Title: Floral scent evaluation of segregating lines of *Alstroemeria caryophyllaea*

Article Type: Research Paper

Section/Category: Genetics and breeding, Polyploid, Omics-based technology, Functional genomics

Keywords: *Alstroemeria caryophyllaea*; breeding; floral scent; genomic organization; sensorial attributes.

Abstract: Floral scent plays an important role in attracting and guiding pollinators and is composed of a bouquet of volatile organic compounds (VOCs). *Alstroemeria* is a commercially important cut flower, however breeding efforts have focussed on flower color and size rather than scent. Recently analysis of two scented cultivars derived from the scented *A. caryophyllaea* revealed a surprising divergence in VOC profiles. Here 13 scented lines of *A. caryophyllaea* derived from selfing were characterised including morphology, evaluation of the floral scent through GC-MS and sensorial analysis. Leaf shape, stem length, flower size, shape, coloration and productivity all varied between lines. Sensorial analyses indicated that two lines (C013 and C017) were most highly rated for their appearance and C017 was also scored highest for its scent contrasting with C004 which scored lowest. Analyses of scent bouquets from six of the lines revealed 23 terpenoid compounds. All lines showed the same most abundant compound putatively identified as  $\beta$ -trans-ocimene, and three further compounds were discriminatory amongst the lines following PCA. Genomic organization of *AlstroTPS*, a previously identified myrcene synthase, showed substantial polymorphism between lines. The multifactorial characterization performed in this study showed differences among the lines confirming parental heterozygosity.

50        **1. Introduction**

51

52            The main function of floral scent is to attract and guide pollinators (Ando et al. 2001;  
53 Reinhard et al. 2004; Dudareva et al. 2004; Jürgens et al. 2003) although Dudareva and  
54 Pichersky (2000) suggest that flowers can also emit specific volatile organic compounds  
55 (VOCs) to repel non-beneficial insects, for example pollen or nectar ‘thieves’ or destructive  
56 insects. Furthermore some flowers are able to emit VOCs with anti-microbial or anti-herbivore  
57 activity to protect their reproductive organs (Friedman et al. 2002; Hammer et al. 2003; Farré-  
58 Armengola et al. 2013). Scent thus forms a key component of the ‘pollination syndrome’. This  
59 includes other pollination rewards and attractants such as petal color and form, and nectar  
60 production, and has been an important driver in floral evolution (Fenster et al. 2004; Galliot et  
61 al. 2006).

62

63            Floral scent is composed of a bouquet of VOCs, including aromatic compounds,  
64 terpenoids and fatty acid derivatives (Knudsen et al. 2006). The composition and relative  
65 amounts of the VOCs in the final bouquet determines the overall scent perceived by the human  
66 olfactory system. Considering both the important role of floral scent in plant reproduction and  
67 its aesthetic value, composition of floral scent has been characterised in several ornamental  
68 species such as *Dianthus inoxianus* (Balaoa et al. 2011), snapdragon (*Antirrhinum majus*;  
69 Dudareva et al. 2005), carnation (*Dianthus* spp.; Jürgens et al. 2003) and petunia (*Petunia*  
70 *axillaris* ; Kondo et al. 2006).

71

72            Sensorial analyses (Morinaka et al. 2001) provide information on the aesthetic qualities  
73 of the bouquet, based on the specific recognition and discrimination between a vast variety and  
74 combinations of odour molecules, by a large gene family of odorant receptors connected to the  
75 human olfactory system (Zhao and Firestein, 1999). Humans have very varied thresholds for  
76 different VOCs, so concentration in the mixture does not directly relate to what is perceived.  
77 For some compounds our olfactory system can be more sensitive than analytical tools, such as

78 GC-MS, for evaluating floral scent (Hinterholzer and Schieberle, 1998). In addition, GC-MS  
79 alone cannot predict what the perceived odour type will be as combinations of compounds can  
80 have unique and specific aromas that are not the same as the individual compounds. On the  
81 other hand, GC-MS provides a very sensitive measure of bouquet composition including  
82 chemical identification of specific VOCs. (Yeon Oh et al. 2008; Kondo et al. 2006; Klahre et al.  
83 2011). Furthermore it is highly reproducible and a total of 1719 chemical compounds have been  
84 identified from samples of floral scent in 991 species of flowering plants to date (Knudsen et al.  
85 2006). In addition to identification and quantification by GC-MS and sensory evaluation of  
86 what is perceived by the human, it is also important to determine whether the aroma is well  
87 liked. Therefore, selection of new ornamental lines benefits from a combination of sensory and  
88 analytical approaches.

89

90 *Alstroemeria* is a commercially important cut flower originating in South America with  
91 main centres of diversity in Brazil and Chile (Bayer, 1987; Muñoz and Moreira, 2003).  
92 Breeding has mainly targeted flower size and color through interspecific hybridisation  
93 (Buitendijk et al. 1995; Burchi et al. 1997), mutant selection (Aros et al. 2012a), development of  
94 polyploids (Lu and Bridgen 1997; Takayuki, 1999) and more recently transformation (Akutsu et  
95 al. 2004). However little attention has been played to scent, as few native species are scented  
96 and breeding programmes have used a narrow genetic background (Aros et al. 2006). Recently  
97 there has been increased interest in scented flowers (Pichersky and Dudareva 2007) and two  
98 scented *Alstroemeria* cultivars: ‘Sweet Laura’ and ‘Ajax’ have been developed by crosses  
99 between the Brazilian scented *A. caryophyllea* and non-scented lines (Pounders et al. 2003; R.  
100 Meijles personal communication). VOC analyses of these genetically related cultivars (Aros et  
101 al. 2012b) revealed a surprising divergence in VOC profiles. Both cv. ‘Ajax’ and *A.*  
102 *caryophyllea* produce a single major terpenoid compound, though different to each other, while  
103 cv. ‘Sweet Laura’ produces at least three major and many more minor terpenoid compounds  
104 including (*E*)-ocimene, (*E*)-caryophyllene, humulene and myrcene. Bouquet composition has  
105 been previously reported to vary even between cultivars of the same species (e.g. in *Petunia*,

106 Klahre et al. 2011), although the precise composition of VOC bouquets as a result of  
107 segregation has not been extensively studied (Andargie et al. 2014).

108

109 Terpenes are one of the most common VOCs in floral scent, particularly mono- and  
110 sesquiterpenes (Knudsen et al. 2006). Terpenoids comprise a large number of primary and  
111 mostly secondary metabolites with a wide variety of structural types and their biosynthesis is  
112 controlled by the action of terpene synthases (TPS). TPS genes have been identified from a  
113 wide range of species (Bohlmann et al. 2000; Dudareva et al. 2003; Yang et al. 2013) to  
114 examine evolutionary relationships within the gene family (Trapp and Croteau, 2001; Lee and  
115 Chappell, 2008). In *Alstroemeria* Aros et al. (2012b) identified a terpene synthase (*AlstroTPS*)  
116 with myrcene synthase activity, which is highly expressed in cv. 'Sweet Laura' tepals during  
117 peak VOC production. Gene structure of *AlstroTPS* placed it amongst class III terpene  
118 synthases according to the classification of Trapp and Croteau (2001), but with 5 introns instead  
119 of the 6 introns common for this class. Expression of *AlstroTPS* has also been confirmed in *A.*  
120 *caryophyllaea* tepals (Aros et al. 2012b), but its genomic structure has not been characterized in  
121 this species.

122

123 An analysis is presented here of a population of F1 lines produced through self  
124 pollination of *A. caryophyllaea* revealing morphological polymorphism followed by a  
125 multifactorial characterization of their floral scent, using both GC-MS and sensorial analysis to  
126 identify levels of variation in bouquet composition as well as aesthetic qualities. An analysis of  
127 genomic organization of *AlstroTPS* in these lines is also presented showing substantial  
128 polymorphism at the level of scent-related genes.

129

## 130 **2. Materials and Methods**

131

### 132 **2.1. Plant material**

133

134 Self-pollination was performed on an *A. caryophyllaea* individual inflorescence. Seeds  
135 were collected from dried fruits 60 – 75 DAP and were soaked in warm water (30-40 °C initial  
136 temperature) for 48 h and then stratified at 4 °C for 2 weeks. Plants were grown at the  
137 University Botanical and Research Garden, Cardiff University (Cardiff, UK) in a greenhouse at  
138 a minimum of 14 °C. Humidity and light were not controlled. After the stratification, seeds were  
139 sown in pots containing a mixture of sand (25 %), coarse grit (25 %) and compost (50 %). A  
140 total of 17 new lines were obtained of which 13 were morphologically characterized and the 5  
141 most promising, from an ornamental point of view, were selected for further evaluation. Each  
142 line was vegetatively propagated in pots containing the same soil mixture as above.

143

## 144 2.2. Morphological characterization

145

146 Morphological characterizations were performed on 13 lines (C001, C002, C003, C004,  
147 C005, C006, C008, C009, C010, C013, C014, C016, C017) when plants were in full bloom  
148 during two flowering seasons (2008/2009 and 2009/2010). Leaf shape was assessed according  
149 to Hickey and King (1997). Stem length was considered as the distance between the soil level  
150 and the highest flower. Flower size was measured as height x width (cm). Width was considered  
151 as the maximum distance between the external margins of the two highest inner tepals or  
152 between the external margins of the two basal outer tepals. Height was considered as the  
153 distance between the margins of the highest outer tepal and the basal inner tepal. Flower shape  
154 was assessed as the ratio of height: width. Flower color was assessed as the main two or three  
155 colors covering the six tepals. Flower markings were assessed by the identification of  
156 dots/stripes covering the tepals in terms of location (inner or outer tepals), abundance (rare,  
157 medium or abundant) and shape (dots or stripes). Pollen abundance was assessed as abundant,  
158 medium or poor.

159

## 160 2.3. Sensorial Evaluation of Scent

161

162           Seventy untrained participants were asked to evaluate five different scented lines of  
163 selfed *A. caryophyllaea* (C001, C004, C010, C013 and C017). The demographic composition  
164 represented both genders and five age ranges (Table 1). Participants were asked to score their  
165 flower purchasing frequency (Table 1) and their purchasing priorities in terms of the relative  
166 importance given to stem length, flower size, flower color, floral scent and vase life by  
167 answering the question “when you buy/look at flowers the character you appreciate most is”. A  
168 5-point category scale was used of “strongly disagree”; “disagree”; “neutral”; “agree” and  
169 “strongly agree”. Samples consisted of three floral stems cut in proportion to their natural  
170 length and placed in a 500 ml measuring cylinder in water. Lines were evaluated individually by  
171 each participant in terms of liking of appearance and scent. Both were rated using a standard 9-  
172 point hedonic category scale: “Dislike extremely”; “dislike very much”; “dislike moderately”;  
173 “dislike slightly”; “neither like nor dislike”; “like slightly”; “like moderately”; “like very much”  
174 and “like extremely”. Intensity of the scent was rated using a 9-point intensity category scale:  
175 “Extremely low”; “very low”; “moderately low”; “slightly low”; “neither high nor low”;  
176 “slightly high”; “moderately high”; “very high” and “extremely high”. Appearance was rated  
177 after scent characters and participants were asked to wait for about one minute between  
178 evaluating each sample.

179

#### 180           2.4.GC-MS Evaluation

181

182           VOC sampling was performed on six selfed *A. caryophyllaea* scented lines (C001,  
183 C003, C004, C008, C013 and C017) as described by Aros et al. (2012b). Briefly, three open  
184 flowers stage 4-5 (anthesis) were enclosed in 250 ml polystyrene bottle with 30 ml of distilled  
185 water and VOCs collected by solid phase microextraction (SPME). A 50/30  $\mu\text{m}$   
186 divinylbenzene/carboxene/PDMS composite SPME silica fibre on 2 cm fused silica (grey fibre,  
187 Sigma Aldrich, Gillingham, UK) was exposed to the head space for 4h. VOCs were desorbed  
188 from fibres for 2 min at 240°C in the injection port of the gas chromatograph (GC 6890,  
189 Agilent, Wokingham, UK) and separated on a 30 m, 0.25 mm ID capillary column over 0.25  $\mu\text{m}$

190 HP-5MS (Agilent) using the following temperature programme: initial temperature 35°C for 2.5  
191 min, first step increase 3°C/min to 140°C, second step increase 16°C/min to 300, followed by  
192 1.5 min at 300°C constant. Electron Impact mass spectra were recorded in full scan mode from  
193 35 – 500 m/z (70 eV, MSD 5873, Agilent) coupled to a GC (GC 6890, Agilent). To monitor  
194 system performance and provide retention time references for calculation of retention (Kovats)  
195 indices (RIs). A C<sub>8</sub>–C<sub>20</sub> alkane standard was analysed regularly (0.1 µL direct injection,  
196 Supelco, Gillingham, UK). Data were analysed using AMDIS 2.71. Signals were integrated  
197 using total ion count and areas normalised. Putative identification was achieved by comparison  
198 of mass spectra with the NIST mass spectra library (v. 2.0, 2011) taking into account available  
199 information on Kovats indices.

200

## 201 2.5. Genomic Organization

202

203 A DNeasy Plant mini kit (QIAGEN, Venlo, The Netherlands) was used to extract  
204 genomic DNA from young leaves of selfed *A. caryophyllaea*, scented lines C001, C003, C004,  
205 C006, C010, C013, C017 and the non-scented *A. psittacina* which was included as a  
206 comparison. Three primer sets were used to amplify the full length sequence of the *AlstroTPS*  
207 gene: TPS-3` (Fw 5`-ATGGCTTCCCATCTTCCTCTTC-3` and Rev 5`-  
208 CCCGTTGTTTCGTCATAGAACC-3`), TPS-I (Fw 5`-  
209 CGCCGAATGTTATGTTACGCATCA-3` and Rev 5`-  
210 CCCCTATCGAAATCCCTGCATTCT-3`) and TPS-5` (Fw 5`-  
211 GCTTTGCACGATTCAGTGGT-3` and Rev 5`-AGGTTCCACCAACATTGCCA-3`)  
212 Amplification was carried out in a PTC-100 machine (MJ Research, St Bruno, Canada) using  
213 GoTaq Master Mix (Promega, Madison, USA) following the thermal profile: 4 min at 95°C; 35  
214 cycles of 95°C for 30 s, 57°C for 20 s, and 72°C for 40 s; and a final extension at 72°C for 5  
215 min. PCR products were purified from agarose gels using a GeneJET Gel Extraction Kit  
216 (Thermo scientific, Loughborough, UK), sequenced and sequences aligned using Geneious  
217 3.6.2. Variations on the conserved domains of the gene were detected using InterProScan

218 software (The European Bioinformatics Institute, Cambridge, UK) available on line  
219 (<http://www.ebi.ac.uk/Tools/pfa/iprscan/>).

220

## 221 2.6. Statistical Analysis

222

223 The scales described for hedonic and intensity evaluation were translated into scores.  
224 For the hedonic scale the scores were: Dislike extremely = 1 and like extremely = 9; for  
225 intensity scale the scores were: Extremely low = 1 and extremely high = 9. Standard deviation  
226 (STEDV) and standard error (SE) were calculated. Analysis of variance (ANOVA) was  
227 performed through SPSS 17.0 for Windows, using Tukey's HSD (Honestly Significant  
228 Difference) test for multiple pairwise comparisons with a significance level of 0.05. Principal  
229 Component Analysis (PCA) (Jolliffe 1986) was applied to the VOC dataset to summarize  
230 graphically differences in VOC abundance between the *A. caryophyllaea* lines and also to assess  
231 biological reproducibility. To prevent the VOC peaks of greatest intensity from dominating the  
232 PCA model, data were first standardized (value-average/STDEV) thus giving all VOCs a  
233 normal distribution. Univariate analysis (Kruskal-Wallis non parametric N-Way ANOVA) was  
234 also performed to test for significant VOC differences between the lines.

235

## 236 3. Results

237

238 3.1. Selfed progeny of *A. caryophyllaea* show morphological differences in both leaves and  
239 flowers

240

241 The most common leaf shape was lanceolate, observed in eight out of the 13 lines  
242 evaluated (C001, C002, C006, C009, C010, C013, C014 and C016). Elliptic leaves were  
243 observed in three of the lines (C004, C005 and C008), while linear leaves were observed only in  
244 C003 and C017 (Table 2). C004 showed the longest stem with an average of 70.6 cm (n=49),  
245 that was statistically different ( $P < 0.05$ ) to six of the other lines, among them C001 and C003,

246 which showed the shortest stems with averages of 35.5 (n=34) and 39.1 cm (n=37) respectively  
247 (Figure 1). C004 had flowers of greatest height (7.48 cm, n=49) and shared greatest width (5.45  
248 cm, n=49), with C001 (5.51 cm, n=38) (Figure 2). The smallest flowers were observed in C005,  
249 C006 and C014. Both mean height and width were lowest in C005 with averages of 5.0 and 4.1  
250 cm respectively although there was a lot of variability especially in height and thus the flower  
251 size of C005 was not statistically distinguishable from the other two lines. The ratio between  
252 height and width showed average values of  $> 1$  in all cases indicating a vertical elliptical shape.  
253 C001 presented the most rounded flowers (ratio 1.13), although not statistically different from  
254 six other lines, while C016 the most elliptical flowers (ratio 1.44) with no statistical differences  
255 with five other lines (Table 3). C006 produced the highest number of single flowers per floral  
256 stem (average value=6.5), significantly higher than all the other lines, excepting C009 and  
257 C014, both with an average of five flowers per stem. The poorest line was C017 producing only  
258 3.6 flowers per stem, although only statistically different to the highest producer, C006 (Figure  
259 3).

260

261 All the lines were white in background color, while different intensities of pink, red and  
262 green were seen as cover color on the margins of the tepals (Figure 3). Markings over the tepals  
263 were abundant in the majority of the lines, excepting on lines C001, C006 and C009 where they  
264 were scored as 'rare' (Figure 3). Characterization of the anthers showed one sterile line with no  
265 pollen (C006), while anthers of the rest of the lines produce morphologically normal pollen  
266 (data not shown).

267

268 3.2. The selfed *A. caryophyllaea* lines differ in their sensorial attributes

269

270 Sensorial analysis was performed to determine whether there were any perceived  
271 significant differences in appearance or scent bouquet between five of the selfed *A.*  
272 *caryophyllaea* lines. The 70 participants in the analysis were first asked to rate their

273 purchasing/rating priorities revealing that both flower color and scent were highly rated and  
274 significantly different from stem length, flower size and vase life (Table 1).

275

276 C013 and C17 were most highly rated in liking for their appearance (significantly  
277 compared to the other lines), and C017 also scored most highly for liking and intensity of its  
278 floral scent bouquet although it was only significantly different from the lowest rated line, C004  
279 (Figure 4). C004 was rated lowest for both scent intensity and liking of scent as well as liking of  
280 appearance, although liking of scent was only significantly different to C017 and appearance  
281 was only significantly lower than C017 and C013.

282

283 3.3. Scent profiles differ amongst the selfed *A. caryophyllaea* lines

284

285 VOCs from four of the lines that had been evaluated sensorially (C001, C004, C013 and  
286 C017) were analysed by GC-MS as well as two further lines (C003 and C008). In total 23  
287 compounds, all terpenoids, were detected and putatively identified with high confidence (Table  
288 4). All lines showed the same major peak as well as several minor peaks. The most abundant  
289 peak was identified as the monoterpene  $\beta$ -trans-Ocimene (C10) (RI: 1038), based on a NIST  
290 library search and on the Kovat index (1040) reported by Porta et al, 1999 (Figure 5A). Three  
291 compounds: 3-Thujene (C3), o/m Ethilanol (C15) and an unidentified sesquiterpene  
292 (sesquiterpene 7, (C28) were only detected in line 008 ( $P < 0.05$ ).

293

294 Sabinene (C5) was detected differentially in three lines, being most abundant in C003  
295 followed by C008 and C017, but was below detection in lines C001, C004, and C013  
296 ( $P < 0.0005$ ) Another unidentified sesquiterpene, (sesquiterpene 2, C19), was detected in lines  
297 C001 and C004 but was below detection in the other lines. Eudesma-4(14),11-diene (C25,  
298 circled black in Figure 5C, Figure 6C) and sesquiterpene 6 (C26) were undetectable in C003  
299 and higher in lines C001 and C004, though both were only significantly higher in C004

300 compared to C008, C013 and C017) ( $P < 0.05$ ) No significant differences in levels of Myrcene  
301 were found between lines (Figure 6E).

302

303           PCA analysis of VOC levels showed that 48% of variance of lines were explained by  
304 PC1 and PC2. The biplot of the components showed clear separation of lines C003, C004 and  
305 C017 along PC2, strong clustering of line C003 and separation of line C008 on PC1 (Figure  
306 5B). The same biplot showing the chemical components (Figure 5C) reflected the role of  
307 compounds mentioned above; position of C3, C28 and C15 clustered strongly at the right end of  
308 PC1 (circled red in Fig 5C), while sabinine (circled blue in Fig 5C) was discriminatory for lines  
309 C003, C008 and C017. C19 (circled green) was strongly discriminatory for lines C001 and  
310 C004 while C26 (circled black) was a strong indicator for line C004.

311

312           3.4. Genomic organization

313

314           Although myrcene levels did not appear to differ between the lines, as this is the only  
315 terpene synthase gene available in *Alstroemeria*, it was used to investigate whether the  
316 differences in VOC profiles were reflected in polymorphism amongst the lines in the structure  
317 of scent-related genes. The genomic organization of the myrcene synthase is constituted by two  
318 domains, near the N terminus is the terpene synthase domain, and at the C terminal end of the  
319 protein is the terpene synthase metal binding domain (Figure 7). This gene has six exons and  
320 five introns in *Alstroemeria* and for all the *A. caryophyllaea* lines and *A. psittacina* evaluated  
321 the presence of an insertion of 105 bp was observed in the fourth exon of the myrcene synthase  
322 genetic sequence (Figure 7). The insertion was located at the same position in all seven of the  
323 selfed *A. caryophyllaea* evaluated showing the same sequence. In the fifth exon a deletion of 61  
324 bp was identified only in lines C001, C004, C006, C010 and C013 (Figure 7), generating a stop  
325 codon in the middle of the terpene synthase metal binding domain of the gene and producing a  
326 shorter protein. Finally an insertion of 4 bp in *A. psittacina* was observed, changing the reading  
327 frame of the gene and generating a stop codon in the first part of the fourth exon of the gene.

328 This insertion would produce a truncated protein lacking most of the terpene synthase metal  
329 binding domain of the myrcene synthase, and the insertion was not present in any of the *A.*  
330 *caryophyllaea* selfed lines.

331

#### 332 4. Discussion

333

334 Although most of the lines evaluated were similar to the parental plant and to the  
335 botanical descriptions available for *A. caryophyllaea* (Assis 2004 and Foster 1945), some  
336 characters showed segregation suggesting a possible underlying heterozygosity within the  
337 parent plant. This suggestion is supported by the natural outcrossing habit described for species  
338 of this genus (Aizen and Basilio 1998; Cavieres et al. 1998; Valdivia and Niemeyer 2005).  
339 Some of this segregation was observed in the differences in leaf shape, stem length, flower size,  
340 shape and color. Line C004 appeared distinctive in several morphological characters including  
341 leaf size, stem length and flower size, however lines C006, C009 and C014 were more  
342 productive in terms of flower number compared to the other lines, and C017 flowers were of the  
343 most intense color (Figure 3). QTLs have been identified in *A. aurea* for leaf length and width,  
344 flower color and size (Han et al. 2002), and may be relevant to the characters seen in this study.  
345 The main pigments found in *Alstroemeria* flowers are anthocyanins, flavonoids and carotenoids,  
346 with the orange/red colors as seen in *A. caryophyllaea* due mainly to anthocyanins, specifically  
347 6-hydroxypelargonidin glycosides (Tatsuzawa et al. 2003). An analysis of the inheritance of  
348 flower color in *Alstroemeria* species and cultivars (Nørbæk et al. 1998) showed a complex  
349 composition and inheritance of various anthocyanin pigments. However Han et al. (2002)  
350 inferred from a QTL analysis of *A. aurea* that flower color inheritance was relatively simple.  
351 The differences in the color intensity and patterning seen here would support a more complex  
352 control given the variability revealed from selfing.

353

354 Although flower color was the most important character influencing purchasing of  
355 flowers by the participants of the sensorial study here, floral scent (in terms of liking and

356 intensity) also scored highly. Floral appearance, floral scent liking and scent intensity were  
357 therefore scored. Both genders were well-represented in the sample, which is important as  
358 olfaction is generally superior in females (Brand and Millot 2001). The design of the sensorial  
359 tests asked participants to score the three criteria separately, however an interaction between  
360 floral scent and appearance cannot be excluded as the scent evaluation was performed in the  
361 presence of the visual stimulus and vice versa and the two stimuli are known to interact  
362 (Gottfried and Dolan 2003). Line C017 was more valued in the sensorial analysis both for  
363 appearance and floral scent bouquet, and was one of the three lines rated highest for floral  
364 intensity suggesting a link between these three criteria. Furthermore, line C004 was distinct  
365 from C017 in all three criteria and was least valued in floral scent. VOC analyses were  
366 performed to explore further the differences in sensorial value. All five lines analysed showed  
367 the same major peak that was identified as the monoterpene  $\beta$ -Ocimene. This was distinct from  
368 the single peak perviously identified from the parental *A. caryophyllaea* (Aros et al. 2012b)  
369 which could not be unequivocally identified, but which had a different RI value to  $\beta$ -Ocimene.  
370 Based on PCA and ANOVA analysis distinctness of the VOC profiles of some of the lines  
371 tested could be ascribed to a small number of compounds. Of particular interest was the higher  
372 level of sabinine in line C0017 compared to line C004 and the higher levels of two  
373 sesquiterpenes putatively identified as eudesma-4(14),11-diene (also known as  $\beta$ -selinene) and  
374 selina-3,5-diene in line C004 compared to line C017. These three compounds are thus good  
375 candidates for a differential sensorial evaluation of these two lines. Sabinene is emitted by a  
376 number of scented species contributing to the spicy fragrance of nutmeg and some varieties of  
377 black pepper (Shulgin et al. 1967; Schenk and Lamparsky 1981; Richard et al. 1971).  $\beta$ -selinene  
378 is a minor component of celery seed oil VOCs (McLeod et al. 1988; McLeod and Ames 1989)  
379 and is described as having a “herbal” or “green, fragrant” odour. Selina-3,5-diene is a minor  
380 component of cashew nut (*Anacardia occidentale*) leaf essential oils (Dzamic et al. 2009).  
381 Further sensorial analyses linked to GC separation would be needed to determine whether these  
382 compounds do in fact make an important contribution to the sensorial value of the lines.  
383 Myrcene was detected as a minor component of the VOC profile in all the lines analyzed, and

384 although there were apparent differences between lines, these were not statistically significant  
385 and are thus unlikely to contribute to the sensorial value differences.

386

387 All the lines evaluated, including *A. psittacina*, showed the same genomic organization  
388 composed by 6 exons and 5 introns for the *Alstroemeria* myrcene synthase gene (*AlstroTPS*).  
389 This organization is the same shown by Aros et al. (2012b) for *A. cv. 'Sweet Laura'* which  
390 clustered as an anomalous member of class III according to the classification of Trapp and  
391 Croteau (2001). However differences in the size of exons and introns were observed among the  
392 lines: an insertion of 105 bp in the fourth exon was observed in both the scented *A.*  
393 *caryophyllaea* lines and the non-scented *A. psittacina*, but not in the scented *A. cv. 'Sweet*  
394 *Laura'*. Therefore this insertion seems to be a common pattern for the Brazilian native species  
395 and not related to the scent character. Furthermore a deletion of 61 bp was identified in the fifth  
396 exon of the myrcene synthase only in five of the seven lines analysed (Figure 7). This indicates  
397 polymorphism at this gene locus, suggesting that this gene is heterozygous in the parent plant  
398 and the two alleles are segregating amongst the selfed F1 lines. The fact that the insertion noted  
399 in all the F1 lines introduces a stop codon, thus truncating the open reading frame suggests that  
400 this gene may not be functional. This is in contrast to *Alstroemeria cv. Sweet Laura* which was  
401 derived from a cross between Chilean non-scented *A. aurea* and scented *A. caryophyllaea*  
402 (Pounders et al. 2003; M. Bridgen, personal communication). This indicates that the functional  
403 *AlstroTPS* in *cv Sweet Laura* may in fact derive from the unscented *A. aurea* parent, and  
404 perhaps have been activated in the new genetic background. It also indicates that other myrcene  
405 synthases are active in *A. caryophyllaea* since myrcene was detected in the scent bouquet by  
406 GC-MS.

407

## 408 5. Conclusions

409

410 In conclusion this work has shown that selfed progeny of the scented Brazilian *A.*  
411 *caryophyllaea* all resemble the parent plant but differ in a number of important morphological

412 features including flower color, size, productivity and markings, reflecting parental  
413 heterozygosity. All the F1 selfed lines are scented, but differ in their VOC profiles from each  
414 other and from their scented parent. Furthermore, the differences in flower morphology and  
415 scent result in differing sensorial value. Thus, even without performing crosses, some of the  
416 underlying diversity in *Alstroemeria* can be released for the development of new scented lines.

417

DANCAR 017	Linear
Parent plant	Linear to lanceolate

**Table 3.** Average ratios calculated from the relationship between flower height and width ( $\pm$ SE, n=4 to 54)\* evaluated on 13 selfed lines of *A. caryophyllaea*, during two periods of flowering ('08/'09 and '09/'10).

\* The number of flowers evaluated (n) depends on the productivity of each line. Different letters indicate statistically significant differences  $P < 0.05$ .

<b>Line</b>	<b>Ratio (height:width)</b>	<b>SE</b>
C001	1.13 a	0.01
C002	1.41 d	0.01
C003	1.35 cd	0.01
C004	1.38 cd	0.02
C005	1.22 abc	0.14
C006	1.15 ab	0.03
C008	1.21 abc	0.00
C009	1.17 ab	0.00
C010	1.22 abc	0.04
C013	1.23 abc	0.01
C014	1.31 bcd	0.02
C016	1.44 d	0.05
C017	1.32 bcd	0.03

**Table 4.** Volatile compounds detected in *Alstroemeria dancar* flowers via Solid Phase Microextraction, Gas Chromatography – Mass Spectrometry (SPME GC-MS).

Compound	VOC#	Common name	RI (DB-5)	RT	RI present in Terpenedata
Hexanal	C2	Hexanal	799.9	4.2327	771
2-Methyl-5-(1-methylethyl)-bicyclo[3.1.0]hex-2-ene	C3	3-Thujene	922.3	8.6598	932
$\alpha$ -Pinene	C4	$\alpha$ -Pinene	926.8	8.8608	936
$\alpha$ -Phellandrene	C5	Sabinene	967.5	10.705	973
$\alpha$ -Pinene	C6	Myrcene	990.2	11.7346	987
3-Isopropenyl-5,5-dimethyl-cyclopentene	C7	3-Carene	1006.1	12.4776	1000
Unidentified Monoterpene	C8	Monoterpene	1028.2	13.4796	
D-Limonene	C9	D-Limonene	1024.2	13.2675	1025
3,7-Dimethyl-, (E)-1,3,6-octatriene	C10	$\beta$ -trans-Ocimene	1038.8	14.0722	1029
11-Methyl-4-(1-methylethyl)-,4-cyclohexadiene	C12	Moslene	1057.4	14.957	
(+)-4-Carene	C13	Terpinolene	1081.1	16.3223	1082
1-Ethyl-6-ethylidene-cyclohexene,	C1	p-Ethylanisol	1091.5	16.7012	
1-Ethyl-6-ethylidene-cyclohexene (20)	C15	o/m-Ethylanisol	1070	15.5046	
1,3,5,5-Tetramethyl-1,3-cyclohexadiene	C16	Allo-ocimene	1128.5	18.5267	
2,6-Dimethyl-, (E,Z)- 2,4,6-octatriene (terpene)	C17	Allocymene	1140	19.0927	
Unidentified sesquiterpene	C19	Sesquiterpene 2	1387.6	30.6225	
Unidentified esquiterpene	C20	Sesquiterpene 3	1410.9	31.1126	
Caryophyllene	C21	Caryophyllene	1411.5	31.9224	
Unidentified esquiterpene	C23	Sesquiterpene 5	1387.6		
$\alpha$ -Caryophyllene	C24	$\alpha$ -Caryophyllene	1446.3	33.2645	
Eudesma-4(14),11-diene	C25	Eudesma-4(14),11-diene	1478.8	34.6524	
Unidentified sesquiterpene	C26	Sesquiterpene 6	1488.4	35.0607	
Unidentified sesquiterpene	C28	Sesquiterpene 7	1445.7	33.1326	

## FIGURES

**Figure 1.** Average stem length ( $\pm$ SE,  $n=3$  to 49)\* observed in selfed *A. caryophyllaea* lines, evaluated during two periods of flowering (2008/2009 and 2009/2010).

\* The number of stems evaluated ( $n$ ) depends on the productivity of each line.

Different letters indicate statistically significant differences  $P<0.05$ .

**Figure 2.** Average flower heights and widths ( $\pm$ SE, n=4 to 54)\* evaluated on 13 selfed lines of *A. caryophyllaea*, during two periods of flowering (2008/2009 and 2009/2010).  
 \* The number of flowers evaluated (n) depends on the productivity of each line.

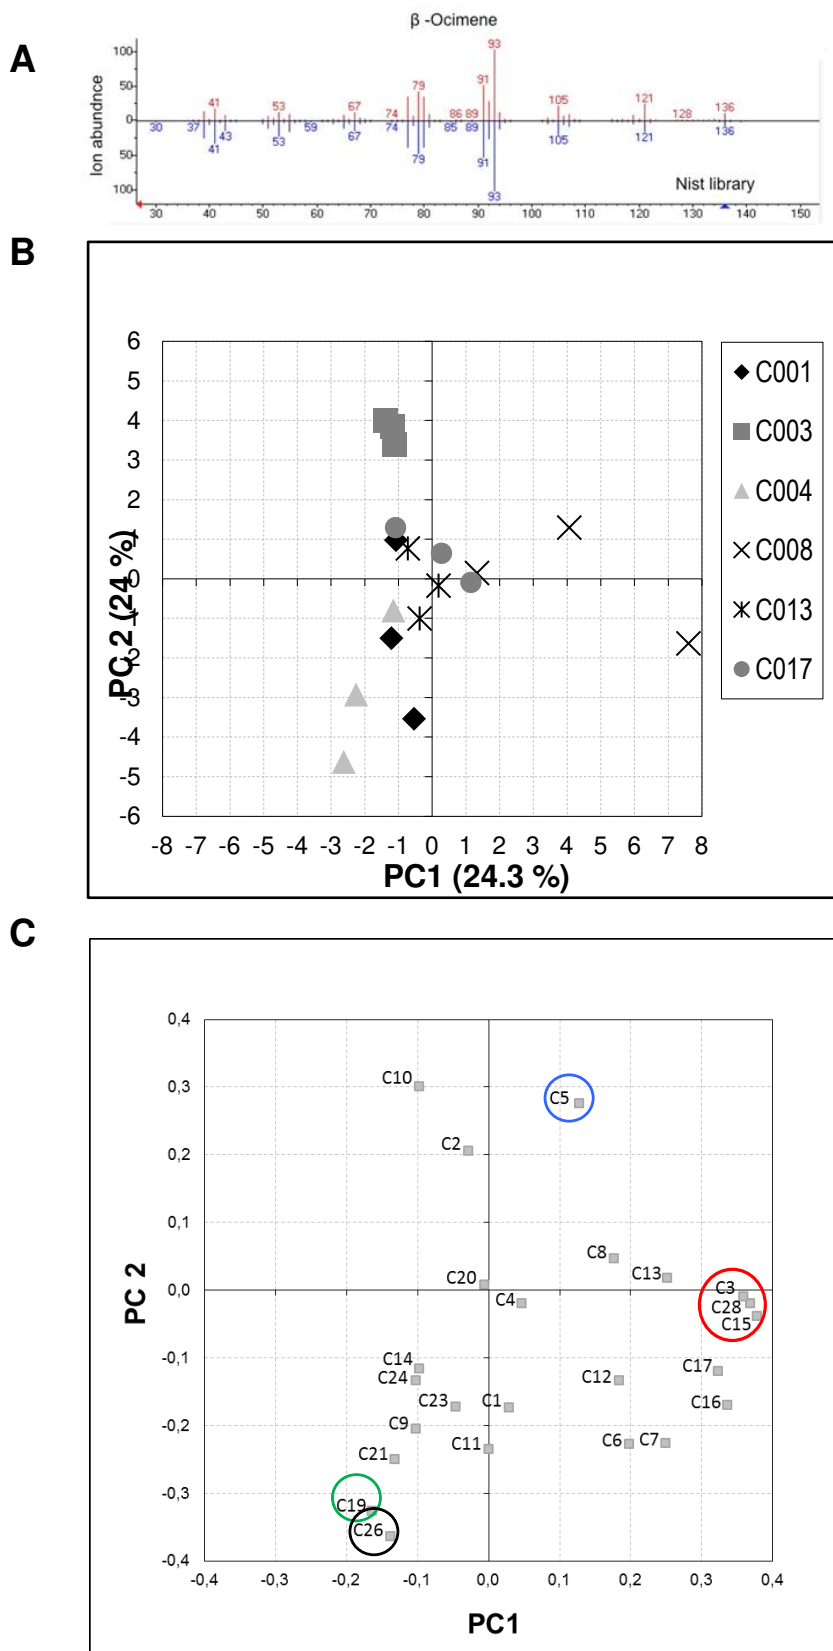

**Figure 3.** Flowers observed in 13 selfed lines of *A. caryophyllaea* and the parental line. Below each picture the average number of flowers per floral stems produced ( $\pm$ SE, n=4 to 54)\* is shown. Evaluations were performed during two periods of flowering (2008/2009 and 2009/2010).

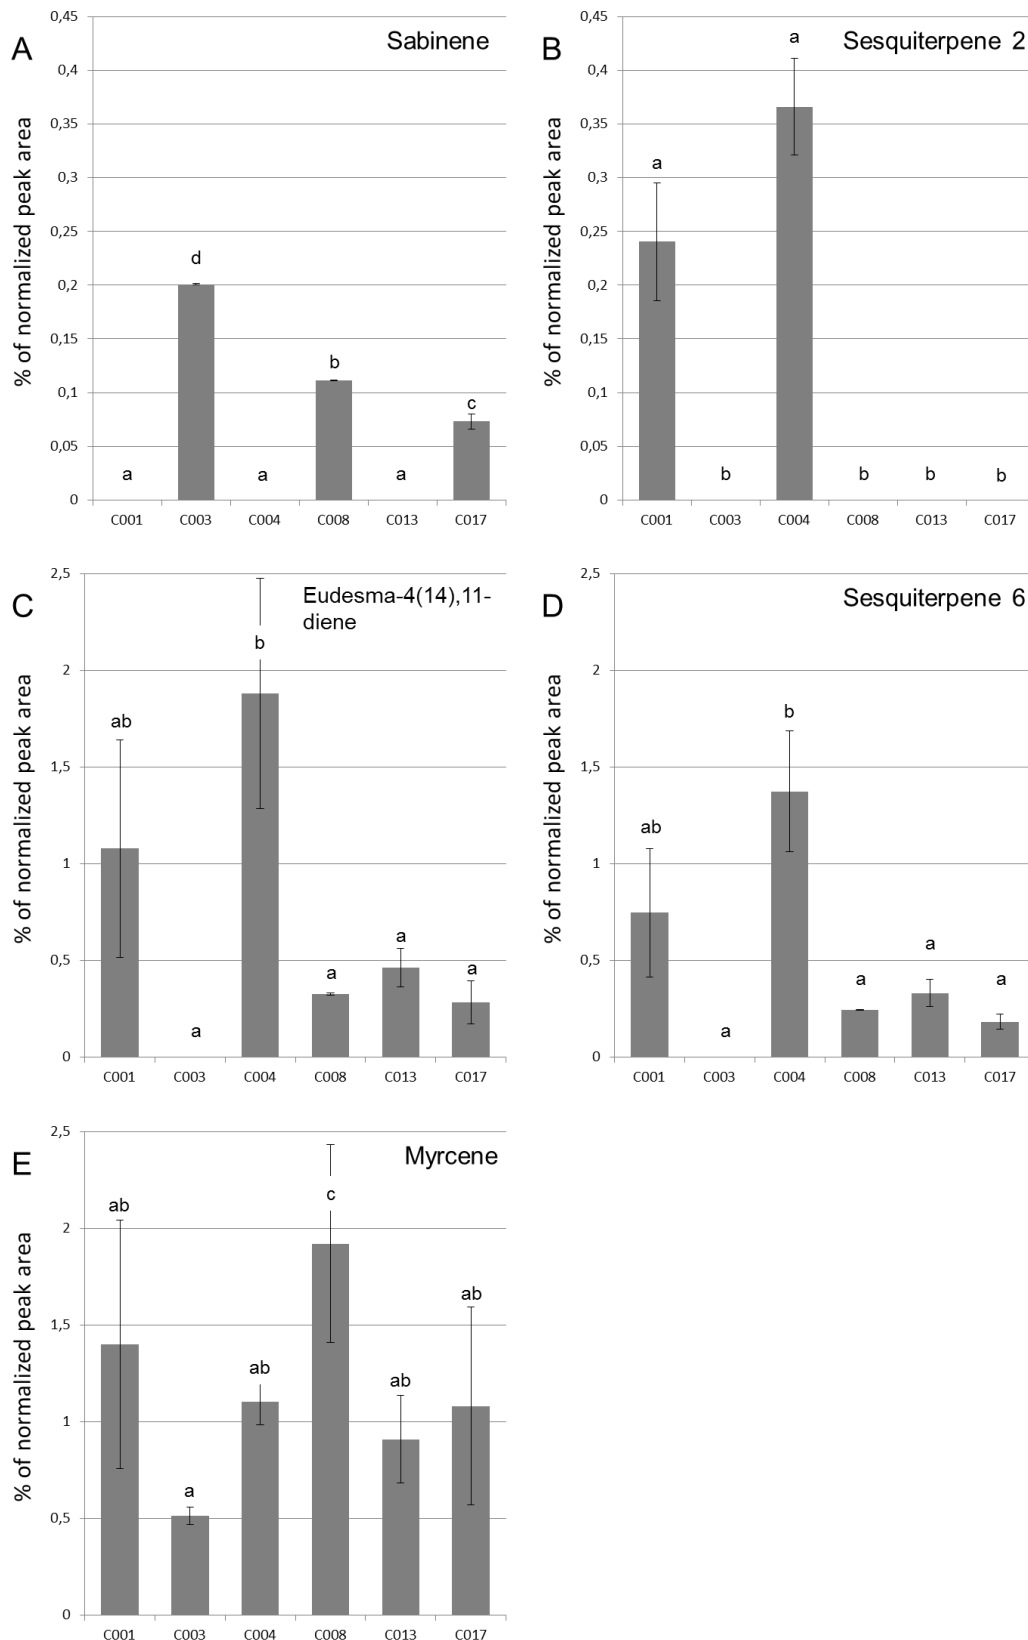

\* The number of floral stem evaluated (n) depends on the productivity of each line.

**Figure 4.** Means of floral scent liking and intensity and appearance liking ( $\pm$  SE,  $n=70$ ) evaluated on 5 selfed lines of *A. caryophyllaea*. The scale ranges from ‘dislike extremely’ (= 1) to ‘like extremely’ (= 9) for liking; and from ‘extremely low’ (=1) to ‘extremely high’ (=9) for intensity. Letters above same-shaded bars indicate statistically significant differences ( $n=70$ ;  $P<0.05$ ).

**Figure 5.** VOC data from six selfed *A. caryophyllaea* lines analysed by GC-MS. (A) Mass spectrum of the peak for  $\beta$  -Ocimene from line C001 and the match from NIST library. (B) PC biplot based on three biological replicates. Identification names of the PC applied (C1 to C28) are listed in Table 3.

**Figure 6.** Average relative abundance of selected compounds in selfed *A. cayophyllaea* lines (A-D) as identified by PCA and Myrcene (E). Letters above bars indicate statistically significant differences (n=3; P<0.05).

**Figure 7.** Genomic organization of *AlstroTPS* observed in 7 selfed lines of *A. caryophyllaea*, compared to the scented *A. cv. Sweet Laura* and the non-scented *A. psittacina*.
