

23 pH conditions and on synthetic medium supplemented with pectin as the sole carbon source,
24 and attenuated virulence towards citrus fruits. Introducing the full length of *PdpacC* into the
25 $\Delta PdpacC$ mutant restored all these phenotypes. The expression of the polygalacturonase gene
26 *Pdpg2* and pectin lyase gene *Pdpnl1* in *P. digitatum* was up-regulated in the wild-type strain
27 but not or weakly up-regulated in the $\Delta PdpacC$ mutant during infection. Disruption of *Pdpg2*
28 also resulted in attenuated virulence of *P. digitatum* towards citrus fruits. Collectively, we
29 conclude that PdPacC plays an important role in pathogenesis of *P. digitatum* via regulation of
30 the expression of cell wall degradation enzyme genes, such as *Pdpg2* and *Pdpnl1*.

31

32

33 **Introduction**

34 Green mold, caused by *Penicillium digitatum* (Pers.:Fr) Sac., is the most destructive
35 postharvest disease of citrus fruit and is responsible for up to 90% of the total losses during
36 postharvest packing, storage, transportation and marketing (Eckert and Eaks 1989). *P.*
37 *digitatum* is a typical necrotrophic pathogen that requires a pre-existing wound in the peel of
38 the fruit to be allowed to penetrate successfully. During the infection, *Penicillium* spp.
39 macerates the host tissue by producing significant amounts of hydrolytic enzymes, especially
40 abundant for polygalacturonases (PG) (Marcet-Houben et al. 2012; Sánchez-Torres and
41 González-Candelas 2003; Yao et al. 1996). Another important characteristic for *Penicillium*
42 spp. is that they are able to acidify the infected tissue by secretion of organic acids, which
43 have been reported to be a virulent factor in these fungi (Prusky et al. 2004; Barad et al.
44 2012).

45 The extracellular pH has been widely demonstrated to be a critical signal for virulence in
46 plant pathogenic fungi. Previous reports indicated that during infection some plant pathogens,
47 like *Colletotrichum* spp. and *Alternaria alternata*, alkalize their host tissue by producing
48 ammonia (Eshel et al. 2002; Prusky et al. 2001), whereas other pathogens, like *Sclerotinia*
49 *sclerotiorum*, *Botrytis cinerea*, *Phomopsis mangiferae* and *Penicillium* spp., acidify the
50 infected tissues by producing organic acids and/or utilizing ammonia (Barad et al. 2012;
51 Davidzon et al. 2010; Prusky et al. 2004; Rollins and Dickman 2001; Verhoeff et al. 1988). By
52 modulating the pH at the colonized tissue, plant pathogens bring the environmental conditions
53 close to the optimum for the production of hydrolytic enzymes and secondary metabolites,
54 ensuring an optimal pH for fully performing the physiological functions of hydrolytic
55 enzymes, etc., thereby enhancing their virulence (Eshel et al. 2002; Miyara et al. 2010;
56 Miyara et al. 2012; Prusky et al. 2001; Prusky et al. 2004; Prusky and Yakoby 2003).

57 Sensing and transduction of ambient pH in fungi is mediated via a conserved PacC/Rim101
58 signaling cascade, which is constituted by PalA, PalB, PalC, PalF, PalH, PalI and PacC
59 (Peñalva and Arst 2004; Peñalva et al. 2008). PacC, the terminal component of the pH
60 signaling pathway, is a transcription factor containing 3 Cys²His² zinc finger DNA binding
61 domains. The full-length PacC polypeptide is cleaved by two successive proteolytic cleavages
62 to produce a shorter and functional polypeptide (Hervás-Aguilar et al. 2007; Orejas et al.
63 1995). The functional form of PacC is translocated into the nucleus, where it regulates the
64 expression of PacC-dependent genes, which are involved in numerous physiological functions,
65 including growth, differentiation and virulence, in several fungal pathogens of humans, plants,
66 insects and fungi (Espeso and Arst 2000; Peñalva and Arst 2002, 2004; Suarez and Penalva

67 1996; Tilburn et al. 1995; Trushina et al. 2013; You et al. 2007).

68 The role of PacC regulating pathogenicity has been shown in several plant pathogens. In
69 *Colletotrichum acutatum*, the *pacC* ortholog is essential for virulence on citrus (You et al.
70 2007). In contrast to the wild type, the *pacC* disrupted mutants of the *S. sclerotiorum* were
71 less virulent on *Arabidopsis* and tomato (Rollins 2003). Oppositely, in *Fusarium oxysporum*,
72 a vascular wilt pathogen, a constitutive-active *pacC* mutant was found to be less virulent than
73 the wild type strain on tomato (Caracuel et al. 2003b). Although the effect of PacC on
74 virulence seems to be dependent on the pathogen, the regulation mechanisms in different
75 pathogens are mainly via controlling the production of virulence factors. Nevertheless,
76 although previous studies have indicated that hydrolytic enzymes, especially
77 polygalacturonases (PG), and organic acids play a role on pathogenesis in postharvest
78 pathogens of the genus *Penicillium* (Barad et al. 2012; Prusky et al. 2004; Sánchez-Torres and
79 González-Candelas 2003; Yao et al. 1996), the role of PacC in the regulation of virulence has
80 not been demonstrated in this important group of fungal pathogens. In the present work, the
81 *pacC* ortholog of *P. digitatum* has been isolated and its role in virulence has been investigated.
82 Our results indicate that PdPacC in *P. digitatum* is a positive regulator of virulence, and this
83 effect is at least partially mediated *via* the regulation of the expression of the
84 polygalacturonase encoding gene *Pdpg2*.

85

86 **Materials and methods**

87 **Culturing of *P. digitatum***

88 The wild-type strain Pd01 of *P. digitatum* used in this study was isolated in Zhejiang

89 province as described previously (Zhu et al. 2006) and deposited in the CBS-KNAW Fungal
90 Biodiversity Centre, Utrecht, the Netherlands (accession number CBS130525). The wild-type
91 and mutant strains were stored as conidial suspensions in 20% glycerol at -80 °C. For this
92 study, all strains were recovered on PDA (extract of 200 g potato boiled water, 20 g dextrose,
93 and 13 g agar per liter). Conidia were obtained from 7 to 10 days' old cultures by scraping
94 them with a sterile spatula, resuspended in sterile water, counted with a haematocytometer
95 and adjusted at the desired concentration. Mycelium was obtained by inoculating 5 µl (1.0
96 ×10⁶ conidia/ml) in 150 ml liquid PDB (PDA without agar). Liquid cultures were incubated
97 on a rotary shaker at 160 rpm and 25 °C.

98 **Isolation of the *pacC* ortholog from *P. digitatum***

99 The *P. digitatum pacC* ortholog, designated *PdpacC*, was amplified from the genomic DNA
100 of *P. digitatum* by PCR using the specific primers PdpacCC-F and PdpacCC-R (Table 1). The
101 primers were designed according to genomic sequence data of *P. digitatum* (Marcet-Houben
102 et al. 2012) and the *pacC* gene sequence from *P. chrysogenum* (GenBank, accession No.
103 U44726). The amplified fragment was cloned into the vector pMD18-T (TaKaRa Biotech. Co.,
104 Dalian, China) and the absence of polymerase-derived errors was checked by DNA
105 sequencing.

106 **Construction of *PdpacC* and *Pdpg2* disruption plasmids**

107 The *PdpacC* disruption vector was constructed by inserting the two flanking sequences of
108 *pacC* into the up- or downstream sides of the hygromycin resistance gene (*hph*) in the vector
109 pTFCM (Wang and Li 2008) (Fig. 1A). The primers used to amplify the homologous arms
110 were synthesized according to the genomic sequence of *P. digitatum* (Marcet-Houben et al.

111 2012). Briefly, a 0.7 kb DNA fragment containing the 3' downstream flanking sequence of
112 *PdpacC* was amplified from *P. digitatum* genomic DNA by PCR using primers PdpacCA and
113 PdpacCB (Table 1). After digestion with *XhoI* and *SpeI* restriction enzymes, the PCR
114 fragment was inserted into the *XhoI/SpeI* site of pTFCM to generate the plasmid pTFCM-3'.
115 Subsequently, a 0.7 kb fragment representing the 5' upstream flanking sequence of the
116 *PdpacC* gene was PCR amplified using primers PdpacCC and PdpacCD (Table 1). After
117 digestion with *SacI* and *KpnI* restriction enzymes, the PCR fragment was inserted into the
118 *SacI/KpnI* site of the plasmid pTFCM-3' to generate the *PdpacC* disruption plasmid
119 pTFCM-*PdpacC*-del, in which the region spanning from the residue P211, located
120 downstream of the zinc finger, to the A397 residue was replaced by *hph* (Fig. 1A). Thereafter,
121 the plasmid pTFCM-*PdpacC*-del was transformed into *Agrobacterium tumefaciens* strain
122 AGL-1 by electroporation following the method described by Wang and Li (2008).

123 The *Pdpg2* disruption vector was constructed using an identical strategy to that described
124 for the plasmid pTFCM-*PdPacC*-del. Briefly, a 0.9 kb DNA fragment containing the 3'
125 downstream flanking sequence of *Pdpg2* was PCR amplified from *P. digitatum* genomic DNA
126 using primers Pdpg2C and Pdpg2D (Table 1). Subsequently, a 0.75 kb fragment representing
127 the 5' upstream flanking sequence of the *Pdpg2* gene was PCR amplified using primers
128 Pdpg2A and Pdpg2B (Table 1). The resulting *Pdpg2* gene deletion plasmid,
129 pTFCM-*Pdpg2*-del, was transformed into *A. tumefaciens* strain AGL-1 by electroporation.

130 **Transformation of *P. digitatum***

131 To obtain a *PdpacC* disruption mutant, the *A. tumefaciens*-mediated transformation was
132 performed as described previously (Wang and Li 2008). Briefly, the *A. tumefaciens* strain

133 AGL-1 containing the plasmid pTFCM-*PdPacC*-del was grown in minimal medium (MM)
134 (Hooykaas et al. 1979) supplemented with kanamycin (50 µg/ml) for two days at 28 °C. Cells
135 were diluted to an OD₆₀₀=0.15 in induction medium (IM) containing 200 µM acetosyringone
136 (AS). After 6 h of incubation, the *A. tumefaciens* cells were mixed with an equal volume of
137 conidial suspension of the wild type *P. digitatum* Pd01 (1×10⁶ conidia/ml). A 200 µl mixture
138 was spread onto a nylon membrane that was placed on an IM plate containing 200 µM AS.
139 After co-cultivation at 25 °C for 2 days, the nylon membrane was transferred to a PDA
140 medium containing 75 µg/ml hygromycin B and 50 µg/ml ceftiofur to select for fungal
141 transformants and to kill *A. tumefaciens* cells. After 3 to 4 days of incubation, individual
142 colonies of *P. digitatum* were transferred to PDA plates containing 75 µg/ml hygromycin B.

143 **Complementation of the *PdpacC* gene**

144 A DNA fragment including the full genomic sequence of *PdpacC* as well as its promoter
145 (1391 bp upstream of the start codon) and terminator (55 bp downstream of the stop codon)
146 regions was PCR amplified using primers *PdpacCC*-F and *PdpacCC*-R (Table 1). After
147 digestion with *EcoRI*, the fragment was cloned into the plasmid pCA-Sur (Yan et al. 2011) to
148 obtain the complementation plasmid pCA-Sur-*PdpacC*. Transformation of the *P. digitatum*
149 Δ *PdpacC* deletant with plasmid pCA-Sur-*PdpacC* was conducted as described above except
150 that chlorimuron-ethyl (800 µg/ml) was used as a selection agent.

151 **pH measurement**

152 The pH value of liquid PDB or SM was measured directly with a micro pH electrode
153 Model 9810BN (Orion, Beverly, MA) in 1- to 3-ml aliquots sampled at indicated times after
154 fungal incubation. Four replicates were tested for each treatment. The pH at the inoculation

155 sites in the peel of citrus fruits was measured by inserting the micro pH electrode directly into
156 the mesocarp at different times after inoculation. 9 citrus fruits were tested for each
157 measurement (at least 30 measurements).

158 **Analysis of *PdpacC* expression in *P. digitatum***

159 Total RNA extraction and first strand cDNA synthesis were conducted as described
160 previously (Wang et al. 2012). Specific primers *PdpacC*-qF and *PdpacC*-qR (Table 1) were
161 used for qRT-PCR using a 7300 Real Time PCR system (ABI, USA). Real time PCR was
162 carried out using the SYBR Premix Ex Taq™ (Perfect Real Time) kit (TaKaRa Biotech. Co.,
163 Dalian, China). The thermal cycling conditions were 95 °C for 30 s, 40 cycles of 95 °C for 5 s,
164 and 60 °C for 31 s. Expression of the *P. digitatum* γ -actin gene (GenBank, AB030227),
165 determined using primers Actin-qF and Actin-qR (Table 1), was used as an internal control.
166 During the validation experiment, PCR efficiency for each gene was calculated using 10-fold
167 serial cDNA dilutions. The relative quantification of the target gene in comparison with the
168 internal control γ -actin was calculated according to the formula $\text{Ratio} = \frac{(E_{\text{target}})^{\Delta C_{\text{t target}}}}{(E_{\text{reference}})^{\Delta C_{\text{t reference}}}}$ (Pfaffl et al. 2002).
169

170 To determine the effect of ambient pH on *PdpacC* expression, about 0.1 g fresh weight of
171 mycelium from 4-day-old *P. digitatum* cultures grown in PDB was transferred to PDB
172 medium, in which the pH was adjusted to 3, 4, 5, 6, 7 and 8, respectively, using 0.1 mol/l
173 citrate-phosphate buffer, and the cultures were incubated on a rotary shaker at 160 rpm, 25 °C
174 for 12 h. Mycelia were harvested by filtration through 3 layers of cheesecloth, washed with
175 double distilled water (ddH₂O), frozen in liquid nitrogen, and stored at -80 °C until RNA
176 isolation. Mycelium of the wild type *P. digitatum* grown in non-buffered PDB (pH 6.32) was

177 used as the control. Three replicates were set for each treatment and the experiment was
178 repeated three times.

179 The expression dynamics of *PdpacC* during infection of citrus fruits was assayed using
180 qRT-PCR. Healthy, non-wounded mature citrus fruits (*Citrus unshiu*) were wounded by
181 pinpricking the fruits with a bunch of 5 needles (2 to 3 mm in depth). Three microliters of a
182 conidial suspension (10^6 conidia/ml) was inoculated onto each wound as described previously
183 (Zhang et al. 2013). Fifty mg of citrus peel tissue at the inoculation site of each fruit was
184 harvested for RNA isolation at 12, 24, 48, 72 and 96 h post inoculation. Three replicates were
185 set for each treatment. The experiment was repeated three times.

186 The effect of Na^+ on *PdpacC* expression was determined by adding NaCl to a final
187 concentration of 0.5 mol/l to 4-day-old *P. digitatum* cultures grown in PDB and followed by
188 additional incubation on a rotary shaker set at 160 rpm for 12 h before mycelium harvesting
189 and RNA extraction. The accumulation of *PdpacC* RNA was determined by qRT-PCR, and
190 the accumulation of *PdpacC* RNA in mycelium grown in PDB was used as the control.

191 The effect of pectin on *PdpacC* expression was determined by transferring 4-day-old *P.*
192 *digitatum* cultures to a synthetic medium SM (DiPietro and Roncero 1996) without agar
193 supplemented with 1% citrus pectin (Sigma, St. Louis, MO, USA) as the sole carbon source
194 (pH 6.3 at beginning). The cultures were then grown on a rotary shaker at 25 °C and 160 rpm
195 for 60 h before mycelium harvesting and RNA extraction. Cultures grown in liquid SM
196 supplemented with 1% glucose (pH 6.3 at beginning) were used as the control. The
197 expression of *PdpacC* was determined by using qRT-PCR. Three replicates were set for each
198 treatment, and the experiment was repeated three times.

199 **Expressions of CWDE genes during infection**

200 Based on the annotation of the genomic *P. digitatum* DNA sequence (Sun et al.,
201 unpublished), several cell wall degradation enzyme (CWDE) genes, including
202 polygalacturonase (*Pdpg1*, Genbank accession No.AB015286, *Pdpg2*, Genbank accession No.
203 JX298854, *Pdexp1*, Genbank accession No. JX495169, *Pdexp2*, Genbank accession No.
204 JX298856), pectin lyase (*Pdpnl1*, Genbank accession No. JX298853, *Pdpnl2*, Genbank
205 accession No. JX495170) and xylanase (*Pdxy1*, Genbank accession No. JX298855, *Pdxy2*,
206 Genbank accession No. JX495171) were chosen for dynamics analysis of RNA accumulation
207 in the wild-type and the $\Delta PdpacC$ *P. digitatum* strains during the infection through qRT-PCR.
208 The primers used in this study were listed in Table 1. The inoculated tissues (50 mg) were
209 harvested at 12, 24, 48, 72 and 96 h post inoculation and used for RNA isolation. The wild
210 type strain grown in PDB was used as the control. Three replicates were set for each treatment
211 and the experiment was repeated three times.

212 **Comparison of radial growth among the wild-type and *PdpacC* mutant strains**

213 To determine the role of *PdpacC* in the response to NaCl or KCl stress in *P. digitatum*,
214 mycelial plugs of the wild type, $\Delta PdpacC$ and complementation mutant (*CPPdpacC*) strains
215 of *P. digitatum* were prepared as described previously (Zhang et al. 2008), then were
216 transferred onto PDA plates supplemented with or without 1.0 mol/l NaCl or KCl. To
217 determine the role of *PdpacC* in the response to different pH conditions in *P. digitatum*,
218 mycelial plugs were transferred onto PDA plates buffered at pH 4, 6 or 8 with 0.1 mol/l
219 citrate-phosphate buffer. To determine the expression pattern of *PdpacC* in the presence of
220 pectin as the sole carbon source, mycelial plugs were transferred onto SM supplemented with

221 1% glucose or 1% pectin as the sole carbon source. The colony diameters of the tested strains
222 of *P. digitatum* were measured after 7 days (10 days for SM) of incubation (25 °C). Three
223 plates were used per strain and the experiment was repeated twice.

224 **Virulence assay**

225 To investigate the function of *PdpacC* on *P. digitatum* virulence, citrus fruits (*C. unshiu*)
226 were wounded with a bunch of 5 needles (2 to 3 mm in depth) as described previously (Wang
227 et al. 2012). Conidial suspensions (10^6 conidia/ml) of the wild type, $\Delta PdpacC$ and $CPPdpacC$
228 mutants were collected from 7-day-old PDA plates. Three μ l of the conidial suspension was
229 added onto each wounded site. The inoculated fruits were incubated at room temperature and
230 disease symptoms were observed daily. The virulence of the wild type and each mutant was
231 determined by measuring the lesion size. Thirty fruits were used for each strain and the
232 experiment was repeated twice. Virulence assay of the $\Delta Pdpg2$ mutant was conducted as
233 described above.

234 **Data analysis**

235 Data obtained in this study were analyzed using analysis of variance (ANOVA) and the
236 least significant test along with the Data Processing System as described by Tang and Feng
237 (2007).

238 **Results**

239 **Cloning of the *P. digitatum*'s *PdpacC* gene**

240 A 3431 bp fragment of the *PdpacC* was amplified using specific primers PdpacCC-F and
241 PdpacCC-R (Table 1). Sequencing results indicates that the coding sequence of *PdpacC* is
242 1985 bp in length and has an intron (59 bp) at nucleotide position 227 to 285. The nucleotide

243 sequence of the *PdpacC* has been deposited in the GenBank with accession number
244 JX298852. This sequence differs in only two nucleotide from the genomic sequences of the
245 two *P. digitatum* Spanish strains recently published (Marcet-Houben et al., 2012), which
246 result in a G to D change at amino acid 636. *PdpacC* is predicted to encode a protein of 641
247 amino acids (aa). The protein PdPacC shares high sequence identity with the PacC orthologs
248 reported in other fungi, including *Aspergillus nidulans* (62%, GenBank accession No.
249 EAA63426), *A. niger* (69%, accession No. CAA67063), *P. chrysogenum* (91%, accession No.
250 CAP94266), *S. sclerotiorum* (42%, accession No. ACO55072) and *F. oxysporum* (43%,
251 accession No. AAM95700). PdPacC contains three C2H2-type zinc finger motifs at its
252 N-terminal region (amino acid residues L57 to H145) and the amino acid sequence of the zinc
253 finger domain is 100% identical to those identified in the above mentioned fungi. The other
254 conserved region observed in PdPacC is located between residues L461 and P483, previously
255 reported as a protease recognition region (Díez et al. 2002). The nucleotide sequence
256 upstream of the start codon (-222 to -723) contains four repeats of the canonical PacC binding
257 site (three repeats are 5'-GCCAAG-3' and one is 5'-GCCAGG-3') (Tilburn et al. 1995).

258 **pH dynamics at inoculated citrus peel**

259 At the beginning of the experiment (0 h after inoculation), the pH value of the citrus peel
260 was 4.64 ± 0.13 . Maceration symptoms appeared at the inoculation sites at 24 h after
261 inoculation. At this moment, the pH value at inoculated sites decreased to 3.83 ± 0.14 . Then, it
262 further decreased and reached a value of 3.33 ± 0.12 at 48 h after inoculation. Thereafter, the
263 pH remained relative stable (Table 2). In contrast, the pH values in non-infected tissue
264 remained stable in a pH range from 4.61 to 4.70 at all time points (data not shown).

265 **Expression of *PdpacC***

266 The effect of pH on the expression of *PdpacC* was evaluated by growing the mycelium in
267 PDB buffered at different pHs for 12 h. In contrast to the expression of *PdpacC* in mycelium
268 grown in un-adjusted pH PDB (pH=6.32 after 12 h), the transcription levels of *PdpacC* in
269 mycelium grown at pH 3, 4, 5 and 6 were significantly lower (ratio<1) than those determined
270 at pH 7 and 8 (ratio>1) (Fig. 2A), indicating that *PdpacC* is an alkaline pH-induced gene *in*
271 *vitro* (pH≥7).

272 During infection of citrus fruits, transcription of *PdpacC* was detected at 12 h post
273 inoculation, at which time the conidia were germinating. The mRNA accumulation of *PdpacC*
274 increased and reached a peak at 48 h post inoculation, then decreased and kept a stable level
275 later on (Fig. 2B), indicating that *PdpacC* is involved in the infection of citrus fruits by *P.*
276 *digitatum*. Our results also showed that the expression of *PdpacC* is induced by NaCl, being
277 the expression of *PdpacC* in Na⁺-added PDB 2.6 fold higher than that in non-Na⁺-added PDB
278 (Fig. 2C).

279 The pH of SM amended with glucose or pectin as the sole carbon source was about 6.3 at
280 the beginning of the experiment, and decreased to 2.9 (glucose as sole carbon source) and 3.1
281 (pectin as sole carbon source), respectively, after 60 h of incubation. Interestingly, in contrast
282 to the mycelium grown in medium using glucose as sole carbon source, the expression of
283 *PdpacC* was about 20-fold higher when grown in medium using pectin as the sole carbon
284 source (Fig. 2D). This result suggests that *PdpacC* is involved in the utilization of pectin.

285 **Generation of *PdpacC*-disruption and -complementation mutants**

286 *PdpacC* disruption mutants ($\Delta PdpacC$) were generated by homologous recombination (Fig.

287 1A). The disrupted *PdpacC* allele lacks a fragment spanning from the residue P211, located
288 downstream of the zinc finger, to the A397 codon, which includes the regions of nuclear
289 localization signal (You et al. 2007) and the proteolytic processing site for final activation
290 (Díez et al. 2002). The resulting 160 hygromycin-resistant transformants were subjected to
291 PCR identification with primers PdpacCjd-F and PdpacCjd-R. A 1.3 kb fragment in the wild
292 type Pd01 was substituted by a 2.8 kb recombinant fragment in the deletion transformants
293 (Fig. 1B). Two deletion transformants were further subjected to Southern blot analysis using a
294 probe specific to the 3' region of *PdpacC* (Fig. 1A). The results confirmed that additional
295 ectopic integration of the replacement cassette did not occur in these transformants (Fig. 1C).
296 The growth phenotypes of $\Delta PdpacCA$ and $\Delta PdpacCB$ were identical during initial assays,
297 thus $\Delta PdpacCA$ was chosen for further analysis and abbreviated as $\Delta PdpacC$.

298 Twelve putative complementation mutants (*CPPdpacC*) were initially selected on medium
299 containing chlorimuron-ethyl (800 $\mu\text{g/ml}$). The insertion of *PdpacC* in the *CPPdpacC* mutants
300 was confirmed by PCR (data not shown) followed by Southern blot analysis (Fig. 1C). One of
301 the mutants with a single insertion of *PdpacC* (Fig. 1C) was then chosen for further studies.

302 The *Pdpg2* disruption mutant was created following the same strategy. Forty five
303 hygromycin-resistant transformants were obtained. PCR and Southern blot analysis indicated
304 that a $\Delta Pdpg2$ transformant contained a disrupted *Pdpg2* without additional ectopic insertions
305 of the replacement cassette (SFig. 1B and C). This mutant was then chosen for further studies.

306 **Disruption of *PdpacC* impairs the tolerance to Na⁺ or K⁺ stress**

307 To determine the role of *PdpacC* in response to Na⁺ or K⁺ stress, mycelium plugs of the
308 wild-type strain, $\Delta PdpacC$ and *CPPdpacC* mutants were placed on PDA media supplemented

309 with 1.0 mol/l NaCl or KCl. Results showed that the radial growth of the three strains were
310 identical on PDA medium (start pH=6.32, Fig. 3 and SFig. 2), indicating that *PdpacC* is
311 dispensable for mycelial growth of *P. digitatum* under non stress conditions. The radial
312 growth of the wild-type *P. digitatum* on PDA medium supplemented with 1.0 mol/l NaCl or
313 KCl was moderately reduced, whereas the growth of the $\Delta PdpacC$ mutant was severely
314 reduced (Fig. 3 and SFig. 2). This growth defect was partially restored in the *CPPdpacC*
315 mutant. However, the radial growth rates of the wild-type strain, $\Delta PdpacC$ and *CPPdpacC*
316 mutants on PDA supplemented with 1.0 mol/l $CaCl_2$ or $MgCl_2$ were not significantly different
317 (date not shown). These results suggest that the *PdpacC* is required for *P. digitatum* in
318 response to Na^+ or K^+ stress but not to Ca^{2+} or Mg^{2+} stress.

319 ***PdpacC* is required for mycelial growth at alkaline pH and full utilization of pectin**

320 Radial growth of the wild-type strains, $\Delta PdpacC$ and *CPPdpacC* mutants were determined
321 by culturing them separately on PDA buffered at pH 4, 6 and 8. Results showed that the radial
322 growth of the $\Delta PdpacC$ mutant on PDA was similar to that of the wild-type at pH 4 (Fig. 4).
323 Contrasting to the growth at pH 4, the radial growth of both mutant and wild type strains at
324 pH 6 and 8 was impaired (Fig. 4), indicating that the conditions of neutral or alkaline pH do
325 not favor the mycelial growth of *P. digitatum*. However, growth reduction was more
326 pronounced in the $\Delta PdpacC$ mutant at pH 6 and 8 in comparison to the wild-type strain (Fig.
327 4). Normal growth was recovered in the *CPPdpacC* mutant, indicating that *PdpacC* is
328 required for mycelial growth of *P. digitatum* at alkaline conditions.

329 The radial growth of the wild-type strain, $\Delta PdpacC$ and *CPPdpacC* mutants on SM
330 supplemented with glucose as the sole carbon source were similar. However, the radial growth

331 of the $\Delta PdpacC$ mutant was reduced by 57.7% compared to the wild type when grown on SM
332 supplemented with pectin as the sole carbon source (Fig. 5 and SFig. 3). Restoring *PdpacC* in
333 the $\Delta PdpacC$ mutant recovered almost completely the phenotype of the wild type strain (Fig.
334 5 and SFig. 3), indicating that *PdpacC* plays an important role in pectin utilization.

335 ***PdpacC* is required for full virulence in *P. digitatum***

336 The role of *PdpacC* on *P. digitatum* virulence was investigated by inoculating citrus fruits
337 with the wild-type, $\Delta PdpacC$ or *CPPdpacC* mutants. Maceration symptoms were observed on
338 all inoculated fruits at 24 h post inoculation, but the symptoms in the fruits inoculated with
339 the $\Delta PdpacC$ mutant developed much more slowly than in those inoculated with the wild-type
340 *P. digitatum* strain. The average diameter of the macerated lesions in citrus fruits inoculated
341 with the wild-type strain was about 4.8 cm at 4 days post inoculation, whereas that of the
342 $\Delta PdpacC$ mutant-inoculated citrus fruits was about 2.9 cm (Fig. 6A and B). The reduction in
343 virulence of the $\Delta PdpacC$ mutant was reversed when *PdpacC* was introduced into $\Delta PdpacC$,
344 as shown in Fig. 6A and B. The average diameter of the lesions induced by *CPPdpacC* was
345 comparable to that of the wild-type *P. digitatum*. These results indicate that *PdpacC* is
346 required for full virulence in *P. digitatum*.

347 ***PdpacC* regulates the expressions of *Pdpg2* and during infection**

348 Expressions of several *CWDE* genes, including polygalacturonases *Pdpg1* (AB015286) and
349 *Pdpg2* (JX298854), *Pdexpg1* (JX495169) and *Pdexpg2* (JX298856), pectin lyases *Pdpnl1*
350 (JX298853) and *Pdpnl2* (JX495170), and xylanases *Pdxy1* (JX298855) and *Pdxy2*
351 (JX495171), during the infection of the wild-type and $\Delta PdpacC$ mutant of *P. digitatum* were
352 evaluated through qRT-PCR. Results showed that during infection of citrus fruits, the

353 expression of *Pdpg2* and *Pdpnl1* in $\Delta PdpacC$ were different from that in the wild-type strain.
354 The expression of *Pdpg2* in both wild-type and $\Delta PdpacC$ strains was detectable at 12 h post
355 infection, and significantly up-regulated in the wild type at 24, 48 and 72 h post inoculation.
356 In contrast, the expression of *Pdpg2* in $\Delta PdpacC$ was not or weakly up-regulated at the
357 corresponding time points (Fig. 7A). The accumulated RNA of *Pdpg2* in the wild-type
358 strain-infected tissue was about 30 fold higher than in the $\Delta PdpacC$ -infected tissue at 72 h
359 post inoculation. In addition, the expression of *Pdpnl1* was also induced to a higher level in
360 the wild-type strain than in the $\Delta PdpacC$ mutant (Fig. 7B). The expression patterns of the
361 other *CWDE* genes tested in this study were similar between the $\Delta PdpacC$ mutant and the
362 wild-type strain (data not shown). These results indicated that *PdpacC* is involved in the
363 regulation of both *Pdpg2* and *Pdpnl1* during infection of citrus fruits.

364

365 **Disruption of the *Pdpg2* resulted in attenuated virulence to citrus**

366 To investigate the role of *Pdpg2* on virulence, a *Pdpg2* disruption mutant ($\Delta Pdpg2$) was
367 obtained following the same method described previously for *PdpacC*. Pathogenicity tests
368 indicated that decay development in citrus fruits inoculated with the $\Delta Pdpg2$ mutant was
369 slower than that in fruits inoculated with the wild type *P. digitatum* (Fig. 8A and B). The
370 diameter of the macerated lesions caused by the $\Delta Pdpg2$ mutant was about 30% smaller than
371 that caused by the wild type *P. digitatum* after 4 days of inoculation (Fig. 8A and B),
372 indicating that the *Pdpg2* is involved in *P. digitatum*'s virulence.

373

374 **Discussion**

375 For adaptation to a variable pH environment, fungi have developed a complex pH
376 signaling cascade by which they are able to sense and respond to extra-cellular pH changes.
377 The pH signaling system has been extensively studied in *A. nidulans* and is known to be
378 conserved in fungi (Lamb et al. 2001; Nobile et al. 2008; Peñalva et al. 2008). PacC, a zinc
379 finger transcription factor, the terminal component of the pH signaling cascade, is responsive
380 to extra-cellular pH changes and mediates the activation or repression of an array of
381 pH-responsive genes (Andersen et al. 2009; Trushina et al. 2013). The roles of PacC on the
382 regulation of growth, differentiation and virulence, as well as the production of secondary
383 metabolites, have been studied in several fungi (Caracuel et al. 2003a, b; Merhej et al. 2011;
384 Rollins 2003; Suarez and Penalva 1996; Trushina et al. 2013; You et al. 2007; Zou et al. 2010).
385 In this study, we have characterized the *A. nidulans pacC* ortholog in *P. digitatum* (*PdpacC*),
386 the most important postharvest pathogen of citrus, and revealed that *PdPacC* is required for
387 the full utilization of pectin and its full virulence towards citrus fruits, most likely by the
388 regulation of the expression of the polygalacturonase *Pdpg2* and the pectin lyase *Pdpnl1*
389 genes. In addition this study also indicated that *PdpacC* participates in the response to Na⁺
390 and K⁺ stresses, and is required for mycelial growth of *P. digitatum* at alkaline conditions.

391 In *A. nidulans*, the full-length PacC polypeptide is processed by two successive proteolytic
392 cleavages and yields a shorter, functional PacC at alkaline pH. The processed and functional
393 PacC is an activator of alkaline-expressed genes and repressor of acid-expressed genes
394 (Orejas et al., 1995; Penalva and Arst, 2002; Penalva et al., 2008). In this study we found that
395 neutral or alkaline pH conditions did not favor the mycelial growth of *P. digitatum* (Fig. 4),

396 but induced the expression of *PdpacC* (Fig. 2A). Disruption of *PdpacC* impaired the mycelial
397 growth of *P. digitatum* at neutral or alkaline conditions, indicating that *PdpacC* is an alkaline
398 pH-induced gene and is required for *P. digitatum* growth at alkaline conditions *in vitro*. This
399 result agrees with previous reports in other fungi, such as *A. nidulans* (Tilburn et al. 1995), *S.*
400 *sclerotiorum* (Rollins 2003), *F. oxysporum* (Caracuel et al. 2003b), *C. rosea* (Zou et al. 2010),
401 *F. graminearum* and *T. virens* (Merhej et al. 2011; Trushina et al. 2013). Previous studies
402 indicated that PacC binds to the consensus sequence “GCCARG” (Espeso et al. 1997; Tilburn
403 et al. 1995). This consensus sequence is present in the promoter of *PdpacC* itself, suggesting
404 that *PdpacC* can activate its own transcription at neutral or basic pH.

405 The expression dynamics of *pacC* during pathogenic fungal infection has been rarely
406 investigated. The PacC ortholog in the nematophagous fungus *C. rosea* was up-regulated
407 during the early stage of its infection of nematode when the pH was higher than 5 (Zou et al.
408 2010). In mature citrus fruits, the pH value of the peel is usually between 4.5 to 5.0, and
409 decreases to 3.0 to 3.5 after infection by *P. digitatum* (Prusky et al., 2004, Table 2). Contrary
410 to the expression pattern observed *in vitro*, the expression of *PdpacC* was definitely
411 up-regulated during infection of citrus fruits regardless of the low pH (Fig. 2B). This result
412 suggests that in addition to the well-known alkaline pH induction, alternative signal pathways
413 that up-regulate or de-repress the *PdpacC* expression have been evolved in *P. digitatum*,
414 thereby up-regulating the expression of *pacC*-dependent genes, such as *Pdpg2* and *Pdpn11*,
415 and allowing *P. digitatum* to adapt to acidic niches. Although other signaling pathways that
416 trigger *PdpacC* overexpression during citrus fruit infection are unknown, our results showed
417 that under *in vitro* conditions there was a clear up-regulation of *PdpacC* in SM medium when

418 pectin was added as the sole carbon source, up-regulation that was not observed in glucose
419 supplemented SM medium, although the pH in both instances was about 3.0 (Fig. 2D). This
420 result indicates that pectin triggers the induction or de-repression of *PdpacC*. Moreover, the
421 impaired utilization of pectin in the $\Delta PdpacC$ mutant (Fig. 5) suggests that *PdpacC* is
422 required for full utilization of pectin by *P. digitatum*.

423 PacC plays an important role in the regulation of virulence *via* programming the expression
424 or secretion of virulent factors such as hydrolytic enzymes, toxins and oxalic acid in different
425 plant pathogenic fungi. In *C. acutatum*, *C. gloeosporioides* and *S. sclerotiorum*, PacC regulates
426 the virulence in a positive manner (Miyara et al. 2008; Rollins 2003; Rollins and Dickman
427 2001; You et al. 2007), whereas in *F. oxysporum* and *F. graminearum* PacC is a negative
428 regulator of virulence (Caracuel et al. 2003b; Merhej et al. 2011). In *C. gloeosporioides* the
429 decreased virulence in a *CgpacC* disrupted mutant was associated with impaired expression of
430 a pectate lyase (*PELB*) (Miyara et al. 2008). In *S. sclerotiorum* the decreased virulence in a
431 disrupted *pacC* mutant was associated with the impaired production of oxalic acid and the
432 shifting of endopolygalacturonase (*pgI*) expression to higher ambient pH (Rollins 2003). In
433 contrast, the increased virulence in the *F. oxysporum pacC^{+/-}* loss-of-function mutant was
434 related to the increased expression of two endopolygalacturonase genes, *pgI* and *pg5*
435 (Caracuel et al. 2003b).

436 The results presented in this study showed that disruption of the *PdpacC* significantly
437 decreased the virulence of *P. digitatum* on citrus fruits (Fig.6). This lower virulence of the
438 $\Delta PdpacC$ mutant could not be attributed to a lower fitness of the mutant because the mycelial
439 growth of the $\Delta PdpacC$ mutant at acidic pH was similar to that of the wild type strain (Fig. 4).

440 However, our study showed that one of endopolygalacturonase gene (*Pdpg2*) and one pectin
441 lyase gene (*Pdpnl1*) were up-regulated during the infection of citrus fruit in the wild-type but
442 not, or weakly up-regulated, in the $\Delta PdpacC$ mutant (Fig. 7), suggesting that *Pdpg2* and
443 *Pdpnl1* are *PdpacC*-responsive genes, and the decreased virulence in the $\Delta PdpacC$ mutant is
444 associated with the impaired expression of *Pdpg2* and *Pdpnl1*. We have provided evidence
445 that disruption of *Pdpg2* led to a decreased the virulence towards citrus fruits (Fig. 8A and B),
446 further indicating that *Pdpg2* is a virulent factor for *P. digitatum*, and its expression is
447 regulated by *PdpacC*. Pectin is the major component of the citrus peel (Mahmood et al. 1998).
448 and the participation of endopolygalacturonases and pectin lyases in pathogenesis of *P.*
449 *digitatum*, a typically necrotrophic pathogen, is expected. Overall, our results lead us to
450 hypothesize that *PdpacC* is involved in pathogenesis of *P. digitatum* via regulation the
451 expression of *CWDE* genes that are required for degradation of pectin, the major component
452 of citrus peel.

453 The pH- and PacC-dependent genes were recently identified in *Trichoderma virens* by
454 comparing the transcriptomes of wild type and *pacC* mutant cultures exposed to high or low
455 pH (Trushina et al. 2013). The attenuation of virulence (Fig. 8A and B) in the $\Delta Pdpg2$ mutant
456 was lower than that observed in $\Delta PdpacC$ (Fig. 6A and B) and could not account for the
457 attenuation of virulence observed upon the loss of *PdpacC*. This difference in virulence
458 between $\Delta Pdpg2$ and $\Delta PdpacC$ suggests that other *PdpacC*-dependent genes are probably
459 involved in virulence, and *Pdpnl1* is probably one of them. Comparison of the transcriptomes
460 of the wild-type and the $\Delta PdpacC$ mutant of *P. digitatum* at acid conditions or during
461 infection of citrus fruit would contribute to the identification of other genes or pathways

462 involved *PacC*-dependent pathogenesis.

602 **Legends to figures**

603 **Fig. 1** Construction and identification of *P. digitatum* *PdpacC* null mutants ($\Delta PdpacC$). **A.**
604 *PdpacC* and hygromycin resistance cassette (*hph*) are denoted by large black and white
605 arrows, respectively. Annealing sites of PCR primers are indicated with small arrows. **B.**
606 Identification of $\Delta PdpacC$ mutants by PCR using primers PdpacCjd-F and PdpacCjd-R (Table
607 1). A 1.3 kb fragment of wild-type strain was replaced by a 2.8 kb in $\Delta PdpacC$ mutants. **C.**
608 Southern blot analysis of genomic DNAs isolated from wild-type *P. digitatum*, $\Delta PdpacCA$,
609 $\Delta PdpacCB$ and *CPPdpacC* mutants. Ten μ g of genomic DNA was digested with *KpnI* and
610 detected using a probe (the probe line shown in panel A) specific to the 3' region of *PdpacC*.

611 **Fig. 2** Expression profiles of *PdpacC* in *P. digitatum*. The relative expression was calculated
612 as fold changes ($2^{-\Delta\Delta C_t}$) using the *P. digitatum* γ -actin as the reference gene. Bars represent the
613 average fold-change plus the calculated standard error calculated from 3 independent samples.
614 **A.** 4-day-old mycelium was transferred to PDB buffered at different pH values and grown for
615 another 12 h at 160 rpm and at 25 °C. The wild-type *P. digitatum* grown in unbuffered PDB
616 was used as the control. **B.** Citrus fruits were inoculated with *P. digitatum* and incubated at
617 room temperature. The tissue around the inoculation site was harvested at the indicated time
618 points post inoculation. Wild-type *P. digitatum* grown in PDB was used as the control. **C.**
619 4-day-old mycelium was transferred to PDB supplemented with 0.5 mol/l NaCl for 12 h at
620 160 rpm and at 25 °C. Wild type *P. digitatum* grown in PDB was used as the control. **D.**
621 Four-day-old cultures of the wild type and the $\Delta PdpacC$ mutant were transferred to SM
622 supplemented with 1% pectin as the sole carbon source. Total RNAs were isolated from
623 mycelium after 60 h of incubation at 160 rpm and at 25 °C. Wild-type of *P. digitatum* grown

624 in SM medium supplemented with 1% glucose as the only carbon source was used as the
625 control.

626

627 **Fig. 3** Effect of Na⁺ and K⁺ stress on growth of *PdpacC* mutants and the wild-type *P.*
628 *digitatum*. 7-mm-diameter mycelial plugs of the wild type and mutant cultures were placed
629 onto PDA supplemented with the 1 mol/l NaCl or KCl and incubated for 7 days at 25 °C. Bars
630 represent the average diameters plus the standard errors calculated from 3 independent
631 colonies. Different letters indicate significant differences between samples ($P = 0.05$).

632

633 **Fig. 4** Growth assay of the wild-type *P. digitatum* and the *PdpacC* mutants at different pH
634 conditions. Mycelial plugs (7-mm-diameter) of the wild-type strain and the *PdpacC* mutants
635 were placed on PDA buffered at pH 4, 6 and 8, and incubated for 7 days at 25 °C. Bars
636 represent the average diameters plus the standard errors calculated from 3 independent
637 colonies. Different letters indicate significant differences between samples ($P = 0.05$).

638

639 **Fig. 5** Growth assay of the wild-type strain and the *PdpacC* mutants of *P. digitatum* on SM
640 with 1% glucose or 1% pectin as the sole carbon sources. Mycelial plugs (7-mm-diameter) of
641 the wild type and the *PdpacC* mutants were placed on SM and incubated for 10 days at 25 °C.
642 Bars represent the average diameters plus the standard errors calculated from 3 independent
643 colonies. Different letters indicate significant differences between samples ($P = 0.05$).

644

645 **Fig. 6** Virulence assay of the wild-type strain and the *PdpacC* mutants of *P. digitatum* on
646 citrus fruits. **A.** Citrus fruits (*Citrus unshiu*) were inoculated with conidial suspensions (10^6

647 ml⁻¹) prepared from the wild type and the mutants and incubated for 4 days at room
648 temperature. **B.** Diameters of the lesions were measured at 4 day post inoculation. Bars
649 indicate the average diameters plus the standard errors calculated from 30 independent lesions.
650 Different letters indicate significant differences between samples ($P = 0.05$).

651

652 **Fig. 7** Relative expression of *Pdpg2* (A) and *Pdpnl1* (B) in the wild-type strain and the
653 $\Delta PdpacC$ mutant of *P. digitatum* during infection of citrus (*Citrus unshiu*) fruits. Fifty mg of
654 peel tissue was harvested from each inoculated site at the times indicated. The relative
655 expression was calculated as fold changes ($2^{-\Delta\Delta Ct}$) using the *P. digitatum* γ -actin as the
656 reference gene and the wild-type *P. digitatum* grown in PDB as the control. Bars represent the
657 average fold-changes plus the calculated standard errors calculated from 3 independent citrus
658 fruits ($P = 0.05$).

659

660 **Fig. 8** Virulence assay of the wild-type and the $\Delta Pdpg2$ mutant of *P. digitatum*. **A.** Citrus
661 (*Citrus unshiu*) fruits were inoculated with conidial suspensions (10^6 ml⁻¹) prepared from the
662 wild-type and the $\Delta Pdpg2$ mutant of *P. digitatum* and incubated at room temperature for 4
663 days. **B.** Diameters of the lesions were measured at day 4 post inoculation. Bars represent the
664 average diameters plus the standard errors calculated from 30 independent lesions. Different
665 letters indicate significant differences between samples ($P = 0.05$).

Table 1. Primers used in this study

Name	Sequence (5' to 3') ^a	Purpose
PdpacCC-F	<u>GGAATTCC</u> GGGAAGAGGGAGGAGATGGG	PCR primers used to amplify full <i>PdpacC</i> including 1391 bp upstream and 55 bp downstream of the coding region
PdpacCC-R	<u>GGAATTCC</u> ACATGTCGTTACGGCGTAAATC	
PdpacCjd-F	CCGAGCATGAAGCATCCTGACA	PCR primers used to identify transformants of <i>PdpacC</i>
PdpacCjd-R	TGGAGTTGGAGAAGCCGACGAG	
PdpacC-qF	AACTGCGGCGGTGAACAA	PCR primers used to amplify the <i>PdpacC</i> gene in qRT PCR assay
PdpacC-qR	CGAATGTGGGAGGTGATGTGAT	
PdpacCA	<u>CCGCTCGAG</u> CCCATCCTCGTCTTCATCCACA	PCR primers used to amplify downstream fragments of <i>PdpacC</i> (probe)
PdpacCB	<u>GACTAGT</u> CGCACAGTCATACACCTCCAACCG	
PdpacCC	<u>CCGAGCTCG</u> GCGGGTTGGTGGCTGCCTGAGGTT	PCR primers used to amplify upstream fragment of <i>PdpacC</i>
PdpacCD	<u>GGGGTACC</u> CCTCTAGGCATTCCGCCAATTCCAG	
Actin-qF	TCCACTACTGCCGAGCGTGAAAT	PCR primers used to amplify the reference gene γ -actin in qRT PCR assay
Actin-qR	CCGCCAGACTCAAGACCAAGAAC	
pg2-qF	GAAGGAACCACCACTTTCCGG	PCR primers used to amplify the <i>Pdpg2</i> gene in qRT PCR assay
pg2-qR	TCAGGCTGTGAGCGTAGAAGAA	
Pdpg2A	CCCA <u>AGCTT</u> GCACTCGACAGGTGGGTAAAA	PCR primers used to amplify upstream fragment of <i>Pdpg2</i>
Pdpg2B	<u>CCGAGCTCG</u> CTTCTGGATAGGACAAGGCA	
Pdpg2C	<u>GACTAGT</u> CGAAGGAACCACCACTTTCCGG	PCR primers used to amplify downstream fragments of <i>Pdpg2</i>
Pdpg2D	<u>CCGCTCGAG</u> GGACCAGTTGGAGCAAGCAC	
Pdpg2jd-F	TTGTGGCTGGGCTTTGGT	PCR primers used to identify transformants of <i>Pdpg2</i>
Pdpg2jd-R	ATCTTGCCGCCGTTGGTT	

670 a The underlined sequences indicate restriction sites in the primers.

671

672

673 Table 2. pH values at the inoculated sites in the peel of *C. unshiu* fruits

Time (h) [*]	0	12	24	48	72	96
pH	4.64 ±0.13	4.61 ±0.18	3.83 ±0.14	3.33 ±0.12	3.31 ±0.23	3.22 ±0.15

674 ^{*} Hours after inoculation. Average pH values ± standard error. pH was measured by inserting the micro combination pH
675 electrode Model 9810BN (Orion, Beverly, MA) directly into the mesocarp. All measurements were repeated on 9 fruits (at
676 least 30 measurements).
