**8ABSTRACT**

9The objectives of this study were to understand the role of ethylene and nutrients ( $\text{Ca}^{2+}$ ,  
10 $\text{Mg}^{2+}$ ,  $\text{K}^+$  and N) on bitter pit (BP) development in wild type (GS) and ethylene  
11suppressed (68G and 103Y) ‘Greensleeves’ apples. The transgenic line 68G is  
12suppressed for 1-aminocyclopropane-1-carboxylic acid (ACC) oxidase (ACO) and line  
13103Y is suppressed for ACC synthase (ACS). Suppression of ethylene biosynthesis  
14reduced BP incidence and severity. Lower ethylene biosynthesis, in ethylene-suppressed  
15genotypes, had no effect on  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$  and N concentrations in fruit cortical tissue.  
16In all genotypes, fruit with BP had lower  $\text{Ca}^{2+}$  and higher  $\text{Mg}^{2+}$  concentrations and  
17higher  $\text{Mg}^{2+}/\text{Ca}^{2+}$  ratio in cortical tissue. The results indicate that high levels of ethylene  
18biosynthesis and  $\text{Mg}^{2+}$  in cortical tissue can enhance fruit susceptibility to BP incidence.

**20RESUMO**

**21Mecanismos envolvidos no desenvolvimento de “bitter pit” em maçãs**  
**22‘Greensleeves’ silenciadas para enzimas da síntese de etileno**

23Os objetivos deste trabalho foram avaliar o efeito do etileno e nutrientes ( $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$   
24e N) sobre o desenvolvimento de “bitter pit” (BP) em maçãs ‘Greensleeves’ tipo  
25selvagem e silenciadas para enzimas da síntese de etileno (68G a 103Y). A linhagem  
26transgênica 68G é silenciada para ácido 1-carboxílico-1-aminociclopropano (ACC)  
27oxidase (ACO) e a linhagem 103Y é silenciada para ACC sintase (ACCS). O  
28silenciamento das enzimas ACCO e ACCS diminuiu a incidência e a severidade de BP,  
29mas não teve efeito sobre as concentrações de  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$  e N no tecido cortical dos  
30frutos. Em todos genótipos, frutos com BP apresentaram baixas concentrações de  $\text{Ca}^{2+}$  e

7‘Greensleeves’ apples with suppression of ethylene biosynthesis. In: **Congresso Brasileiro de**  
8**Processamento mínimo e Pós-colheita de frutas, flores e hortaliças**, 001. Anais... Aracaju-SE.

31altas de  $Mg^{2+}$ , resultando em alta razão  $Mg^{2+}/Ca^{2+}$  no tecido cortical. Estes resultados  
32indicam que alta síntese de etileno e alta concentração de  $Mg^{2+}$  no tecido cortical dos  
33frutos pode aumentar a susceptibilidade dos mesmos a incidência de BP.

36Although bitter pit (BP) is believed to be a calcium ( $Ca^{2+}$ ) deficiency disorder, it may  
37also be regulated by ethylene and other nutrients in fruit tissue (AMARANTE;  
38CHAVES; ERNANI, 2006; LÖTZE; THERON; JOUBERT, 2010). Ethylene is key  
39regulator of many metabolic processes controlling fruit ripening that can affect fruit  
40susceptibility to BP. Plant nutrients such as  $K^+$  and  $Mg^{2+}$  may enhance fruit  
41susceptibility to BP by competing with  $Ca^{2+}$  for binding sites in the cell and inhibiting  
42 $Ca^{2+}$ -binding dependent cellular processes (HO; WHITE, 2005; SAURE, 2005). High N  
43content is usually related to high shoot growth, which may enhance  $Ca^{2+}$  movement  
44towards the leaves and decrease  $Ca^{2+}$  in the fruit (HO; WHITE, 2005). N and  $K^+$  also  
45trigger cell expansion (HO; WHITE, 2005; SAURE, 2005), suggesting that high levels  
46of these nutrients could favor rapid plant and fruit growth leading to a reduction in fruit  
47 $Ca^{2+}$  uptake and dilution of fruit  $Ca^{2+}$  content. The objectives of this study were to  
48understand the role of ethylene and other nutrients ( $Mg^{2+}$ ,  $K^+$  and N) on BP development  
49in wild type and ethylene suppressed ‘Greensleeves’ apples.

## 50MATERIALS AND METHODS

51Wild type ‘Greensleeves’ (GS) apple trees (*Malus domestica*) and trees from two  
52ethylene biosynthesis-suppressed lines developed at the University of California-Davis -  
5368G (*1-aminocyclopropane-1-carboxylate oxidase (ACO)* suppressed) and 103Y (*1-*  
54*aminocyclopropane-1-carboxylate synthase (ACS)* suppressed) - were cultivated in an  
55orchard located in Davis, California. The trees were 14 years old and did not receive  
56any  $Ca^{2+}$  supplement in the field during fruit growth or after harvest. A factorial design  
57was used, with combinations between apple genotypes (GS, 68G, 103Y) and BP  
58incidence (with or without BP). There were four blocks per treatment and one tree per  
59block. All plants were shaded at 70 days after full bloom (DAFB) by covering the plants  
60with a black net suspended above the trees that reduced the light intensity reaching the  
61canopy of the plants by ~50%. Shading was used to avoid fruit damage by sunlight.  
62Two hundred preclimacteric fruit from each block were harvested at 120 DAFB. After

11Freitas, S.T., Amarante, C.V.T., Mitcham, E.J. 2015. Mechanisms regulating bitter pit development in  
12'Greensleeves' apples with suppression of ethylene biosynthesis. In: **Congresso Brasileiro de**  
13**Processamento mínimo e Pós-colheita de frutas, flores e hortaliças**, 001. Anais... Aracaju-SE.

63harvest, fruit were stored at 0 ( $\pm 0.5$ ) °C and 90 to 95% RH for three months. The  
64ethylene concentration in the storage environment was minimized by constantly  
65circulating the air through a potassium permanganate filter.

66At harvest, each genotype was analyzed for starch content, flesh firmness, soluble solids  
67content (SSC) and titratable acidity (TA). These analyses were accomplished using four  
68replications with 10 fruit for each genotype. Starch clearing was estimated by cutting  
69the fruit in half, then dipping the fruit in a solution containing iodine:potassium iodide  
70(1:4) (QA Supplies, LLC, Norfolk, VA) for 1 min for staining. The degree of flesh  
71staining was then evaluated according to the California 'Granny Smith' Starch Index  
72where 0=100% starch and 6=0% starch. Fruit flesh firmness was measured as resistance  
73to penetration with an 11 mm probe on opposite sides at the equator of the fruit after  
74removal of a small area of peel using a Fruit Texture Analyzer (Güss, Strand, South  
75Africa). Soluble solids content (SSC) and titratable acidity (TA) were determined in  
76juice sample extracted by squeezing two cortical wedges cut from both sides of the fruit  
77in two layers of cheese cloth. Soluble solids were determined with an Abbe 10450  
78digital refractometer (American Optical, Buffalo, NY, USA). The acidity, determined as  
79the percentage of malic acid equivalents, was measured with an automatic titrator  
80(Radiometer, Copenhagen, Denmark) by titrating 4mL of juice with 0.1N NaOH to pH  
818.2.

82At three months of storage, all fruit were analyzed for BP incidence and severity. Fruit  
83with and without BP were then segregated and outer cortical tissue was manually cut  
84from the calyx end right underneath the skin up to a depth of 5 mm, frozen in liquid N<sub>2</sub>  
85and stored at -80°C for later analysis. Frozen samples were analyzed for total nitrogen  
86(N), potassium (K<sup>+</sup>), calcium (Ca<sup>2+</sup>), and magnesium (Mg<sup>2+</sup>) concentrations. Bitter pit  
87was assessed by incidence (%) and severity (BP index). BP index was assessed  
88according to a five-point visual scale (0 = no pit, 1 = 1 to 5 pits, 2 = 6 to 10 pits, 3 = 11  
89to 15 pits, 4 = 16 to 20 pits, 5 = >20 pits per fruit) and calculated with the formula  
90described by Pesis et al. (2010):

$$\text{BP index} = \sum_{0}^{5} \frac{(\text{index level}) \times (\text{fruit at this level})}{\text{total number of fruit}}$$

91

16Freitas, S.T., Amarante, C.V.T., Mitcham, E.J. 2015. Mechanisms regulating bitter pit development in  
17'Greensleeves' apples with suppression of ethylene biosynthesis. In: **Congresso Brasileiro de**  
18**Processamento mínimo e Pós-colheita de frutas, flores e hortaliças**, 001. Anais... Aracaju-SE.

92Nitrogen concentration was analyzed by a combustion method. Potassium was extracted  
93with 2% acetic acid and quantitatively assessed by atomic emission spectrometry.  
94Calcium and  $Mg^{2+}$  were determined by subjecting tissue to microwave acid  
95digestion/dissolution and subsequent analysis by inductively coupled plasma atomic  
96emission spectrometry.

97Statistical analysis was performed for each variable by means of analysis of variance  
98(ANOVA) using the SAS statistical package. The mean values (of four replicates  $\pm$   
99standard error) were compared using Tukey's test ( $p = 0.05$ ). Canonical discriminant  
100analysis (CDA) was performed to identify the best mineral variable ( $Ca^{2+}$  concentration  
101and nutrient concentration ratios  $Mg^{2+}/Ca^{2+}$ ,  $K^+/Ca^{2+}$ , and  $N/Ca^{2+}$  in cortical tissue) to  
102discriminate between fruit with and without visual symptoms of BP by using the PROC  
103CANDISC procedure of SAS. The power of each variable to discriminate between fruit  
104with and without BP was investigated by calculating the standardized canonical  
105coefficients (SCC), canonical correlation ( $r$ ) between canonical discriminant function  
106( $CDF_i$ ) and the mineral variables, and the parallel discriminant ratio coefficient ( $DRC =$   
107 $SCC \times r$ ) (AMARANTE; CHAVES; ERNANI, 2006).

## 108RESULTS AND DISCUSSION

109The starch index and malic acid content at harvest were similar among all genotypes  
110evaluated (Table 1). The lowest flesh firmness was observed in GS fruit (Table 1). The  
111highest SSC was observed in the 103Y ethylene suppressed line (Table 1).

112There was no BP at the time of harvest. After three months of storage at 0°C, BP  
113incidence and index were lower in ethylene-suppressed fruit than wild type fruit (GS)  
114(Figure 1). Accordingly, other studies have shown that BP can be induced by treating  
115apple fruit with ethylene (LÖTZE; THERON; JOUBERT, 2010). In addition, apple fruit  
116treated with an inhibitor of ethylene responses, 1-methylcyclopropene, are less  
117susceptible to BP development in cold storage than untreated fruit (PESIS et al., 2010).  
118Although the mechanisms involved are not well understood, ethylene may trigger BP by  
119accelerating fruit ripening and senescence and possibly the processes leading to BP  
120symptoms development. Ethylene may increase plasma membrane leakiness, enhancing  
121the effect of low tissue  $Ca^{2+}$  concentration on fruit susceptibility to BP. Increasing

21Freitas, S.T., Amarante, C.V.T., Mitcham, E.J. 2015. Mechanisms regulating bitter pit development in  
22'Greensleeves' apples with suppression of ethylene biosynthesis. In: **Congresso Brasileiro de**  
23**Processamento mínimo e Pós-colheita de frutas, flores e hortaliças**, 001. Anais... Aracaju-SE.

122plasma membrane leakiness has been suggested to be involved in BP symptoms  
123development (HO; WHITE, 2005; SAURE, 2005).

124Although suppression of ethylene biosynthesis reduced fruit susceptibility to BP, wild  
125type and ethylene-suppressed lines had statistically similar  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$  and N  
126concentrations, as well as  $\text{Mg}^{2+}/\text{Ca}^{2+}$ ,  $\text{K}^+/\text{Ca}^{2+}$  and  $\text{N}/\text{Ca}^{2+}$  ratios in fruit cortical tissue  
127(Tables 2 and 3). Accordingly, studies have shown that treating apple trees before  
128harvest with ethylene or the ethylene biosynthesis inhibitors had no effect on fruit  
129nutrient uptake (DRAKE et al., 2005). In all genotypes, fruit with and without BP had  
130similar  $\text{K}^+$  and N concentrations in cortical tissue (Table 2). Pitted fruit showed lower  
131 $\text{Ca}^{2+}$  and higher  $\text{Mg}^{2+}$  concentrations (Tables 2), as well as bigger  $\text{Mg}^{2+}/\text{Ca}^{2+}$ ,  $\text{K}^+/\text{Ca}^{2+}$   
132and  $\text{N}/\text{Ca}^{2+}$  ratios in cortical tissue (Tables 3), compared to sound fruit. The lower  $\text{Ca}^{2+}$   
133concentration in pitted fruit can be attributed to different factors such as fruit position in  
134the canopy, number of functional xylems in the fruit, fruit transpiration rates, as well as  
135different concentrations of growth regulators in fruit tissue (HO; WHITE, 2005;  
136SAURE, 2005).

137According to the CDA of mineral attributes related to  $\text{Ca}^{2+}$  concentration and  $\text{Mg}^{2+}/\text{Ca}^{2+}$ ,  
138 $\text{K}^+/\text{Ca}^{2+}$ , and  $\text{N}/\text{Ca}^{2+}$  ratios in the fruit cortical tissue only one canonical discriminate  
139function ( $\text{CDF}_1$ ) can explain 100% of the total data variation. ANOVA of canonical  
140scores showed a highly significant difference ( $p < 0.01$ ) between fruit with and without  
141BP on  $\text{CDF}_1$ . The  $\text{Mg}^{2+}/\text{Ca}^{2+}$  ratio had the highest values of SCC,  $r$  and DRC for  $\text{CDF}_1$   
142and, therefore, better define differences between fruit with and without BP than  $\text{Ca}^{2+}$   
143concentration alone or the  $\text{N}/\text{Ca}^{2+}$  and  $\text{K}^+/\text{Ca}^{2+}$  ratios (Table 4). The  $\text{Mg}^{2+}/\text{Ca}^{2+}$ ,  $\text{K}^+/\text{Ca}^{2+}$ ,  
144and  $\text{N}/\text{Ca}^{2+}$  ratios in fruit tissue may play an important role in determining fruit  
145susceptibility to BP (BRAMLAGE; DRAKE; LORD, 1980; LANAUSKAS;  
146KVIKLIENE, 2006; AMARANTE; CHAVES; ERNANI, 2006). However, the  
147mechanisms through which these nutrient ratios affect fruit susceptibility to BP are still  
148poorly understood. According to our results, the  $\text{Mg}^{2+}/\text{Ca}^{2+}$  ratio in fruit cortical tissue  
149better explains fruit susceptibility to BP than  $\text{Ca}^{2+}$  alone or  $\text{K}^+/\text{Ca}^{2+}$  and  $\text{N}/\text{Ca}^{2+}$  ratios.  
150Our results show that the average  $\text{Mg}^{2+}$  concentration in cortical tissue of fruit with BP  
151( $222.6 \mu\text{mol } 100 \text{ g fw}^{-1}$ ) was higher than in fruit without BP ( $182.9 \mu\text{mol } 100 \text{ g fw}^{-1}$ ).  
152Since cortical  $\text{Ca}^{2+}$  was higher in fruit without BP than in fruit with BP, our results  
153suggest that high  $\text{Mg}^{2+}$  uptake may enhance the effect of low  $\text{Ca}^{2+}$  uptake on increasing

26Freitas, S.T., Amarante, C.V.T., Mitcham, E.J. 2015. Mechanisms regulating bitter pit development in  
27‘Greensleeves’ apples with suppression of ethylene biosynthesis. In: **Congresso Brasileiro de**  
28**Processamento mínimo e Pós-colheita de frutas, flores e hortaliças**, 001. Anais... Aracaju-SE.

154fruit susceptibility to BP. Higher content of  $Mg^{2+}$  could compete with  $Ca^{2+}$  for binding  
155sites at the plasma membrane surface. Greater  $Mg^{2+}$  binding at the plasma membrane  
156could then replace  $Ca^{2+}$ , but not the role of  $Ca^{2+}$  in maintaining proper plasma membrane  
157structure and integrity, which could lead to leaky plasma membranes and BP  
158development. Although other studies suggested that  $K^+/Ca^{2+}$ , and  $N/Ca^{2+}$  ratios are  
159related to fruit susceptibility to BP (BRAMLAGE; DRAKE; LORD, 1980;  
160LANAUSKAS; KVIKLIENE, 2006), our data showed no clear relationship between  
161these nutrient ratios and BP incidence.

162Suppression of ethylene biosynthesis decreases fruit susceptibility to BP. The  $Mg^{2+}/Ca^{2+}$   
163ratio in fruit tissue is a better attribute to estimate or predict fruit susceptibility to BP  
164than  $Ca^{2+}$  concentration alone or as part of  $K^+/Ca^{2+}$  or  $Mg^{2+}/Ca^{2+}$  ratios.

217Figure 1. BP incidence (A) and severity (B) of wild type (GS), ACO-silenced  
 218(103Y) ‘Greensleeves’ apple fruit stored for three months at 0°C. Mean values are compared by Tukey’s  
 219test ( $p = 0.05$ ). Different letters show statistical differences between plant lines (GS, 68G, and 103Y).  
 220Values represent the mean of four replicates  $\pm$  SE.

221

## 222ACKNOWLEDGEMENTS

223We would like to thank Dr. Abhaya M. Dandekar for the wild type, ACO-silenced  
 224(68G), and ACS-silenced (103Y) ‘Greensleeves’ apples used in our study.
