.144(3)$ |  |  |
| $\mathrm{C}_{2}-\mathrm{O}_{2}$ | $1.162(3)$ |  |  |
| $\mathrm{C}_{3}-\mathrm{O}_{3}$ | $1.142(3)$ |  |  |
| $\mathrm{C}_{4}-\mathrm{O}_{4}$ | $1.157(3)$ |  |  |

Table 2. Selected bond lengths and angles for [(1,2-bis(di-tertiarybutylphosphinomethyl)benzene)tetracarbonyl molybdenum (0)] 7.

Reaction via substitution of the two cis-piperidine ligands of 8 led to the desired 1:1 $\mathrm{Mo}(\mathrm{CO})_{4}(1)$ complex, where the molybdenum tetracarbonyl fragment is chelated by the phosphine ligand.

The solid state structure of 7 (Figure 5), shows a $\mathrm{P}_{1}-\mathrm{Mo}_{1}-\mathrm{P}_{2}$ "bite" angle of $94.161(18)^{\circ}$ slightly larger than the $90.0^{\circ}$ expected in an ideal octahedral environment. Conversely, the carbonyl ligands trans to the phosphine give a smaller C-Mo-C angle of $86.15(10)^{\circ}$ in order to accommodate the slightly enlarged bite angle dictated by the rigid, chelating phosphine ligand.

The carbonyl ligands cis to the phosphine are also noticeably distorted out of the $z$ axis and away from the phosphine ligand giving a $\mathrm{C}_{1}-\mathrm{Mo}_{1}-\mathrm{C}_{3}$ angle of $160.79(10)^{\circ}$, a consequence of the steric bulk of the tertiary-butyl groups on the phosphine ligand 1.

As would be expected, the mean Mo-C bond length for the carbonyl ligands trans to the phosphine is $1.967(2) \AA$, marginally shorter than that for the carbonyls (2.035(2) $\AA$ ) cis to the phosphorus donors. The effect is attributed to the change in bond order resulting from the influence of the relative $\pi$ acidity of the ligand trans to the carbonyl. The bond lengths compare favourably to those previously observed in the related Molybdenum tetracarbonyl complex of the bidentate phosphine, dppm (1,1bis(diphenylphosphino)methane). ${ }^{17}$ Again the same trend between Mo-CO bond lengths of the cis and trans carbonyls is observed. The P-Mo and Mo-C bond lengths observed for 7 are comparable to those previously reported by Cheung et al. ${ }^{17}$

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with the proposed formulation of 7. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows the expected singlet with a chemical shift of $\delta_{\mathrm{P}} 57.28 \mathrm{ppm}$ for the two chelating phosphorus atoms in a chemically equivalent environment. The 36 tertiary-butyl protons are observed as a doublet with a chemical shift of $\delta_{\mathrm{H}} 1.42 \mathrm{ppm}\left({ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.98 \mathrm{~Hz}\right)$ in the ${ }^{1} \mathrm{H}$ NMR spectrum. The methylene protons are also observed as a doublet ( $\delta_{\mathrm{H}} 3.32 \mathrm{ppm},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 6.36 \mathrm{~Hz}$ ). Two multiplets ( $\delta_{\mathrm{H}} 7.08 \mathrm{ppm}, \delta_{\mathrm{H}} 7.31 \mathrm{ppm}$ ) can be assigned to the two sets of chemically equivalent aromatic protons of the ortho-xylene backbone.

The (APCI) mass spectrum of 7 shows the molecular ion $\left(\mathrm{M}^{+}\right)$at $m / z$ 604.5. The fragment due to the loss of one carbonyl ligand $\left(\mathrm{M}^{+},-\mathrm{CO}\right)$ was also observed at $\mathrm{m} / \mathrm{z}$ 576.5.

The Infrared spectrum of 7 showed four strong absorptions in the carbonyl region ( $v$ co 2001, 1877, 1871(br, sh) $\mathrm{cm}^{-1}$ ), which are assigned to the $\mathrm{A}_{1}{ }^{(2)}, \mathrm{A}_{1}{ }^{(1)}, \mathrm{B}_{1}$ and $\mathrm{B}_{2}$ stretching modes of the carbonyl ligands respectively. The infrared spectrum of $\mathbf{7}$ is consistent with that reported for the related molybdenum tetracarbonyl complex of the $\mathrm{C}_{4}$ bridged diphosphine dppb (1,4 bis(diphenyl phosphino)butane) (Figure 6). ${ }^{17}$ The carbonyl stretches were reported at $v_{\mathrm{CO}} 2022,1916,1900,1884 \mathrm{~cm}^{-1},{ }^{17}$ the increase in wave number reflecting the higher $\pi$ acidity of the phenyl substituted phosphine dppb when compared to 1.

Figure 6.

### 2.2.2.3 [bis(acetonitrile)(1,2-bis(di-tertiary-butylphosphino methyl)benzene) palladium bis(tetrafluoroborate)] 9 .

The title compound 9 was synthesised via the reaction of one equivalent of 1 with [tetrakis(acetonitrile)palladium(II)] bis(tetrafluoroborate) $\mathbf{1 0}$ in acetonitrile as solvent. After stirring for three hours, the volume of solvent was reduced by half under vacuum. The dropwise addition of diethyl ether to the solution then caused the precipitation of 9 as a crystalline yellow solid.

The compound is observed to be the $1: 1$ complex. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with this formulation. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows a singlet with a chemical shift of $\delta_{\mathrm{p}} 50.74 \mathrm{ppm}$. In common with the previously
described compounds, the $t$-butyl protons are observed as a doublet and have a chemical shift of $\delta_{\mathrm{P}} 1.52 \mathrm{ppm}\left({ }^{3} J_{\mathrm{H}-\mathrm{P}} 15.18 \mathrm{~Hz}\right)$. The methylene protons are also observed as a doublet ( $\delta_{\mathrm{H}} 3.73 \mathrm{ppm},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 9.03 \mathrm{~Hz}$ ) with the four aromatic protons of the ortho-xylene backbone being assigned to two multiplets observed at $\delta_{\mathrm{H}} 7.33 \mathrm{ppm}$ and $\delta_{\mathrm{H}} 7.49 \mathrm{ppm}$. The six protons of the acetonitrile ligands are observed as a singlet with a chemical shift of $\delta_{\mathrm{H}} 2.18 \mathrm{ppm}$, slightly downfield from free acetonitrile.

Two peaks in the infra-red spectrum of 9 were observed for the nitrile bonds of the coordinated acetonitrile ligands ( $v_{\mathrm{CN}} 2312,2282 \mathrm{~cm}^{-1}$ ), along with two broader absorptions with lower wavenumber for the $\mathrm{BF}_{4}{ }^{-}$counter ions ( $v_{\mathrm{BF}} 1084,1028 \mathrm{~cm}^{-1}$ ). This is consistent with the data reported for the related complex [bis(acetonitrile)(1,3-bis(di-n-heptylphosphino)propane)palladium bis(tetrafluoroborate) ${ }^{19}$ ( $v_{\mathrm{CN}} 2323,2294$ $\mathrm{cm}^{-1}$ ) and ( $\mathrm{v}_{\mathrm{BF}} 1063 \mathrm{~cm}^{-1}$ ). The lower wave numbers $\left(v_{\mathrm{CN}}\right)$ reflecting the influence of the more $\pi$ acidic phenyl phosphine ligand trans to the acetonitrile ligands when compared to complex 9.

At first glance the complex 9 appears to be unremarkable. However, it is unusual in the respect that it was synthesised via a source of $\mathrm{Pd}(\mathrm{II})$. Often, the reaction of orthoxylene bridged diphosphine ligands with Pd(II) species (and other divalent sources of group X metals), does not lead to a complex where the phosphine is in the usual $\kappa^{2}$ chelating coordination mode.

This observation is neatly demonstrated by the work of Clegg et al. ${ }^{20}$ Reaction of 1 with the $\mathrm{Pd}(\mathrm{II})$ source $\left(\mathrm{Pd}(\mathrm{OAc})_{2}\right)$ in acetone leads to a dimeric complex (Figure 7). Each of the phosphine donors is coordinated to one of two $\mathrm{Pd}(\mathrm{OAc})$ moieties rather than chelating a single metal atom. Both of the Palladium atoms are then orthometallated to the aromatic ring of the ortho-xylene backbone to form two five membered chelate rings.

Figure 7. Complex synthesised by Clegg et al. ${ }^{20}$

### 2.2.2.4 [trichloro (1,2-bis(di-t-butylphosphinomethyl)benzene) nickel (II)] 11.

An unusual coordination mode was also observed when one equivalent of 1 was reacted with [dichloro(1,2-dimethoxyethane) $\mathrm{Ni}(\mathrm{II})]^{21} 12$ in dichloromethane. After stirring for three hours, the deep green solution was concentrated under vacuum. Slow vapour diffusion of diethyl ether into the dichloromethane solution gave 11 as a crop of deep blue crystals.

The solid state structure was determined by X-ray diffraction (Figure 8). Selected bond lengths and angles are given in Table 3.

| Bond | Length $(\AA)$ | Group | Angle ( ${ }^{\circ}$ ) |
| :---: | :---: | :---: | :---: |
| $\mathrm{Ni}_{1}-\mathrm{Cl}_{1}$ | $2.258(2)$ | $\mathrm{Cl}_{1}-\mathrm{Ni}_{1}-\mathrm{Cl}_{2}$ | $102.12(11)$ |
| $\mathrm{Ni}_{1}-\mathrm{Cl}_{2}$ | $2.268(3)$ | $\mathrm{Cl}_{2}-\mathrm{Ni}_{1}-\mathrm{Cl}_{3}$ | $120.12(12)$ |
| $\mathrm{Ni}_{1}-\mathrm{Cl}_{3}$ | $2.258(3)$ | $\mathrm{Cl}_{3}-\mathrm{Ni}_{1}-\mathrm{Cl}_{1}$ | $111.63(11)$ |
| $\mathrm{P}_{1}-\mathrm{Ni}_{1}$ | $2.563(3)$ | $\mathrm{C}_{1}-\mathrm{P}_{1}-\mathrm{Ni}_{1}$ | $117.2(3)$ |
| $\mathrm{C}_{1}-\mathrm{P}_{1}$ | $1.866(9)$ | $\mathrm{P}_{1}-\mathrm{Ni}_{1}-\mathrm{Cl}_{1}$ | $110.79(10)$ |
| $\mathrm{C}_{6}-\mathrm{P}_{1}$ | $1.885(7)$ | $\mathrm{P}_{1}-\mathrm{Ni}_{1}-\mathrm{Cl}_{2}$ | $110.38(9)$ |
| $\mathrm{C}_{2}-\mathrm{P}_{1}$ | $1.889(7)$ | $\mathrm{P}_{1}-\mathrm{Ni}_{1}-\mathrm{Cl}_{3}$ | $101.98(12)$ |

| $\mathrm{C}_{17}-\mathrm{P}_{2}$ | $1.855(8)$ | $\mathrm{C}_{16}-\mathrm{P}_{2}-\mathrm{C}_{17}$ | $108.4(4)$ |
| $\mathrm{C}_{21}-\mathrm{P}_{2}$ | $1.838(8)$ | $\mathrm{C}_{21}-\mathrm{P}_{2}-\mathrm{C}_{17}$ | $119.3(4)$ |
|  | $\mathrm{C}_{16}-\mathrm{P}_{2}-\mathrm{C}_{21}$ | $110.4(4)$ |  |

Table 3. Selected bond lengths and angles for 11.

Figure 8.Crystal structure of $\mathbf{1 1}$. Hydrogen atoms have been omitted for clarity.
Thermal ellipsoids are drawn at $50 \%$ probability.

The crystal structure of 11 shows that only one of the phosphines has coordinated to the nickel atom. A third chloride ligand is also coordinated giving an anionic Nickel (II) species. The second phosphorus atom is protonated to form a phosphonium ion and carries a positive charge to become the counter ion for the negatively charged metal fragment. The source of the additional chloride ligand and proton remains unclear, but could be from either the solvent or residual 12 (the yield of $63 \%$ may suggest the solvent). The mean bond angle around the nickel ( $\mathrm{P}-\mathrm{Ni}-\mathrm{Cl}$ and $\mathrm{Cl}-\mathrm{Ni}-\mathrm{Cl}$ ) was found to be $109.50(12)^{\circ}$. The long P-Ni bond (2.563(3) $\AA$ ) is consistent with that previously measured for other complexes of this type. ${ }^{24}$

The complex was found to be paramagnetic ( $\mu=4.1 \mathrm{BM}$ in dichloromethane) (Evans method), in common with some other tetrahedral $\mathrm{Ni}(\mathrm{II})$ complexes described in the literature. ${ }^{22,} 23,24,25$ Indeed, reaction of the phenyl analogue of 1 (1,2bis(diphenylphosphinomethyl) benzene) with $\mathrm{NiCl}_{2}$ also gave a paramagnetic
complex. ${ }^{22}$ The red coloured complex synthesised by Camilla et al ${ }^{22}$ was only partially characterised, but formulated as a tetrahedral ([(L-L)NiX $\left.{ }_{2}\right]$ ) Nickel(II) complex, with the phosphine chelating the Ni atom.

Other, paramagnetic tetrahedral $\mathrm{Ni}(\mathrm{II})$ complexes are also known, the Nickel dichloride complex of the phosphine 2,3-o-isopropylidene-2,3-dihydroxy-1,4-bis (diphenylphosphino)butane (DIOP) was characterised by X-Ray crystallography, ${ }^{23}$ again the diphosphine ligand chelates the metal atom.

It appears that the steric size of the phosphine ligand employed here has a dramatic effect upon the structure of the observed complex. Reaction of $\mathrm{NiCl}_{2}$ with two equivalents of sterically demanding monodentate phosphines, tris-( $t$ butyl)phosphine ${ }^{24}$ or di-t-butylmethylphosphine ${ }^{25}$ led to complexes of the form $\left.\left[\mathrm{R}_{3} \mathrm{PH}\right]^{+} \mathrm{R}_{3} \mathrm{PNiCl}_{3}\right]^{-}$i.e. analogous to 11 (Scheme 6). The coordination mode observed in 11 is clearly dictated by the steric size of the ligand 1.

Scheme 6.

### 2.2.2.5 [(1,2-bis(di-tertiary-butylphosphinomethyl)benzene) (trans, trans dibenzylideneacetone) palladium (0)] 13.

This complex has previously been reported by Clegg et al. ${ }^{26}$ It is included here for completeness, and has been employed in the catalytic studies undertaken for this work.

13 was found to have the trigonal planar arrangement of ligands common to complexes of the form $\left[\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{Pd} \mathrm{DBA}\right]$ or [(P-P)Pd DBA] (where P-P is a chelating diphosphine ligand and DBA is trans, trans dibenzylideneacetone). ${ }^{27}$ The DBA ligand being coordinated $\eta^{2}$ via only one of its olefinic bonds.

## Chapter 2

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are consistent with this formulation. The ${ }^{31} \mathrm{P}\{\mathrm{H}\}$ NMR spectrum consists of two broad resonances of equal intensity with chemical shifts of $\delta_{\mathrm{P}} 49.94 \mathrm{ppm}$ and $\delta_{\mathrm{P}} 51.57 \mathrm{ppm}$. This is consistent with the observations of previous workers. ${ }^{27}$ The ${ }^{1} \mathrm{H}$ NMR spectrum was again dominated by the resonances assigned to the tertiary-butyl protons of the phosphine ligand ( $\delta_{\mathrm{H}} 1.23 \mathrm{ppm},{ }^{3} J_{\mathrm{H}-\mathrm{P}}$ 9.66 Hz ). The methylene protons of the phosphine were observed as a doublet ( $\delta_{\mathrm{H}} 3.06$ ppm). Downfield ( $\delta_{\mathrm{H}}$ 6.89-7.36 ppm) from these well defined resonances are a complex pattern of peaks that can be assigned to the aromatic protons of the phosphine ligand 1, and those of the phenyl groups of the DBA ligand. The broad nature of the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum can be rationalised by the dynamic nature of the DBA ligand in solution at room temperature, ${ }^{28}$ where the coordinated and free olefinic bonds of the DBA ligand can be exchanged intramolecularly.

### 2.3 Experimental

All compounds were prepared using standard Schlenk techniques under an atmosphere of dinitrogen or argon. ${ }^{31} \mathrm{P}$ (referenced to $\mathrm{H}_{3} \mathrm{PO}_{4}$ at $\delta_{\mathrm{P}}=0$ ) and ${ }^{11} \mathrm{~B}$ (referenced to $\mathrm{Et}_{2} \mathrm{O} \cdot \mathrm{BF}_{3}$ at $\delta_{\mathrm{B}}=0$ ) NMR data was collected on a Jeol Eclipse 300 MHz spectrometer; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ data on a Bruker 400 MHz DPX Avance spectrometer. Mass spectra (ES and APCI) were obtained on a VG Fisons Platform II. Tetrahydrofuran, Diethyl ether and hexane were dried over sodium benzophenone and freshly distilled under $\mathrm{N}_{2}$ prior to use. Toluene was dried over sodium. Methanol and acetonitrile were dried over calcium hydride. Water used during the work-up of all compounds was carefully deoxygenated by several cycles of heating at reflux and cooling to room temperature under a nitrogen purge. $\mathrm{CDCl}_{3}, \mathrm{~d}_{6}$-acetone and $\mathrm{d}_{3}$-acetonitrile were purchased from Aldrich, dried over $3 \AA$ molecular sieves and freeze-thaw degassed before use. $\mathrm{C}_{6} \mathrm{D}_{6}$ was purchased from Goss scientific and dried over sodium prior to use. Unless stated otherwise all chemicals were purchased from Aldrich and used without further purification.

Di-tertiary-butylchlorophosphine 2. ${ }^{4}$

Di-tertiary-butylchlorophosphine was prepared by the literature method ${ }^{3}$ and was found to have the following spectral characteristics.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 146.81(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.21$ (d, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{P}} 15.71 \mathrm{~Hz}, 2\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 27.83(\mathrm{~d}, 2) 39.94 \mathrm{ppm}(\mathrm{d}$, 1).

## Di-tertiary-butylphosphine 3.

$\mathrm{LiAlH}_{4}(2.97 \mathrm{~g}, 66 \mathrm{mmol})$ was slurried in diethyl ether $\left(80 \mathrm{~cm}^{3}\right)$ and cooled to $0^{\circ} \mathrm{C}$ in an ice bath. To the stirred slurry was then added (dropwise via cannula) a diethyl ether ( $40 \mathrm{~cm}^{3}$ ) solution of di-tertiary-butylchlorophosphine $2(9.92 \mathrm{~g}, 55 \mathrm{mmol}$ ) over a one hour period. Upon full addition the solution was allowed to warm to room temperature and was stirred for an additional 20 hrs. The grey suspension was then cooled to $0^{\circ} \mathrm{C}$, and a degassed aqueous solution of $\mathrm{HCl}\left(110 \mathrm{~cm}^{3}, 1 \mathrm{M}\right)$ was added over a 2 hr period. Upon full addition the mixture was allowed to stir for an additional 0.5 hrs . The stirring was then stopped and the two phases allowed to separate. The organic phase was then removed with a cannula and the aqueous phase extracted with a further two portions of diethyl ether ( $50 \mathrm{~cm}^{3}$ ). The combined diethyl ether washings were then dried over magnesium sulphate and subsequently filtered via cannula. The solvent was then removed by distillation, to give the title compound as a colourless liquid with a strong, unpleasant odour.

Yield: 5.42g, 68\%.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 20.14(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.20(\mathrm{~d}$, $\left.{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{P}} 11.21 \mathrm{~Hz}, 2\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 29.26(\mathrm{~d}, 2) 31.84 \mathrm{ppm}(\mathrm{d}, 1)$.

## Di-tertiary-butylphosphinetrihydroboron 4.

To a cooled $\left(0^{\circ} \mathrm{C}\right)$ solution of di-tertiary-butylphosphine $3(5 \mathrm{~g}, 34 \mathrm{mmol})$ in THF ( 50 $\mathrm{cm}^{3}$ ), was added a solution of borane.THF ( 51 mmol ) via syringe. A mildly exothermic reaction followed and effervescence was observed. Upon full addition the solution was stirred for a further 1 hr at $0^{\circ} \mathrm{C}$, allowed to warm to room temperature and then stirred for an additional 4hrs. The solvent was removed in vacuo to yield the title compound as a colourless solid.
Yield: $5.44 \mathrm{~g}, 100 \%$.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 48.55\left(\mathrm{q},{ }^{1} \mathrm{~J}_{\mathrm{P}-\mathrm{B}} 44.65 \mathrm{~Hz}\right) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 96.42 \mathrm{MHz}\right)-43.31(\mathrm{~d}, \mathrm{br}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right) 0.83(3 \mathrm{H}, \mathrm{m}, \mathrm{br}) 1.25$ $\left(18 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 13.6 \mathrm{~Hz}, 2\right) 4.07\left(1 \mathrm{H}, \mathrm{dq},{ }^{1} J_{\mathrm{H}-\mathrm{P}} 430.74 \mathrm{~Hz},{ }^{2} \mathrm{~J}_{\mathrm{H}-\mathrm{B}} 6.36 \mathrm{~Hz}, 3\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $\left.\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right) 27.88(\mathrm{~d}, 2) 29.60 \mathrm{ppm}(\mathrm{d}, 1)$.

## 1,2-bis(di-tertiary-butylphosphinotrihydroboronmethyl)benzene 5.

Di-tertiary-butylphosphinetrihydroboron $4(5.0 \mathrm{~g}, 31 \mathrm{mmol})$ was dissolved in THF $\left(50 \mathrm{~cm}^{3}\right)$ and cooled to $-78^{\circ} \mathrm{C}$. ${ }^{\mathrm{sec}} \mathrm{BuLi}(34.4 \mathrm{mmol})$ was then added gradually via syringe to give an intensely coloured yellow solution. The solution was stirred at $78^{\circ} \mathrm{C}$ for 0.5 hrs , allowed to warm to room temperature, and stirred for an additional 2hrs. The deprotonation can be monitored by both ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy (data given below). The solution was cooled to $-78^{\circ} \mathrm{C}$ and a THF solution ( $30 \mathrm{~cm}^{3}$ ) of $\alpha, \alpha$ 'dichloro- $o$-xylene $(3.0 \mathrm{~g}, 17.2 \mathrm{mmol})$ added dropwise via
cannula. The solution was then allowed to warm to room temperature and was stirred overnight. The solvent was then removed under vacuum and the residues dissolved in DCM ( $60 \mathrm{~cm}^{3}$ ). The solution was washed with two portions of water $\left(50 \mathrm{~cm}^{3}\right)$ and the organic phase isolated and dried over magnesium sulphate. The solvent was then removed under vacuum to yield 5 as a colourless solid.
Yield: $6.54 \mathrm{~g}, 93 \%$.
FW: 421.94
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 55.42\left(\mathrm{q},{ }^{1} \mathrm{~J}_{\mathrm{P}-\mathrm{B}} 68.48 \mathrm{~Hz}\right) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 96.42 \mathrm{MHz}\right)-42.30(\mathrm{~d}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.243\left(36 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}}\right.$ $12.30 \mathrm{~Hz}, 2) 3.373\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 11.88 \mathrm{~Hz}, 3\right) 7.139(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.593(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-$ H); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right) 24.93(\mathrm{~d}, 3) 28.85(\mathrm{~d}, 2) 33.46(\mathrm{~d}, 1) 126.32$ (s, 6) $132.64(\mathrm{~d}, 5) 134.18 \mathrm{ppm}(\mathrm{d}, 4)$.

## Di-tertiary-butyltrihydroboronlithium phosphide.

${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (121.65MHz) $\delta 5.73(\mathrm{q}) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 96.42 MHz ) $-36.59 \mathrm{ppm}(\mathrm{d}$, ${ }^{1} J_{\mathrm{B}-\mathrm{P}} 40.06 \mathrm{~Hz}$ ).

1,2-bis(di-tertiary-butylphosphinomethyl)benzene 1.

To a cooled $\left(0^{\circ} \mathrm{C}\right)$ DCM $\left(50 \mathrm{~cm}^{3}\right)$ solution of 1,2-bis(di-tertiary-butylphosphino trihydroboronmethyl)benzene $1(4 \mathrm{~g}, 9 \mathrm{mmol})$ was added tetrafluoroboric acid dimethyl ether complex ( $10 \mathrm{eq}, 90 \mathrm{mmol}$ ) via syringe. Upon the initial addition, the evolution of hydrogen gas was noted. Upon full addition the solution was stirred for a further 0.5 hrs at $0^{\circ} \mathrm{C}$, allowed to warm to room temperature and then stirred for 18 hrs . Saturated sodium hydrogen carbonate solution $\left(150 \mathrm{~cm}^{3}\right)$ was then added and the solution stirred vigorously for 3 hrs . The stirring was then stopped, and the two phases allowed to separate. The organic phase was isolated with a cannula and the aqueous phase washed with a further two portions of DCM ( $30 \mathrm{~cm}^{3}$ ). The DCM
extracts were combined and dried over magnesium sulphate and subsequently filtered via cannula. The solvent was then removed under vacuum to yield 1 as a colourless solid. Further purification was achieved by recrystalisation from hot methanol.

Yield: $2.77 \mathrm{~g}, 78 \%$
${ }^{31} \mathrm{P}\left\{{ }^{\mathrm{I}} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 28.06(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.14$ $\left(36 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.77 \mathrm{~Hz}, 2\right) 3.03\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 2.85 \mathrm{~Hz}, 3\right) 7.05(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.53(2 \mathrm{H}$, m, Ar-H); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 26.47(\mathrm{~d}, 3) 29.98(\mathrm{~d}, 2) 31.98(\mathrm{~d}, 1)$ $125.29(\mathrm{~s}, 6) 131.00(\mathrm{~d}, 5) 138.88 \mathrm{ppm}(\mathrm{d}, 4)$.

MS (APCI): m/z 395 (M, +H).
[chloro (1,2-bis(di-tertiary-butylphosphinomethyl)benzene) silver (I)] 6.

Note: All manipulations were performed with the exclusion of light from the vessels.
Silver trifluoromethanesulphonate $(0.22 \mathrm{~g}, 0.84 \mathrm{mmol})$ and 1,2-bis(di-tertiarybutylphosphinomethyl)benzene ( $0.40 \mathrm{~g}, 1.01 \mathrm{mmol}$ ) were weighed into a Schlenk flask in a glove box. Dichloromethane ( $40 \mathrm{~cm}^{3}$ ) was then added to the solids and the solution allowed to stir for 18 hrs . The solution was then added to sodium chloride ( $0.35 \mathrm{~g}, 5.99 \mathrm{mmol}$ ) and the mixture stirred for an additional 2 hrs , and before filtering through celite to remove the excess sodium chloride. The solvent was removed under vacuum to yield the title compound as a colourless solid.

## [(1,2-bis(di-tertiary-butylphosphinomethyl)benzene)tetracarbonyl molybdenum

 (0)] 7.

A dichloromethane ( $50 \mathrm{~cm}^{3}$ ) solution of 1,2-bis(di-tertiary-butylphosphinomethyl) benzene ( $1.03 \mathrm{~g}, 2.6 \mathrm{mmol}$ ) was added to $\left.\left[\mathrm{Mo}(\mathrm{CO})_{4} \text { (piperidene) }\right)_{2}\right] \mathbf{8 ( 1 \mathrm { g } , 2 . 6 \mathrm { mmol } )}$ to give an orange suspension. The solution was then heated at reflux for 0.5 hrs , during which time the solid dissolved to give a yellow solution. The solution was allowed to cool to room temperature and the solvent removed under vacuum. The yellow coloured solid obtained was dissolved in chloroform and was recrystallised upon the addition of methanol. X-ray quality crystals were obtained by layering a concentrated chloroform solution of the complex with methanol.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65\right) \delta 57.28(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.42(36 \mathrm{H}$, $\left.\mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.98 \mathrm{~Hz}, 2\right) 3.32\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 6.36 \mathrm{~Hz}, 3\right) 7.08(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.31(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-$ H); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 29.85(\mathrm{~d}, 3) 31.30(\mathrm{~d}, 2) 37.65(\mathrm{~d}, 1) 126.33$ $(\mathrm{s}, 6) 133.29(\mathrm{~d}, 5) 136.91 \mathrm{ppm}(\mathrm{d}, 4)$.

[cis-bis(piperidine)tetracarbonylmolybdenum(0)] 8. ${ }^{16}$

A round bottom flask equipped with a reflux condenser was charged with molybdenum hexacarbonyl ( $5 \mathrm{~g}, 18.9 \mathrm{mmol}$ ) piperidine ( $10.76 \mathrm{~g}, 126 \mathrm{mmol}$ ) and
hexane ( $60 \mathrm{~cm}^{3}$ ). Upon heating the molybdenum hexacarbonyl dissolved and the solution became yellow in colour. The solution was then heated under reflux for a total of 5 hrs. Upon cooling the product precipitated and was isolated by filtration of the warm solution through a Hersch funnel. The yellow solid was then washed with three portions of hexane $\left(15 \mathrm{~cm}^{3}\right)$ and was dried under vacuum.

## [bis(acetonitrile)(1,2-bis(di-tertiary-butylphosphino methyl)benzene) palladium

 bis(tetrafluoroborate)] 9.

1,2-bis(di-tertiary-butylphosphinomethyl)benzene ( $0.30 \mathrm{~g}, \quad 0.76 \mathrm{mmol}$ ) and [tetrakis(acetonitrile) bis(tetrafluoroborate) palladium(II)] ( $0.33 \mathrm{~g}, 0.76 \mathrm{mmol}$ ) were weighed into a Schlenk in a glove box. Acetonitrile $\left(20 \mathrm{~cm}^{3}\right)$ was added to afford an orange coloured solution that lightened to yellow. The solution was allowed to stir for 3 hrs. The volume of solvent was reduced by half under vacuum. Diethyl ether was added dropwise via syringe to afford the title compound as a crystalline yellow solid. The solid was isolated via cannula filtration and subsequently dried under vacuum.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 121.65 \mathrm{MHz}\right) \delta 50.74(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 300 \mathrm{MHz}\right) 1.52$ $\left(36 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 15.18 \mathrm{~Hz}, 2\right) 2.18(6 \mathrm{H}, \mathrm{s}, 7) 3.73\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 9.03 \mathrm{~Hz}, 3\right) 7.33(2 \mathrm{H}, \mathrm{m}$, Ar-H) $7.49(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) ;{ }^{1} \mathrm{H}\left\{{ }^{31} \mathrm{P}\right\}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 300 \mathrm{~Hz}\right) 1.52(36 \mathrm{H}, \mathrm{s}, 2) 2.18$ $(6 \mathrm{H}, \mathrm{s}, 7) 3.73(4 \mathrm{H}, \mathrm{s}, 3) 7.33(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.49(2 \mathrm{H}, \mathrm{s}, \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{l} \mathrm{H}\right\} \mathrm{NMR}$ ( $\mathrm{CD}_{3} \mathrm{CN}, 75.56 \mathrm{MHz}$ ) 26.75 (d, 3) 30.37 (d, 2) 41.82 (d, 1) 128.61 (s, 6) 132.55 (d, 5) $133.37 \mathrm{ppm}(\mathrm{d}, 4)$.

IR (KBr): $v_{\mathrm{CN}} 2312,2282 \mathrm{~cm}^{-1} . v_{\mathrm{BF}} 1084,1028 \mathrm{~cm}^{-1}$.
MS (ES): $m / z 542.4\left(\mathrm{M}^{+},-\mathrm{MeCN}\right) 501.4\left(\mathrm{M}^{+},-2 \mathrm{MeCN}\right)$.

## [bis(2,4-pentanedionato)palladium(II)]. ${ }^{29}$

Palladium chloride $(0.89 \mathrm{~g}, 5.0 \mathrm{mmol})$ and sodium chloride $(2.5 \mathrm{eq}, 0.73 \mathrm{~g}, 12.5$ mmol ) were dissolved in water ( $14 \mathrm{~cm}^{3}$ ) and stirred for 1 hr . 2,4-pentanedione ( 2.5 $\mathrm{cm}^{3}$ ) and sodium hydroxide ( 0.8 g ) were added, and the yellow coloured suspension that formed was stirred for an additional 15 hrs . The yellow precipitate was isolated on a Buchner funnel and was washed with water, methanol and then diethyl ether. The yellow solid obtained was dissolved in chloroform and filtered to remove a small quantity of palladium black. The solvent was removed under vacuum to yield the title compound as a crystalline yellow solid. Further purification was achieved by recrystallisation from hot benzene.
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right) \delta 2.01(12 \mathrm{H}, \mathrm{s}) 5.36(4 \mathrm{H}, \mathrm{s}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}\right.$, 100 MHz ) 25.86 (s) 101.99 (s) 187.56 ppm (s).

## [bis(tetrafluoroborate) tetrakis(acetonitrile) palladium(II)] 10. ${ }^{\mathbf{3 0}}$

Bis(2,4-pentanedionato)palladium ( $1.40 \mathrm{~g}, 4.59 \mathrm{mmol}$ ) was dissolved in acetonitrile $\left(20 \mathrm{~cm}^{3}\right) . \mathrm{HBF}_{4}(3 \mathrm{eq}, 1.21 \mathrm{~g}, 13.8 \mathrm{mmols})$ was then added to the solution via syringe, causing the precipitation of finely divided palladium. The solution was then stirred for 18 hrs . During this time the majority of the palladium black was consumed and a yellow coloured solution was obtained. The solution was filtered through a frit and the solvent removed under vacuum to yield the title compound as a crystalline yellow solid.
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 400 \mathrm{MHz}\right) \delta 2.66 \mathrm{ppm}(\mathrm{s})$.
IR (KBr): $v_{\mathrm{CN}} 2355 \mathrm{~cm}^{-1}$.

## [trichloro (1,2-bis(di-t-butylphosphinomethyl)benzene) nickel (II)] 11

To [dichloro(1,2-dimethoxyethane)nickel(II)] $12(0.20 \mathrm{~g}, 0.5 \mathrm{mmol})$ was added a dichloromethane ( $30 \mathrm{~cm}^{3}$ ) solution of 1,2-bis(di-tertiary-butylphosphinomethyl) benzene ( $0.11 \mathrm{~g}, 0.5 \mathrm{mmol}$ ). Upon the addition of the phosphine, there was an instant colour change of the solution from orange to aquamarine. The solution was allowed to stir for 3 hrs and was then concentrated under vacuum to half its initial volume. Slow vapour diffusion of diethyl ether into the solution gave the title complex as blue crystals.

No NMR data was available as the complex was found to be paramagnetic. No EPR data was available as the complex was found to be both EPR and ENDOR silent. The magnetic moment of the complex in solution (Evans method) was found to be $\mu=4.1$ BM.

Yield: $0.18 \mathrm{~g}, 63 \%$

## [dichloro(1,2-dimethoxyethane) $\mathbf{N i}$ (II)] 12.

A three necked round bottom flask fitted with a reflux condenser was charged with finely ground $\mathrm{Ni} .2 \mathrm{H}_{2} \mathrm{O}^{*}(33.1 \mathrm{~g}, 0.20 \mathrm{mols})$, ,, 2 -dimethoxyethane $\left(100 \mathrm{~cm}^{3}\right)$ and triethyl orthoformate $(65.10 \mathrm{~g}, 0.44 \mathrm{mols})$. The slurry was rapidly stirred and heated at reflux for 2 hours. The reaction mixture was allowed to cool and the orange solid collected on a glass frit under $\mathrm{N}_{2}$. The solid was washed with 1,2dimethoxyethane and pentane and subsequently dried under vacuum.

* $\mathrm{NiCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was obtained by dehydration of nickel chloride $\left(\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right)$ in a warm oven over several days. The colour of the material was observed to change from the initial deep green colour of $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ to become light yellow. The yellow powder was then stored under a $\mathrm{N}_{2}$ atmosphere.

## [(1,2-bis(di-tertiary-butylphosphinomethyl)benzene) (trans, trans dibenzylidene acetone) Palladium (0)ل 13.

THF ( $60 \mathrm{~cm}^{3}$ ) was added to a mixture of 1,2-bis(di-tert-butylphosphino methyl)benzene $(1.34 \mathrm{~g}, 3.40 \mathrm{mmol})$ and $\left[\mathrm{Pd}_{2}(\mathrm{DBA})_{3}\right](1.86 \mathrm{~g}, 1.45 \mathrm{mmol})$ that had previously been weighed out in a glove box. The turbid red / orange solution was stirred for three hours. The solution was filtered via cannula to yield a red filtrate and a small quantity of residue. The solvent was removed under vacuum to afford a red powdery solid. Hexane $\left(30 \mathrm{~cm}^{3}\right)$ was added via syringe and trituration performed with a glass rod, resulting in an orange solid separating out. The hexane washings were then removed via cannula filtration and the solid dried under vacuum.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}, 121.65 \mathrm{MHz}\right) \delta 49.94(\mathrm{~s}, \mathrm{br}) 51.57(\mathrm{~s}, \mathrm{br}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right.$, $300 \mathrm{MHz}) 1.231\left(36 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 9.66 \mathrm{~Hz}\right) 3.055(4 \mathrm{H}, \mathrm{d}, \mathrm{br}) 6.885-7.359(14 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H})$; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}, 75.56 \mathrm{MHz}\right) 30.366$ (d) 30.472 (d) 36.076 (d) 126.548 (s) 133.267 (d) 137.818 (d) 190.935.

MS (ES): m/z 735 ( $\mathbf{M}^{+}$)

## Chapter Three

## Chapter 3

## 3. 1 Introduction

### 3.1.1 Phosphorus heterocycles

Phosphetanes belong to a larger homologous series of saturated heterocyclic compounds containing a single phosphorus atom. Examples of a wide variety of these compounds are known in the chemical literature, from three membered phosphiranes through to the larger ring compounds, phospholanes (5), phosphinanes (6), phosphepanes (7) and phosphocanes (8).

### 3.1.2 Synthesis of phosphetanes

The first synthesis of a phosphetane ring was reported by Kosolapoff and Struck in 1957. ${ }^{1}$ In this example the phosphetane was prepared in poor yield via the Michaelis Arbuzov coupling of triethylphosphite and 1,3-dibromopropane. Since Kosalapoff and Struck's work, two general methods have been devised for the synthesis of phosphetane rings.

A significant breakthrough came in 1962, when McBride and Jungermann were, for the first time, able to demonstrate the synthesis of a phosphetane ring in high yield. ${ }^{2}$ The "McBride" synthesis (Scheme 1), involves the reaction of an electron-rich olefin with $\mathrm{PCl}_{3}$ in the presence of $\mathrm{AlCl}_{3}$. The attack of an olefinic carbon at a phosphenium cation, followed by a 1,2 shift of a methyl group, and subsequent electrophilic addition to phosphorus affords a phosphetanium ion. Hydrolysis then gives the corresponding phosphinic chloride (1-chloro-2,2,3,4,4-pentamethyl phosphetane-1oxide 14).

Scheme 1. The McBride Synthesis
It was later established (via X-ray crystallography) ${ }^{3}$ that the synthesis described by McBride was selective for the trans-isomer of 14 . Where the methyl group at the C3 position of the phosphetane ring is trans across the ring relative to the chlorine at phosphorus (Figure 1). McBride's route is limited by the number of suitable olefins that will cyclise to give the phosphetane ring. Since McBride described the reaction of 2,4,4-trimethylpent-2-ene in 1962, relatively few suitable olefins have been found. ${ }^{4,5}$, 6

A second methodology has been developed more recently. In this example, the reaction of a di-lithiumphosphide reagent with a 1,3 -electrophile has proven to give phosphetanes. A variety of 1,3-electrophiles have been investigated (dihalides, mesylates, tosylates). In common with larger rings in the homologous series, the most successful dielectrophiles in the synthesis of phosphetanes have been cyclic sulphates. Cyclic sulphates can be synthesised from a variety of Diols, not only bringing diversity in the functionality pendant on the phosphetane ring but also providing control over the stereochemistry of these substituents (scheme 2). ${ }^{7}$

Cis

Trans

Figure 1. Isomers of 14
It has been the McBride synthesis that has been of interest during this work. Other methodologies of phosphetane synthesis will not be discussed in further detail.

### 3.1.3 Structural properties of the phosphetane ring

Initial studies of phosphetanes concentrated upon the stereochemistry of substitution reactions at the phosphorus atom, ${ }^{8}$ and the structural properties of the four membered ring. The majority of compounds studied (until recently) have been phosphorus (V) derivatives of the phosphetane ring (oxides, sulphides, borane adducts, phosphonium salts).

It was found that phosphetanes have a folded structure ${ }^{9}$ (Figurel), with the fold angle made by the C-C-C and C-P-C plane being between $0-30^{\circ}$. The direction of the fold is usually dictated by the steric size of substituents at phosphorus and the C 3 position of the ring.

Scheme 2. Phosphetane synthesis via cyclic sulphates.

P-C bond lengths have been found to be in the range of 1.79-1.96 $\AA$ for monocyclic phosphetanes (P-C for classical acyclic phosphines is $1.84 \AA$ ). The angles at the ring

## Chapter 3

carbons being between $84-88^{\circ}$ (P-C-C) and $96-102^{\circ}$ (C-C-C), this enforces a small C-$\mathrm{P}-\mathrm{C}$ angle at phosphorus, which commonly falls into the range of $76-86^{\circ}$.

### 3.1.4 Phosphetanes in homogeneous catalysis

Recent work by Marinetti has described the synthesis of several novel chiral bidentate phosphetane ligands. ${ }^{10}$ It was shown that this novel class of ligand can provide active catalysts in the Ruthenium catalysed hydrogenation of carbonyl compounds. ${ }^{10}$ The control of chirality in the products having a marked dependence upon the steric size of substituents on the phosphetane ring.

This interesting work by Marinetti also provides insight into the coordination chemistry of phosphetanes. ${ }^{10}$ Indeed, up until this point relatively few metal complexes with phosphetane ligands had been described. ${ }^{14,15}$

This chapter describes the synthesis of two novel ligands with the pentamethylphosphetane functionality. Several novel transition metal complexes are also described.

### 3.2 Results and discussion.

### 3.2.1 Ligand synthesis.

The synthetic protocols outlined in chapter 2 to access ortho-xylene bridged diphosphine ligands have been applied to the phosphetane ligands described in this chapter. Importantly, the strategy chosen has provided access to either of the two isomers of the 2,2,3,4,4-pentamethylphosphetane ring.

### 3.2.1.1 1 -chloro-2,2,3,4,4-pentamethylphosphetane-1-oxide 14

14 was synthesised via a methodology adapted from that described by Jungermann. ${ }^{2}$ After several attempts to prepare 14 by Jungermann and McBride's methodology (Scheme 1), ${ }^{2}$ it was found that better results (in terms of yield and purity) where achieved by allowing the reaction mixture to stir for a prolonged period of 24 hrs , rather than the 0.5 hr suggested. Both yield and purity where also enhanced by a more cautious work-up procedure where hydrolysis of the phosphetanium salt was carried out at $0^{\circ} \mathrm{C}$ and over a longer period of time. It was found that samples of 14 should be

## Chapter 3

stored under a dry nitrogen or argon atmosphere, as 14 was found to gradually hydrolyse when in contact with the air.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra of 14 were found to be consistent with those previously reported. ${ }^{8}$ The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consists of a singlet indicative of a single isomer of 14 , with a chemical shift of $\delta_{P} 82.93 \mathrm{ppm}$. The ${ }^{1} \mathrm{H}$ NMR spectrum consists of a doublet ( $\delta_{\mathrm{H}} 0.92 \mathrm{ppm}{ }^{3} J_{\mathrm{HCCH}} 7.11 \mathrm{~Hz}$ ), assigned to the protons of the methyl group at the 3 position of the ring coupled to the adjacent proton. Two doublets were observed that integrated to the 12 protons of the methyl groups at the 2 and 4 positions of the ring ( $\delta_{\mathrm{H}} 1.31 \mathrm{ppm},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.95 \mathrm{~Hz}$ and $\delta_{\mathrm{H}} 1.38{ }^{3} J_{\mathrm{H}-\mathrm{P}} 9.30 \mathrm{~Hz}$ ). A multiplet ( $\delta_{\mathrm{H}} 1.78 \mathrm{ppm}$ ) was also observed for the single proton at C 3 of the phosphetane ring.

### 3.2.1.2 2,2,3,4,4-Pentamethylphosphetane 15

The title compound was synthesised in $80 \%$ yield via the reduction of 14 with $\mathrm{LiAlH}_{4} .15$ was isolated as a volatile clear liquid with a strong unpleasant odour. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra were fully consistent with that previously reported. ${ }^{4,8}$ In common with previous workers, 15 was isolated as a 9:1 mixture of trans:cis isomers.

### 3.2.1.3 2,2,3,4,4-pentamethylphosphetane-trihydroboron 16

Reaction of 2,2,3,4,4-pentamethylphosphetane 15 with an excess of borane-THF adduct afforded 16 as a colourless low-melting solid in near quantitative yield. The structure of 16 was confirmed by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. In common with 15 the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of two resonances ( $\delta_{\mathrm{P}} 57.99$ ppm, (q), ${ }^{1} J_{\mathrm{P}-\mathrm{B}} 29.78 \mathrm{~Hz}, 9 \mathrm{eq}$ and $\delta_{\mathrm{P}} 55.73 \mathrm{ppm}$, (q), ${ }^{1} J_{\mathrm{P}-\mathrm{B}} 32.75 \mathrm{~Hz}$, leq), again the $9: 1$ ratio of isomers (trans:cis) was observed. The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum was concordant with the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, in that two doublets were observed in the $9: 1$ ratio ( $\delta_{\mathrm{B}}-44.62 \mathrm{ppm}$, 9 eq and $\delta_{\mathrm{B}}-43.79$, leq). The ${ }^{1} \mathrm{H}$ NMR spectrum consisted of a complex pattern of peaks due to the mixture of two isomers. However, the resonances due to the trans isomer could be assigned. In common with 14 , the protons of the C 3 methyl group were observed as a doublet with a chemical shift of $\delta_{\mathrm{H}}$ $0.92 \mathrm{ppm}\left({ }^{3} J_{\mathrm{H}-\mathrm{H}} 7.26 \mathrm{~Hz}\right.$ ). The methyl groups at the 2 and 4 position of the ring were also observed as a doublet $\left(\delta_{\mathrm{H}} 1.320,{ }^{3} J_{\mathrm{H}-\mathrm{P}} 11.64 \mathrm{~Hz}\right)$. The final ring proton at C 3 was
observed as a quartet with a chemical shift of $\delta_{\mathrm{H}} 2.603\left({ }^{3} J_{\mathrm{H}-\mathrm{H}} 7.26 \mathrm{~Hz}\right)$. In common with 4 (see chapter 2), the P-H proton could be assigned to a doublet of quartets $\delta_{\mathrm{H}}$ $5.169\left({ }^{1} J_{\mathrm{H}-\mathrm{P}} 331.92 \mathrm{~Hz},{ }^{2} J_{\mathrm{H}-\mathrm{B}} 6.15 \mathrm{~Hz}\right)$ the AMX pattern being consistent with coupling to both phosphorus and boron. Partial NMR spectroscopy data for the cis isomer of 14 is given in the experimental section.

### 3.2.1.4 1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene 17

17 was prepared via a reaction analogous to that described by Moulton and Shaw (Scheme 3). ${ }^{11}$ Reaction of 16 (as a 9:1 mixture of trans and cis isomers) with $\alpha, \alpha$ '-dibromo-o-xylene in acetone led to the dihydrobromide-phosphonium salt 18.

18 was characterised via ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of four singlets, three of which integrate to give a ratio of 16:4:1. Each peak can be assigned to a diphosphonium salt that contains two phosphetane rings, which can be in one of two possible isomeric forms.
Since the electrophilic addition to phosphorus(III) in the phosphetane system is known to invert the configuration of the substituents at phosphorus, ${ }^{8}$ and from the statistical distribution of products likely to be observed from the 9:1 mixture of isomers in the starting materials, the peaks can be assigned to diphosphonium salts where both rings are the cis isomer ( $\delta_{\mathrm{P}} 49.7 \mathrm{ppm}, 16$ equivalents), the mixed form where one ring is the trans isomer and the other cis ( $\delta_{\mathrm{P}} 39.54 \mathrm{ppm}, 4$ equivalents) and the all trans form ( $\delta_{\mathrm{P}} 35.9 \mathrm{ppm}, 1$ equivalent). The formation of a phosphonium salt in this reaction was confirmed by ${ }^{31} \mathrm{P}$ NMR spectroscopy, where the coupling to the $\mathrm{P}-\mathrm{H}$ proton gave the familiar double multiplet pattern of a phosphonium salt. The P-H coupling constant was found to be 467 Hz .

## Chapter 3

Scheme 3. Synthesis of 17

A fourth resonance in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum ( $\delta_{\mathrm{P}} 92.2 \mathrm{ppm}$ ) was assigned to the formation of a phospholanium salt 19 (Figure 2) similar to that described in the analogous reaction of di-t-butylphosphine 3 (Chapter 2). ${ }^{11}$

Figure 2. Phospholanium salt 19

The full characterisation of 19 is given in the experimental section.

In common with that observed in Chapter 2, reaction of the phosphonium salts with a base (sodium bicarbonate) led to the corresponding (16:4:1) mixture of phosphines in modest yield (38\%). Subsequent recrystalisation of this mixture from hot methanol gave the single isomer (shown to be 17) as a crop of colourless crystalline needles. The solid-state structure was determined by X-ray crystallography and is shown in Figure 3. Selected bond lengths and angles are given in Table 1.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ NMR spectra and mass spectra are consistent with the proposed structure of 17 and that determined by X-Ray crystallography. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consists of a singlet with a chemical shift of $\delta_{\mathrm{P}} 29.31 \mathrm{ppm}$, as expected for two chemically and magnetically equivalent phosphorus atoms. The ${ }^{1} \mathrm{H}$ NMR spectrum showed the basic pattern of resonances now familiar to the pentamethylphosphetane functionality. ${ }^{4,8}$ The methyl protons adjoining the 3 position of the ring where observed as a doublet with a chemical shift of $\delta_{\mathrm{H}} 0.842 \mathrm{ppm}\left({ }^{3} J_{\mathrm{HCCH}}\right.$ 7.05 Hz ). The twelve protons of the methyl groups at the 2 and 4 position of the ring were observed as a set of two doublets with chemical shifts of $\delta_{\mathrm{H}} 1.20$ and $\delta_{\mathrm{H}} 1.24$ ppm . The methine proton at the 3 position of the ring was observed as the familiar quartet with a chemical shift of $\delta_{\mathrm{H}} 2.26\left({ }^{3} J_{\mathrm{HCCH}} 7.05 \mathrm{~Hz}\right)$.

Figure 3. X-Ray Crystal structure of 17. Hydrogen atoms have been omitted for clarity. Thermal ellipsoids are drawn at $50 \%$ probability

Table 1. Selected bond lengths and angles for 17

As observed by previous workers, ${ }^{8}$ electrophilic addition at phosphorus(III) occurs with inversion of configuration at phosphorus. Hence the reaction of the transphosphetane 15 inverts the configuration to give the cis isomer of 17 . This observation is confirmed by the crystal structure (Figure 3).

The solid state structure of 17 is consistent with that previously reported for related 2,2,3,4,4-pentamethylphosphetanes. ${ }^{3,12}$ The mean torsion angle of the rings being $21.25^{\circ}$, which is within the expected range of $0-30^{\circ}$ known for phosphetane rings. ${ }^{13}$ The mean C-P-C angle is also unremarkable (77.9(2) ${ }^{\circ}$ ), and falls at the lower end of the known range of $76-86^{\circ}$ for related compounds. ${ }^{13}$

It was found that an inversion of configuration at the phosphetane rings was not observed in 17, even after prolonged periods at elevated temperature ( $110^{\circ}, 48 \mathrm{hrs}$ ). This is consistent with the observations of Cremer et al, ${ }^{19}$ where the related 1,2,2,3,4,4-hexamethylphosphetane was also found to be configurationally stable. However, The configuration of the 1-phenyl and 1-tert-butyl analogues was found to invert under similar conditions. ${ }^{19}$

## Chapter 3

3.2.1.5 1,2-bis(2,2,trans-3,4,4-pentamethylphosphetanemethyl)benzene-trihydroboron 20

The title compound was synthesised via a methodology analogous to that described for 5 (see Chapter 2). A THF solution of a 9:1 mixture of trans:cis isomers of 16 was cooled to $-78^{\circ} \mathrm{C}$ and 1.2 equivalents of $\sec -\mathrm{BuLi}$ where added gradually via syringe. The resulting highly coloured solution (yellow) was then allowed to warm to room temperature and was stirred for an additional 1 hr . The deprotonation can be monitored via ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy. The lithium phosphetanides are observed as two quartets with chemical shifts of $\delta_{\mathrm{P}} 23.89 \mathrm{ppm}\left({ }^{1} J_{\mathrm{P}-\mathrm{B}} 29.77 \mathrm{~Hz}\right.$, trans isomer) and $\delta_{\mathrm{P}} 30.12 \mathrm{ppm}\left({ }^{1} J_{\mathrm{P}-\mathrm{B}} 29.78 \mathrm{~Hz}\right.$, cis isomer) via ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy. Two doublets were observed in the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum with chemical shifts of $\delta_{\mathrm{B}}-37.310 \mathrm{ppm}$ (trans isomer) and $\delta_{\mathrm{B}}-35.840 \mathrm{ppm}$ (cis isomer). Again the 9:1 ratio of trans:cis isomers is maintained.

Upon re-cooling $\left(-78^{\circ} \mathrm{C}\right)$, a THF solution of 0.5 equivalents of $\alpha, \alpha^{\prime}$-dichloro- $o$-xylene was added drop wise via cannula to afford 20 in $89 \%$ yield (Scheme 4).

Scheme 4. Synthesis of 20
The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 20 revealed a broad resonance with a chemical shift of $\delta_{\mathrm{P}} 66.36 \mathrm{ppm}$. As expected, upon alkylation of the $2^{\circ}$-phosphetane-borane adduct to form the $3^{\circ}$ phosphetane-borane adduct, a downfield shift of 8.37 ppm is observed. The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a broad resonance at $\delta_{\mathrm{B}}-43.03 \mathrm{ppm}$. The ${ }^{1} \mathrm{H}$ NMR spectrum was also found to be consistent with the proposed structure of 20.

## Chapter 3

A doublet observed at $\delta_{\mathrm{H}} 0.91 \mathrm{ppm}$ could be assigned to the methyl protons at the 3 position of the phosphetane ring. The twelve protons of the methyl groups at the 2 and 4 positions of the phosphetane ring were observed as a doublet at $\delta_{\mathrm{H}} 1.35\left({ }^{3} J_{\mathrm{HCCP}}\right.$ 9.90 Hz ). The final ring proton at the 3 position of the phosphetane ring was observed as a quartet with a chemical shift of $\delta_{\mathrm{H}} 2.56 \mathrm{ppm}\left({ }^{3} J_{\mathrm{HCCH}} 7.27 \mathrm{~Hz}\right)$. The methylene protons of the $o$-xylene moiety, in common with that observed previously, could be assigned to a doublet at $\delta_{\mathrm{H}} 3.51 \mathrm{ppm}\left({ }^{2} J_{\mathrm{H}-\mathrm{P}} 11.85 \mathrm{~Hz}\right)$. Finally, two multiplets with chemical shifts of $\delta_{\mathrm{H}} 7.15 \mathrm{ppm}$ and $\delta_{\mathrm{H}} 7.36 \mathrm{ppm}$ were assigned to each of the two sets of chemically equivalent aromatic protons of the $o$-xylene backbone.

### 3.2.1.6 1,2-bis(2,2,trans-3,4,4-pentamethylphosphetanemethyl)benzene 21

In common with 5, compound 20 was deprotected using the methodology described in Chapter 2 to give 21. Reaction of 20 with 10 equivalents of $\mathrm{HBF}_{4} . \mathrm{OMe} 2$ and subsequent reaction with base gave the free phosphine 21 in a mixture with the other ring isomers. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of the crude reaction mixture revealed three peaks, again in a ratio of 16:4:1 analogous to those observed in the synthesis of 17. However, the distribution of products was different to that previously observed. The resonance corresponding to the compound with both phosphetane rings in the trans form ( $\delta_{\mathrm{P}} 42.55 \mathrm{ppm}$ ) was now the major product of the reaction. This observation is consistent with previous work. ${ }^{8}$ It was found that addition reactions of the phosphetane system involving phosphorus $(\mathrm{V})$, led to the retention of the configuration at phosphorus. 21 was purified by recrystallisation from hot methanol to give fine colourless needles. The crystals were subsequently found to be unsuitable for determination of the solid-state structure by X-ray diffraction.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra and the mass spectrum are consistent with the proposed formulation of 21 . The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consists of a single peak ( $\delta_{\mathrm{P}}$ $42.55 \mathrm{ppm})$, highlighting the chemical equivalence of the two phosphorus atoms. The ${ }^{1} \mathrm{H}$ NMR spectrum has the familiar pattern of peaks seen for the compounds previously described. The six protons of the methyl groups at the 3 position of the rings were observed as a doublet at $\delta_{\mathrm{H}} 0.81 \mathrm{ppm}\left({ }^{3} J_{\mathrm{HCCH}} 9.66 \mathrm{~Hz}\right)$. The twelve methyl protons adjoining the 2 and 4 positions are observed as two doublets with chemical shifts of $\delta_{\mathrm{H}} 1.14 \mathrm{ppm}\left({ }^{3} J_{\mathrm{HCCP}} 7.26 \mathrm{~Hz}\right)$ and $\delta_{\mathrm{H}} 1.24 \mathrm{ppm}\left({ }^{3} J_{\mathrm{HCCP}} 18.48 \mathrm{~Hz}\right.$ ). The final two ring protons at the 3 position of the rings being observed as a quartet at $\delta_{\mathrm{H}} 2.71$
ppm ( ${ }^{3} J_{\mathrm{HCCH}} 7.26 \mathrm{~Hz}$ ). The methylene protons of the $o$-xylene backbone are observed as a broad doublet at $\delta_{\mathrm{H}} 3.34 \mathrm{ppm}$. Two multiplets at $\delta_{\mathrm{H}} 7.06 \mathrm{ppm}$ and $\delta_{\mathrm{H}} 7.16 \mathrm{ppm}$ were observed for the aromatic protons of the $o$-xylene moiety.

The APCI mass spectrum of 21 was consistent with that previously observed for $\mathbf{1 7}$, with the ion corresponding to the singly protonated species being observed at $\mathrm{m} / \mathrm{z}$ 391.2.

### 3.2.2 Complexation Chemistry.

### 3.2.2.1 1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene tetracarbonyl

 molybdenum(0) 22In a reaction analogous to that described for 7 , one equivalent of 17 was reacted with 8 in warm dichloromethane (Scheme 5). Subsequent recrystalisation via layering a chloroform solution of the buff coloured solid with methanol, led to a crop of colourless crystals of $\mathbf{2 2}$. The solid state structure of 22 was determined by X-Ray diffraction and is shown in Figure 4. Selected bond lengths and angles are given in Table 2.

Scheme 5. Synthesis of 22

Table 2. Selected bond lengths and angles for 22

## Chapter 3

The solid state structure (Figure 4) shows a P-Mo-P "bite" angle of $100.68(18)^{\circ}$, slightly larger than the expected $90^{\circ}$ for ideal octahedral geometry. To accommodate the large bite angle of the phosphine ligand the two carbonyl ligands trans to the phosphine give a C-Mo-C angle of $83.5(9)^{\circ}$. The two carbonyl ligands mutually cis to the phosphine ligand give a C-Mo-C angle of $171.6(9)^{\circ}$, showing slight distortion out of the $z$-axis and towards the phosphine ligand. The distortion of the two mutually cis carbonyl ligands is likely to minimise non-bonding interactions with the methyl groups of the phosphetane rings. The distortion is in contrast to that observed for 7 (see Chapter 2), where the two cis carbonyl ligands are distorted away from the chelating phosphine.

The mean bond length (Mo-C) for the carbonyl ligands trans to the phosphine ligand (1.991 (2) $\AA$ ) are as expected, marginally shorter than those of the carbonyl ligands cis to the phosphine (2.033(2) $\AA$ ). The Mo-C bond length for the trans carbonyls of 22 are marginally shorter than that observed in the related compound 7. The mean P-Mo bond length is of interest in $22(2.544(6) \AA)$ as it appears to differ significantly from that in $\mathbf{7 ( 2 . 6 5 8 ( 6 ) ~} \AA)$. It is however, difficult to rationalise this observation in terms of the $\sigma$-basicity and $\pi$-acidity of the phosphine ligand employed.

The mean fold angle of the rings was found to be $20.20^{\circ}$, similar to that observed in the free phosphine $\left(21.25^{\circ}\right)$. The mean C-P-C angle in the phosphetane rings $\left(77.81(10)^{\circ}\right)$ also remained relatively unchanged upon coordination, when compared to the free ligand $17\left(77.90(2)^{\circ}\right)$. Both observations are indicative of the rigid and constrained structure of the phosphetane ring.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with the proposed structure of 22. A singlet ( $\delta_{\mathrm{P}} 69.863 \mathrm{ppm}$ ) is observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, indicating that the two phosphorus atoms are chemically equivalent. The familiar pattern of resonances previously observed for the pentamethylphosphetane and o-xylene functionalities were observed in the ${ }^{1} \mathrm{H}$ NMR spectrum.

The APCI mass spectrum of 22 was also consistent with that previously observed for 7. The molecular ion was observed at $m / z 598\left(\mathrm{M}^{+}\right)$. The fragment due to the loss of
one carbonyl ligand was also observed at $m / z 570\left(\mathrm{M}^{+}-\mathrm{CO}\right)$. Both showing the isotopic pattern expected for a molybdenum complex.

The infra-red spectrum was recorded from a KBr disc of $\mathbf{2 2}$. Four bands were observed in the carbonyl region of the infrared ( $v_{\mathrm{CO}} 1847.7$ (sh), 1914.6, $2013.6 \mathrm{~cm}^{-1}$ ) consistent with that previously described for 7 . The $\mathrm{A}_{1}$ band for 22 (2013.6 $\mathrm{cm}^{-1}$ ) seems to imply lower $\sigma$-basicity for the phosphetane 17 when compared to that of the analogous complex of $\mathbf{1}\left(2001 \mathrm{~cm}^{-1}\right)$ (see Chapter 2).

### 3.2.2.2[1,2-bis(2,2,trans-3,4,4-pentamethylphosphetanemethyl)benzene tetracarbonyl molybdenum(0)] 23

23 was synthesised via a reaction analogous to that for 22 (Scheme 5). Similarly, a crop of colourless crystals of $\mathbf{2 3}$ was obtained by layering a chloroform solution of $\mathbf{2 3}$ with methanol. The X-Ray crystal structure of 23 is shown in Figure 5. Selected bond lengths and angles are given in Table 3.

Figure 5. X-Ray Crystal structure of 23. Hydrogen atoms have been omitted for clarity. Thermal ellipsoids are drawn at $50 \%$ probability

| Bond | Length $(\AA)$ | Group | Angle ( $\left.{ }^{\circ}\right)$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{P}_{1}-\mathrm{Mo}_{1}$ | $2.559(7)$ | $\mathrm{C}_{13}-\mathrm{P}_{1}-\mathrm{C}_{18}$ | $77.12(12)$ |
| $\mathrm{P}_{2}-\mathrm{Mo}_{1}$ | $2.560(6)$ | $\mathrm{C}_{13}-\mathrm{C}_{16}-\mathrm{C}_{18}$ | $99.1(2)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{2}$ | $1.968(3)$ | $\mathrm{C}_{21}-\mathrm{P}_{2}-\mathrm{C}_{26}$ | $77.71(12)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{4}$ | $1.988(3)$ | $\mathrm{C}_{21}-\mathrm{C}_{24}-\mathrm{C}_{26}$ | $99.8(2)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{1}$ | $2.055(3)$ | $\mathrm{P}_{1}-\mathrm{Mo}_{1}-\mathrm{P}_{2}$ | $88.12(2)$ |
| $\mathrm{Mo}_{1}-\mathrm{C}_{3}$ | $2.021(3)$ | $\mathrm{C}_{2}-\mathrm{Mo}_{1}-\mathrm{C}_{4}$ | $84.13(11)$ |
| $\mathrm{P}_{1}-\mathrm{C}_{13}$ | $1.903(3)$ | $\mathrm{C}_{1}-\mathrm{Mo}^{2}-\mathrm{C}_{4}$ | $84.92(11)$ |
| $\mathrm{P}_{1}-\mathrm{C}_{18}$ | $1.908(3)$ | $\mathrm{C}_{1}-\mathrm{Mo}_{1}-\mathrm{C}_{2}$ | $82.86(12)$ |
| $\mathrm{P}_{2}-\mathrm{C}_{21}$ | $1.900(3)$ | $\mathrm{C}_{1}-\mathrm{Mo}_{1}-\mathrm{C}_{3}$ | $168.30(10)$ |
| $\mathrm{P}_{2}-\mathrm{C}_{26}$ | $1.899(3)$ |  |  |

Table 3. Selected bond lengths and angles for 23.

The X-ray crystal structure (Figure 5) shows a P-Mo-P "bite" angle of 88.12(2) ${ }^{\circ}$, close to the natural metal dictated bite angle of $90^{\circ}$ expected for a complex with ideal octahedral geometry. Interestingly the P-Mo-P bite angle of 23 is significantly smaller than that observed for $22\left(100.68(18)^{\circ}\right)$.

The mean bond length Mo-C for the carbonyl ligands trans to the phosphine (1.978(3) $\AA$ ) are as expected, marginally shorter than those of the carbonyl ligands cis to the phosphine (2.038(3) $\AA$ ). The mean Mo-C bond length for the trans carbonyls of 23 (1.978(3) $\AA$ ) are marginally shorter than that observed in the related compound 22 (1.990(2) $\AA$ ).

Again, the mean P-Mo bond length is of interest in 23 (2.560(7) $\AA$ ) as it appears to differ significantly from that in 7 (2.658(6) $\AA$ ), but is comparable to that observed previously for 22 ( $2.544(6) \AA$ ). The mean fold angle of the phosphetane rings was found to be $17.3^{\circ}$, and the C-P-C angle $77.42(12)^{\circ}$, again both are consistent with the free ligand 17.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with the proposed structure of 23. A singlet ( $\delta_{\mathrm{P}} 84.058 \mathrm{ppm}$ ) is observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, indicating that the two phosphorus atoms are chemically equivalent. The now familiar pattern of resonances previously observed for the pentamethylphosphetane and o-xylene functionalities were observed in the ${ }^{1} \mathrm{H}$ NMR Spectrum.

The APCI mass spectrum of 23 was similar to that previously observed for 22 . The molecular ion was observed at $m / z 598\left(\mathrm{M}^{+}\right)$. The fragment due to the loss of one carbonyl ligand was also observed at $m / z 570\left(\mathrm{M}^{+}-\mathrm{CO}\right)$. Both showing the isotopic pattern expected for a molybdenum complex.

The IR spectrum was recorded from a KBr disc of 23 . Four bands were observed in the carbonyl region of the infrared ( $v_{\mathrm{CO}}$ 1857, 1877, 1912, $2016 \mathrm{~cm}^{-1}$ ) consistent with that previously described for 22. Again, the $A_{1}$ band for 22 ( $2016 \mathrm{~cm}^{-1}$ ) seems to infer lower $\sigma$-basicity for the phosphine 21 when compared to that of the analogous complex of 1 ( $2001 \mathrm{~cm}^{-1}$ ).

### 3.2.2.3 [(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) (trans, trans dibenzylideneacetone) palladium (0)] 24

24 was synthesised via reaction of 17 with $\left[\mathrm{Pd}(\mathrm{DBA})_{2}\right]$ in THF to afford an orange coloured solution. Subsequent work up gave 24 in $76 \%$ yield.
The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum $(298 \mathrm{~K})$ consisted of two broad resonances ( $\delta_{\mathrm{P}} 58.3$ and $64.4 \mathrm{ppm})$, resulting from the dynamic behaviour of the DBA ligand. When the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra was recorded at low temperature ( 248 K ), the two broad resonances where resolved into a complex pattern of peaks, each corresponding to complexes with one of the possible conformations of the DBA ligand. ${ }^{19}$

Scheme 6. Fluxional nature of the DBA ligand (where * distinguishes between the two double bonds)
The ${ }^{1} \mathrm{H}$ NMR spectrum of 24 recorded at low temperature, also revealed resonances due to the protons of the coordinated and uncoordinated olefinic bonds of the DBA ligand ( $\delta_{\mathrm{H}} 5.03$ and 7.65 ppm respectively), this being consistent with that observed by previous workers. ${ }^{23}$

### 3.2.2.4 [Dichloro (1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) palladium (II)] 25

25 was synthesised via displacement of the DBA ligand in complex 24 with 1,4-pbenzoquinone and subsequent oxidation with anhydrous HCl in diethyl ether. Upon standing the complex was precipitated as a yellow solid. Crystals of 25 were grown by the slow vapour diffusion of diethyl ether into a concentrated THF solution of the complex to give 25 as a crop of yellow to orange coloured crystals. A small amount of red crystals were also isolated, and subsequently found to be the THF solvate. The solid state structure was determined via X-ray diffraction, and is shown in Figure 6. Selected bond lengths and angles are given in Table 4.

The most striking feature of the structure is the deviation from the perfect squareplanar geometry commonly observed in $\mathrm{d}^{8} \mathrm{Pd}$ (II) halide complexes. The two chloride ligands being twisted out of the $x-y$ plane by $22.5^{\circ}$. The distortion is also carried through into the $o$-xylene unit bridging between the two phosphetane donors.

Figure 6. X-Ray Crystal structure of 25. Hydrogen atoms have been omitted for clarity. Thermal ellipsoids are drawn at $50 \%$ probability

Table 4. Selected bond lengths and angles for 25

## Chapter 3

This has previously been observed in solution, where it is believed that the $o$-xylene moiety can adopt different conformations. ${ }^{20}$ The most stable conformation of the ligand being the $\mathrm{C}_{2}$ symmetrical "scorpionate" arrangement, similar to that observed in the solid state structures of 22 and 23 where the $o$-xylene moiety "hangs" below the $x-y$ coordination plane. This conformation is the only one observed via ${ }^{31} \mathrm{P}\{\mathrm{H}\}$ NMR spectroscopy at room temperature for 25. NMR spectroscopy studies have revealed the "twisted" conformation observed in Figure 6 becomes more stable in solution at lower temperatures for related complexes. ${ }^{20}$

The mean P-Pd and $\mathrm{Pd}-\mathrm{Cl}$ bond lengths (2.247(9) $\AA$ and $2.386(10) \AA$ respectively) (Figure 6) are unremarkable. In common with 22 and 23 the mean C-P-C (79.13(18) ${ }^{\circ}$ ) and C-C-C (100.4(3) ${ }^{\circ}$ ) internal angles of the phosphetane ring also remain relatively unchanged from that of the free ligand 17.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra were found to be fully consistent with the proposed formulation of 25 . The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a singlet with a chemical shift of $\delta_{\mathrm{P}\{\mathrm{H}\}} 84.03 \mathrm{ppm}$ indicating that the two-phosphine donors are in a chemically equivalent environment.

The ${ }^{1} \mathrm{H}$ NMR spectrum showed the pattern of peaks expected for the $2,2,3,4,4-$ pentamethylphosphetane functionality. The resonance for the methylene protons of the $o$-xylene backbone were observed as two doublets ( $\delta_{\mathrm{H}} 3.55 \mathrm{ppm}$ and 3.59 ppm ), rather than the expected doublet observed in previous complexes. The multiplicity of these resonances suggesting the distorted structure observed via X-ray diffraction (figure 6) may occur in solution.

### 3.2.2.5 [(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) ( $\eta^{2}$ ethylene) palladium (0)] 26

26 was synthesised via the reaction of 17 with [ $\left(\eta^{5}\right.$-cyclopentadiene)( $\eta^{2}$-allyl) palladium(II)] $28,{ }^{16}$ in cold $\left(-40^{\circ} \mathrm{C}\right)$ diethyl ether under an atmosphere of high purity ethylene. Addition of $\mathbf{1 7}$ to $\mathbf{2 8}$ presumably causes the reductive elimination of the cyclopentadienyl and allyl ligands to give a coordinatively unsaturated phosphine
$\operatorname{Pd}(0)$ complex in common with that observed by previous workers with bulky monodentate phosphine ligands. ${ }^{21}$ Coordination of ethylene to this intermediate complex then gave 26, which was isolated as a red/orange coloured solid.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 26 when recorded at room temperature consisted of a single broad resonance ( $\delta_{\mathrm{P}\{\mathrm{H}\}} 54.79$ ) due to the propeller like rotation of the ethylene ligand around the metal-ethylene $\sigma$-bond. However, at low temperature $(258 \mathrm{~K})$ the broad resonance was resolved into a doublet of doublets, consistent with coupling between phosphorus and each of the inequivalent protons of the ethylene ligand (Figure 7).

Figure 7.
The ${ }^{1} \mathrm{H}$ NMR Spectrum consisted of the pattern of resonances now familiar to the pentamethylphosphetane functionality. The $\eta^{2}$-ethylene ligand was observed as a broad resonance ( $\delta_{\mathrm{H}} 2.39 \mathrm{ppm}$ ) at both room and lower temperature.

### 3.2.2.6 [(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) ( $\eta^{1}$-ethyl) palladium (II) tetrafluoroborate] 27

The gradual addition of a diethyl ether solution of $\mathrm{HBF}_{4}$ to a cooled diethyl ether solution of $\mathbf{2 6}$ caused the immediate precipitation of $\mathbf{2 7}$ as an orange coloured solid. The reaction being analogous to that previously demonstrated by Conroy-Lewis et al. ${ }^{22}$

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of two resonances $\left(\delta_{\mathrm{P}\{\mathrm{H}\}} 49.11\right.$ and 62.59 ppm), each corresponding to one of the inequivalent phosphorus atoms. Again the ${ }^{1} \mathrm{H}$ NMR spectrum showed the familiar pattern of resonances for the
pentamethylphosphetane functionality. The most striking feature of the ${ }^{1} \mathrm{H}$ NMR spectrum was the complex resonance observed at high field ( $\delta_{\mathrm{H}}-8.34 \mathrm{ppm}$ ), corresponding to the proton of the ethyl ligand that is interacting with the palladium atom. The resonance assigned to the five remaining protons of the ethyl ligand was partially obscured by resonances due to the methyl groups at the 2 and 4 positions of the phosphetane ring.

## Chapter 3

### 3.3 Experimental

All compounds were prepared using standard Schlenk techniques under an atmosphere of dinitrogen or argon. ${ }^{31} \mathrm{P}$ (referenced to $\mathrm{H}_{3} \mathrm{PO}_{4}$ at $\delta_{\mathrm{P}}=0$ ) and ${ }^{11} \mathrm{~B}$ (referenced to $\mathrm{Et}_{2} \mathrm{O} . \mathrm{BF}_{3}$ at $\delta_{\mathrm{B}}=0$ ) NMR data was collected on a Jeol Eclipse 300 MHz spectrometer; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ data on a Bruker 400 MHz DPX Avance. Mass spectra (ES and APCI) were obtained on a VG Fisons Platform II. Tetrahydrofuran, Diethyl ether and hexane were dried over sodium benzophenone. Toluene was dried over sodium. Methanol and acetonitrile were dried over calcium hydride. Water used during the work-up of all compounds was carefully deoxygenated by several cycles of heating at reflux and cooling to room temperature under a nitrogen purge. $\mathrm{CDCl}_{3}$ and $d_{3}$-acetonitrile were purchased from Aldrich, dried over $3 \AA$ molecular sieves and freeze-thaw degassed before use. $\mathrm{C}_{6} \mathrm{D}_{6}$ was purchased from Goss scientific and dried over sodium prior to use. Unless otherwise stated all chemicals were purchased from Aldrich and used without further purification. [( $\eta^{5}$-cyclopentadiene) $\left(\eta^{3}\right.$-allyl) $\left.\operatorname{Pd}(I I)\right]$ and $\left[\mathrm{Pd}\left(\eta^{3} \text {-allyl }\right) \mathrm{Cl}\right]_{2}$ were prepared as detailed in the literature. ${ }^{17}$

## 1-chloro-2,2,3,4,4-pentamethylphosphetane-1-oxide 14

(Adapted from the method of Jungermann). ${ }^{2}$

To a cooled ( $0^{\circ} \mathrm{C}$ ) dichloromethane ( $250 \mathrm{~cm}^{3}$ ) suspension of $\mathrm{PCl}_{3}$ ( 0.134 mols, 18.4 g) and $\mathrm{AlCl}_{3}(0.168$ mols, 22.33 g ) was gradually added (over 1 hr ) via cannula a DCM solution ( $50 \mathrm{~cm}^{3}$ ) of 2,4,4 trimethylpent-2-ene. During the addition of the alkene the amount of suspended $\mathrm{AlCl}_{3}$ noticeably decreased until the solution became clear and yellow in colour. The reaction was stirred for 24 hrs , where upon the solution darkened to a deep orange colour. Methanol $\left(110 \mathrm{~cm}^{3}\right)$ was then added to the cooled ( $0^{\circ} \mathrm{C}$ ) reaction mixture over 3 hrs . The addition was performed cautiously at first due to the exothermic nature of the reaction. After the full addition of the methanol, the reaction was stirred at $0^{\circ} \mathrm{C}$ for a further 0.5 hr . Ice cooled water (200 $\mathrm{cm}^{3}$ ) was then added to the cooled reaction mixture. The organic layer was removed via cannula and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solution was filtered via cannula and the solvent removed under reduced pressure to yield the product as fine off-white crystals that were dried carefully under vacuum.

Yield: $21.6 \mathrm{~g}, 82 \%$.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 82.93(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 0.92$ $\left(3 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCH}} 7.11 \mathrm{~Hz}\right) 1.31\left(6 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 10.95 \mathrm{~Hz}\right) 1.38\left(6 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 9.30 \mathrm{~Hz}\right) 1.778$ $(1 \mathrm{H}, \mathrm{m}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 7.31$ (d) 18.23 (d) 25.96 (d) 42.29 (d) 56.87 ppm (d).

MS (APCI): m/z 159.1 (M, -Cl).

## 2,2,3,4,4-Pentamethylphosphetane 15

To a slurry of $\mathrm{LiAlH}_{4}(2.83 \mathrm{mmol}, 0.11 \mathrm{~g})$ in $\mathrm{Et}_{2} \mathrm{O}\left(20 \mathrm{~cm}^{3}\right)$ was slowly added a $\mathrm{Et}_{2} \mathrm{O}$ solution ( $20 \mathrm{~cm}^{3}$ ) of 1-chloro 2,2,3,4,4 pentamethylphospetane-1-oxide $(2.57 \mathrm{mmol}$, 0.5 g ). The solution was stirred for a further 1 hr at $0^{\circ} \mathrm{C}$ and then allowed to warm to room temperature before stirring for a further 24 hrs . Water $\left(1 \mathrm{~cm}^{3}\right)$ was added to the cooled ( $0^{\circ} \mathrm{C}$ ) reaction mixture cautiously via cannula. $4 \mathrm{~cm}^{3}$ of $15 \% \mathrm{NaOH}$ solution was then added and the solution was stirred at $0^{\circ} \mathrm{C}$ for a further 0.5 hrs . $\mathrm{The}_{\mathrm{Et}}^{2} \mathrm{O}$ layer was removed via cannula and dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. $\mathrm{The}_{\mathrm{Et}_{2} \mathrm{O}}$ was then removed by distillation to yield the $2,2,3,4,4$ pentamethylphosphetane as a clear liquid, with a strong unpleasant odour.

Yield: $0.28 \mathrm{~g}, 80 \%$.
9:1 mixture of trans:cis isomers.
(trans 15) ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 16.95(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300\right.$ $\mathrm{MHz}) 0.79\left(3 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCH}} 7.02 \mathrm{~Hz}\right) 1.22\left(12 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 7.92 \mathrm{~Hz}\right) 2.68\left(1 \mathrm{H}, \mathrm{q},{ }^{3} J_{\mathrm{HCCH}}\right.$ $7.02 \mathrm{~Hz}) 3.78\left(1 \mathrm{H}, \mathrm{d},{ }^{1} \mathrm{~J}_{\mathrm{H}-\mathrm{P}} 176.06 \mathrm{~Hz}\right) ;{ }^{1} \mathrm{H}\left\{{ }^{31} \mathrm{P}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 0.79(3 \mathrm{H}$, d, $\left.{ }^{3} J_{\mathrm{HCCH}} 7.02 \mathrm{~Hz}\right) 1.23(12 \mathrm{H}, \mathrm{s}) 2.68\left(1 \mathrm{H}, \mathrm{q}^{3} J_{\mathrm{HCCH}} 7.05 \mathrm{~Hz}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right.$, $75.56 \mathrm{MHz}) 10.24$ (s) 23.16 (d) 31.75 (d) 56.64 ppm (d).

## Chapter 3

## 1,2-bis(2,2,trans-3,4,4-pentamethylphosphetanemethyl)benzene-trihydroboron 20

To a cooled ( $-78^{\circ} \mathrm{C}$ ) THF solution ( $25 \mathrm{~cm}^{3}$ ) of 2,2,3,4,4-pentamethylphosphetanetrihydroboron ( $0.31 \mathrm{~g}, 1.95 \mathrm{mmol}$ ) was added, via syringe, sec-BuLi ( 2.10 mmol ) upon full addition of the sec-BuLi the solution became bright yellow. The solution was stirred for 2 hrs at $-78^{\circ} \mathrm{C}$ and then a further 0.5 hr at room temperature to give 1 -lithio-2,2,3,4,4-pentamethylphosphetanide-trihydroboron. The deprotonation can monitored by either ${ }^{31} \mathrm{P}\{\mathrm{H}\}$ or ${ }^{11} \mathrm{~B}\{\mathrm{H}\}$ NMR spectroscopy (data given below). The solution was cooled to $-78{ }^{\circ} \mathrm{C}$ and a THF solution $\left(10 \mathrm{~cm}^{3}\right)$ of $\alpha, \alpha^{\prime}$-dichloro-o-xylene ( $0.17 \mathrm{~g}, 0.97 \mathrm{mmol}$ ) was added slowly via cannula. The solution was allowed to stir for 1 hr at $-78^{\circ} \mathrm{C}$ and then allowed to warm to room temperature before being left to stir for a further 18 hr . During this time the solution became cloudy as LiCl precipitated. The solvent was removed under vacuum, and dichloromethane ( $30 \mathrm{~cm}^{3}$ ) and water ( $30 \mathrm{~cm}^{3}$ ) added to give a two-phase system. The organic phase was then removed via cannula and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was removed under reduced pressure to yield the product as a white solid.

Yield: $0.36 \mathrm{~g}, 89 \%$

## 1,2-bis(2,2,trans-3,4,4-pentamethylphosphetanemethyl)benzene 21

To a stirred cooled $\left(0^{\circ} \mathrm{C}\right)$ solution of 1,2-bis(2,2,3,4,4pentamethylphosphetane methyl)benzene-trihydroboron ( $0.40 \mathrm{~g}, 0.97 \mathrm{mmol}$ ) in DCM ( $40 \mathrm{~cm}^{3}$ ) was added, via syringe, tetrafluoroboric acid dimethylether complex ( $10 \mathrm{eq}, 9.70 \mathrm{mmol}$ ). The solution was stirred at $0^{\circ} \mathrm{C}$ for 30 minutes and then allowed to warm to room temperature. After stirring for 6 hrs at room temperature, $80 \mathrm{~cm}^{3}$ of saturated sodium bicarbonate solution was added and the solution stirred rapidly for 16 hrs . The stirring was stopped and the two phases allowed to separate. The organic phase was removed via cannula and the aqueous phase washed with a $30 \mathrm{~cm}^{3}$ portion of DCM. The combined organic phases were dried over $\mathrm{MgSO}_{4}$ and subsequently filtered via cannula. The solvent was removed under reduced pressure to yield 1,2-bis(2,2,3,4,4pentamethylphosphetanemethyl)benzene as a white solid.

## 1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene 17

17 can also be conveniently synthesised, without isolation of the intermediate phosphonium salt, by employing the following procedure.

An acetone solution ( $70 \mathrm{~cm}^{3}$ ) of $\alpha, \alpha^{\prime}$-dibromo- $o$-xylene ( $16 \mathrm{mmols}, 4.10 \mathrm{~g}$ ) was added via cannula to a stirred acetone solution ( $25 \mathrm{~cm}^{3}$ ) of 2,2,3,4,4Pentamethylphosphetane ( $31 \mathrm{mmols}, 4.47 \mathrm{~g}$ ). The solution was allowed to stir for 16 hrs. An aqueous solution ( $100 \mathrm{~cm}^{3}$ ) of sodium bicarbonate ( $2.6 \mathrm{~g}, 31 \mathrm{mmols}$ ) was then added to the solution and the mixture vigorously stirred for 1 hr . The organic layer was removed via cannula, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and subsequently filtered via cannula. The solvent was removed under reduced pressure to yield 1,2-bis(2,2,3,4,4pentamethylphosphetanium methyl) benzene as a white solid. The crude product was then recrystallised from hot methanol to give a mixture of the cis-cis and trans-trans isomers in a ratio of 9:1.

Yield: $2.30 \mathrm{~g}, 38 \%$
NMR data (crude reaction mixture): ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 29.31$ (s, $16 \mathrm{eq}) 42.549$ (s, 4 eq$) 59.972 \mathrm{ppm}$ (s, 1 eq ).

## Chapter 3

1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene tetracarbonyl molybdenum(0) 22

A DCM solution (15 $\mathrm{cm}^{3}$ ) of 1,2-bis(2,2,cis-3,4,4-pentamethylphosphatane methyl)benzene ( $0.21 \mathrm{~g}, 0.53 \mathrm{mmol}$ ) was added to [cis(piperidine) $\left.)_{2}(\mathrm{CO})_{4} \mathrm{Mo}\right](0.20 \mathrm{~g}$, 0.53 mmol ) to give an orange coloured suspension. Upon heating under reflux ( 0.25 hrs), the suspended material dissolved to give a yellow coloured solution. The solution was allowed to cool to room temperature and the solvent removed under vacuum to leave a buff coloured solid, which was recrystallised by layering a chloroform solution of the solid with methanol.

Yield: $0.16 \mathrm{~g}, 52 \%$
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 69.86(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 0.86$ $\left(6 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCH}} 6.72 \mathrm{~Hz}\right) 1.34\left(12 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 17.46 \mathrm{~Hz}\right) 1.49\left(12 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{H}-\mathrm{P}} 9.69 \mathrm{~Hz}\right)$ $2.49\left(2 \mathrm{H}, \mathrm{q},{ }^{3} J_{\mathrm{HCCH}} 6.06 \mathrm{~Hz}\right) 3.39\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 5.70 \mathrm{~Hz}\right) 7.12(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.31(2 \mathrm{H}$, $\mathrm{m}, \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 8.76$ (s) 21.91 (d) 26.93 (d) 30.90 (d) 33.66 (d) 49.12 (d) 126.64 (s) 131.77 (d) 135.37 ppm (d).

[(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene)(trans, trans dibenzylideneacetone) palladium (0)l 24

To $\left[\operatorname{Pd}_{2}(\mathrm{DBA})_{3}\right](0.28 \mathrm{~g}, 0.30 \mathrm{mmols})$ was added, via cannula, a THF $\left(20 \mathrm{~cm}^{3}\right)$ solution of $1,2-b i s(2,2, c i s-3,4,4-$ pentamethylphosphatanemethyl)benzene $(0.190 \mathrm{~g}$, 0.48 mmols). The solution was stirred for 2 hrs whereupon a gradual colour change from deep violet to red/orange was observed. The solvent was removed under reduced pressure and the remaining red solid dissolved in three $30 \mathrm{~cm}^{3}$ portions of hexane to remove any residual $\left[\mathrm{Pd}_{2}(\mathrm{DBA})_{3}\right]$. After filtering via cannula the hexane was reduced in volume under reduced pressure and the orange complex precipitated from solution, the remaining hexane was removed via filter cannula and the orange complex washed with three $5 \mathrm{~cm}^{3}$ portions of cold $\left(-15^{\circ} \mathrm{C}\right)$ diethyl ether.

Yield: $0.27 \mathrm{~g}, 76 \%$

## Chapter 3

[Dichloro (1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) palladium (II)] 25

A solution of [(1,2-bis(2,2,cis-3,4,4-pentamethylphosphatane methyl)benzene) (trans, trans-dibenzylidene acetone) Palladium(0)] ( $0.1 \mathrm{~g}, 0.14 \mathrm{mmol}$ ) in diethyl ether ( 8 $\mathrm{cm}^{3}$ ) was added to 1,4 -p-benzoquinone ( $0.01 \mathrm{~g}, 0.14 \mathrm{mmols}$ ). The solution was stirred for 1 hr during which time it gradually darkened to a red colour. An anhydrous diethyl ether solution of $\mathrm{HCl}(0.28 \mathrm{mmols})$ was then added via syringe to the solution and an instant colour change to yellow was observed. At this point the stirring was stopped and, over 2.5 hrs a yellow solid precipitated. The supernatant was removed via cannula filtration and the solid dried under vacuum. X-ray quality crystals were obtained via the slow vapour diffusion of diethyl ether into a concentrated solution of the complex in THF.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 84.03(\mathrm{~s}) ;{ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 0.96$ $\left(6 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCH}} 7.26 \mathrm{~Hz}\right) 1.45\left(12 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCP}} 14.94 \mathrm{~Hz}\right) 1.66\left(12 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCP}} 20.43 \mathrm{~Hz}\right)$ $3.026(2 \mathrm{H}, \mathrm{q}, \mathrm{br}) 3.554\left(2 \mathrm{H}, \mathrm{d},{ }^{2} \mathrm{~J}_{\mathrm{HCP}} 4.17 \mathrm{~Hz}\right) 3.590(\mathrm{~d}, 2 \mathrm{H}) 7.249(\mathrm{~m}, \mathrm{Ar}-\mathrm{H}) 7.290$ ppm (m, Ar-H).
(Found: C, 49.97 ; H 6.89\%. Calc. For complex: C, 50.76; H, 7.10; Cl, 12.48; P, 10.90\%).

MS (APCI): m/z 531.8 (M, -Cl).

I(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) ( $\eta^{2}$-ethylene) palladium (0)] 26

A diethyl ether ( $20 \mathrm{~cm}^{3}$ ) solution of 1,2-bis(2,2,cis-3,4,4-pentamethylphosphatane methyl)benzene was added gradually via cannula to a cooled $\left(-40^{\circ} \mathrm{C}\right)$ diethyl ether ( 15 $\mathrm{cm}^{3}$ ) solution of $\left[\left(\eta^{3}\right.\right.$-allyl) $\left(\eta^{5}\right.$-cyclopentadiene)palladium(II)] ( $0.12 \mathrm{~g}, 0.54 \mathrm{mmols}$ ) under a ethylene atmosphere, to give an orange solution. A small portion of the solution was removed via cannula and the solvent removed under vacuum to give an orange coloured solid.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $d_{6}$-acetone, $298 \mathrm{~K}, 121.65 \mathrm{MHz}$ ) $\delta 54.79$ (br)

## Chapter 3

[(1,2-bis(2,2,cis-3,4,4-pentamethylphosphetanemethyl)benzene) ( $\eta^{1}$-ethyl) palladium (II) tetrafluoroboratel 27

To the cooled $\left(-40^{\circ} \mathrm{C}\right)$ diethyl ether solution of [(1,2-bis(2,2,cis-3,4,4pentamethylphosphatanemethyl)benzene) ( $\eta^{2}$ ethylene)Palladium(0)] (see above 26) was added a diethyl ether solution of $\mathrm{HBF}_{4}(0.54 \mathrm{mmols})$ via syringe. Upon addition there was an instant precipitation of the title compound as an orange coloured solid. The supernatant was then removed via cannula filtration and the solid was then dried under vacuum.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(d_{2}\right.$-DCM, 121.65 MHz$) \delta 49.11(\mathrm{~s}, \mathrm{br}) 62.59(\mathrm{~s}, \mathrm{br}) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $d_{2}$-DCM, 96.42 MHz ) - $2.01(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR ( $d_{2}$-DCM, 300 MHz ) $-8.34(1 \mathrm{H}, \mathrm{m}) 0.97$ $\left(6 \mathrm{H}, \mathrm{d},{ }^{3} J_{\mathrm{HCCH}} 6.90 \mathrm{~Hz}\right) 1.23(12 \mathrm{H}, \mathrm{d}, \mathrm{br}) 1.39(12 \mathrm{H} . \mathrm{d}, \mathrm{br}) 1.44(4 \mathrm{H}, \mathrm{m}, \mathrm{br}) 2.74(2 \mathrm{H}$, q, $\left.{ }^{3} J_{\mathrm{HCCH}} 6.90 \mathrm{~Hz}\right) 3.65(4 \mathrm{H}, \mathrm{d}, \mathrm{br}) 7.15(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.44(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $d_{2}$-DCM, 75.56 MHz ) 8.31 (d) 17.49 (Et) 20.23 (s) 22.96 (s) 27.13 (d) 29.24 (s) 30.30 (s) 127.96 (s) 130.07 (s) 133.23 ppm (s).
$\amalg \eta^{5}$-cyclopentadiene) $\left(n^{3}\right.$-allyl)palladium(II) $\ 28 .{ }^{17}$

[ $\mu^{2}$ dichloro $\left(\eta^{3} \text { allyl }\right)_{2}$ dipalladium(II)] $29(1 \mathrm{~g}, 2.73 \mathrm{mmol})$ was degassed in a Schlenk vessel and then dissolved in THF ( $10 \mathrm{~cm}^{3}$ ). Benzene $\left(10 \mathrm{~cm}^{3}\right)$ was then added to give a yellow coloured solution. The solution was cooled $\left(-20^{\circ} \mathrm{C}\right)$ and a THF solution of sodium cyclopentadiene ( 5.46 mmol ) was added dropwise over a 0.5 hr period, via a
cannula, during the addition the solution gradually became deep red in colour. The solution was stirred at $-20^{\circ} \mathrm{C}$ for a further 1 hr and allowed to warm to room temperature and stirred for an additional 0.5 hrs . The solvent was then removed under vacuum whilst cooling the flask to prevent any product subliming. The red solid obtained was then extracted with $20 \mathrm{~cm}^{3}$ of hexane and filtered via cannula. The solvent was then removed under a mild vacuum (40-60 Tor) whilst being stirred slowly in order to prevent sublimation of the product. The product was isolated as a deep red solid with an unusual odour.

Sodium cyclopentadienide was prepared by the gradual addition of freshly distilled cyclopentadiene dimer to a cooled $\left(0^{\circ}\right)$ THF solution of finely divided sodium metal to give a light pink coloured solution. After filtration, the concentration of sodium cyclopentadiene was found by the reaction of $1 \mathrm{~cm}^{3}$ of the solution with water and titration against standard acid.

## I $\mu_{2}$ dichloro $\left(\eta^{3} \text {-allyl }\right)_{2}$ dipalladium(II)] $\mathbf{2 9}^{17}$

A $200 \mathrm{~cm}^{3}$ flask fitted with a condenser topped with a gas outlet and oil bubbler was charged with palladium chloride $(2.22 \mathrm{~g}, 12.5 \mathrm{mmol}) \mathrm{NaCl}(1.5 \mathrm{~g}, 25.9 \mathrm{mmol})$ and $\mathrm{H}_{2} \mathrm{O}\left(5 \mathrm{~cm}^{3}\right)$ and allowed to stir for 0.5 hrs . A $\mathrm{MeOH}\left(30 \mathrm{~cm}^{3}\right)$ solution of allylchloride ( $3.0 \mathrm{~g}, 33.5 \mathrm{mmol}$ ) was then added to the flask and carbonmonoxide bubbled into the solution by means of a glass tube for a 1 hr period. The yellow suspension obtained from the reaction was poured into water ( $150 \mathrm{~cm}^{3}$ ) and extracted with two portions of $\mathrm{CHCl}_{3}\left(50 \mathrm{~cm}^{3}\right)$. The $\mathrm{CHCl}_{3}$ solution was dried over calcium chloride and subsequently filtered on a buchner funnel. Slow evaporation of the solvent under vacuum yielded the title compound as a crystalline yellow solid.

## Chapter Four

### 4.1 Introduction.

An efficient synthesis of di-1-adamantylphosphine was first described by Goerlich and Schmutzler in $1995 .{ }^{1}$ Their work providing access to the precursors required to synthesise a range of di-1-adamantyl substituted phosphine ligands. Since this point, di-1-adamantyl phosphines have been implied in the chemical literature to provide an effective alternative to $t$-butyl substituted phosphine ligands in a number of catalysed reactions.

Buchwald has described the use of 2-[di(1-adamantyl)phosphino)]biphenyl (Figure 1) in the palladium catalysed formation of diaryl ethers (Scheme 1). ${ }^{3}$

Figure 1. 2-[di(1-adamantyl)phosphino)]biphenyl

Buchwald noted that there was a difference in catalytic activity between the adamantyl substituted ligand when compared to the $t$-butyl analogue. The difference was most apparent in coupling of electron rich aryl-chlorides, with the adamantyl substituted ligand giving higher yields of the coupled product. The authors imply that the difference in catalyst activity is due to the differing steric influence of the adamantyl groups.

Scheme 1. Catalytic formation of diarylethers ${ }^{3}$

## Chapter 4

Bulky monodentate phosphine ligands have also been established as effective ligands in the heck coupling of arylchlorides, tri-t-butylphosphine being a well established example. ${ }^{4}$ Di-1-adamantyl substituted phosphines have also recently been examined in this reaction by Beller. ${ }^{5}$

Beller was able to demonstrated that di-1-adamantyl-n-butylphosphine provided catalysts with similar and sometimes higher activity than those formed with tri-tbutylphosphine. The difference in activity being most apparent with coupling reactions with non-activated arylchlorides.

### 4.1.2 Phosphorylation reactions

Phosphorylation reactions performed in the presence of aluminium chloride are well known in the chemical literature. Some of the earliest examples were described by Clay. ${ }^{6}$ A number of different substrates have been phosphorylated under these conditions.

Kinnear and Perren ${ }^{7}$ described the phosphorylation of alkyl chlorides in the presence of aluminium chloride in DCM solution. The reactions gave compounds of the form $\mathrm{RP}(\mathrm{O}) \mathrm{Cl}_{2}$ (phosphonic dichlorides) after aqueous work-up. The reaction proved to be applicable to a variety of alkyl chlorides ( $\mathrm{R}: \mathrm{Me}, \mathrm{Et}, i-\mathrm{Pr}, t-\mathrm{Bu}$ ) and gave good yields of product in most cases.

Olah, ${ }^{8}$ employed a number of cyclic and polycyclic hydrocarbons, and again isolated compounds with the general form $\mathrm{RP}(\mathrm{O}) \mathrm{Cl}_{2}$. It was found that adamantane, alkyl adamantanes and diamantane gave reasonable yields (64, 40-46 and 60\% respectively). However, in reactions with bicyclic, monocyclic and acyclic hydrocarbons the yield was significantly lower ( 10-20\%).
The reactions described by Perren ${ }^{7}$ and Olah $^{8}$ are selective for the singly alkylated phosphonic dichlorides. Examples of selective reactions were the major product is doubly alkylated are more unusual. Indeed, the example described by Goerlich ${ }^{1}$ appears to unique in this respect.

### 4.2 Results and discussion

### 4.2.1 Ligand synthesis.

The synthetic strategies outlined in chapter 2 to access ortho-xylene bridged diphosphine ligands have been applied to the novel phosphines described in this chapter. Both ligands could have been accessed via the xylene metallation chemistry described previously. However, because of the nature of the organophosphorus starting materials (i.e. phosphinic chlorides) (30,37), it is more convenient to utilise the phosphino-borane chemistry previously described in chapters 2 and 3.

### 4.2.1.1 Di-1-Adamantylphosphinic chloride 30

30 was synthesised via a methodology (Scheme 1) modified from that of Goerlich et al. ${ }^{1}$ Adamantane, aluminium chloride ( 1.5 equivalents) and a large excess of phosphorus trichloride where slurried together in a round-bottomed flask to give a buff coloured suspension. Upon heating under reflux, a bright orange coloured suspension was afforded. Subsequent work up gave $\mathbf{3 0}$ as an off white crystalline solid in $\mathbf{9 9 \%}$ yield. Unlike $\mathbf{1 4}$, it was found that 30 did not rapidly hydrolyse in air.

Scheme 1. Goerlich's synthesis of 30

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of 30 where found to be fully consistent with those previously reported. ${ }^{1}$

### 4.2.1.2 Di-1-Adamantylphosphine 31

31 was synthesised via a methodology adapted from that described previously by Goerlich. ${ }^{1}$ The reduction of 30 with lithium aluminium hydride afforded 31 as a
colourless solid in $67 \%$ yield. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR Spectra of 31 were found to be fully consistent with those previously reported. ${ }^{1}$

### 4.2.1.3 Di-1-Adamantylchlorophosphine 32

The title compound was prepared via an adaptation of the methodology of Goerlich et $a l .{ }^{1}$ The phosgene solution employed by Goerlich, was replaced by triphosgene for reasons of safety and ease of handling. 32 was isolated as a yellow solid in moderate yield (47\%). The NMR Spectra of 32 were fully consistent with those previously described. ${ }^{1}$

### 4.2.1.4 Di-1-Adamantylphosphine trihydroboron 33

Reaction of 32 with borane THF adduct, afforded 33 as a colourless solid in near quantitative yield. The structure of 33 was confirmed via $^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR Spectroscopy. As would be expected, the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a single broad quartet ( $\delta_{\mathrm{P}} 41.37 \mathrm{ppm},{ }^{1} J_{\mathrm{P}-\mathrm{B}} 64.45 \mathrm{~Hz}$ ) indicative of a phosphine-borane adduct seen in previous compounds. The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum reflected that observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, and consisted of a single sharp doublet $\left(\delta_{\mathrm{B}}-\right.$ 43.78 ppm ). In common with related compounds described in the chemical literature, ${ }^{1}$ the ${ }^{1} \mathrm{H}$ NMR spectrum consisted of a broad resonance ( $\delta_{\mathrm{H}} 1.74-2.02 \mathrm{ppm}$ ) that could be assigned to the 30 adamantyl protons. A smaller double quartet ( $\delta_{\mathrm{H}} 3.72 \mathrm{ppm},{ }^{1} J_{\mathrm{H}-\mathrm{P}}$ $350.58 \mathrm{~Hz},{ }^{2} J_{\mathrm{H}-\mathrm{B}} 6.64 \mathrm{~Hz}$ ) was also observed for the phosphorus bound proton.

### 4.2.1.5 1,2-bis(di-1-adamantylphosphinotrihydroboronmethyl)benzene $34^{10}$

34 was synthesised via the methodology previously described for the synthesis of 5 and 20 (scheme 2). To a cooled $\left(-78^{\circ} \mathrm{C}\right)$ THF solution of $\mathbf{3 3}$ was gradually added 1.1 equivalents of ${ }^{\text {sec } B u L i, ~ t o ~ a f f o r d ~ a ~ i n t e n s e l y ~ c o l o u r e d ~ s o l u t i o n ~(y e l l o w) . ~ T h e ~ s o l u t i o n ~}$ was stirred for 0.5 hr and then allowed to warm to room temperature and stir for an additional 1 hr . The deprotonation was monitored by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy. The lithium phosphide being observed as a broad quartet, with a chemical shift of $\delta_{\mathrm{P}} 9.67 \mathrm{ppm}$ via ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy and a doublet with a chemical shift of $\delta_{\mathrm{B}}-\mathbf{3 9 . 0 0} \mathrm{ppm}$ in the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum.

Upon recooling $\left(-78^{\circ} \mathrm{C}\right)$, a THF solution of 0.5 equivalents of $\alpha, \alpha^{\prime}$-dichloro-orthoxylene was added drop wise via cannula. After subsequent work-up, 34 was isolated as a colourless solid in $92 \%$ yield.

1. ${ }^{\text {sec }} \mathrm{BuLi}$

Scheme 2. Synthesis of 34

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra of 33 are fully consistent with the proposed structure. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a broad quartet with a chemical shift of $\delta_{P} 41.37 \mathrm{ppm}$. Conversely the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a sharp doublet with a chemical shift of $\delta_{\mathrm{B}}-46.35 \mathrm{ppm}\left({ }^{1} J_{\mathrm{B}-\mathrm{P}} 51.84 \mathrm{~Hz}\right)$, both being indicative of a phosphine-borane adduct. The ${ }^{1} \mathrm{H}$ NMR spectrum displayed two broad resonance's ( $\delta_{\mathrm{H}} 1.722$ and 1.9-2.2 ppm) that integrate and can be assigned to the 60 protons of the adamantyl groups. The methylene protons of the ortho-xylene backbone were observed as a doublet ( $\delta_{\mathrm{H}} 3.29 \mathrm{ppm},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 12.0 \mathrm{~Hz}$ ) with the aromatic protons being assigned to two multiplets ( $\delta_{\mathrm{H}} 7.11$ and 7.61 ppm respectively).

### 4.2.1.6 1,2-bis(di-1-adamantylphosphinomethyl)benzene 35

In common with 5 and 20, 34 was deprotected to give the free phosphine 35 upon reaction with 10 equivalents of tetrafluoroboric acid dimethylether complex, and subsequent reaction with sodiumbicarbonate. Attempts to grow crystals of 35 were unsuccessful. However, it was found that $\mathbf{3 5}$ could be precipitated from a saturated DCM solution upon cooling at $-40^{\circ} \mathrm{C}$ for a prolonged period.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra were consistent with the proposed structure of 35 . The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a singlet with a chemical shift of $\delta_{\mathrm{P}} 26.37$ ppm . A chemical shift similar to that previously observed for the $t$-butyl analogue 1 ( $\delta_{\mathrm{P}} 28.06 \mathrm{ppm}$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum consisted of the now familiar pattern of resonances. Two multiplets ( $\delta_{\mathrm{H}} 1.70$ and 1.91 ppm ) were assigned to the 60 protons of the adamantyl groups. The methylene protons of the $o$-xylene backbone were observed as a doublet ( $\delta_{\mathrm{H}} 3.01 \mathrm{ppm},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 3.00 \mathrm{~Hz}$ ), and each set of chemically equivalent aromatic protons were observed as a multiplet ( $\delta_{\mathrm{H}} 7.036$ and 7.544 ppm ). The APCI mass spectra showed a peak for the molecular ion of 35 at $m / z 707.5$.

### 4.2.1.7 Di (1-methylcyclopentyl)phosphinic chloride 36

36 was synthesised via a methodology similar to that employed for 30 (Scheme 3). Methylcyclopentane, $\mathrm{AlCl}_{3}$ and $\mathrm{PCl}_{3}$ were slurried together, unlike the previous reaction with adamantane there was no initial colour change. Upon the suspension being heated to reflux, the suspension became bright orange in colour, as observed previously. After work-up 36 was isolated as a viscous colourless oil.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 36 consisted of a singlet with a chemical shift of $\delta_{P}$ 95.51 ppm , and is similar to that observed for the related compound 30 ( $\delta_{\mathrm{P}} 86.80$ ppm).

The ${ }^{1} \mathrm{H}$ NMR spectrum of 36 was also found to be consistent with the proposed structure. A doublet was observed at $\delta_{\mathrm{H}} 1.26 \mathrm{ppm}$ and can be assigned to the six methyl protons of the methylcyclopentyl groups. A double multiplet with chemical shifts of $\delta_{\mathrm{H}} 1.55$ and $\delta_{\mathrm{H}} 2.27 \mathrm{ppm}$ could be assigned to the eight protons at the 2 position of the cyclopentyl rings. The final eight protons were assigned to a multiplet observed at $\delta_{\mathrm{H}} 1.69 \mathrm{ppm}$.

Scheme 3. Synthesis of 36

The APCI mass spectrum further supports the proposed structure of 36, with the molecular ion being observed at $m / z 249$.

Further investigation into the scope of this reaction was also carried out. When methylcyclohexane was employed as the hydrocarbon substrate, a viscous oil similar to 36 was isolated. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of the oil revealed a complicated pattern of resonances. The largest two resonances having chemical shifts consistent with the mono and dialkylated species ( $\delta_{\mathrm{P}} 58.80$ and 96.44 ppm respectively) in a $1: 1$ ratio. Attempts to isolate either of these compounds were unsuccessful.

Norbornane was also trialed as the substrate under the conditions used in previous reactions. Again, a viscous colourless oil was isolated from the reaction. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of the oil showed a mixture of compounds, with the major component having a chemical shift of $\delta_{\mathrm{P}} 56.40 \mathrm{ppm}$, consistent with a monoalkylated phosphonic dichloride.

### 4.2.1.8 Di(1-methylcyclopentyl)phosphine 37

37 was synthesised via the reduction of 36 with $\mathrm{LiAlH}_{4}$ in diethyl ether. 37 was isolated as a colourless, unpleasant smelling oil in $78 \%$ yield.

The structure of 37 was confirmed by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a singlet with a chemical shift of $\delta_{\mathrm{P}} 15.63$ ppm, this being similar to that of the other secondary alkyl phosphines previously described (3, 32). The ${ }^{1} \mathrm{H}$ NMR spectrum was also consistent with the proposed structure of 37 . A doublet with a chemical shift of $\delta_{\mathrm{H}} 1.28 \mathrm{ppm}$ could be assigned to

## Chapter 4

the six methyl protons of the methylcyclopentyl groups. The eight ring protons at the 2 position were assigned to a double multiplet with chemical shifts of $\delta_{\mathrm{H}} 1.65$ and 2.30 ppm . The remaining eight ring protons were then assigned to a broad multiplet with a chemical shift of $\delta_{\mathrm{H}} 1.72 \mathrm{ppm}$.

### 4.2.1.9 Di(1-methylcyclopentyl)phosphine trihydroboron 38

Reaction of a THF solution of 37 with 1.5 equivalents of borane THF adduct, yielded the phosphine-borane adduct 38 as a low melting solid in almost quantitative yield.

As would be expected for a phosphine-borane adduct, the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a broad quartet which had a chemical shift of $\delta_{\mathrm{P}} 48.59 \mathrm{ppm}$. In common with the phosphine-borane adducts previously described, the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a doublet with a chemical shift of $\delta_{B}-44.28 \mathrm{ppm}$.

### 4.2.1.10 1,2-bis(di-1-methylcyclopentylphosphinotrihydroboronmethyl)benzene 39

Synthesis of 39 (Scheme 4) was carried out via the methodology previously described for the related compounds 5, 20 and 34.
$\mathrm{Di}(1-$ methylcyclopentyl)phosphine trihydroboron 38 was deprotonated with sec-BuLi in THF solution at $-78^{\circ} \mathrm{C}$ to give the corresponding lithium phosphide. The solution becomes a distinctive yellow colour and can be monitored by either ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ or ${ }^{11} \mathrm{~B}$ $\left\{{ }^{1} H\right\}$ NMR spectroscopy. The lithium phosphide of 38 having a chemical shift of $\delta_{P}$ 12.37 ppm in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and $\delta_{\mathrm{B}}-37.52 \mathrm{ppm}$ in the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum.

Scheme 4. Synthesis of 39

The synthesis of 39 was then completed upon the addition of 0.5 equivalents of $\alpha, \alpha$ 'dichloro- $o$-xylene as a THF solution.

The ${ }^{31} P\left\{{ }^{1} H\right\},{ }^{11} B\left\{{ }^{1} H\right\}$ and ${ }^{1} H$ NMR spectrum of 39 were found to be consistent with the proposed structure. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a broad quartet with a chemical shift of $\delta_{\mathrm{P}} 52.70 \mathrm{ppm}$, and is in agreement with that observed for the related compounds 5,20 and 34 . The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum consisted of a doublet with a chemical shift $\delta_{\mathrm{B}}-\mathbf{4 3 . 3 5} \mathrm{ppm}$.

The ${ }^{1}$ H NMR spectrum of 39 exhibited the now familiar pattern of resonances due to the methylcyclopentyl groups. A doublet with a chemical shift of $\delta_{\mathrm{H}} 3.33 \mathrm{ppm}$ could also be assigned to the four methylene protons of the $o$-xylene backbone. The two sets of chemically equivalent aromatic protons were observed as two multiplets with chemical shifts of $\delta_{\mathrm{H}} 7.06$ and 7.37 ppm

### 4.2.1.11 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene 40

The phosphine borane adduct 39 was deprotected upon reaction with ten equivalents of tetrafluoroboric acid dimethyl ether complex, and subsequently sodium bicarbonate solution to give the phosphine 40.

It was found that $\mathbf{4 0}$ could also be synthesised by the addition of two equivalents of $\mathrm{di}\left(1-\right.$ methylcyclopentyl)phosphine to $\alpha, \alpha^{\prime}$ dibromo- $o$-xylene, to give the hydrobromide diphosphonium salt (not isolated). Reaction with sodium hydroxide then gave the free phosphine. In common with that observed previously (19) the major product of the addition reaction was an iso-phosphindolinium salt (41) (Figure 2), the full characterisation of this compound is given in the experimental section.

Figure 2. iso-phosphindolinium salt 41

The NMR data generated with the material isolated from either route was found to be identical. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum was found to consist of a singlet with a chemical shift of $\delta_{\mathrm{P}} 33.84 \mathrm{ppm}$. The ${ }^{1} \mathrm{H}$ NMR spectrum consisted of a doublet with a chemical shift of $\delta_{\mathrm{H}} 1.16 \mathrm{ppm}$ that could be assigned to the twelve methyl protons of the methylcyclopentyl groups. The remaining ring protons of the methylcyclopentyl groups were observed as a broad complex multiplet, with a chemical shift of $\delta_{\mathrm{H}} 1.54$ ppm . The four methylene protons of the $o$-xylene backbone were observed as a doublet with $\delta_{\mathrm{H}} 3.08 \mathrm{ppm}$, and the remaining aromatic protons were observed as two multiplets $\delta_{\mathrm{H}} 7.01$ and 7.40 ppm .

### 4.2.2 Complexation chemistry

### 4.2.2.1 [(1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene) tetracarbonyl molybdenum (0)] 42

In a reaction analogous to that described for the synthesis of 7, 22 and 23, 42 was synthesised by reaction of the phosphine ligand 40 with one equivalent of [cisbis(piperidine)tetracarbonylmolybdenum(0)] 8 in hot DCM solution (Scheme 5). Initially an orange coloured suspension of material was obtained. However, after heating the solution at reflux for 0.75 hrs , the suspended material dissolved and the
solution became yellow in colour. After work-up, 42 was isolated as a buff coloured solid. Further purification was achieved by recrystalisation from a chloroform solution layered with methanol. The crystals obtained were found to be slightly too small for determination of the solid state structure by X-ray diffraction.

Scheme 5. Synthesis of 42.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of 42 are consistent with the proposed structure. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows the expected singlet with a chemical shift of $\delta_{\mathrm{P}} 56.69 \mathrm{ppm}$ for the two chemically equivalent, chelating phosphorus donors. The twelve methyl protons of the methylcyclopentyl groups are observed as a sharp doublet in the ${ }^{1} \mathrm{H}$ NMR spectrum ( $\delta_{\mathrm{H}} 1.40 \mathrm{ppm}$ ) due to three bond H-P coupling. The remaining ring protons of the methylcyclopentyl groups are observed as a broad multiple resonance ( $\delta_{\mathrm{H}} 1.74 \mathrm{ppm}$ ). The four methylene protons are observed as a
doublet ( $\delta_{\mathrm{H}} 3.31 \mathrm{ppm}$ ), the remaining two multiplets ( $\delta_{\mathrm{H}} 7.08$ and 7.15 ppm ) could each be assigned to one of the two chemical equivalent sets of aromatic protons.

The ${ }^{1} \mathrm{H}\left\{{ }^{31} \mathrm{P}\right\}$ NMR spectrum of 42 was also recorded, and provided further confidence in the assignment of resonances observed in the ${ }^{1} \mathrm{H}$ NMR spectrum. The doublet observed for the methyl protons of the methylcyclopentyl groups in the ${ }^{1} \mathrm{H}$ NMR spectrum, is observed as a singlet ( $\delta_{\mathrm{H}} 1.40 \mathrm{ppm}$ ) in the phosphorus decoupled spectrum. Similarly, the doublet due to the methylene protons of the $o$-xylene backbone in the ${ }^{1} \mathrm{H}$ NMR also collapses to a singlet in the phosphorus decoupled spectrum ( $\delta_{\mathrm{H}} 1.74 \mathrm{ppm}$ ). Little effect is observed with the ring protons of the methylcyclopentyl groups, which are again observed as a complex broad resonance.

The FAB mass spectrum further confirms the structure of 42 , and shows the molecular ion $\left(\mathrm{M}^{+}\right)$at $m / z$ 706.7. Further ions are also observed with masses that correspond to the sequential loss of the carbonyl ligands (678.7 ( $\left.\mathrm{M}^{+},-\mathrm{CO}\right), 650.2\left(\mathrm{M}^{+}\right.$, -2 CO ), $622.7\left(\mathrm{M}^{+},-3 \mathrm{CO}\right)$ ).

The infra-red spectrum of $\mathbf{4 2}$ is consistent with that observed previously for the related compounds 7, 22 and 23.

### 4.2.2.2 [(1,2-bis(di-1-adamantylphosphinomethyl)benzene) tetracarbonyl molybdenum (0) 43

43 was synthesised by the same methodology as 42 . The buff coloured solid isolated from the reaction was then further purified by precipitation upon the addition of methanol to a chloroform solution of the title compound.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with the proposed structure of 43. A singlet ( $\delta_{\mathrm{P}} 51.84 \mathrm{ppm}$ ) is observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, indicating that the two phosphorus atoms are chemically equivalent. The ${ }^{1} \mathrm{H}$ NMR spectrum of 43 showed the pattern of resonances familiar to the adamantyl functionality. The methylene protons of the $o$-xylene backbone were observed as a doublet with a chemical shift of $\delta_{\mathrm{H}} 3.30 \mathrm{ppm}$. The two sets of chemically equivalent aromatic
protons were observed as two multiplets with a chemical shift of $\delta_{\mathrm{H}} 7.05$ and 7.32 ppm.

The FAB mass spectrum of 43 is also in agreement with the proposed structure. The molecular ion being observed at $m / z 810$. A further ion due to the loss of two of the carbonyl ligands was also observed at $m / z 754$.

### 4.2.2.3[(1,2-bis(di-1-adamantylphosphinomethyl)benzene)(trans, transdibenzylidene acetone) palladium (0)] 44

44 was synthesised via the reaction of one equivalent of phosphine 35, with $\left[\mathrm{Pd}(\mathrm{DBA})_{2}\right]$ in THF solution. The complex 44 was isolated as a orange solid in $88 \%$ yield.

In common with complex 24 , the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 44 consisted of two complex broad resonances ( $\delta_{\mathrm{P}} 43.94$ and 47.90 ppm ). These being due to the dynamic behaviour of the DBA ligand, as the coordinated and uncoordinated double bond is exchanged. ${ }^{9}$ The ${ }^{1} \mathrm{H}$ NMR spectrum further confirmed the structure of 24 , with the now familiar pattern of resonances due to the adamantyl groups and the methylene protons of the $o$-xylene backbone. The DBA ligand was also observed with a complex pattern of resonances being observed for the aromatic groups ( $\delta_{\mathrm{H}} 7.03-7.23 \mathrm{ppm}$ ) and smaller resonances for the coordinated and uncoordinated double bonds ( $\delta_{\mathrm{H}} 5.31$ and $6.93-7.79 \mathrm{ppm}$ respectively. The pattern of resonances in the aromatic region of the ${ }^{1} \mathrm{H}$ NMR spectrum is further complicated by the presence of peaks due to the aromatic protons of the phosphines backbone.

The FAB mass spectrum of 44 shows the molecular ion with $m / z$ 1047, further supporting the proposed formulation.

### 4.2.2.4 [(1,2-bis(di-1-adamantylphosphinomethyl)benzene)(1,4-para-benzoquinone)

 palladium (0)] 45Reaction of complex 44 with one equivalent of 1,4-para-benzoquinone resulted in a ligand exchange reaction. The DBA ligand of 44 being replaced by 1,4-parabenzoquinone to give complex 45 (Scheme 6).

Scheme 6. Synthesis of 45

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of $\mathbf{4 5}$ confirms the ligand exchange with a sharp singlet ( $\delta_{\mathrm{P}} 50.48 \mathrm{ppm}$ ) observed rather than the broad resonances of 44 . The ${ }^{1} \mathrm{H}$ NMR spectrum of 45 confirms the coordination of the benzoquinone ligand, with a singlet observed ( $\delta_{\mathrm{H}} 5.91 \mathrm{ppm}$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum is dominated by the broad resonances that can be assigned to the sixty protons of the four adamantyl groups. The methylene
protons of the $o$-xylene backbone were observed as a doublet ( $\delta_{\mathrm{H}} 3.00 \mathrm{ppm}$ ) and the aromatic protons as two multiplets ( $\delta_{\mathrm{H}} 6.95$ and 7.35 ppm ).

### 4.2.2.5 [Dichloro (1,2-bis(di-1-adamantylphosphinomethyl)benzene) palladium

 (II)]46Complex 46 was synthesised by the oxidation of the palladium (0) complex 45 with an anhydrous diethylether solution of HCl (Scheme 7). Upon addition of the HCl solution, there was an instant colour change from red to yellow.

Scheme 7. Synthesis of 46

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR Spectrum consists of a singlet with a chemical shift of $\delta_{\mathrm{P}} 31.46$ ppm. Again the ${ }^{1} H$ NMR spectrum is dominated by the broad resonances due to the sixty protons of the adamantyl groups ( $\delta_{\mathrm{H}}$ 1.34-2.35 ppm). The methylene protons of the $o$-xylene backbone are observed as a doublet ( $\delta_{H} 2.55 \mathrm{ppm}$ ). The ${ }^{1} \mathrm{H}$ NMR

## Chapter 4

spectrum is completed by the two multiplets due to the two chemically equivalent sets of aromatic protons of the $o$-xylene backbone ( $\delta_{\mathrm{H}} 7.15$ and 7.45 ppm ).

## Chapter 4

### 4.3 Experimental.

All compounds were prepared using standard Schlenk techniques under an atmosphere of dinitrogen or argon. ${ }^{31} \mathrm{P}$ (referenced to $\mathrm{H}_{3} \mathrm{PO}_{4}$ at $\delta_{\mathrm{P}}=0$ ) and ${ }^{11} \mathrm{~B}$ (referenced to $\mathrm{Et}_{2} \mathrm{O}_{2} \mathrm{BF}_{3}$ at $\delta_{\mathrm{B}}=0$ ) NMR data was collected on a Jeol Eclipse 300 MHz spectrometer; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ data on a Bruker 400 MHz DPX Avance. Mass spectra (ES and APCI) were obtained on a VG Fisons Platform II. Tetrahydrofuran, Diethyl ether and hexane were dried over sodium benzophenone. Toluene was dried over sodium. Methanol and acetonitrile were dried over calcium hydride. Water used during the work-up of all compounds was carefully deoxygenated by several cycles of heating at reflux and cooling to room temperature under a nitrogen purge. $\mathrm{CDCl}_{3}, \mathrm{~d}_{6}$-acetone and $\mathrm{d}_{3}$-acetonitrile were purchased from Aldrich, dried over $3 \AA$ molecular sieves and freeze-thaw degassed before use. $\mathrm{C}_{6} \mathrm{D}_{6}$ was purchased from Goss scientific and dried over sodium prior to use. Unless otherwise stated all chemicals were purchased from Aldrich and used without further purification.

## Di-1-Adamantylphosphimic chloride 30 ${ }^{1}$

Adapted from the method of Goerlich ${ }^{1}$.
Phosphorus trichloride ( $83 \mathrm{~cm}^{3}, 0.98 \mathrm{~mol}$ ) was added rapidly via cannula to a mixture of (freshly sublimed) $\mathrm{AlCl}_{3}(26.66 \mathrm{~g}, 0.2 \mathrm{~mol})$ and adamantane $(27.2 \mathrm{~g}, 0.20 \mathrm{~mol})$ to afford a buff coloured suspension. Upon reflux and stirring of the solution a tangerine coloured suspension was obtained. Upon further reflux the suspension darkened to reach a deep orange colour. The suspension was refluxed for a total of 18 hrs . Excess phosphorus trichloride was then removed via distillation (BP: $75^{\circ} \mathrm{C}$ ) to afford an orange solid. Upon cooling to ambient temperature, chloroform ( $250 \mathrm{~cm}^{3}$ ) was added to regenerate the orange suspension. This was then cooled to $0{ }^{\circ} \mathrm{C}$ and water ( 150 $\mathrm{cm}^{3}$ ) was added gradually via syringe. From this point onward it was unnecessary to employ an inert atmosphere. The orange suspension was Buchner filtered (with celite) to remove the orange solid impurity. The lower (chloroform) phase of the filtrate was then separated with a separating funnel and dried with magnesium sulphate. After a second Buchner filtration (with celite) the solvent was removed from the suspension via rotary evaporation, to afford the title compound as an off white solid.

Yield: 36.28 g , 99\%.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right): \delta 86.8(\mathrm{~s}) ;{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right) 1.670$ $(6 \mathrm{H}, \mathrm{br}, 4), 1.972(3 \mathrm{H}, \mathrm{br}, 3), 2.068(6 \mathrm{H}, \mathrm{br}, 2),{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 27.922$ (d, ${ }^{3} \mathrm{~J} 10.38 \mathrm{~Hz}, \mathbf{3}$ ), 36.397 (d, 4), 36.931 (d, 2), $46.077 \mathrm{ppm}(\mathrm{d})$.

## Di-1-Adamantylphosphine 31 ${ }^{1}$

$\mathrm{LiAlH}_{4}(3.5 \mathrm{~g}, 74 \mathrm{mmol})$ was added over 2 hrs to a cooled solution $\left(0^{\circ} \mathrm{C}\right)$ of di-1adamantyl phosphinic chloride ( $16 \mathrm{~g}, 45 \mathrm{mmol}$ ) in THF $\left(250 \mathrm{~cm}^{3}\right)$. The reaction was then allowed to warm to ambient temperature and was stirred for 20 hrs . The grey
suspension was then cooled $\left(0^{\circ} \mathrm{C}\right)$ and $\mathrm{HCl}\left(75 \mathrm{~cm}^{3}, 1 \mathrm{M}\right)$ was slowly added via syringe, to afford a two-phase system with some solid present in the lower phase. Conc. $\mathrm{HCl}\left(8 \mathrm{~cm}^{3}, 11 \mathrm{M}\right)$ was then added to improve the separation of the two layers. The (upper) organic phase was removed via cannula and dried over magnesium sulphate. After filtration via cannula, the volatiles were removed under vacuum to afford the product as a white solid.

Yield: $9.1 \mathrm{~g}, 67 \%$.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 18.0(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.58-$ $1.89(30 \mathrm{H}, \mathrm{m}, \mathrm{br}), 2.72\left(1 \mathrm{H}, \mathrm{d},{ }^{1} \mathrm{~J}_{\mathrm{H}-\mathrm{P}} 210.3 \mathrm{~Hz}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 29.13$ (d, 3) $33.98(\mathrm{~d}, 1) 36.73(\mathrm{~d}, 4) 43.54 \mathrm{ppm}(\mathrm{d}, 2)$.

## Di-1-Adamantylchlorophosphine $32^{1}$

Triphosgene ( $4.0 \mathrm{~g}, 13 \mathrm{mmol}$ ) solution ( $60 \mathrm{~cm}^{3}$ toluene) was added gradually via cannula to a stirred, cooled $\left(0^{\circ} \mathrm{C}\right)$ solution of DBU $\left(6 \mathrm{~cm}^{3}, 40 \mathrm{mmol}\right)$ and di-1adamantylphosphine ( $5.65 \mathrm{~g}, 19 \mathrm{mmol}$ ) ( $170 \mathrm{~cm}^{3}$ toluene). Full addition of the triphosgene afforded a viscous, bright yellow suspension. Further toluene ( $100 \mathrm{~cm}^{3}$ ) was added to lower the viscosity and ease the stirring. The suspension was stirred at ambient temperature for 24 hrs . The suspension was then filtered via cannula to afford a yellow solid. The solid was then washed with ( 4 * $100 \mathrm{~cm}^{3}$ ) toluene, which was combined with the original filtrate. The volatiles were then removed in-vacuo to afford the product as a yellow solid. The product was then washed with pentane (2 * $30 \mathrm{~cm}^{3}$ ) and dried under vacuum.

Yield: $3.25 \mathrm{~g}, 47 \%$.
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 139.55(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.72-$ 2.03 (m, br); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 26.97(\mathrm{~d}, \mathbf{3}) 36.09(\mathrm{~d}, 2) 36.30(\mathrm{~d}$, 4) $40.13 \mathrm{ppm}(\mathrm{d}, 1)$.

## Di-1-Adamantylphosphine trihydroboron 33

Borane (THF adduct) ( $10 \mathrm{~cm}^{3}, 10 \mathrm{mmol}$ ) was added to stirred solution of di-1adamantyl phosphine ( $1.5 \mathrm{~g}, 4.5 \mathrm{mmol}$ ) in THF ( $30 \mathrm{~cm}^{3}$ ). Stirring for a further 5 hrs afforded a slightly turbid solution. The volatiles were then removed in-vacuo to yield the product as a white solid.

Yield: 1.55 g, 99\%
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 41.374\left(\mathrm{q},{ }^{1} J_{\mathrm{P}-\mathrm{B}} 64.45 \mathrm{~Hz}\right) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 96.42 \mathrm{MHz}\right)-43.787(\mathrm{~d}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.741-2.005(30 \mathrm{H}, \mathrm{m}$, br) $3.720\left(1 \mathrm{H}, \mathrm{dq},{ }^{1} J_{\mathrm{H}-\mathrm{P}} 350.58 \mathrm{~Hz},{ }^{2} J_{\mathrm{H}-\mathrm{B}} 6.6 \mathrm{~Hz}, 5\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56\right.$ $\mathrm{MHz}) 28.176$ (d, 3), 34.687 (d, 1), 36.462 (d, 4), $40.035 \mathrm{ppm}(\mathrm{d}, 2)$.

## 1,2-bis(di-1-adamantylphosphinotrihydroboronmethyl)benzene 34

Di-1-Adamantylphosphine trihydroboron ( $5 \mathrm{~g}, 15 \mathrm{mmol}$ ) was dissolved in $40 \mathrm{~cm}^{3}$ THF and cooled to $-78{ }^{\circ} \mathrm{C}$. sec-BuLi ( 16.5 mmol ) was then added to the cooled solution via syringe to give an intensely coloured yellow solution. The solution was then allowed to stir at $-78^{\circ} \mathrm{C}$ for 0.5 hr and allowed to warm to room temperature and was stirred for an additional two hours. The deprotonation can be monitored by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ or ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy (data given below). The THF solution of di-1-adamantyltrihydroboronlithium phosphide was then recooled to $-78{ }^{\circ} \mathrm{C}$ and regained its yellow colouration, a THF solution $\left(30 \mathrm{~cm}^{3}\right)$ of $\alpha, \alpha$ 'dichloro- $o$-xylene ( $1.44 \mathrm{~g}, 8.25 \mathrm{mmol}$ ) was then added drop wise via cannula. The solution was then allowed to warm to room temperature and stir overnight. The solvent was then removed under vacuum and the white solid washed with $\mathrm{Et}_{2} \mathrm{O}$ (two $20 \mathrm{~cm}^{3}$ portions) and dried under vacuum to give the title compound as a white solid.

Yield: $5.57 \mathrm{~g}, 92 \%$
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right): \delta 41.374(\mathrm{q}, \mathrm{br}) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 96.42\right.$ $\mathrm{MHz})-46.353\left(\mathrm{~d},{ }^{1} J_{\mathrm{B}-\mathrm{P}} 51.84 \mathrm{~Hz}\right) ;{ }^{1} \mathrm{H}$ NMR ( $\left.\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.722(24 \mathrm{H}, \mathrm{br}, 4)$ 1.9-2.2 (36H, br, 3,2) $3.287\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{p}} 12.0 \mathrm{~Hz}, 5\right) 7.110(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.612(2 \mathrm{H}$, $\mathrm{m}, \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\left(\mathrm{CDCl}_{3}, 75.57 \mathrm{MHz}\right) 21.319(\mathrm{~d}, 5) 28.372(\mathrm{~d}, 3) 36.616(\mathrm{~d}, 4)$ $38.250(\mathrm{~d}, 2) 40.036(\mathrm{~d}, 1) 126.372(\mathrm{~s}, 7) 129.783(\mathrm{~d}, 8) 132.434 \mathrm{ppm}(\mathrm{d}, 6)$.

APCI MS: $\boldsymbol{m} / \boldsymbol{z} 734.8\left(\mathbf{M}^{+}\right)$.
Di-1-adamantyltrihydroboronlithium phosphide. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 121.65 MHz ) $\delta$ $9.667\left(\mathrm{q},{ }^{1} \mathrm{~J}_{\mathrm{P}-\mathrm{B}} 38.71 \mathrm{~Hz}\right) ;{ }^{1 \mathrm{H}} \mathrm{B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 96.42 MHz ) -39.008 ppm (d).

## Chapter 4

## 1,2-bis(di-1-adamantylphosphinomethyl)benzene 35

To a cooled $\left(0^{\circ} \mathrm{C}\right) \mathrm{DCM}\left(80 \mathrm{~cm}^{3}\right)$ solution of 1,2-bis(di-1-adamantylphosphino trihydroboronmethyl)benzene ( $5 \mathrm{~g}, 6.8 \mathrm{mmol}$ ) was added tetrafluoroboric acid dimethyl ether complex ( $10 \mathrm{eq}, 68 \mathrm{mmol}$ ) via syringe. Upon the addition of the acid the evolution of hydrogen gas was noted. Upon full addition the solution was allowed to stir at $0{ }^{\circ} \mathrm{C}$ for an additional one hour and then allowed to warm to room temperature and was stirred overnight. $150 \mathrm{~cm}^{3}$ of saturated sodium bicarbonate solution was then added and the two-phase system was stirred rapidly for 9 hrs. The stirring was stopped and the two phases allowed to separate. The organic phase was then removed via cannula and the aqueous phase washed with a further $30 \mathrm{~cm}^{3}$ portion of dichloromethane. The combined portions of DCM were then dried over magnesium sulphate and subsequently filtered via cannula. The solvent was then removed under reduced pressure to yield the title compound as a white solid. 1,2-bis(di-1-adamantylphosphinomethyl)benzene could be further purified by precipitation from a concentrated DCM solution by cooling at $-40^{\circ} \mathrm{C}$.
Yield: $3.41 \mathrm{~g}, 71 \%$
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 26.371(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right)$ $1.703(24 \mathrm{H}, \mathrm{d}, \mathrm{br}, 4) 1.914(36 \mathrm{H}, \mathrm{m}, \mathrm{br}, \mathbf{2 , 3}) 3.005\left(4 \mathrm{H}, \mathrm{d},{ }^{2} J_{\mathrm{H}-\mathrm{P}} 3.0 \mathrm{~Hz}, 5\right) 7.036(2 \mathrm{H}$, $\mathrm{m}, \mathrm{Ar}-\mathrm{H}) 7.544(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 25.685(\mathrm{~d}, 5)$ $28.777(\mathrm{~d}, 3) 36.678(\mathrm{~d}, 4) 37.120(\mathrm{~d}, 6) 41.032(\mathrm{~d}, 1) 124.218(\mathrm{~s}, 7) 130.846(\mathrm{~d}, 8)$ $135.312 \mathrm{ppm}(\mathrm{d}, 7)$.

APCI MS: $m / z 707.5\left(\mathbf{M}^{+}\right)$.
[(1,2-bis(di-1-adamantylphosphinomethyl)benzene)(trans,transdibenzylidene acetone) palladium (0)] 44

THF (40 $\mathrm{cm}^{3}$ ) was added to a combination of 1,2-bis(di-1-adamantyl phosphinomethyl)benzene $(1.05 \mathrm{~g}, 1.45 \mathrm{mmol})$ and $\left[\operatorname{Pd}(\mathrm{DBA})_{2}\right](0.8 \mathrm{~g}, 1.45 \mathrm{mmol})$ that had previously been weighed out in a glove box. The red / orange turbid solution was stirred for three hours. The solution was then filtered via cannula to yield a red filtrate and a small quantity of residue. The solvent was then removed under vacuum to afford a red powdery solid. Hexane ( $30 \mathrm{~cm}^{3}$ ) was added via syringe and trituration performed with a glass rod, resulting in an orange solid separating out. The hexane washings were then removed via cannula filtration and the solid dried under vacuum.

Yield $1.34 \mathrm{~g}, 88 \%$.

MS (FAB): m/z $914\left(\mathrm{M}^{+}\right), 858\left(\mathrm{M}^{+},-2 \mathrm{CO}\right)$.

A two neck round bottom flask fitted with a condenser topped with a gas inlet was charged with $\mathrm{AlCl}_{3}(7.88 \mathrm{~g}, 59 \mathrm{mmol})$ and methylcyclopentane $(5.00 \mathrm{~g}, 59 \mathrm{mmol})$. Phosphorus trichloride ( $32.5 \mathrm{~cm}^{3}$ ) was then added rapidly via cannula. The solution was then heated to reflux and became bright orange after 0.5 hrs . The solution was heated under reflux for a total time of 24 hrs . The orange suspension was then allowed to cool and the excess $\mathrm{PCl}_{3}$ was then removed via distillation. The orange coloured oil obtained was then poured cautiously onto crushed ice ( 200 g ). The reaction flask was washed with chloroform ( $250 \mathrm{~cm}^{3}$ ), and the washings added to the previously decanted material. The two phase system was filtered through celite to remove the solid orange impurity. The two phases were then separated and the organic phase dried over magnesium sulphate. After filtration, the chloroform was removed via distillation to afford the title compound as a viscous clear oil.

Yield: $7.34 \mathrm{~g}, 74 \%$.

## Di(1-methylcyclopentyl)phosphine 37

$\mathrm{LiAlH}_{4}$ ( $1.09 \mathrm{~g}, 28.8 \mathrm{mmols}$ ) was slurried in diethylether ( $50 \mathrm{~cm}^{3}$ ) and cooled in an ice bath. A diethylether ( $50 \mathrm{~cm}^{3}$ ) solution of $\mathrm{Di}(1-$ methylcyclopentyl)phosphinic chloride ( $6.20 \mathrm{~g}, 25.0 \mathrm{mmol}$ ) was then added to the slurry via cannula over a 2 hr period to prevent overheating. The solution was then stirred for a further 1 hr at $0^{\circ} \mathrm{C}$ and then allowed to warm to room temperature and stir for an additional 18 hrs . The solution was then cooled in an ice bath and $4 \mathrm{~cm}^{3}$ of $15 \%$ aqueous NaOH was gradually added via cannula until the remaining grey solid became granular in appearance. The solution was then filtered via cannula to remove the grey solid, and was dried over magnesium sulphate. After cannula filtration the solvent was removed by distillation to leave the title compound as a colourless oil with a strong, unpleasant odour.

Yield: $3.85 \mathrm{~g}, 78 \%$
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 15.627(\mathrm{~s}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right)$ $1.284\left(3 \mathrm{H}, \mathrm{d},{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{P}} 10.77 \mathrm{~Hz}, 2\right) 1.654(2 \mathrm{H}, \mathrm{m}, 4) 1.719(4 \mathrm{H}, \mathrm{m}, 3) 2.300(2 \mathrm{H}, \mathrm{m}, 4)$; ${ }^{1} \mathrm{H}\left\{{ }^{31} \mathrm{P}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.298(3 \mathrm{H}, \mathrm{s}) 1.661(2 \mathrm{H}, \mathrm{m}) 1.725(4 \mathrm{H}, \mathrm{m}) 2.325$ $(2 \mathrm{H}, \mathrm{m}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 23.693(\mathrm{~d}, 2) 25.346(\mathrm{~d}, 4) 27.892(\mathrm{~d}$, 3) $41.420 \mathrm{ppm}(\mathrm{d}, 1)$.

## Di(1-methylcyclopentyl)phosphine trihydroboron 38

Di(1-methylcyclopentyl)phosphine ( $3.85 \mathrm{~g}, 19.5 \mathrm{mmols}$ ) was dissolved in THF ( 40 $\mathrm{cm}^{3}$ ) and cooled in an ice bath. Borane THF adduct ( $1.50 \mathrm{eq}, 29.25 \mathrm{mmol}$ ) was then added to the cooled solution via syringe. The solution was stirred for 0.5 hrs and then allowed to warm to room temperature and was stirred for an additional 3 hrs . The solvent was removed under vacuum to give the title compound as a colourless solid.
Yield: $4.05 \mathrm{~g}, 98 \%$
${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 121.65 \mathrm{MHz}\right) \delta 48.595\left(\mathrm{q},{ }^{1} \mathrm{~J}_{\mathrm{P}-\mathrm{B}} 53.599 \mathrm{~Hz}\right) ;{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}, 96.42 \mathrm{MHz}\right)-44.276(\mathrm{~d}) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) 1.173-1.778(\mathrm{~m}) ;{ }^{13} \mathrm{C}$ $\left\{^{1} \mathrm{H}\right\}\left(\mathrm{CDCl}_{3}, 75.56 \mathrm{MHz}\right) 23.738(\mathrm{~d}, 4) 24.457(\mathrm{~d}, 3) 38.321 \mathrm{ppm}(\mathrm{d}, 1)$.

## 1,2-bis(di-1-methylcyclopentylphosphinotrihydroboronmethyl)benzene 39

To a cooled ( $-78^{\circ} \mathrm{C}$ ) THF solution ( $60 \mathrm{~cm}^{3}$ ) of Di(1-methylcyclopentyl) phosphine trihydroboron ( $6.5 \mathrm{~g}, 30.6 \mathrm{mmol}$ ) was added, via syringe, sec-BuLi ( 33.66 mmol ) upon full addition of the sec-BuLi the solution became bright yellow. The solution was stirred for 1.5 hrs at $-78^{\circ} \mathrm{C}$ and then a further 0.5 hr at room temperature to give lithio-di(1-methylcyclopentyl)phosphide-trihydroboron. The deprotonation can monitored by either ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ or ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy (data given below). The

## Chapter 4

solution was cooled to $-78^{\circ}$ and a THF solution ( $30 \mathrm{~cm}^{3}$ ) of $\alpha, \alpha^{\prime}$-dichloro-o-xylene $(2.66 \mathrm{~g}, 15.2 \mathrm{mmol})$ was added slowly via cannula. The solution was allowed to stir for 1 hr at $-78^{\circ} \mathrm{C}$ and then allowed to warm to room temperature before being left to stir overnight. During this time the solution became cloudy as LiCl precipitated. The solvent was removed under vacuum, and dichloromethane ( $60 \mathrm{~cm}^{3}$ ) and water (40 $\mathrm{cm}^{3}$ ) added to give a two-phase system. The organic phase was then removed via cannula and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was removed under reduced pressure to yield the product as a white solid.

## 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene 40

To a cooled (0 $\left.{ }^{\circ} \mathrm{C}\right) \quad \mathrm{DCM} \quad\left(75 \quad \mathrm{~cm}^{3}\right)$ solution of 1,2-bis(di-1methylcyclopentylphosphinotrihydroboronmethyl)benzene ( $6.05 \mathrm{~g}, 11.55 \mathrm{mmol}$ ) was added tetrafluoroboric acid dimethyl ether complex ( $10 \mathrm{eq}, 115.5 \mathrm{mmol}$ ) via syringe. Upon the addition of the acid the evolution of a gas was noted. Upon full addition the solution was allowed to stir at $0{ }^{\circ} \mathrm{C}$ for an additional one hour and then allowed to warm to room temperature and was stirred overnight. $250 \mathrm{~cm}^{3}$ of saturated sodium bicarbonate solution was then added and the two-phase system was stirred rapidly for 9 hrs . The stirring was stopped and the two phases allowed to separate. The organic phase was then removed via cannula and the aqueous phase washed with a further 40 $\mathrm{cm}^{3}$ portion of dichloromethane. The combined portions of DCM were then dried over magnesium sulphate and subsequently filtered via cannula. The solvent was then removed under reduced pressure to yield the title compound as a white solid.

## Chapter Five

## Chapter 5

### 5.1 Introduction

The catalytic reactions described in this chapter were carried out in the semi-technical area at Lucite international, Wilton. Four, two litre mechanically stirred hastelloy autoclaves (A, B, E and F) were used to carry out the catalysis with 1,2-bis(di-1methylcyclopentylphosphinomethyl)benzene and 1,2-bis(2,2,3,4,4-pentamethyl phosphetanemethyl)benzene. Catalysis with 1,2-bis(di-1-adamantyl phosphinomethyl)benzene was carried out in a magnetically stirred 300 ml glass Buchi autoclave.

Each autoclave was standardised by performing a catalytic run with 1,2-bis(di-tbutylphosphinomethyl)benzene 1 . The properties and catalytic activity of complexes derived from this ligand being well understood in the methoxycarbonylation of ethylene. ${ }^{1,2,6}$

Each of the novel phosphine ligands previously described (17, 21, 35 and 40), was tested in the methoxycarbonylation of ethylene under standard conditions established for 1. Two palladium sources $\left(\operatorname{Pd}(\mathrm{OAc})_{2}\right.$ and $\left.\operatorname{Pd}(\mathrm{DBA})_{2}\right)$ were employed under differing conditions. Each test acting as a screen for either activity or catalyst robustness.

The palladium species used as catalysts in the hastelloy autoclaves were formed insitu. Reactions were carried out with a $1: 1$ mixture of carbon monoxide:ethylene maintained at a pressure of 10 bar above vapour pressure $\left(100{ }^{\circ} \mathrm{C}\right.$ (hastelloy autoclave), $80{ }^{\circ} \mathrm{C}$ (Buchi autoclave)). The rate of reaction was monitored by measurement of the amount of the gaseous mixture consumed by the reaction (Hastelloy autoclave). Reaction commences upon the introduction of the carbon monoxide / ethylene mixture to the autoclave. After the reaction is complete, the solution isolated was analysed via gas chromatography and the weight gain recorded.

Catalysis carried out with $\mathrm{Pd}(\mathrm{OAc})_{2}$ was performed in methanol with a Pd loading of $0.0014 \mathrm{~mol} \%$. The initial rate of the reaction under these conditions is a good measure of the catalyst systems activity.

Reactions carried out with $\operatorname{Pd}(\mathrm{DBA})_{2}$ as the palladium source (ligand 1, 40), were run with a palladium loading of $0.00031 \mathrm{~mol} \%$ in a methylpropionate / methanol ( $70 \mathrm{wt} \%$ MeP ) solution (Hastelloy autoclave). This alternative solvent system provides a higher ratio of methanol : Pd. However, the reactants are diluted with MeP. Under these conditions the Pd catalyst isn't dissolved solely in methanol, which also acts as a reactant in the catalytic cycle. Therefore the catalytic species are more likely to be involved in side reactions which may remove intermediates from the catalytic cycle. This provides conditions were the stability of the catalytic system can be assessed. 1,2-bis(di-1-adamantylphosphinomethyl)benzene was used with $\operatorname{Pd}(D B A)_{2}$ as the palladium source in neat methanol, as a test for activity.

### 5.2 Results and Discussion

A summary of the weight gain from each catalytic run where $\mathrm{Pd}(\mathrm{OAc})_{2}$ was used as the palladium source is given in Table 1.

| Reaction | Ligand | Autoclave | Ratio | Wt <br> gain <br> $(\mathrm{g})$ | Average <br> wt gain <br> $(\mathrm{g})$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Pd:Lig:Acid |  |  |
| 1 | 1,2 -bis(di- - -butylphosphino <br> methyl)benzene | E | $1: 5: 100$ | 251.56 | 224.46 |

Table 2. Catalysis performed with $\operatorname{Pd}(\mathrm{DBA})_{2}$

### 5.2.1 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene

When $\operatorname{Pd}(\mathrm{OAc})_{2}$ was used as the palladium source, the catalyst system derived from 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene (40) gave a weight gain comparable to that seen with the 1,2-bis(di-t-butylphosphinomethyl)benzene (1) standard (Table 1). 40 was found to give a catalyst system selective for methylpropionate.

Reaction rate and turnover data for the reactions carried out with $\operatorname{Pd}(\mathrm{OAc})_{2}$ with phosphine ligand 1 and 40 is shown in Figure 1 and 2.

Figure 1. Reaction rate data $\mathrm{Pd}(\mathrm{OAc})_{2}$

The initial reaction rate (Figure 1) of the reaction with 1,2-bis(di-1-methylcyclopentyl phosphinomethyl)benzene (40) is considerably lower than that with 1,2-bis(di-tbutylphosphinomethyl)benzene (1). However, as the reaction progresses the rate of reaction observed with 1 decreases sharply in the early stages. A similar drop in the reaction rate is not observed with $\mathbf{4 0}$, rather a gradual decline in the rate is observed.

Figure 2. TON data $\mathrm{Pd}(\mathrm{OAc})_{2}$
The trend observed in the rate data (Figure 1) is reflected in the turnover data (Figure 2 ), with the lower but more stable rate of $\mathbf{4 0}$ giving approximately equal turnover number when compared to 1 after 3 hrs.

Reaction rate and turn over data for the reactions carried out with $\operatorname{Pd}(\mathrm{DBA})_{2}$ is shown in Figure 3 and 4. Catalytic runs with $\mathbf{4 0}$ were found to give a weight gain comparable to those observed with 1 (Table 2). The catalyst system derived from 40 was again found to be selective for methylpropionate.

When rate of reaction is compared to that of the standard, it can be seen that the initial rate of reaction with $\mathbf{1}$ is approximately double that of $\mathbf{4 0}$. As the reaction proceeds the rate decreases in both cases. The decrease in rate being attributed to the consumption of methanol in the reaction.

Interestingly, the drop in reaction rate for 40 appears to be linear, as would be expected if the change in reaction rate were due to methanol consumption. However, the drop in reaction rate observed for $\mathbf{1}$ is non-linear. The deviation being attributed to the decay of the catalyst.

Figure 3. Reaction rate data $\operatorname{Pd}(\mathrm{DBA})_{2}$

Figure 4. TON data $\operatorname{Pd}(\mathrm{DBA})_{2}$

## Chapter 5

The results suggest that catalyst formed from phosphine 40 have a similar selectivity to methylpropionate as those formed from ligand 1. Both ligands have provided similar weight gains over 3 hrs . However, ligand 40 appears to give catalysts that are less active but more robust than those derived from phosphine 1, under these conditions.

### 5.2.2 1,2-bis(di-1-adamantylphosphinomethyl)benzene ${ }^{7}$

1,2-bis(di-1-adamantylphosphinomethyl)benzene 35 was tested for activity using $\operatorname{Pd}(\mathrm{DBA})_{2}$ as the palladium source. As with phosphine ligands 1 and 40 , the catalyst formed from 35 was found to be selective for methylpropionate.

No reaction rate or TON data is available for these reactions. However, when compared to the standard ligand 1, 35 gave a large increase in the weight gain obtained ( 29.6 g and 75.7 g respectively) (Table 2). Under these conditions it would appear that the catalysts system derived from 35 is more active / stable than that derived from 1.

### 5.2.3 1,2-bis(2,2,3,4,4-pentamethylphosphetanemethyl)benzene

Both isomers of 1,2-bis(2,2,3,4,4-pentamethylphosphetanemethyl)benzene (17, 21) were tested under the standardised conditions with $\mathrm{Pd}(\mathrm{OAc})_{2}$. No gas uptake was observed in either case. After 3 hours, the contents of the autoclave were isolated and weighed, no weight gain was observed.

This is a disappointing result considering the wide variety of phosphine ligands known to give active catalysts in this reaction. ${ }^{1,3,4,5}$ As demonstrated in previous chapters, 1,2-bis(2,2,3,4,4-pentamethylphosphetanemethyl) benzene can stabilise the reactive intermediates implicated in the catalytic cycle. However, the reason for the apparent inactivity under these conditions remains unclear.

### 5.3 Experimental

## Standard procedure $\left(\mathbf{P d}(\mathrm{OAc})_{2}\right.$ (Hastelloy autoclave)

$\operatorname{Pd}(\mathrm{OAc})_{2}(22 \mathrm{mg}, 0.1 \mathrm{mmol})$ and the respective phosphine ligand $(0.5 \mathrm{mmol})$ were weighed out in a glove box into a 500 ml three necked round bottom flask. Methanol ( 300 ml ) was added and the mixture allowed to stir for 1 hr . Methanesulphonic acid ( 10 mmol ) was then added to the solution. The weight of the catalyst solution was taken and it was charged to the autoclave and heated to $100{ }^{\circ} \mathrm{C}$ with stirring. The reaction was started by the introduction of carbon monoxide / ethylene 1:1 mixture to the autoclave. The total pressure was controlled at 12.3 bar by a TESCOM valve. The autoclave was maintained at this temperature and pressure for 3 hrs during which period the amount of gas consumed was recorded. The gases were then isolated and the autoclave allowed to cool to room temperature. The depressurised autoclave was then emptied and the mass of the solution recorded.

Mass of ligand charged: 1,2-bis(di-t-butylphosphinomethyl)benzene ( 201 mg ), 1,2-bis(di-1-methylcyclopentylphosphinomethyl)benzene (200 mg), 1,2-bis(di-1adamantylphosphinomethyl)benzene (360 mg), 1,2-bis(2,2,3,4,4pentamethylphosphetanemethyl)benzene ( 200 mg ).

## Standard procedure (Pd(DBA)2) (Hastelloy autoclave)

A mechanically stirred 2 litre Hastelloy autoclave was evacuated and charged with a previously weighed out solution comprising of: Methylpropionate : Methanol (300 $\mathrm{ml}, 70 \mathrm{wt} \% \mathrm{MeP}$ ), $\mathrm{Pd}($ as DBA salt) ( 0.014 mmols ), appropriate phosphine ligand ( 0.076 mmols), methanesulphonic acid ( 2.25 mmols ). The autoclave was heated to $100^{\circ} \mathrm{C}$ and when at temperature, 8 bar of ethylene was added on top of the vapour pressure of the solvents and immediately a further 2 bar of a $1: 1$ mixture of carbon monoxide and ethylene was added to the system. At this point the autoclave was opened up to the reservoir containing a $1: 1$ mixture of carbon monoxide and ethylene and the reaction allowed to proceed. The temperature and pressure were maintained for 3 hours during which time the volume of gas consumed was recorded. The
autoclave was isolated and vented, and then allowed to cool to room temperature. The depressurised autoclave was emptied and the final weight of the solution recorded.

## Procedure (Pd(DBA)2) (Buchi autoclave)

The catalyst system was prepared by reacting one equivalents of the appropriate phosphine ligand with $\operatorname{Pd}(\mathrm{DBA})_{2}(50 \mathrm{mg})$ in methanol $(100 \mathrm{ml})$ followed by reaction with methanesulphonic acid ( 10 eq ). The solution was then charged to the autoclave under an inert atmosphere. The solution was heated to $80^{\circ} \mathrm{C}$, before the addition of carbon monoxide / ethylene ( $1: 1$ mixture) at 10 bar above vapour pressure. The reaction was allowed to proceed for 2 hrs before the solution was isolated and the weight gain calculated.

## Appendix

Crystal data and structure refinement for compound 25. (DENNIS6 (RED CRYSTAL)).

| Empirical formula | C24 H40 C12 P2 Pd |
| :---: | :---: |
| Formula weight | 567.80 |
| Temperature | 150(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Monoclinic |
| Space group | P2 (1) |
| Unit cell dimensions | $\begin{aligned} & \mathrm{a}=8.7462(2) \mathrm{A} \quad \text { alpha }=90 \mathrm{deg} . \\ & \mathrm{b}=16.7335(3) \mathrm{A} \quad \text { beta }= \end{aligned}$ |
| 103.4470(19) deg. | $\mathrm{c}=8.9946(4) \mathrm{A}$ gamma $=90 \mathrm{deg}$. |
| Volume | 1280.31(7) $\mathrm{A}^{\wedge} 3$ |
| Z | 2 |
| Density (calculated) | $1.473 \mathrm{Mg} / \mathrm{m}^{\wedge} 3$ |
| Absorption coefficient | $1.068 \mathrm{~mm}^{\wedge}-1$ |
| F(000) | 588 |
| Crystal size | $0.18 \times 0.16 \times 0.12 \mathrm{~mm}$ |
| Theta range for data collection | 2.93 to 27.44 deg. |
| Index ranges | $-11<=\mathrm{h}<=11,-21<=\mathrm{k}<=21,-11<=1<=11$ |
| Reflections collected | 22112 |
| Independent reflections | $5738[\mathrm{R}($ int $)=0.1095]$ |
| Max. and min. transmission | 0.8825 and 0.8310 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Data / restraints / parameters | 5738 / 1 / 272 |
| Goodness-of-fit on $\mathrm{F}^{\wedge} 2$ | 1.054 |
| Final R indices [ $\mathrm{I} \times 2$ sigma(I)] | $\mathrm{R} 1=0.0352, \mathrm{wR} 2=0.0810$ |
| R indices (all data) | $\mathrm{R} 1=0.0419, \mathrm{wR} 2=0.0849$ |
| Absolute structure parameter | -0.03(2) |
| Largest diff. peak and hole | 0.496 and -0.874 e. $\mathrm{A}^{\wedge}-3$ |

Table 1. Crystal data and structure refinement for Compound 22 (02DENNIS12).

| Empirical formula | C28 H40 Mo O4 P2 |
| :---: | :---: |
| Formula weight | 598.48 |
| Temperature | 150(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Monoclinic |
| Space group | P2 (1)/n |
| Unit cell dimensions | $\begin{array}{ll} \mathrm{a}=12.5960(2) & \mathrm{A} \\ \mathrm{~b}=17.2901(3) \mathrm{A} & \text { alpha }=90 \mathrm{deg} . \end{array}$ |
| 105.5887(7) deg. | $\mathrm{c}=13.8362(2) \mathrm{A}$ gamma $=90 \mathrm{deg}$. |
| Volume | 2902.49(8) $\mathrm{A}^{\wedge} 3$ |
| z | 4 |
| Density (calculated) | $1.370 \mathrm{Mg} / \mathrm{m}^{\wedge} 3$ |
| Absorption coefficient | $0.592 \mathrm{~mm}^{\wedge}-1$ |
| F(000) | 1248 |
| Crystal size | $0.20 \times 0.06 \times 0.06 \mathrm{~mm}$ |
| Theta range for data collection | 3.05 to 27.49 deg . |
| Index ranges | $-16<=h<=15,-22<=\mathrm{k}<=22,-17<=1<=17$ |
| Reflections collected | 39770 |
| Independent reflections | $6638[\mathrm{R}($ int $)=0.0761]$ |
| Max. and min. transmission | 0.9653 and 0.8907 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Data / restraints / parameters | 6638 / 0 / 326 |
| Goodness-of-fit on $\mathrm{F}^{\wedge} 2$ | 1.024 |
| Final R indices [I>2sigma(I)] | $\mathrm{R} 1=0.0324, \mathrm{wR} 2=0.0707$ |
| R indices (all data) | $\mathrm{R} 1=0.0432, \mathrm{wR} 2=0.0748$ |
| Largest diff. peak and hole | 0.537 and -0.567 e. A^-3 |
