Abstract

Objective: To develop a timeline for evaluating public health nutrition policy interventions.

Design: Concept mapping, a stakeholder-driven approach for developing an evaluation framework to estimate the 'time to impact' for policy interventions. The Schools (Health Promotion and Nutrition) (Scotland) Act 2007 was used as the model to develop the evaluation timeline as it had typical characteristics of government policy. Concept mapping requires stakeholders to generate a list of the potential outcomes, sort and rate the outcomes. Multidimensional scaling and hierarchical cluster data analysis were used to develop an anticipated timeline to impact for the policy.

Setting: United Kingdom.

Subjects: One hundred and eleven stakeholders representing nutrition, public health, medicine, education and catering in a range of sectors: research, policy, local government, National Health Service and schools.

Results: Eighty-five possible outcomes were identified and grouped into thirteen clusters describing higher-level themes (e.g. long-term health, food literacy, economics, behaviour, diet, education). Negative and unintended consequences were anticipated relatively soon after implementation of the policy, whereas positive outcomes (e.g. dietary changes, health benefits) were thought likely to take longer to emerge. Stakeholders responsible for implementing the legislation anticipated that it would take longer to observe changes than those from policy or research.

Conclusions: Developing an anticipated timeline provides a realistic framework upon which to base an outcome evaluation for policy interventions and identifies positive and negative outcomes as well as considering possible unintended consequences. It offers benefit to both policy makers and researchers in mapping the progress expected towards long-term health goals and outcomes.

Nutrition

There is increasing demand for evaluation of public health policy to demonstrate effectiveness⁽¹⁻³⁾. Such policies, however, tend to be complicated with multiple interacting components, complex partnerships and external factors which have the potential to reduce the impact of the intervention, and this provides a challenge for evaluation⁽⁴⁻⁶⁾. Unlike most clinical studies, the theory underpinning a policy and the specific aims and objectives are not always clear. Issues associated with evaluating policy interventions are still debated⁽⁵⁾, but it is increasingly recognised that a different approach from that for clinical studies is needed⁽⁷⁻¹⁰⁾. Often a wide range

of strategically chosen outcomes need to be identified which are consistent with and sensitive to the purpose of the intervention^(6,11,12). A single outcome may not give adequate assessment of the policy intervention, or may ask too much of the intervention^(13,14). Realistic expectations are also needed for what policy interventions can deliver within a specified time frame, particularly as they often involve a process of social change^(15,16).

Several different methods have been used to try to conceptualise this complexity (e.g. logic models^(17,18), concept mapping⁽¹⁹⁾), with a common aim to identify short-, medium- and long-term outcomes, showing a

Table 1 Summary of the main principles of the Schools (Health Promotion and Nutrition) Act (Scotland) 2007

Places health promotion at the heart of a school's activities
Ensures that food and drink served in schools (i.e. school lunches, breakfast and snacks at any other time of the day) meet nutritional requirements specified by the Scottish Ministers by regulations
Ensures local authorities promote the uptake and benefits of school meals and, in particular, free school meals
Reduces the stigma associated with free school meals by requiring local authorities to protect the identity of those eligible for free school meals
Gives local authorities the power to provide pupils with healthy snacks and drinks, either at a cost or free of charge
Requires local authorities to consider sustainable development guidance when they provide food or drink in schools

More detailed information about the Act can be found on the Scottish government website (www.scotland.gov.uk/Topics/Education/Schools/HLivi/foodnutrition).

logical progression of change. Concept mapping, which brings together knowledge and experiences of stakeholders to develop a common framework for evaluation⁽¹⁹⁾, is particularly useful for long-term programmes, such as public health policies, where there is limited theoretical and empirical knowledge of the time to impact. The estimated time for a policy intervention to have a measureable impact is often not specified, which can lead to unrealistic expectations of the outcome and the issue of whether it has failed or if the outcomes have simply not occurred yet^(13,20,21). Concept mapping has been used in the evaluation and planning of a number of public health policies (e.g. evaluation of the Smoking, Health and Social Care (Scotland) Act 2005, planning health improvement initiatives⁽²²⁾ and determining intervention strategies to increase physical activity⁽²³⁾).

Despite raised awareness of diet and health and the number of community-based interventions aimed at improving dietary intakes, there is a lack of well-planned evaluations^(2,24). The UK House of Commons Health Committee⁽³⁾ recently highlighted this, stating that 'even where evaluation is carried out, it is usually "soft", amounting to little more than examining processes and asking those involved what they thought about them'.

The aim of the project described here was to develop an evaluation framework with a timeline for assessing the impact of nutrition-related policy interventions; the development used the implementation of the Schools (Health Promotion and Nutrition) (Scotland) Act 2007⁽²⁵⁾ in primary schools since it is an example of typical government policy, but the intention was that the framework would have wider relevance. The Act applies to both primary and secondary schools but the focus for the project was primary schools (pupils aged 5–11 years). The legislation covers a range of health promotion issues as well as setting regulations for all food and drink provided in schools to meet nutritional standards. The main principles of the Act are shown in Table 1; more detailed information (e.g. the nutrient regulations, restriction of specific food and drinks, and the health promotion within schools) can be found on the Scottish government website (www.scotland.gov.uk/Topics/Education/Schools/HLivi/foodnutrition). This policy is similar to others being implemented in other countries and is typical of many public health policies which have a number of objectives and actions within a single policy^(26,27). There was also

sufficient detail to allow stakeholders with a range of expertise and prior knowledge of the Act to participate.

Methods

Participants

Concept mapping is a stakeholder-driven method. Stakeholders from scientific research, national and local government, the National Health Service (NHS), schools, community organisations and parents with children in primary school participated in the study. This wide range of stakeholders collectively had expert knowledge of the day-to-day schools context, research knowledge associated with schools-based health promotion, behaviour change and nutrition issues, as well as knowledge on policy processes and their intended aims. Stakeholder participation varied at different stages of the project, as described in subsequent sections. Key stakeholders were sent a written invitation to participate in the sorting and rating stage of the project (n 291), with additional invitations sent out via national and local nutrition organisations in the UK (Food and Health Alliance, The Nutrition Society, British Dietetic Association, Scottish Colloquium on Food and Feeding).

Concept mapping process

Concept mapping is a mixed-methods approach, combining qualitative research methods with multivariate statistical analyses, identifying and grouping key outcomes of an intervention. The process has six stages: (i) defining the evaluation question; (ii) brainstorming the possible outcomes; (iii) sorting and rating the outcomes; (iv) data analysis; (v) interpretation of the results; and (vi) development of a timeline.

Evaluation question

The aim of the project was to identify the likely outcomes resulting from the implementation of the Schools Act in primary schools. The following statement was developed for stakeholders to complete in the brainstorming session: 'I think the introduction of the Schools (Health Promotion and Nutrition) (Scotland) Act 2007 in primary schools will ...'.

Brainstorming: generate outcome statements

Three methods were used to generate outcome statements: a workshop, semi-structured interviews and focus

groups. The workshop was run with nineteen stakeholders from research and policy sectors across Scotland. Following a presentation describing in detail the Schools Act and purpose of the workshop, participants were asked to individually generate between six and eight outcomes that completed the statement 'I think the introduction of the Schools (Health Promotion and Nutrition) (Scotland) Act 2007 in primary schools will ...', then to work in groups to agree and refine the list of statements. The groups included a mix of stakeholders from different sectors, with varying prior knowledge of the Act. Statements from all the groups were collated. Semi-structured interviews were carried out with stakeholders from local government departments involved with the implementation of the Schools Act (education (n 2), catering (n 3) and health (n 4)) in Scotland. Interviewees described their role and previous experience of nutrition and health promotion policies in schools and were asked to describe what they thought would be the likely outcomes from the implementation of the Act. Interviews were transcribed and statements describing the outcomes extracted independently by two researchers (J.I.M., J.L.) and then combined. The opinions of parents with children in primary school were explored through two focus groups (six parents per group). The discussion focused on their views of school lunches and health promotion in schools, their knowledge of the Schools Act and the changes that they anticipated with the implementation of the Act.

Structuring: sorting and rating the statements

All the statements from the workshop, interviews and focus groups were combined (removing duplications) and reviewed both internally and externally, reducing the final list to eighty-five possible outcomes. A larger group of stakeholders was then sent information about the project (including the concept mapping methodology), a detailed description of the Schools Act and instructions for completing the sorting and rating. They were asked to first sort the statements into groups based on the similarity between statements in a way that made sense to them. Each statement could be placed in only one group and the statements could not all be put in a single group or grouped simply as positive or negative, but had to be grouped into themes. Next they rated each of the statements in terms of the relative likelihood of the outcome occurring, the importance of the outcome and the anticipated earliest time to measurable impact. Both the likelihood and importance were rated on a 5-point Likert scale from 1 (not at all) to 5 (extremely). Time to impact was rated on a 7-point scale with yearly intervals from 0 (immediate) to 6 (6 years or more). The sorting and rating exercise was completed online using the Concept System Global software (Concept Systems Inc., Ithaca, NY, USA), enabling a larger, more geographically dispersed group to participate. Stakeholders provided background

information on age, sex, the type of sector they worked in, their area of expertise, their knowledge of and role in the Schools Act and whether they had children in primary school.

Representation: data analysis

Individual matrices were generated from the sorted data showing groupings by individuals, which were then aggregated into a similarity matrix to show the number of participants who sorted each pair of statements together. Using multidimensional scaling (MDS), two-dimensional coordinates were created for each statement on the concept map to give a visual representation of the data. The distance between the points (i.e. statements) on the map represents the similarity between the statements, with those sorted together by more of the participants being closer together. The stress value was calculated for the MDS as a measure of the goodness-of-fit of the map (lower values indicate a better fit). Hierarchical cluster analysis was performed using the coordinates produced by the MDS to group the statements. An iterative process reducing the number of clusters from an initial twenty clusters down to eight was examined for interpretability. Data from fifteen stakeholders were excluded because they had not grouped the statements according to the instructions described above. Data were analysed using the Concept System software.

The average likelihood, importance and time to impact ratings were calculated for each statement and each cluster. The average rating for each cluster was compared between stakeholder groups using general linear models in the SPSS statistical software package version 17.0 (SPSS Inc., Chicago, IL, USA). The groups were based on their type of work: research (academic researchers with knowledge of scientific studies, 35%); policy (national government or government organisations involved in policy making, 19%); and implementation (local government, NHS, schools and community groups responsible for implementing legislation, 44%).

Interpretation: development of the timeline

The average rating of the anticipated time to impact for each cluster was used to develop the timeline. Time to impact ratings for individual statements were excluded if rated as 'not at all' likely to occur, as it was considered to be meaningless if the participant thought it would not occur. The number excluded per statement ranged from 0 to 35 ratings (median per statement, 3).

Results

Participant characteristics

Table 2 shows the characteristics of the stakeholders who completed the online rating exercise (n 102). It was not possible to estimate the exact response rate since the

authors did not have access to the number of additional invitations emailed via professional societies. One hundred and fifty-four stakeholders signed up to the website and 111 completed the sorting (72%); 102 completed all three sets of ratings (66%).

Concept maps

Over 300 statements were generated, many of these were duplications and the list was reduced to eighty-five unique statements. From the cluster analysis a consensus was reached that the thirteen cluster option provided logical groupings. Positioning of the statements and clusters is shown on the concept map (Fig. 1), with clusters comprising between three and thirteen statements. The stress value for the MDS was 0.251, which was comparable with previous studies (0.205 to 0.365⁽²⁸⁾).

The clusters included positive and negative aspects of health, diet, knowledge, social norms and economics (Table 3). Nine clusters were positive outcomes, i.e. improvements in the uptake of school meals, diet and food intake, healthy dietary choices, food literacy, food culture, local economy, educational benefits, long-term health and well-being. Four clusters were negative or unintended consequences, i.e. undesirable eating behaviours, adverse economic consequences, negative attitudes and

behaviours and a range of unintended consequences (e.g. bullying, food waste, reduction in family meals together).

Ratings by cluster

'Increase food literacy' (cluster 4) was rated as the most likely outcome, followed by 'improve school meals and uptake' (cluster 7) and 'improve food culture' (cluster 5). Negative and unintended consequences (clusters 11, 12 and 13) were rated as less likely to occur. Clusters tended to have higher ratings for importance than likelihood, with the exception of 'adverse economic consequences' (cluster 10). Figure 2 shows the relationship between importance and likelihood ratings for individual statements.

Timeline

Using the average earliest anticipated time for impact for each cluster, it was possible to identify short-, medium- and long-term outcomes (Fig. 3). The arrows intercepting the timeline (*x*-axis) represent the average rating for each cluster. The width of each box is set by the minimum and maximum rating for individual statements within the cluster. For example, in cluster 1 the average time to impact was 5.02, ranging from 4.22 (dental health) to 5.71 (health of the general population and reduce costs to

Fig. 1 Concept map (the numbers in the clusters relate to the statements in Table 3)

the NHS). The timeline serves to illustrate realistic expectations for change. Although there is a clear order for the clusters based on the average time to impact there is considerable overlap between them. The timeline does not serve as a precise single time point to assess change but a realistic guide for approximate estimates when change would be anticipated. Different levels of shading of the clusters in Fig. 3 illustrate the likelihood of the outcome, with darker shading illustrating a higher likelihood.

Time to impact by stakeholder group

The anticipated time to impact for each of the clusters was compared between stakeholder groups. A significant difference in the anticipated time to impact was found between groups for all of the clusters except clusters 1 (‘long-term health gains and impact’), 11 (‘unintended consequences in school and on the family’) and 13 (‘undesirable eating behaviours’; Table 4). *Post hoc* tests showed significant differences between the implementation and research groups for clusters 2, 3, 4, 5, 6, 7, 8 and 12 and between the implementation and policy groups for clusters 4, 5, 7, 8, 9 and 10. In all cases the implementation group anticipated that the time to impact would be longer. The research and policy groups did not differ significantly on average time to impact for any of the clusters. Detailed prior knowledge about the Schools Act varied between groups, 11% for the research group, 58% for the policy group and 65% for the implementation group, but adjusting for this did not alter the differences found between the groups.

Discussion

A systematic process was used to conceptualise and develop a timeline for evaluating nutrition policy in schools. This analysis grouped a complex range of behavioural, socio-cultural, health and economic outcomes into clusters and estimated realistic expectations of the time lag between implementation and impact on the range of outcomes. A common problem in evaluating public health policy is that programme theories (if stated) seldom specify the length of time for observed behavioural changes and long-term health gains to emerge, which can lead to unrealistic expectations^(13,21). In the present study, stakeholders anticipated that on average it would take over 5 years to detect any measurable change in long-term health outcomes (e.g. obesity, dental health and diabetes), which was 2 years longer than when they anticipated dietary changes. This presents a huge challenge for both policy makers and researchers trying to determine the impact of a long-term policy within a relatively short policy cycle. This highlights the importance of short- and intermediate-term outcomes as proximal indicators of whether the policy intervention is likely to produce the desired long-term outcome. Furthermore, initial success can often create the conditions for further success; for example, children need to try a new food, made available to them through school meals, before they decide if they like it and subsequently include it in their diet or not, and it is important to monitor these small changes.

Table 3 Statements included in each of the thirteen clusters and relative ratings of likelihood and importance

	Likelihood	Importance	Time
Cluster 1: LONG-TERM HEALTH GAINS & IMPACT	3-03	4-16	5-02
1. Improve the health of the general population			
3. Increase the number of children with a healthy weight			
7. Reduce the prevalence of overweight and obesity			
35. Lower blood pressure and cholesterol levels among children			
55. Reduce the prevalence of diabetes in children (type 2)			
75. Improve dental health			
19. Reduce costs to the National Health Service			
Cluster 2: PROMOTE WELL-BEING	3-41	4-10	3-13
20. Encourage other healthy lifestyle choices			
25. Help children achieve the Scottish dietary targets			
26. Improve the micronutrient status of children			
31. Improve self-esteem			
46. Give children more energy and increase physical activity			
Cluster 3: IMPROVE DIET & FOOD INTAKE	3-50	4-12	2-30
10. Reduce the taste preference for a high salt content in foods			
14. Reduce consumption of sugary drinks			
17. Reduce salt intake			
21. Reduce consumption of banned and restricted foods			
23. Encourage children to try a wider range of foods and new foods			
59. Increase the amount of fruit juice and fruit drinks consumed by children			
69. Increase consumption of oily fish			
76. Increase fruit and vegetable consumption at home			
81. Increase the consumption of complex carbohydrates (e.g. bread)			
82. Encourage children to eat healthier packed lunches			
Cluster 4: INCREASE FOOD LITERACY	3-83	4-50	2-69
29. Increase children's preferences for healthy foods			
32. Encourage children to make healthier food choices outside school			
44. Increase children's knowledge of healthy eating and a balanced diet			
58. Help healthy foods and drinks to become the norm			
85. Increase children's awareness of healthy foods			
Cluster 5: IMPROVE FOOD CULTURE	3-63	4-08	2-47
12. Increase expectations among children and parents for better quality foods			
13. Encourage eating to become a more enjoyable and social event			
47. Encourage positive attitudes towards a healthy diet			
56. Have a positive influence on family diet			
62. Improve children's knowledge of food sources and production			
Cluster 6: ENCOURAGE HEALTHY DIET CHOICES	3-49	3-80	1-87
16. Make food choices easier for children at school			
51. Encourage children to view unhealthy foods as a treat			
61. Increase peer pressure to eat healthy food			
Cluster 7: IMPROVE SCHOOL MEALS & UPTAKE	3-67	3-97	1-88
8. Improve the parents' perception of school lunches			
28. Eliminate mixed health messages between the classroom and food served in the canteen			
40. Improve the quality (e.g. taste and presentation) of food provided in schools			
48. Reduce parental anxieties about the type of food provided in school			
53. Reduce the stigma of free school meals			
57. Increase purchasing pressure on parents ('pester power') to buy healthier foods			
70. Increase the uptake of school lunches			
Cluster 8: EDUCATIONAL BENEFITS	3-31	3-80	2-72
15. Improve the concentration and behaviour of children in class			
33. Improve the diet of teachers			
41. Reduce sickness absences from schools			
42. Create a new school ethos about healthy lifestyles			
52. Increase educational attainment			
65. Increase parents' knowledge of healthy eating and a balanced diet			
Cluster 9: IMPROVE LOCAL FOOD ECONOMY	3-52	3-61	2-41
24. Boost demand for local food production			
30. Encourage manufacturers to make healthier products which meet the new guidelines			
37. Encourage greater partnership within and between local authorities			
66. Increase job satisfaction for catering staff			
71. Encourage improved catering standards in other institutions, e.g. hospitals, nurseries			
73. Eliminate inappropriate food subsidies in schools			

Table 3 Continued

	Likelihood	Importance	Time
Cluster 10: ADVERSE ECONOMIC CONSEQUENCES	3-47	3-05	1-08
2. Encourage other vendors to capitalise on any demand for snack foods and drinks			
4. Increase the cost of school meals			
22. Encourage new marketing tactics for unhealthy foods to reach children outside school			
34. Create a financial strain on parents by buying fruits and vegetables at home			
64. Increase the pressure on school catering services			
67. Place additional duties on teaching staff			
Cluster 11: UNINTENDED CONSEQUENCES IN SCHOOL & ON THE FAMILY	2-69	2-95	1-38
6. Increase the amount of time children have to wait for lunch			
18. Increase the number of children eating packed lunches			
38. Increase the amount of food wasted			
39. Create negative attitudes towards health promotion from teachers			
43. Increase the concern of parents who may not know what their child eats at lunchtime			
45. Reduce social interaction in families who no longer eat an evening meal together			
49. Create conflict within the family between what is eaten at school and at home			
50. Increase the number of children going out of schools at lunchtime			
60. Generate a negative reaction towards school lunches from the media			
68. Increase bullying in schools			
72. Decrease the uptake of school lunches			
74. Widen health inequalities among children			
78. Increase stigmatisation of children with weight problems			
Cluster 12: NEGATIVE IMPACT ON ATTITUDES & BEHAVIOUR TOWARDS FOOD	2-95	3-08	1-13
5. Create peer pressure to eat banned or restricted food and drinks			
11. Increase the consumption of banned or restricted foods and drinks out of school			
27. Make children complacent about wasting food they don't like			
54. Reduce the nutritional quality of food provided at home			
63. Increase children becoming hungry in the afternoon if they don't like the school lunches			
80. Reduce children's freedom of choice			
83. Increase high-fat and sugary foods and drinks brought into school			
84. Increase the appeal of banned or restricted food and drinks			
Cluster 13: UNDESIRABLE EATING BEHAVIOURS	2-34	2-99	2-17
9. Increase the amount of unhealthy foods and drinks consumed within the home			
36. Increase the total daily calorie intake and over consumption of food			
77. Increase the prevalence of eating disorders			
79. Increase fussy eating			

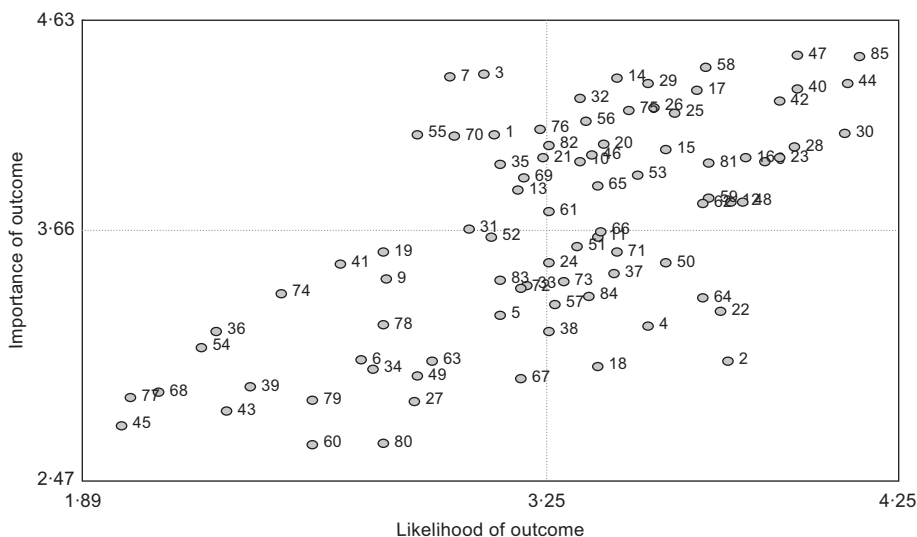

Fig. 2 The association between ratings of 'likelihood' and 'importance' for individual statements; $r = 0.65$ (the number at each point relates to the statements in Table 3)

The time to impact of the thirteen clusters provided a logical sequence of how the intervention might change behaviours, shift social norms and ultimately impact on

health outcomes. The analysis revealed that the time to impact for the clusters often overlapped, because they were made up of several outcomes. For example, the

13. Undesirable eating behaviours	1.76	1.30, 2.29	2.29	1.46, 3.11	2.16	1.71, 2.60	<i>P</i> = 0.426

*Differences between groups (*post hoc* comparisons using Tukey’s Honestly Significant Difference test): ^aresearch v. implementation, ^bpolicy v. implementation (*P* < 0.05).

food literacy cluster included knowledge, attitudes and food choices. Measurable changes in awareness and knowledge of a healthy diet were anticipated within 2 years, while for social norms, preferences and food choice the anticipated time was over 3 years (cluster average 2.7 years). The time points that emerged in this framework typically spanned several months or years.

The mean time points therefore were intended to serve as a guide to indicate when to expect change, not to identify an exact time point.

With the high prevalence of obesity among children and adults^(29,30) there is a growing pressure for policies and community interventions to tackle this major public health problem^(31–33). Although the aim would be to

reduce the prevalence of obesity, using weight status as the primary outcome of population-based interventions, without short- and medium-term indicators, would need a very long period of follow-up to reach a conclusion about the impact of the intervention. Kropski *et al.*⁽³⁴⁾ recently reviewed fourteen school-based obesity prevention programmes which used weight or BMI as a primary or secondary outcome. The review concluded that the evidence for school-based interventions was weak, but the authors stated the 'time required for small behavioural changes in diet or physical activity to manifest in anthropometric measures may exceed the duration of the studies reviewed'. The duration of the studies included in the review ranged from 6 months to 6 years, with the median duration of 1.8 years. This contrasts with results from our study, where it was anticipated that the earliest time to impact for a reduction in the prevalence of overweight or obesity was over 5 years. The need for short- and intermediate-term outcomes is supported by the conclusions of other reviews stating that the duration for evaluation of impact on weight or BMI for many studies is too short and that a broader range of outcomes needs to be measured^(34,35).

In general, stakeholders working in the community and involved in implementing policy in practice anticipated the time to impact would be longer than that anticipated by those working in research or policy. This difference may reflect their experiences of implementing complex policy interventions in different settings. A researcher's evidence base is likely to come from studies carried out under ideal situations where a controlled intervention is fully implemented; this is likely to be in contrast to stakeholders implementing public health policies in the 'real world' where there is less control over the intervention, which may result in only partial implementation, and other external factors^(4,23,36,37). This highlights the importance of including the expertise and experience of stakeholders, because if the evaluation timeline was based only on empirical evidence from studies carried out under ideal conditions it is likely that it would underestimate the real time to impact. Policies need time to be fully implemented and embedded in practice, before judgements about their impacts on distal outcomes such as dietary changes and health outcomes are made^(7,11,15,16).

Rating the likelihood of the outcome occurring was an important factor. It can help decide which outcome variables would be most useful to monitor and gives an indication of the size of impact of different outcomes. This can reduce the risk of measuring outcomes that may be thought to be important but unlikely to have an impact. Reducing the cost to the NHS and reducing the prevalence of type 2 diabetes among children were both rated highly on importance but low on likelihood, suggesting that these would not be good indicators to include in the evaluation of this policy. Unintended and negative consequences tended to be rated as less likely to occur

than behaviours more closely associated with action of the Act. The low level of the importance given to the economic outcomes may reflect a bias towards a more health-oriented group of stakeholders.

The use of concept mapping would be considered too detailed for simple, well-controlled and well-defined interventions with a clear theory underpinning the intervention and predictable time to impact, but highly relevant for policy interventions where the theory and empirical data are often lacking. Ideally all policies should have a sound theory underpinning them⁽³⁸⁾, but in practice this is not always the case and therefore this type of approach to evaluation is needed⁽²¹⁾. The increasing demand for evidence-based policy requires better evaluation of policy and, as such, appropriate methods to develop evaluations.

This method for developing an evaluation framework has strengths and limitations. A stakeholder-driven approach combines knowledge of the empirical evidence with 'real-world' perspective and experiences of working directly with the intended beneficiaries of policy interventions. This serves to give a more realistic, plausible and achievable evaluation timeline to guide data collection and the evaluation. Including this in the planning stage gives stakeholders and policy developers a better understanding of the intervention and the logical progression. One strength of the current study was that a diverse range of stakeholders participated giving different perspectives and who collectively had expert knowledge of the day-to-day schools context, research knowledge associated with health promotion, behaviour change and nutrition issues, and policy processes. Some stakeholders had little prior knowledge about the Schools Act before participating, but they were given detailed information about it before completing each stage of the process. Furthermore, no significant differences in the timeline were found between stakeholders with little or no prior knowledge of the Act before the study compared with those who had detailed prior knowledge.

A general limitation of any model developed for policy evaluation is that it assumes a stable environment, which does not take into account implementation failure. Therefore, a cautionary note has to be considered with the final timeline as it is based on the assumption that the intervention was fully implemented as intended; but in contrast to research studies this does not necessarily happen with all policy interventions. This could delay changes in the outcomes on the timeline. It was interesting to note that negative outcomes (e.g. economic, uptake of school meals) were considered to be more likely to emerge sooner than positive health or dietary change outcomes. Stakeholders expected some indicators to get worse before they got better (e.g. uptake of school meals) and this is important to note within a public policy context that is currently underpinned by tight fiscal constraints. Interestingly this trend has now been observed

for uptake since the implementation of the Act; an initial reduction in uptake was observed in the year that changes were first made but over subsequent years there has been a recovery and increase in uptake⁽³⁹⁾. A populated timeline of outcomes, derived from an exercise like this, may assist policy makers to make the case to continue a public health policy intervention, in challenging economic conditions, that may not yet have yielded positive health-related results but is considered likely to do so in the longer term. Conversely it can help to detect possible negative impacts (such as economic issues and implications) with a policy, especially in the early stages post implementation, and help provide a more realistic picture of the overall impact. A potential limitation of the study was that we did not include the views of children as a stakeholder group, which could have given an additional dimension during the brainstorming. Completing the rating and sorting exercise was time-consuming, which can place a burden on stakeholders.

In summary, the purpose of the current study was to develop a timeline for evaluating nutrition-related policy interventions and it has demonstrated an approach to developing a conceptual framework. It produced a time-to-impact 'road map' connecting a broad range of outcomes to better understand the likely impact. The Schools Act provided a multilevel example of a policy intervention which not only aims to change individual behaviour through education to develop knowledge and understanding about healthy eating, but is also concerned with developing supportive organisational and cultural changes through local environmental modifications. This integrated health promotion approach can form the basis of strategies for tackling obesity through other settings such as the workplace. We believe our study offers a way of gaining a better understanding of the range of outcomes that can be affected by policy, as well as identifying potential unintended consequences. The timeline could be adapted and used as a guide for future evaluations. It offers policy makers and researchers a way of identifying possible progress towards challenging long-term public health goals, within the constraints of relatively short government policy cycles.
