THEORETICAL BACKGROUND AND **RESEARCH AIMS**

The current and former relation with the ex-partner can be a resource but also a chronic stressor affecting psychological adaptation to divorce on this topic especially regarding in breakups after a long-term relationship.

Aims and Hypotheses:

Considering this gap and based on the divorce-stress-adjustment-perspective (Amato, 2000), we want

- (1) to explore how quantity and quality of current contact to the ex-partner is associated with psychological adaptation (i.e., life satisfaction and depressive symptoms) across three waves (2012, 2014, 2016)
- (2) to examine the association of satisfaction with prior relationship and reason of separation with the (2a) quality of the current relationship and with (2b) psychological adaptation at t1. We consider intrapersonal variables as well as the current relationship status and socio-demographic

We hypothesize that

- (H1a) independent of time, being in conflictual contact with the ex partner is related to poorer adjustment (higher depressive symptoms, lower life satisfaction) (cf.
- relationship is related to (H2a) better quality of contact to the ex-partner and to (H2b) better psychological
- Regarding separation reason, we expect that infidelity of the ex-partner is related to (H3a) poorer psychological adaptation and (H3b) lower quality of contact at t1.

METHODS

Study description and statistical analyses

- Data stem from the longitudinal, survey-based study 'relationships in later life' with three measurement points (2012, 2014, 2016), which are a part of the Swiss National Centre of Competence in Research 'LIVES' (funded by the Swiss National Science Foundation).
- Sample: 411 persons aged 45 65 years (M = 51.17 years, SD = 6.68) at t1 (117 men; 294 women); breakup after 21.60 years (SD = 8.1). Time since separation: 3.74 years (SD = 2.70). 70% (n = 275) were still in contact with their ex-partner at t3
- Statistical analyses were carried out with longitudinal structural equation modeling (Mplus).

Variables

- Psychological adaptation
 Life Satisfaction: Life Scale (Diener et al., 1985)
 Depressive symptoms: CES-D (Radloff, 1977)
- Current and former relation with ex-partner

- Quantity of current contact (dummy coded: no contact [reference category], daily/weekf, contact, monthly contact, yearly contact). Quality of current contact to ex-partner. Former relation: satisfaction in ex-relationship; separation reasons; relationship assessed since separation.

- Neuroticism, extraversion, openness, agreeableness, conscientiousness: BFI-10 (Rammstedt & John, 2007)

Current relationship status (new relationship: yes, no)

Socio-demographic variables

Socio-demographics (age, gender, financial resources); common children with ex-partner

RESULTS

Quantity of contact with the ex-partner was not related to depressive symptoms nor to life satisfaction (all p's >.05).

Quality of current contact with the ex-partner, former relation and adaptation to breakup

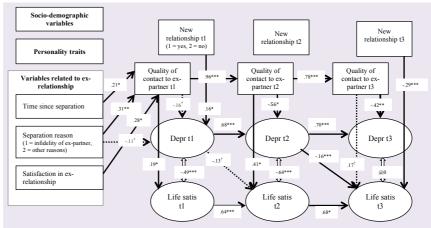

Figure 1. Psychological adaptation across three waves, predicted by prior and current relation to the ex-partner, personality traits and socio-demographic variables (final latent autoregressive model). Depr = depressive Symptoms; Life satis sel life satisfaction. For simplicity, we omitted the effects of control variables. All the reported parameters are standardized. Fit indices: χ^2 (2804) = 3331, ρ < .001, CFI = .967; TLI = .965; RMSEA = .026, 90% CI [.023 .030]. $^{\dagger}p$ < .10. $^{\star}p$.05. **p < .01. ***p < .001.

DISCUSSION

- Our results demonstrate that being in contact or not (and quantity of contact) to the ex-partner was not related to psychological adaptation. However, in line with our hypothesis, quality of current relationship to the ex-partner was significantly related to adaptation at all three waves, even when new partnership status, personality traits and socio-demographic variables were considered. It can therefore be assumed that current contact to the ex-partner can be a long-term stressor – or in case of high contact quality a resource - for psychological adaptation.
- In contrast to our expectations, prior marital satisfaction and separation reasons were not predictive for psychological adaptation at t1, but of current relationship quality at t1 (higher dissatisfaction with ex-relationship and ex-partner infidelity was related to worse quality of the current relationship).
- Our results support the crisis approach: participants reported better psychological adaptation over the three waves, and more time passed since separation was marginally related to lower scores in depressive symptoms.
- In line with prior research, personality variables (i.e., lower scores in neuroticism, higher scores in extraversion and agreeableness) and being in a new relationship predicted better psychological adaptation.
- Knowledge about variables accounting for inter-individual differences is important to gain a deeper understanding of the process of adaptation to separation after long-term accounting for Inter-materials and a second process of divorce for adults and children.
