| <b>Abstract:</b>                                  | <p>Long-term stability and selectivity are crucial for the practical application of gas sensors, which are closely related to the microstructure and composition of sensor materials. In this work, Co-based metal organic framework (MOF) is used as a precursor and prepared by a simple hydrothermal method. After calcination, a series of Co<sub>3</sub>O<sub>4</sub> nanospheres with various microstructures are derived. When the calcination temperature increases from 300°C to 500°C, the microstructure of Co<sub>3</sub>O<sub>4</sub> nanospheres changed from rough solid to porous, and then transformed into porous core-shell. When assembled into the gas sensors, the Co<sub>3</sub>O<sub>4</sub> nanospheres with porous structure calcined at 400°C (Co<sub>3</sub>O<sub>4</sub>-400) show the highly selective response of 53.78 for 100 ppm n-butanol at the operating temperature of 140°C. Moreover, the theoretical limit of detection was calculated to be 150 ppb. The reproducibility, selectivity and stability of the gas sensor were further verified to be excellent. After 45 days, the response value of Co<sub>3</sub>O<sub>4</sub>-400 is at 86.74%, even after 75 days, the response value remains at 74.93%. The main reason can be attributed to the large specific surface area, abundant pore structure and a large number of oxygen vacancies on its surface. These findings provide reference for the development of p-type metal oxide semiconductor (MOS) sensors with long-term stability and high performance.</p> |

Dear Editor:

We would like to submit the enclosed manuscript entitled "MOF-derived synthesis of  $\text{Co}_3\text{O}_4$  nanospheres with rich oxygen vacancies for long-term stable and highly selective n-butanol sensing performance ", which we wish to be considered for publication in *Journal of Alloys and Compounds*.

In this work, the nano-spherical Co-MOF was chosen as a self-sacrificial template, which was synthesized by a simple solvothermal method. Then, by controlling the calcination temperature, a series of  $\text{Co}_3\text{O}_4$  samples with different microstructure and composition have been prepared. Through the performance tests, the relationship between microstructure and performance has been verified. The  $\text{Co}_3\text{O}_4$  nanospheres calcinated at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) possess the best response sensitivity for n-butanol and long-term stability, which can be attributed to the porous and rich oxygen vacancies microstructure of it. Under the test temperature at  $140^\circ\text{C}$ , the response value of  $\text{Co}_3\text{O}_4$ -400 to 100 ppm n-butanol achieves 53.78, and the response value remains at 74.93% even after 75 days. Our work provides a facile MOF pyrolysis method for preparing long-term stable and high-performance gas sensitive MOS materials.

This paper is our original unpublished work and it has not been published previously. All authors have seen the manuscript and approved to submit to your journal. If our manuscript can be accepted by *Journal of Alloys*

*and Compounds*, it will not be published elsewhere in the same form, in English or in any other language, without the written consent of the Publisher. Thank you very much for your attention and consideration.

Sincerely

Lingli Cheng

The material prepared in our work has the following advantages:

Three kinds of  $\text{Co}_3\text{O}_4$  nanospheres with different microstructure were prepared through MOF derivative method. The relationship between microstructure and gas sensing performance of materials has been clarified. The  $\text{Co}_3\text{O}_4$  nanospheres calcinated at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) possess the best response sensitivity for n-butanol and long-term stability, for its porous and rich oxygen vacancies microstructure. Under the test temperature at  $140^\circ\text{C}$ , the response value of  $\text{Co}_3\text{O}_4$ -400 to 100 ppm n-butanol achieves 53.78, and the response value remains at 74.93% even after 75 days.

Dear Editor,

We would like to send our response to reviewers of JALCOM-D-20-12174.

We are grateful for valuable comments and for careful and critical reading of this manuscript.

-----  
**To reviewer 2:**

We are grateful for valuable comments and for careful and critical reading of this manuscript. Our paper was much improved by helpful advices. We have revised our manuscript in line with the comments as follows.

1. As author has found that the order of % of oxygen vacancy in  $\text{Co}_3\text{O}_4$  is  $\text{Co}_3\text{O}_4$  400 (53.75%) >  $\text{Co}_3\text{O}_4$  500 (35.76%) >  $\text{Co}_3\text{O}_4$  300 (25.69%), why it is such in order? As we all know that Co(II) get oxidized into Co(III) when it thermally treated, hence it was expected that as the synthesis temperature was increased, the oxygen vacancy should decrease monotonously. However here the similar trend has not been followed.

Answer) Thanks for your valuable suggestion. You are right, generally, Co(II) get oxidized into Co(III) when it thermally treated, while the oxygen vacancy will decrease simultaneously. However, in our work, the XPS analysis results of  $\text{Co}_3\text{O}_4$  samples (Fig. 1) show that the corresponding oxygen vacancy ( $\text{O}_v$ ) contents of  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 are 25.69%, 53.75%, and 35.76%, respectively. To explain this, the TG and DTA analysis of Co-MOF precursor has been measured, as shown in Fig. 2. According to Fig. 2, the tricarboxylate linkers of Co-MOF precursors gradually decomposed in the temperature range of 150°C to 300°C. At this stage, the decomposition rate of organic frames is relatively slow, so they mainly

react with the oxygen in air. And at the same time, the Co in the Co-MOF precursors also react with the oxygen in air to produce  $\text{Co}_3\text{O}_4$ . When the temperature goes from  $300^\circ\text{C}$  to  $450^\circ\text{C}$ , the apparent mass loss is 48.8%, indicating the decomposition rate of organic frames is significantly accelerated. The higher decomposition rate results in the oxygen in air not meeting the decomposition of the organic framework, therefore the oxygen in  $\text{Co}_3\text{O}_4$  participates in the reaction to produce oxygen vacancy on the surface of  $\text{Co}_3\text{O}_4$ . As we all know,  $\text{Co}_3\text{O}_4$  can be regarded a compound formed by CoO and  $\text{Co}_2\text{O}_3$ . When the temperature increases to  $500^\circ\text{C}$ , the higher temperature results in the oxidation of Co(II) to Co(III). Hence the oxygen vacancy content of  $\text{Co}_3\text{O}_4$ -500 decreases.

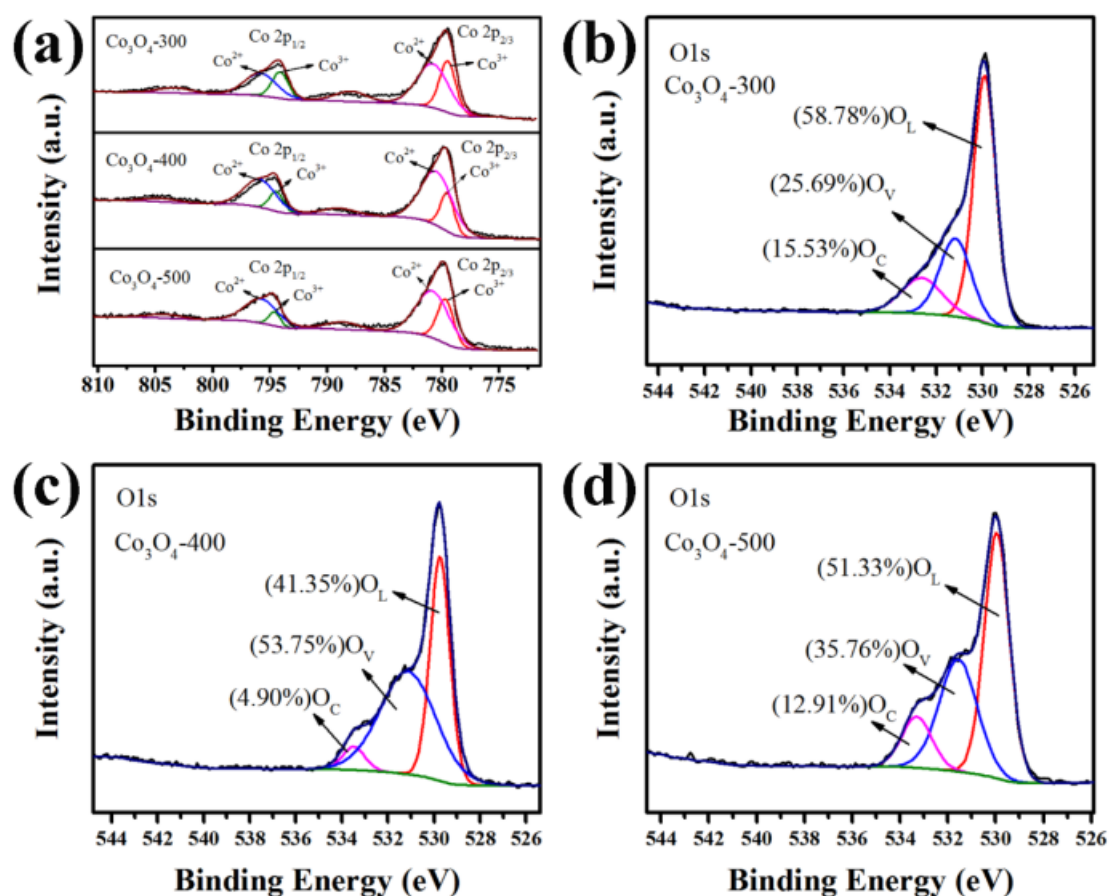

Fig. 1 (a) XPS spectra of Co 2p for porous  $\text{Co}_3\text{O}_4$  samples; XPS spectra of O 1s and curve-fitting for (b)  $\text{Co}_3\text{O}_4$ -300, (c)  $\text{Co}_3\text{O}_4$ -400, (d)  $\text{Co}_3\text{O}_4$ -500.

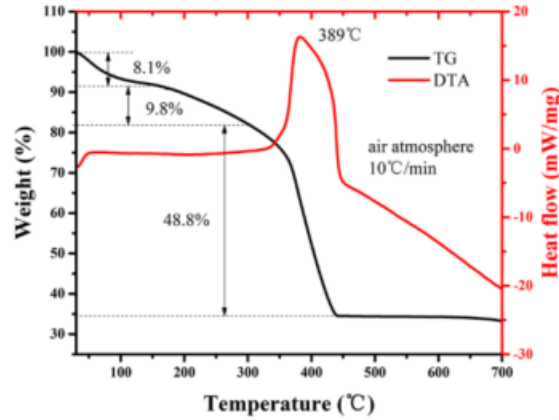

Fig. 2 TG and DTA analysis curves of the Co-MOF precursor

2. Author has provided the TG analysis of the MOF precursor, did author perform the TG of  $\text{Co}_3\text{O}_4$  400,  $\text{Co}_3\text{O}_4$  500, and  $\text{Co}_3\text{O}_4$  300. I would suggest to do that in order to understand any carbonaceous materials present in the final  $\text{Co}_3\text{O}_4$  structure.

Answer) Thanks for your valuable suggestion. With your suggestion, the TG analysis of  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 has been tested and the results are shown as Fig. 3. In Fig. 3, it is clear that the mass loss of the three samples is within 3.5%, indicating that the residual carbon content in all the samples is very low and the purity of samples is high.

Fig. 3 TG analysis curves of  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500

3. Add some of the recent  $\text{Co}_3\text{O}_4$  based gas sensor in the introduction part.

Answer) Thanks for your valuable suggestion. With your suggestion, the above papers of recent  $\text{Co}_3\text{O}_4$  based gas sensor have been added in the manuscript as the references [15], [21] and [24].

-----  
**To reviewer 4:**

We are grateful for valuable comments and for careful and critical reading of this manuscript. Our paper was much improved by helpful advises. We have revised our manuscript in line with the comments as follows.

1. Fig. 1 should be move to SI file.

Answer) Thanks for your valuable suggestion. Fig. 1 has been moved to SI file.

2. The response to  $\text{NO}_2$  and  $\text{SO}_2$  gases which are oxidizing gases should be evaluated.

Answer) Thanks for your valuable suggestion. The responses of the  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 samples to 100 ppm  $\text{SO}_2$  and  $\text{NO}_2$  were tested. As shown in Fig. 1,  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 sensors exhibit extremely low response to  $\text{SO}_2$  and  $\text{NO}_2$  at the optimal operating temperature as  $140^\circ\text{C}$ . It means all

Co<sub>3</sub>O<sub>4</sub> sensors show the best selectivity to n-butanol among the examined gases at the operating temperature as 140°C.

Fig. 1 Responses of Co<sub>3</sub>O<sub>4</sub> samples to different gases at 140°C

3. Please statically calculate the LOD of sensor.

Answer) Thanks for your valuable suggestion. The LOD of Co<sub>3</sub>O<sub>4</sub>-300, Co<sub>3</sub>O<sub>4</sub>-400 and Co<sub>3</sub>O<sub>4</sub>-500 are calculated to be 215 ppb, 150 ppb and 190 ppb, respectively. The related content has been added in the revised paper, the specific description is as follows:

The theoretical detection limits for n-butanol in Co<sub>3</sub>O<sub>4</sub> samples can be evaluated through linear extrapolation, the calculating of the LOD is  $LOD = 3 \times (\text{Standard Deviation/Slope})$ , which are calculated to be 215 ppb, 150 ppb, and 190 ppb, respectively.

4. BET surface areas as necessary to related the sensing properties to the surface area.

Answer) Thanks for your valuable suggestion. With the increment of calcination temperature, the specific surface area of Co<sub>3</sub>O<sub>4</sub> samples decreased. The Co<sub>3</sub>O<sub>4</sub>-300 sample has the largest specific surface area of 69.8 m<sup>2</sup>/g, while Co<sub>3</sub>O<sub>4</sub>-400 and Co<sub>3</sub>O<sub>4</sub>-500 are 39.3 m<sup>2</sup>/g and 17.8 m<sup>2</sup>/g, respectively. The pore size distribution calculated by the BJH method is shown in the inset of Fig. 1. The average pore

diameters of  $\text{Co}_3\text{O}_4$ -300 and  $\text{Co}_3\text{O}_4$ -400 are 10.5 nm and 23.6 nm, respectively. The pore sizes of  $\text{Co}_3\text{O}_4$ -500 are mainly distributed around 3.1 nm and 41.8 nm. The superior gas sensing performance of  $\text{Co}_3\text{O}_4$ -400 can be attributed to the large specific surface area, abundant pore structure and a large number of oxygen vacancies on its surface.

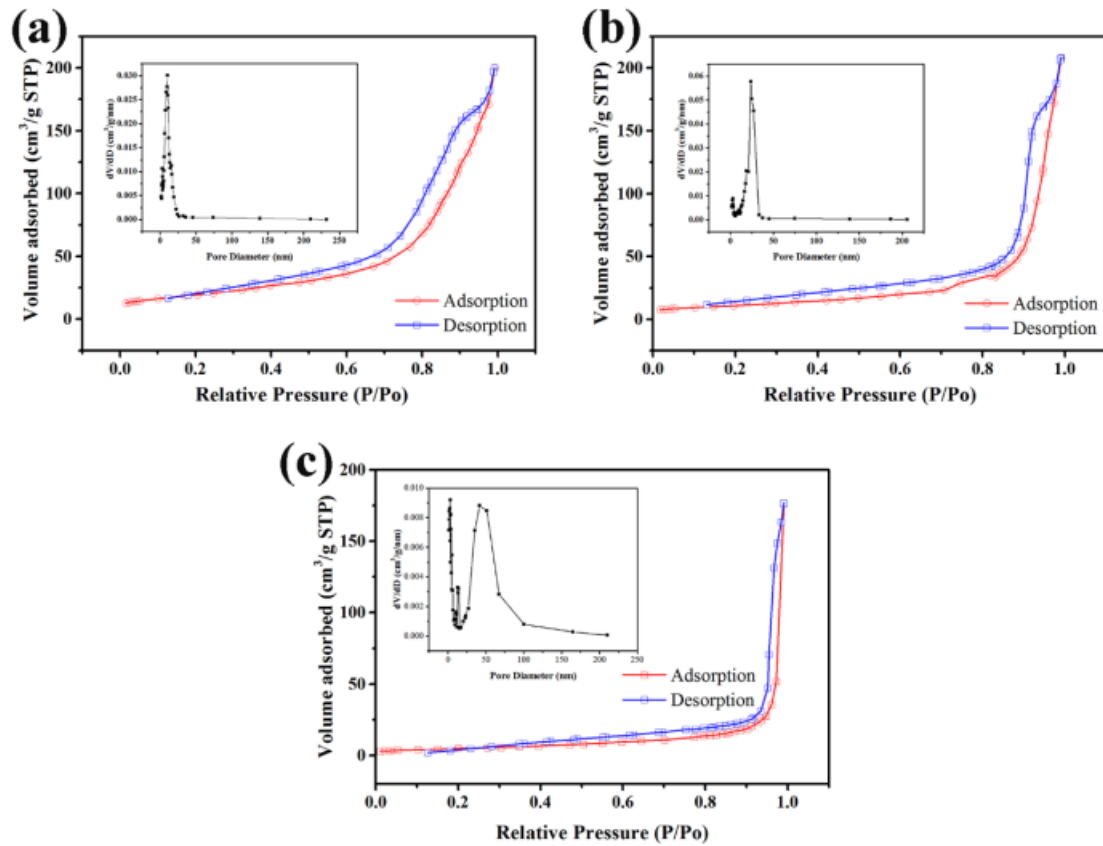

Fig. 2 Nitrogen adsorption-desorption isotherms and BJH pore size distribution plots (inset) of (a) $\text{Co}_3\text{O}_4$ -300, (b) $\text{Co}_3\text{O}_4$ -400, (c) $\text{Co}_3\text{O}_4$ -500.

5. At 140 degree the dominant species are ionic oxygen ions rather than molecular oxygen ions. So equations should be modified.

Answer) Thanks for your valuable suggestion. You are right. According to the related reference,  $\text{O}^-$  is formed between  $100^\circ\text{C}$  and  $300^\circ\text{C}$  [55]. The optimum operating temperature of the  $\text{Co}_3\text{O}_4$  sensor in our work is  $140^\circ\text{C}$ , so the main oxygen species is  $\text{O}^-$  (Eq. (1)). We have modified equations and revised corresponding description in the revised manuscript.

[55] J. Guo, Y. Li, B. Jiang, H. Gao, G. Hao, Xylene gas sensing properties of hydrothermal synthesized SnO<sub>2</sub>-Co<sub>3</sub>O<sub>4</sub> microstructure, *Sensors and Actuators B: Chemical*, 310 (2020) 127780.

6. Why the gas sensor shows selectivity to butanol among all other gases. This is very important issue.

Answer) Thanks for your valuable suggestion. According to your suggestion, the selectivity of Co<sub>3</sub>O<sub>4</sub>-400 to n-butanol has been analyzed in details. The reasons for the selectivity of Co<sub>3</sub>O<sub>4</sub>-400 to n-butanol include two points:

- (i) The polarity of hydroxyl group (-OH) is stronger than amino group (-NH<sub>2</sub>), aldehyde (-CHO), carbonyl group (-C=O) and phenyl group. For containing hydroxyl group, the polarity of n-butanol is stronger than ammonia, formaldehyde, acetone, xylene, toluene and benzene. That means n-butanol has a very strong ability to provide electrons. And the large intrinsic crystal defects and rich oxygen vacancies of Co<sub>3</sub>O<sub>4</sub>-400 make it prefer to bound extra electrons as free carries, so it shows good selectivity to n-butanol. Furthermore, the excellent electron donor characteristics of n-butanol causes it react with the adsorbed oxygen species at the relatively low concentration, exhibiting relatively high response.
- (ii) The diffusivity determines the residence time of the detected gas on the surface of gas sensor. And the longer residence time can improve the response of gas sensors to the detected gas. Comparing with ethanol and methanol, n-butanol has a lower diffusivity for its higher molecular weight. Hence, the residence time of n-butanol on Co<sub>3</sub>O<sub>4</sub>-400 is longer than other detected gases, which endows n-butanol higher response.

Once again, we like to express our heartfelt thanks to the editor and reviewers. We believe that our manuscript will be acceptable in this journal.

Sincerely yours,

Lingli Cheng

## **Abstract**

Long-term stability and selectivity are crucial for the practical application of gas sensors, which are closely related to the microstructure and composition of sensor materials. In this work, Co-based metal organic framework (MOF) is used as a precursor and prepared by a simple hydrothermal method. After calcination, a series of  $\text{Co}_3\text{O}_4$  nanospheres with various microstructures are derived. When the calcination temperature increases from  $300^\circ\text{C}$  to  $500^\circ\text{C}$ , the microstructure of  $\text{Co}_3\text{O}_4$  nanospheres changed from rough solid to porous, and then transformed into porous core-shell. When assembled into the gas sensors, the  $\text{Co}_3\text{O}_4$  nanospheres with porous structure calcined at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) show the highly selective response of 53.78 for 100 ppm n-butanol at the operating temperature of  $140^\circ\text{C}$ . Moreover, the theoretical limit of detection was calculated to be 150 ppb. The reproducibility, selectivity and stability of the gas sensor were further verified to be excellent. After 45 days, the response value of  $\text{Co}_3\text{O}_4$ -400 is at 86.74%, even after 75 days, the response value remains at 74.93%. The main reason can be attributed to the large specific surface area, abundant pore structure and a large number of oxygen vacancies on its surface. These findings provide reference for the development of p-type metal oxide semiconductor (MOS) sensors with long-term stability and high performance.

## 1. Introduction

In recent years, with the strengthening of environmental remediation, volatile organic compounds (VOCs) has received more and more attention. VOCs, which widely exist in the modern society, refer to the organic compounds that exist at room temperature in the form of gas, including ethanol, acetone, n-butanol, et al [1]. Due to their volatile nature at room temperature, VOCs are potentially harmful to human health. Such as n-butanol, an important chemical raw material, is mainly used for the preparation of plasticizers, surfactants, butyl acrylate, butyl acetate and ethylene glycol butyl ether. It is also used as a solvent for coatings and as an extractant for biochemicals. N-butanol is an irritant and can cause damage to the respiratory system and the skin. When people are exposed in the n-butanol environment, they may feel drowsy and dizzy [2, 3]. Therefore, it is necessary to develop high performance n-butanol gas sensor for human health and industrial environment monitoring.

Metal oxide semiconductors (MOS) are the most promising gas sensing materials for detecting VOCs, due to their low cost, excellent reliability, high sensitivity and environmental friendliness [4-6]. Metal oxide semiconductors are classified into n-type and p-type, and most of the researchers are focused on the n-type MOS, such as ZnO [7], SnO<sub>2</sub> [8, 9], In<sub>2</sub>O<sub>3</sub> [10], WO<sub>3</sub> [11]. Recently, p-type MOS with unique surface redox properties and good catalytic properties are being extensively studied. Co<sub>3</sub>O<sub>4</sub> is a typical p-type metal oxide semiconductor with a unique AB<sub>2</sub>O<sub>4</sub> spinel structure. The transformation between different valence states of Co<sup>2+</sup>/Co<sup>3+</sup> endows

with the excellent gas sensitive reactivity of  $\text{Co}_3\text{O}_4$  materials [12-14]. However, p-type metal oxide semiconductors generally have some drawbacks, such as low sensitivity and long response/recovery time [15-17]. Researchers have used substantial methods to solve the problems, such as changing the morphology and structure of the materials [1, 18, 19], increasing their specific surface area and porosity [20, 21], doping [22, 23], loading [24, 25], forming composite materials [6, 26, 27], and so on.

Metal–organic frameworks (MOFs) are a new class of porous materials composed by metal ions and organic ligands [28]. Due to its various topologies, tunable structure and pore size, ultra-high specific surface area, unique morphology and other excellent properties, MOFs have received extensive attention from researchers. In terms of energy storage [29], adsorption [30], catalysis [31], gas sensing [6], drug delivery [32], etc., MOFs have great application prospects. In the field of gas sensing, MOFs can be used as self-sacrificing templates to prepare hollow, core-shell or porous nanostructures by controlling thermolysis conditions to improve the performance of gas sensors [16, 19]. Morphology of materials is the main factor on determining their performance. For instance, Zhang et al. [33] reported that ZIF-67 was used as a precursor template to synthesize the core shell, porous core shell and porous popcorn structure of  $\text{Co}_3\text{O}_4$  by controlling the calcination environment, which significantly improved its response to acetone. The porous  $\text{ZnO-Co}_3\text{O}_4$  hollow polyhedral structure synthesized by Xiong et al. [34] has a response value of 106 to 1000 ppm ethanol at 200°C. Shi et al. [27] synthesized hollow  $\text{Co}_3\text{O}_4/\text{In}_2\text{O}_3$  microtubules derived from MOFs to significantly improve the sensing performance of triethylamine, and the

response to 50ppm TEA was 786.8. The above reports have demonstrated that metal oxides derived from MOFs generally have good morphology, large specific surface area, high porosity and more exposed active sites, which is benefit to improve the gas sensitivity of materials.

In this work, the nano-spherical Co-MOF was chosen as a self-sacrificial template, which was synthesized by a simple solvothermal method. Then, by controlling the calcination temperature, a series of  $\text{Co}_3\text{O}_4$  samples with different microstructure and composition have been prepared. Through the performance tests, the relationship between microstructure and performance has been verified. The  $\text{Co}_3\text{O}_4$  nanospheres calcinated at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) possess the best response sensitivity for n-butanol and long-term stability, which can be attributed to the porous and rich oxygen vacancies microstructure of it. Under the test temperature at  $140^\circ\text{C}$ , the response value of  $\text{Co}_3\text{O}_4$ -400 to 100 ppm n-butanol achieves 53.78, and the response value remains at 74.93% even after 75 days. Therefore, our work provides a facile MOF pyrolysis method for preparing long-term stable and high-performance gas sensitive MOS materials.

## **2. Experimental section**

### **2.1 Materials**

Cobalt nitrate hexahydrate ( $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ ,  $\geq 99\%$ ), polyvinyl pyrrolidone (PVP, M.W.30,000) and N,N-dimethylformamide (DMF) were purchased from Sinopharm Chemical Reagent. 1,3,5-benzenetricarboxylic acid ( $\text{H}_3\text{BTC}$ ) was obtained from Tokyo Chemical Industry. All chemicals used in this study were of analytical grade and

without any further purification.

## 2.2 Synthesis of $\text{Co}_3\text{O}_4$ nanospheres

Typically, 3.000g PVP was dissolved into the 60 mL DMF to form a clear solution. In the synthesis process, PVP acts as a stabilizer, which is beneficial to the formation of the spherical structure Co-MOF [35]. Then, 0.300g  $\text{H}_3\text{BTC}$ , 1.048g  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  were added to the above solution under magnetic stirring vigorously for 1 hour. After that, the mixed solution was transferred into a 100 ml Teflon-lined stainless steel autoclave, and placed into an oven with a constant temperature of  $150^\circ\text{C}$  for 16 h. The obtained purple product was collected and purified by centrifugation, washed several times with DMF and ethanol, and then dried at  $60^\circ\text{C}$  overnight. Finally, the as-prepared Co-MOF was annealed in a Tube furnace at  $400^\circ\text{C}$  for 2 h with a heating rate of  $2^\circ\text{C}/\text{min}$  in air. And then, the porous structure  $\text{Co}_3\text{O}_4$  nanospheres were successfully prepared. The complete synthesis process was simulated in Scheme. 1. The black  $\text{Co}_3\text{O}_4$  powder obtained by calcination at three different temperatures ( $300^\circ\text{C}$ ,  $400^\circ\text{C}$ ,  $500^\circ\text{C}$ ) in air was labeled as  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500, respectively.

<Scheme 1>

## 2.3 Characterization

The crystallographic structure of the prepared  $\text{Co}_3\text{O}_4$  samples were determined by X-ray diffraction (XRD, Rigaku D/max-2200, Japan). The morphologies and microstructure were investigated by field-emission scanning electron microscope (FESEM, Hitachi, S-4800, Japan) and transmission electron microscope (TEM, JEOL,

200CX, Japan). More detailed structural and crystal features were characterized by selected-area electron diffraction (SAED) and high-resolution TEM (HRTEM, JEOL, 2100F, Japan). The chemical components of the samples were investigated by X-ray photoelectron spectroscopy (XPS, Thermo, ESCALAB 250XI, USA). The N<sub>2</sub> adsorption–desorption isotherms were measured on an automatic surface analyzer (Quantachrome, Quadrasord SI, USA). The surface area and the pore size distribution were evaluated using Brunauer–Emmett–Teller (BET) and Barrett–Joyner–Halenda (BJH) methods, respectively. The thermal decomposition behavior of the MOF precursor was studied by thermogravimetric analyzer (TGA, Mettler Toledo, TGA/DSC 3+, Switzerland).

#### **2.4 Fabrication and measurements of gas sensors**

The Co<sub>3</sub>O<sub>4</sub> samples obtained by calcination at different temperatures were mixed with an appropriate amount of ethanol and ground to form a uniform paste. Then, the paste was applied to the surface of a hollow Al<sub>2</sub>O<sub>3</sub> ceramic tube. The sample completely covered the area between the two gold electrodes on the surface of the ceramic tube. Subsequently, the ceramic tube coated with the sample was placed in an oven and dried at 60 ° C for 2 hours. Next, a Ni-Cr alloy heating wire was inserted into the ceramic tube, and the operating temperature was changed by adjusting the heating voltage. Finally, the heating wire and the two pairs of Pt wires on the ceramic tube gold electrode were welded to the sensor base to form a complete sensor device, as shown in Fig.1. The sensing performance of the material was tested using the WS-30A gas sensor test system (Winsen Electronics Co., Ltd., Henan, China) as

shown in Fig.1S. Before the test, the sensor was aged at 300 ° C for 2 days on an aging device to improve the stability of its sensing performance. The gas response (sensitivity) is defined as  $S=R_g/R_a$ , where  $R_g$  is the resistance of the sensor in the target gas and  $R_a$  is the resistance in ambient air. The response of the sensor is the relative change in resistance of the material in the air and in the target gas [15]. The response and recovery times are defined as the time required for the sensor to reach 90% of the total resistance change during the process of adsorbing and desorbing the target gas, respectively [36].

< Fig. 1 >

### 3. Results and discussion

#### 3.1. Structural and morphological characteristics

The Co-MOF was used as the precursor, and a series of  $Co_3O_4$  nanospheres were synthesized by calcinating at different temperature. The XRD pattern of Co-MOF is shown in Fig. S2, revealing that the Co-MOF precursor is a crystalline material, which is consistent with the results reported by previous researchers [37, 38]. Subsequently, the morphological and structural changes of Co-MOF-derived metal oxide  $Co_3O_4$  at different calcination temperatures were investigated.

< Fig. 2 >

The corresponding powder X-ray diffraction (XRD) patterns of the calcined products can provide information on the crystallinity and phase composition, as shown in Fig. 2. The XRD patterns of the three samples all have identical diffraction peak positions and similar peak shapes, which are in good agreement with the cubic

spinel structure of  $\text{Co}_3\text{O}_4$  (JCPDS no. 043-1003), indicating that the Co-MOF had been successfully converted into  $\text{Co}_3\text{O}_4$ . The diffraction lines are located at  $2\theta = 19.0, 31.3, 36.8, 44.8, 59.4, 65.2^\circ$  marked by their index's planes ((1 1 1), (2 2 0), (3 1 1), (4 0 0), (5 1 1), (4 4 0)), respectively. No other impurity peaks were detected, indicating that the  $\text{Co}_3\text{O}_4$  samples are of high purity, and the strong peaks and spikes of the samples also confirm the high crystallinity. The change of the calcination temperature only changed the crystallinity of the products, but had no effect on the composition. Among the three kinds of  $\text{Co}_3\text{O}_4$  samples,  $\text{Co}_3\text{O}_4$ -500 has the best crystallinity and the strongest diffraction peak intensity followed by  $\text{Co}_3\text{O}_4$ -400. And  $\text{Co}_3\text{O}_4$ -300 has the lowest crystallinity.

< Fig. 3 >

The morphologies of the precursor and products were characterized by field emission scanning microscopy, as shown in Fig. 3. Fig. 3(a) shows that the synthesized Co-MOF is about 600 nm-900 nm in diameter, and the particles formed are relatively uniform. As observed in Fig. 3(b), the as-prepared Co-MOF precursor has a regular spherical structure and the surface is slightly rough. Fig. 3(c-h) exhibits the FESEM image of  $\text{Co}_3\text{O}_4$  samples at different calcination temperatures. For the calcined sample at 300°C, Fig. 3 (c, d) show the spherical structure similar to that of the Co-MOF precursor, and the morphology remained intact. As observed from the inset in Fig. 3(d), the  $\text{Co}_3\text{O}_4$ -300 sample has a rougher surface than the precursor, which was mainly caused by thermal decomposition of the organic ligand. When the calcination temperature was raised to 400°C,  $\text{Co}_3\text{O}_4$ -400 still maintained a complete

spherical shape, as shown in Fig.3 (e, f). It can be seen from Fig. 3(f) and its inset that the surface roughness of the  $\text{Co}_3\text{O}_4$  sample is further increased, and the particle size is gradually reduced to a diameter of about 500 nm. At the same time, the framework structure exhibits a complete sphere composed of ~25nm tiny nanoparticles, and the pore diameter is further increased. When the calcination temperature was 500°C, the  $\text{Co}_3\text{O}_4$ -500 sample produced ~50nm nanoparticles during the formation process, and significant large pores can be seen between the tiny nanoparticles, as shown in Fig. 3 (g, h). Compared to  $\text{Co}_3\text{O}_4$ -400, the nanoparticles constituting the  $\text{Co}_3\text{O}_4$ -500 sample are larger in size, resulting in an increase in pores between the particles. The calcination temperature was increased from 300°C to 500°C, the  $\text{Co}_3\text{O}_4$  products were able to maintain a complete spherical morphology, but the surface became rougher and the pores became larger.

< **Fig. 4** >

In order to further study the microstructure changes of  $\text{Co}_3\text{O}_4$  products affected by calcination temperature, TEM and HRTEM were used to characterize the samples. In Fig. 4(a), the internal structure of the  $\text{Co}_3\text{O}_4$ -300 sample is in a solid state, and no obvious porous structure can be observed. Fig. 4(b) shows that a large number of pores can be identified on the surface of  $\text{Co}_3\text{O}_4$ -400, and the porous nanospheres were successfully prepared. When the calcination temperature was raised to 500°C, the porous structure gradually transformed into the core-shell structure and the internal pore size increased, as shown in Fig. 4(c). When the calcination temperature increased from 300°C to 500°C, the structure of the products changed from the rough solid

structure to the porous structure, and then further transformed into the porous core-shell structure. The formation of a large number of pores in the products are due to the organic ligands being oxidized to CO<sub>2</sub> and H<sub>2</sub>O and volatilized into the air. Moreover, it can be seen from the HRTEM in Fig. 4(d) that the lattice fringes of the Co<sub>3</sub>O<sub>4</sub>-400 sample is 2.86 Å, which corresponds to the (220) crystal planes of spinel Co<sub>3</sub>O<sub>4</sub>. The selected area electronic diffraction (SAED) pattern (inset image of Fig. 4(d)) exhibits several concentric rings, indicating that the Co<sub>3</sub>O<sub>4</sub>-400 spherical nanostructure is polycrystalline in nature and has good crystallinity.

In addition, the thermal decomposition behavior of the Co-MOF precursor was first studied by thermogravimetric analysis (TG) and differential thermal analysis (DTA), as shown in Fig.S3. Below 150°C, the mass loss is about 8.1%, mainly to remove adsorbed water molecules, gases and solvents. The tricarboxylate linkers gradually decomposed in the temperature range of 150°C to 300°C. From 300°C to 450°C, the apparent mass loss is 48.8%, indicating that the organic ligands decomposed and the metal-organic frameworks were completely converted into the metal oxides. Such a significant mass reduction means that a large amount of gas (CO<sub>2</sub>, H<sub>2</sub>O) was produced in the process of decomposing the organic matter [39-41]. According to the DTA analysis, the corresponding exothermic peak appeared at 389°C. When the pyrolysis temperature exceeded 450°C, the sample quality remained substantially stable.

Nitrogen adsorption-desorption isotherms were conducted in order to identify the specific surface areas and porosity structure of as-synthesized Co<sub>3</sub>O<sub>4</sub> nanospheres, and the results are shown in Fig. S4. The N<sub>2</sub> adsorption-desorption curves of all products

show typical IV isotherms with H3 hysteresis loop, indicating the presence of the mesoporous structure. The specific surface area of the product decreases as the calcination temperature increases. The  $\text{Co}_3\text{O}_4$ -300 sample has the largest specific surface area of  $69.8 \text{ m}^2/\text{g}$ , and  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 are  $39.3 \text{ m}^2/\text{g}$  and  $17.8 \text{ m}^2/\text{g}$ , respectively. The pore size distribution calculated by the BJH method is shown in the inset of Figure S4 . The average pore diameters of  $\text{Co}_3\text{O}_4$ -300 and  $\text{Co}_3\text{O}_4$ -400 are 10.5 nm and 23.6 nm, respectively, and the pore sizes of  $\text{Co}_3\text{O}_4$ -500 are mainly distributed at 3.1 nm and 41.8 nm. As the calcination temperature increases, the pore size of the  $\text{Co}_3\text{O}_4$  product increases, which is consistent with the results observed in the SEM. The results of various characterizations show that the calcination temperature has a significant effect on the structure and morphology of  $\text{Co}_3\text{O}_4$  nanospheres formed by self-assembly of nanoparticles, especially with MOF as a self-sacrificing template.

### 3.2. Gas sensing properties

< Fig. 5 >

The gas sensing performance of as prepared  $\text{Co}_3\text{O}_4$  samples were evaluated through testing the working temperature, response value, response/recovery time, stability and selectivity. The working temperature is an important indicator to measure the performance of gas sensors, which is of great significance for the practical application of sensors. Fig. 5 depicts the response of three  $\text{Co}_3\text{O}_4$  samples to 100 ppm n-butanol over a range of  $100^\circ\text{C}$ - $220^\circ\text{C}$ . From  $100^\circ\text{C}$  to  $140^\circ\text{C}$ , the response of these three sensors increases with the increment of operating temperature until the maximum response at  $140^\circ\text{C}$  is obtained. The  $\text{Co}_3\text{O}_4$ -400 sample exhibits the highest response

of 53.78 for 100 ppm n-butanol at 140°C, comparing with 33.40 for Co<sub>3</sub>O<sub>4</sub>-300, and 13.86 for Co<sub>3</sub>O<sub>4</sub>-500. Subsequently, when the operating temperature increases, the response decreases gradually. This phenomenon can be attributed to the following reasons [12]. At first, when the operating temperature is relatively low, most target gas is inactive, as well as there is not enough activation energy to react with the surface-adsorbed oxygen species, which leads to a low response. As the temperature increases, the gas molecules obtain enough energy to overcome the activation energy barrier, so the response enhances. Then, when the temperature exceeds the optimum reaction temperature, the desorption rate of the gas molecules on the surface of sensing materials is greater than the corresponding adsorption rate, which causes the response value diminish greatly. Therefore, the sensor exhibits the response characteristics of "increase-maximum-decrease" [42]. The optimal operating temperature can be determined to be 140°C, which is critical for subsequent gas-sensitive performance tests.

< Fig. 6 >

The transient sensing curves of the three sensors for 100ppm n-butanol at the optimum operating temperature are shown in Fig. 6(a). All the sensors show similar response and recovery processes. Fast response and recovery processes are very important for the practical application of gas sensors. The response and recovery time are calculated and labeled in Fig. 6(b, c, d). The response times of Co<sub>3</sub>O<sub>4</sub>-300, Co<sub>3</sub>O<sub>4</sub>-400, and Co<sub>3</sub>O<sub>4</sub>-500 are 152s, 99s, and 153s, respectively, and the recovery times are 37s, 50s, and 53s, respectively. Comparing with Co<sub>3</sub>O<sub>4</sub>-300 and Co<sub>3</sub>O<sub>4</sub>-500,

$\text{Co}_3\text{O}_4$ -400 has a much shorter response time, but its recovery time is slightly longer than that of  $\text{Co}_3\text{O}_4$ -300.

< Fig. 7 >

Fig. 7 (a) is the typical dynamic sensing transient curves of  $\text{Co}_3\text{O}_4$  sensors at different n-butanol concentrations (3ppm-100ppm). All the sensors showed good response, and the response value enhanced with the increment of n-butanol concentration. The relationship of response values and n-butanol concentrations for three samples are displayed in Fig. 7(b). When the concentration of n-butanol is 3ppm, the response of  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 are 1.87, 8.74 and 1.94, respectively. It is obvious that  $\text{Co}_3\text{O}_4$ -400 has the lowest detection limit in the three sensors. Meanwhile, the  $\text{Co}_3\text{O}_4$ -400 exhibits the highest response value at each n-butanol concentration. It can also be observed in Fig. 7(b) that the response value of the  $\text{Co}_3\text{O}_4$ -400 sample increases significantly in the concentration range from 3 ppm to 20 ppm, and then it gets saturated. The linear relationship between n-butanol concentration and the response values in the range from 3 ppm to 20 ppm is shown in Fig. 7(c). The theoretical detection limits for n-butanol in  $\text{Co}_3\text{O}_4$  samples can be evaluated through linear extrapolation, which are calculated to be 215 ppb, 150 ppb, and 190 ppb, respectively [43]. The above results indicate that the  $\text{Co}_3\text{O}_4$ -400 sample owns excellent sensitivity for n-butanol, which means that it has great application potential in low concentration n-butanol sensing.

Stability (repeatability) is crucial for a sensor in the commercial application. To test the stability of  $\text{Co}_3\text{O}_4$  sensors, they were measured over 6 periods (a period means a

complete cycle of response and recovery procedures to 100 ppm n-butanol). The sensing transient curves are shown in Fig. 7(d). During 6 periods, the instantaneous response values of the sensors have no obvious change, which proves the good reversibility and repeatability of the  $\text{Co}_3\text{O}_4$  sensors prepared in our work.

Selectivity is another important factor for the practical application of gas sensors. The response of all  $\text{Co}_3\text{O}_4$  samples toward 100 ppm VOCs mixture (including n-butanol, formaldehyde, methanol, ethanol, acetone, isopropanol, ammonia, xylene, toluene and benzene) is shown in Fig. 7(e). The  $\text{Co}_3\text{O}_4$ -400 sample not only shows the highest response to all the VOCs, but also exhibits the best selectivity to n-butanol. The response value of  $\text{Co}_3\text{O}_4$ -400 to n-butanol is 1.3-5.5 times than other VOCs. Among them, only xylene could make interference with n-butanol, which may be due to similar optimal operating temperature and chemical reactivity energy.

Long-term stability as a significant impact on the durability of sensors has been tested. In order to evaluate the influence of the external environment on the stability of the gas sensor, the  $\text{Co}_3\text{O}_4$ -400 sensor was placed in the air for 45 days. After 45 days, the response value of  $\text{Co}_3\text{O}_4$ -400 to n-butanol still can achieve 46.65, which was 86.74% of the initial value, and show good response-recovery performance, indicating that the stability of  $\text{Co}_3\text{O}_4$ -400 is splendid. Then, the response of the  $\text{Co}_3\text{O}_4$ -400 to 100 ppm n-butanol at  $140^\circ\text{C}$  was continuously tested for 30 days, as shown in Fig.7(f). Within 30 days, the response of the  $\text{Co}_3\text{O}_4$ -400 sensor fluctuated slightly. After the 75 days' test, the response value of the  $\text{Co}_3\text{O}_4$ -400 is tested to be 40.30, retaining 74.93% without significant reduction, further indicating that it has good

long-term stability and guarantees its service life. Furthermore, the  $\text{Co}_3\text{O}_4$ -400 sensor synthesized in this work is compared with the reported  $\text{Co}_3\text{O}_4$  sensors. The results are listed in Table 1. It can be seen from this, the gas sensor prepared in this work can effectively enhance the response of n-butanol and reduce the operating temperature. Considering the response and the optimal operating temperature, the unique 3D porous structure  $\text{Co}_3\text{O}_4$  nanospheres gas sensor shows superior gas sensing properties and has great practical application potential.

< **Table 1** >

### **3.3. Gas sensing mechanism**

< **Fig. 8** >

The reaction process of the target gas on the surface of the material plays an important role in the sensing process. In order to further study the electronic states of the surface elements, the XPS analysis of  $\text{Co}_3\text{O}_4$  samples was performed. Fig. 8(a) shows the high-resolution spectrum of Co 2p, in which there are two characteristic peaks and two satellite peaks. Both the positions and distributions of the Co 2p XPS peaks in all the  $\text{Co}_3\text{O}_4$  samples are similar. Two characteristic peaks at 779.8 eV and 794.9 eV belong to the Co  $2p_{3/2}$  and Co  $2p_{1/2}$  spin-orbital peaks of  $\text{Co}_3\text{O}_4$ , respectively, and their corresponding satellite peaks are at 789.7 eV and 804.6 eV. The difference between  $\text{Co}^{2+}$  and  $\text{Co}^{3+}$  peaks can be observed after curve-fitting, as shown in Fig. 8(a). Fig. 8 (b-d) show the high resolution XPS spectra of O1s for  $\text{Co}_3\text{O}_4$  samples. These spectra can be divided into three fitted peaks, corresponding to  $\text{O}_L$ ,  $\text{O}_V$  and  $\text{O}_C$ , respectively.  $\text{O}_L$  refers to the lattice oxygen species, which contributes little to the gas

response for its stability.  $O_V$  means that there are oxygen vacancies on the surface of samples, which can provide active sites for the gas adsorption and reaction on the surface of sensing materials.  $O_C$  represents the chemically adsorbed oxygen species, such as  $O_2^-$ ,  $O^-$ ,  $O^{2-}$ . When the calcination temperature is 300°C, 400°C, and 500°C, the corresponding  $O_V$  contents are 25.69%, 53.75%, and 35.76%, respectively. Obviously,  $Co_3O_4$ -400 has the highest oxygen vacancy content, which leads to its highest response to 100 ppm n-butanol at 140°C. Heat treatment is one of the common methods for the controllable defect generation of nanomaterials, and it can be adjusted by controlling the calcination temperature and the atmosphere. The defects due to heat treatment are mainly the result of the release and recovery of O atoms in the material lattice. Therefore, in the presence of oxygen, the oxygen vacancy concentration will have a high point [50]. The presence of surface oxygen vacancies plays a crucial role in chemical sensing. Positively charged oxygen vacancies tend to trap electrons, effectively separating electron-hole pairs and improving sensing performance. The oxygen vacancy content of  $Co_3O_4$ -300 is 25.69 %, which is lower than 35.76 % of  $Co_3O_4$ -500, but  $Co_3O_4$ -300 has higher response to 100ppm n-butanol. This may be due to the fact that the specific surface area of  $Co_3O_4$ -300 is much larger than that of  $Co_3O_4$ -500.

The other major factor affecting gas sensing performance is specific surface area and pore size. In general, a large specific surface area enables the sensing material to adsorb more oxygen species. The  $Co_3O_4$ -400 sample has a specific surface area of 39.3 m<sup>2</sup>/g. Meanwhile, the porous structure of  $Co_3O_4$ -400 provides a large amount of

exposed area for gas sensing, which is conducive to improving its sensing performance of n-butanol. According to surveys, the average pore size of many metal oxide sensing materials is around 25 nm [8, 22, 45, 47]. The unique porous structure of the product and the appropriate pore size facilitate the penetration of gas molecules into the interior of the sensing material. This allows the hole accumulation layer to be formed on both the outer layer and the inner layer of the materials, resulting in a low initial resistance in the air.

Furthermore, the good catalytic activity of  $\text{Co}_3\text{O}_4$  also plays a positive role in improving gas sensitivity, in which  $\text{Co}^{3+}$  is capable of oxidizing reductive gases [26]. During the catalytic process, the reductive gas reacts with oxygen ions adsorbed on the  $\text{Co}^{3+}$  active site, causing a change in resistance and generating  $\text{Co}^{2+}$ . Then  $\text{Co}^{2+}$  can be oxidized to active  $\text{Co}^{3+}$  by the gaseous oxygen molecule in the air. In the target gas,  $\text{Co}^{3+}$  in  $\text{Co}_3\text{O}_4$  can promote the oxidation reaction of n-butanol, improving the sensing performance. In summary, the excellent gas sensing performance of the  $\text{Co}_3\text{O}_4$ -400 material for n-butanol can be attributed to the following three factors: (i) abundant oxygen vacancies; (ii) the unique porous structure with a large specific surface area; (iii) Catalytic activity of  $\text{Co}_3\text{O}_4$  for n-butanol.

< **Fig. 9** >

The sensing characteristics of MOS-based gas sensors are affected by the surface reaction of the sensor layer. The sensing mechanism of p-type semiconductor oxide  $\text{Co}_3\text{O}_4$  is closely related to the change of resistance. However, the change in resistance is mainly due to the change in the concentration of holes in the surface region [51]. As

shown in Fig. 9, when the  $\text{Co}_3\text{O}_4$  sensor is exposed to the air, oxygen molecules are adsorbed on the surface of  $\text{Co}_3\text{O}_4$ , and electrons ( $e^-$ ) are trapped from the conduction band to form different oxygen species (such as  $\text{O}_2^-$ ,  $\text{O}^-$ ,  $\text{O}^{2-}$ ). When the temperature is lower than  $150^\circ\text{C}$ , the main oxygen species is  $\text{O}_2^-$ .  $\text{O}^-$  is formed between  $150^\circ\text{C}$  and  $400^\circ\text{C}$ , and  $\text{O}^{2-}$  is formed above  $400^\circ\text{C}$  [14, 52]. The optimum operating temperature of the  $\text{Co}_3\text{O}_4$  sensor in this work is  $140^\circ\text{C}$ , so the main oxygen species is  $\text{O}_2^-$  (Eq. (1)). With the changing of adsorbed oxygen species, the electron depletion layer of  $\text{Co}_3\text{O}_4$  is generated and the hole concentration is increased to form the hole accumulation layer [53]. Since the majority carrier of  $\text{Co}_3\text{O}_4$  is hole, the resistance of  $\text{Co}_3\text{O}_4$  in the air is low. When the n-butanol gas is injected, the adsorbed oxygen species ( $\text{O}_2^-$ ) react with the reductive n-butanol (Eq. (2)). The electrons generated in this process return to the conduction band of  $\text{Co}_3\text{O}_4$ , causing the electron-hole pairs recombine, the hole accumulation layer shrink, and the resistance of materials increase. The recovery process is just the reversible process of the above reaction. When the n-butanol gas is removed, the oxygen molecules again capture electrons from the conduction band, reducing the resistance to its initial value.

#### 4. Conclusion

The porous structure  $\text{Co}_3\text{O}_4$  was successfully prepared by the precursor derivatization strategy of metal-organic framework and applied to gas sensing.

Through performance test, the  $\text{Co}_3\text{O}_4$ -400 exhibits the best gas sensitivity. At the optimum testing temperature, the response to 100 ppm n-butanol is 53.78 and the theoretical limit of detection is 150 ppb.  $\text{Co}_3\text{O}_4$ -400 also owns good stability and reproducibility. After six consecutive cycles of testing, there was no significant change in the response curve to n-butanol. After left in the air for 45 days, the response value of  $\text{Co}_3\text{O}_4$ -400 to n-butanol was tested to be 46.65, which was 86.74% of the initial value. Even in the following 30-day long-term test, the response value was still stable, retaining 74.93% of the initial value. The unique spherical porous microstructure make  $\text{Co}_3\text{O}_4$ -400 have a large specific surface area and a suitable pore size. The larger specific surface area can adsorb a large amount of gas, and the proper pore size is conducive to the diffusion of gas molecules into the sensing material, thereby helping to improve the gas sensing performance. Additionally, the abundant oxygen vacancies generated by the heat treatment provide a large number of active sites and also help to improve the sensing performance. Our work provides a strategy for developing p-type semiconductor metal oxide sensors with high response, low detection limit and low temperature.

## Graphic Abstract:

## Highlights

- MOF-derived porous  $\text{Co}_3\text{O}_4$  nanospheres with different microstructures were fabricated.
- The  $\text{Co}_3\text{O}_4$ -400 exhibits long-term stable and highly selective sensing performance for n-butanol.
- The excellent sensing performance of  $\text{Co}_3\text{O}_4$ -400 was attributed to its porous and rich oxygen vacancy microstructure.

## Abstract

Long-term stability and selectivity are crucial for the practical application of gas sensors, which are closely related to the microstructure and composition of sensor materials. In this work, Co-based metal organic framework (MOF) is used as a precursor and prepared by a simple hydrothermal method. After calcination, a series of  $\text{Co}_3\text{O}_4$  nanospheres with various microstructures are derived. When the calcination temperature increases from  $300^\circ\text{C}$  to  $500^\circ\text{C}$ , the microstructure of  $\text{Co}_3\text{O}_4$  nanospheres changed from rough solid to porous, and then transformed into porous core-shell. When assembled into the gas sensors, the  $\text{Co}_3\text{O}_4$  nanospheres with porous structure calcined at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) show the highly selective response of 53.78 for 100 ppm n-butanol at the operating temperature of  $140^\circ\text{C}$ . Moreover, the theoretical limit of detection was calculated to be 150 ppb. The reproducibility, selectivity and stability of the gas sensor were further verified to be excellent. After 45 days, the response value of  $\text{Co}_3\text{O}_4$ -400 is at 86.74%, even after 75 days, the response value remains at 74.93%. The main reason can be attributed to the large specific surface area, abundant pore structure and a large number of oxygen vacancies on its surface. These findings provide reference for the development of p-type metal oxide semiconductor (MOS) sensors with long-term stability and high performance.

**Keywords:**  $\text{Co}_3\text{O}_4$  porous structure; metal–organic frameworks; oxygen vacancies; long-term stability; Gas sensing; n-butanol

## 1. Introduction

In recent years, with the strengthening of environmental remediation, volatile organic compounds (VOCs) has received more and more attention. VOCs, which widely exist in the modern society, refer to the organic compounds that exist at room temperature in the form of gas, including ethanol, acetone, n-butanol, et al [1]. Due to their volatile nature at room temperature, VOCs are potentially harmful to human health. Such as n-butanol, an important chemical raw material, is mainly used for the preparation of plasticizers, surfactants, butyl acrylate, butyl acetate and ethylene glycol butyl ether. It is also used as a solvent for coatings and as an extractant for biochemicals. N-butanol is an irritant and can cause damage to the respiratory system and the skin. When people are exposed in the n-butanol environment, they may feel drowsy and dizzy [2, 3]. Therefore, it is necessary to develop high performance n-butanol gas sensor for human health and industrial environment monitoring.

Metal oxide semiconductors (MOS) are the most promising gas sensing materials for detecting VOCs, due to their low cost, excellent reliability, high sensitivity and environmental friendliness [4-6]. Metal oxide semiconductors are classified into n-type and p-type, and most of the researchers are focused on the n-type MOS, such as ZnO [7], SnO<sub>2</sub> [8, 9], In<sub>2</sub>O<sub>3</sub> [10], WO<sub>3</sub> [11]. Recently, p-type MOS with unique surface redox properties and good catalytic properties are being extensively studied. Co<sub>3</sub>O<sub>4</sub> is a typical p-type metal oxide semiconductor with a unique AB<sub>2</sub>O<sub>4</sub> spinel structure. The transformation between different valence states of Co<sup>2+</sup>/Co<sup>3+</sup> endows

1 with the excellent gas sensitive reactivity of  $\text{Co}_3\text{O}_4$  materials [12-15]. However, p-type  
2  
3 metal oxide semiconductors generally have some drawbacks, such as low sensitivity  
4  
5 and long response/recovery time [16-18]. Researchers have used substantial methods  
6  
7 to solve the problems, such as changing the morphology and structure of the materials  
8  
9  
10  
11 [1, 19, 20, 21], increasing their specific surface area and porosity [22, 23, 24], doping  
12  
13  
14 [25, 26], loading [27, 28], forming composite materials [6, 29, 30], and so on.  
15  
16

17 Metal–organic frameworks (MOFs) are a new class of porous materials composed  
18  
19 by metal ions and organic ligands [31]. Due to its various topologies, tunable structure  
20  
21 and pore size, ultra-high specific surface area, unique morphology and other excellent  
22  
23 properties, MOFs have received extensive attention from researchers. In terms of  
24  
25 energy storage [32], adsorption [33], catalysis [34], gas sensing [6], drug delivery [35],  
26  
27 etc., MOFs have great application prospects. In the field of gas sensing, MOFs can be  
28  
29 used as self-sacrificing templates to prepare hollow, core-shell or porous  
30  
31 nanostructures by controlling thermolysis conditions to improve the performance of  
32  
33 gas sensors [17, 20]. Morphology of materials is the main factor on determining their  
34  
35 performance. For instance, Zhang et al. [36] reported that ZIF-67 was used as a  
36  
37 precursor template to synthesize the core shell, porous core shell and porous popcorn  
38  
39 structure of  $\text{Co}_3\text{O}_4$  by controlling the calcination environment, which significantly  
40  
41 improved its response to acetone. The porous  $\text{ZnO-Co}_3\text{O}_4$  hollow polyhedral structure  
42  
43 synthesized by Xiong et al. [37] has a response value of 106 to 1000 ppm ethanol at  
44  
45 200°C. Shi et al. [30] synthesized hollow  $\text{Co}_3\text{O}_4/\text{In}_2\text{O}_3$  microtubules derived from  
46  
47 MOFs to significantly improve the sensing performance of triethylamine, and the  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 response to 50 ppm TEA was 786.8. The above reports have demonstrated that metal  
2  
3 oxides derived from MOFs generally have good morphology, large specific surface  
4  
5 area, high porosity and more exposed active sites, which is benefit to improve the gas  
6  
7 sensitivity of materials.  
8  
9

10  
11 In this work, the nano-spherical Co-MOF was chosen as a self-sacrificial template,  
12  
13 which was synthesized by a simple solvothermal method. Then, by controlling the  
14  
15 calcination temperature, a series of  $\text{Co}_3\text{O}_4$  samples with different microstructure and  
16  
17 composition have been prepared. Through the performance tests, the relationship  
18  
19 between microstructure and performance has been verified. The  $\text{Co}_3\text{O}_4$  nanospheres  
20  
21 calcinated at  $400^\circ\text{C}$  ( $\text{Co}_3\text{O}_4$ -400) possess the best response sensitivity for n-butanol  
22  
23 and long-term stability, which can be attributed to the porous and rich oxygen  
24  
25 vacancies microstructure of it. Under the test temperature at  $140^\circ\text{C}$ , the response value  
26  
27 of  $\text{Co}_3\text{O}_4$ -400 to 100 ppm n-butanol achieves 53.78, and the response value remains at  
28  
29 74.93% even after 75 days. Therefore, our work provides a facile MOF pyrolysis  
30  
31 method for preparing long-term stable and high-performance gas sensitive MOS  
32  
33 materials.

## 3 **2.2 Synthesis of Co<sub>3</sub>O<sub>4</sub> nanospheres** 4

5  
6 Typically, 3.000g PVP was dissolved into the 60 mL DMF to form a clear solution.  
7  
8  
9 In the synthesis process, PVP acts as a stabilizer, which is beneficial to the formation  
10  
11 of the spherical structure Co-MOF [38]. Then, 0.300g H<sub>3</sub>BTC, 1.048g  
12  
13 Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O were added to the above solution under magnetic stirring vigorously  
14  
15 for 1 hour. After that, the mixed solution was transferred into a 100 ml Teflon-lined  
16  
17 stainless steel autoclave, and placed into an oven with a constant temperature of 150°C  
18  
19  
20 for 16 h. The obtained purple product was collected and purified by centrifugation,  
21  
22 washed several times with DMF and ethanol, and then dried at 60°C overnight. Finally,  
23  
24 the as-prepared Co-MOF was annealed in a Tube furnace at 400°C for 2 h with a  
25  
26 heating rate of 2°C/min in air. And then, the porous structure Co<sub>3</sub>O<sub>4</sub> nanospheres were  
27  
28 successfully prepared. The complete synthesis process was simulated in Scheme. 1.  
29  
30  
31 The black Co<sub>3</sub>O<sub>4</sub> powder obtained by calcination at three different temperatures  
32  
33 (300°C, 400°C, 500°C) in air was labeled as Co<sub>3</sub>O<sub>4</sub>-300, Co<sub>3</sub>O<sub>4</sub>-400 and Co<sub>3</sub>O<sub>4</sub>-500,  
34  
35 respectively.

## 47 **2.3 Characterization** 48

49  
50  
51 The crystallographic structure of the prepared Co<sub>3</sub>O<sub>4</sub> samples were determined by  
52  
53 X-ray diffraction (XRD, Rigaku D/max-2200, Japan). The morphologies and  
54  
55 microstructure were investigated by field-emission scanning electron microscope  
56  
57 (FESEM, Hitachi, S-4800, Japan) and transmission electron microscope (TEM, JEOL,  
58  
59  
60  
61  
62  
63  
64  
65

1 200CX, Japan). More detailed structural and crystal features were characterized by  
2  
3 selected-area electron diffraction (SAED) and high-resolution TEM (HRTEM, JEOL,  
4  
5 2100F, Japan). The chemical components of the samples were investigated by X-ray  
6  
7 photoelectron spectroscopy (XPS, Thermo, ESCALAB 250XI, USA). The N<sub>2</sub>  
8  
9 adsorption–desorption isotherms were measured on an automatic surface analyzer  
10  
11 (Quantachrome, Quadrasord SI, USA). The surface area and the pore size distribution  
12  
13 were evaluated using Brunauer–Emmett–Teller (BET) and Barrett–Joyner–Halenda  
14  
15 (BJH) methods, respectively. The thermal decomposition behavior of the MOF  
16  
17 precursor was studied by thermogravimetric analyzer (TGA, Mettler Toledo,  
18  
19 TGA/DSC 3+, Switzerland).

#### 28 **2.4 Fabrication and measurements of gas sensors**

30  
31 The Co<sub>3</sub>O<sub>4</sub> samples obtained by calcination at different temperatures were mixed  
32  
33 with an appropriate amount of ethanol and ground to form a uniform paste. Then, the  
34  
35 paste was applied to the surface of a hollow Al<sub>2</sub>O<sub>3</sub> ceramic tube. The sample  
36  
37 completely covered the area between the two gold electrodes on the surface of the  
38  
39 ceramic tube. Subsequently, the ceramic tube coated with the sample was placed in an  
40  
41 oven and dried at 60 ° C for 2 hours. Next, a Ni-Cr alloy heating wire was inserted  
42  
43 into the ceramic tube, and the operating temperature was changed by adjusting the  
44  
45 heating voltage. Finally, the heating wire and the two pairs of Pt wires on the ceramic  
46  
47 tube gold electrode were welded to the sensor base to form a complete sensor device,  
48  
49 as shown in Fig. S1. The sensing performance of the material was tested using the  
50  
51 WS-30A gas sensor test system (Winsen Electronics Co., Ltd., Henan, China) as  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 shown in Fig.S2. Before the test, the sensor was aged at 300 ° C for 2 days on an  
2  
3 aging device to improve the stability of its sensing performance. The gas response  
4  
5 (sensitivity) is defined as  $S=R_g/R_a$ , where  $R_g$  is the resistance of the sensor in the  
6  
7 target gas and  $R_a$  is the resistance in ambient air. The response of the sensor is the  
8  
9 relative change in resistance of the material in the air and in the target gas [16]. The  
10  
11 response and recovery times are defined as the time required for the sensor to reach  
12  
13 90% of the total resistance change during the process of adsorbing and desorbing the  
14  
15 target gas, respectively [39].

### 22 **3. Results and discussion**

#### 23 **3.1. Structural and morphological characteristics**

24  
25 The Co-MOF was used as the precursor, and a series of  $Co_3O_4$  nanospheres were  
26  
27 synthesized by calcinating at different temperature. The XRD pattern of Co-MOF is  
28  
29 shown in Fig. S3, revealing that the Co-MOF precursor is a crystalline material,  
30  
31 which is consistent with the results reported by previous researchers [40, 41].  
32  
33 Subsequently, the morphological and structural changes of Co-MOF-derived metal  
34  
35 oxide  $Co_3O_4$  at different calcination temperatures were investigated.  
36  
37  
38  
39  
40  
41  
42  
43  
44

45 < Fig. 1 >

46  
47 The corresponding powder X-ray diffraction (XRD) patterns of the calcined  
48  
49 products can provide information on the crystallinity and phase composition, as  
50  
51 shown in Fig. 1. The XRD patterns of the three samples all have identical diffraction  
52  
53 peak positions and similar peak shapes, which are in good agreement with the cubic  
54  
55 spinel structure of  $Co_3O_4$  (JCPDS no. 043-1003), indicating that the Co-MOF had  
56  
57  
58  
59

1 been successfully converted into  $\text{Co}_3\text{O}_4$ . The diffraction lines are located at  $2\theta = 19.0,$   
2  
3 31.3, 36.8, 44.8, 59.4, 65.2° marked by their index's planes ((1 1 1), (2 2 0), (3 1 1), (4  
4  
5 0 0), (5 1 1), (4 4 0)), respectively. No other impurity peaks were detected, indicating  
6  
7 that the  $\text{Co}_3\text{O}_4$  samples are of high purity, and the strong peaks and spikes of the  
8  
9 samples also confirm the high crystallinity. The change of the calcination temperature  
10  
11 only changed the crystallinity of the products, but had no effect on the composition.  
12  
13 Among the three kinds of  $\text{Co}_3\text{O}_4$  samples,  $\text{Co}_3\text{O}_4$ -500 has the best crystallinity and the  
14  
15 strongest diffraction peak intensity followed by  $\text{Co}_3\text{O}_4$ -400. And  $\text{Co}_3\text{O}_4$ -300 has the  
16  
17 lowest crystallinity.  
18  
19  
20  
21  
22  
23  
24

25 < Fig. 2 >  
26

27  
28 The morphologies of the precursor and products were characterized by field  
29  
30 emission scanning microscopy, as shown in Fig. 2. Fig. 2(a) shows that the  
31  
32 synthesized Co-MOF is about 600 nm-900 nm in diameter, and the particles formed  
33  
34 are relatively uniform. As observed in Fig. 2(b), the as-prepared Co-MOF precursor  
35  
36 has a regular spherical structure and the surface is slightly rough. Fig. 3(c-h) exhibits  
37  
38 the FESEM image of  $\text{Co}_3\text{O}_4$  samples at different calcination temperatures. For the  
39  
40 calcined sample at 300°C, Fig. 2 (c, d) show the spherical structure similar to that of  
41  
42 the Co-MOF precursor, and the morphology remained intact. As observed from the  
43  
44 inset in Fig. 2(d), the  $\text{Co}_3\text{O}_4$ -300 sample has a rougher surface than the precursor,  
45  
46 which was mainly caused by thermal decomposition of the organic ligand. When the  
47  
48 calcination temperature was raised to 400°C,  $\text{Co}_3\text{O}_4$ -400 still maintained a complete  
49  
50 spherical shape, as shown in Fig.2 (e, f). It can be seen from Fig. 2(f) and its inset that  
51  
52  
53  
54

61  
62  
63  
64  
65

1 the surface roughness of the  $\text{Co}_3\text{O}_4$  sample is further increased, and the particle size is  
2  
3 gradually reduced to a diameter of about 500 nm. At the same time, the framework  
4  
5 structure exhibits a complete sphere composed of ~25nm tiny nanoparticles, and the  
6  
7 pore diameter is further increased. When the calcination temperature was 500°C, the  
8  
9  $\text{Co}_3\text{O}_4$ -500 sample produced ~50nm nanoparticles during the formation process, and  
10  
11 significant large pores can be seen between the tiny nanoparticles, as shown in Fig. 2  
12  
13 (g, h). Compared to  $\text{Co}_3\text{O}_4$ -400, the nanoparticles constituting the  $\text{Co}_3\text{O}_4$ -500 sample  
14  
15 are larger in size, resulting in an increase in pores between the particles. The  
16  
17 calcination temperature was increased from 300°C to 500°C, the  $\text{Co}_3\text{O}_4$  products were  
18  
19 able to maintain a complete spherical morphology, but the surface became rougher  
20  
21 and the pores became larger.  
22  
23  
24  
25  
26  
27  
28  
29

30  
31 < Fig. 3 >  
32

33  
34 In order to further study the microstructure changes of  $\text{Co}_3\text{O}_4$  products affected  
35  
36 by calcination temperature, TEM and HRTEM were used to characterize the samples.  
37  
38 In Fig. 3(a), the internal structure of the  $\text{Co}_3\text{O}_4$ -300 sample is in a solid state, and no  
39  
40 obvious porous structure can be observed. Fig. 3(b) shows that a large number of  
41  
42 pores can be identified on the surface of  $\text{Co}_3\text{O}_4$ -400, and the porous nanospheres were  
43  
44 successfully prepared. When the calcination temperature was raised to 500°C, the  
45  
46 porous structure gradually transformed into the core-shell structure and the internal  
47  
48 pore size increased, as shown in Fig. 3(c). When the calcination temperature increased  
49  
50 from 300°C to 500°C, the structure of the products changed from the rough solid  
51  
52 structure to the porous structure, and then further transformed into the porous  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 core-shell structure. The formation of a large number of pores in the products are due  
2  
3 to the organic ligands being oxidized to CO<sub>2</sub> and H<sub>2</sub>O and volatilized into the air.  
4  
5 Moreover, it can be seen from the HRTEM in Fig. 3(d) that the lattice fringes of the  
6  
7 Co<sub>3</sub>O<sub>4</sub>-400 sample is 2.86 Å, which corresponds to the (220) crystal planes of spinel  
8  
9 Co<sub>3</sub>O<sub>4</sub>. The selected area electronic diffraction (SAED) pattern (inset image of Fig.  
10  
11 3(d)) exhibits several concentric rings, indicating that the Co<sub>3</sub>O<sub>4</sub>-400 spherical  
12  
13 nanostructure is polycrystalline in nature and has good crystallinity.  
14  
15  
16  
17  
18  
19

20 In addition, the thermal decomposition behavior of the Co-MOF precursor was first  
21  
22 studied by thermogravimetric analysis (TG) and differential thermal analysis (DTA),  
23  
24 as shown in Fig. S4(a). Below 150°C, the mass loss is about 8.1%, mainly to remove  
25  
26 adsorbed water molecules, gases and solvents. The tricarboxylate linkers gradually  
27  
28 decomposed in the temperature range of 150°C to 300°C. From 300°C to 450°C, the  
29  
30 apparent mass loss is 48.8%, indicating that the organic ligands decomposed and the  
31  
32 metal-organic frameworks were completely converted into the metal oxides. Such a  
33  
34 significant mass reduction means that a large amount of gas (CO<sub>2</sub>, H<sub>2</sub>O) was produced  
35  
36 in the process of decomposing the organic matter [42-44]. According to the DTA  
37  
38 analysis, the corresponding exothermic peak appeared at 389°C. When the pyrolysis  
39  
40 temperature exceeded 450°C, the sample quality remained substantially stable. Fig.  
41  
42 S4(b) shows the TG analysis curves of Co<sub>3</sub>O<sub>4</sub>-300, Co<sub>3</sub>O<sub>4</sub>-400 and Co<sub>3</sub>O<sub>4</sub>-500,  
43  
44 respectively. The mass loss of the three samples is within 3.5%, indicating that the  
45  
46 residual carbon content in all the samples is very low and the purity of samples is  
47  
48 high.

1 Nitrogen adsorption-desorption isotherms were conducted in order to identify the  
2  
3 specific surface areas and porosity structure of as-synthesized  $\text{Co}_3\text{O}_4$  nanospheres, and  
4  
5 the results are shown in Fig. S5. The  $\text{N}_2$  adsorption-desorption curves of all products  
6  
7 show typical IV isotherms with H3 hysteresis loop, indicating the presence of the  
8  
9 mesoporous structure. With the increment of calcination temperature, the specific  
10  
11 surface area of  $\text{Co}_3\text{O}_4$  samples decreased. The  $\text{Co}_3\text{O}_4$ -300 sample has the largest  
12  
13 specific surface area of  $69.8 \text{ m}^2/\text{g}$ , while  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -300 are  $39.3 \text{ m}^2/\text{g}$  and  
14  
15  $17.8 \text{ m}^2/\text{g}$ , respectively. The pore size distribution calculated by the BJH method is  
16  
17 shown in the inset of Fig. S5. The average pore diameters of  $\text{Co}_3\text{O}_4$ -300 and  
18  
19  $\text{Co}_3\text{O}_4$ -400 are  $10.5 \text{ nm}$  and  $23.6 \text{ nm}$ , respectively. And the pore sizes of  $\text{Co}_3\text{O}_4$ -500  
20  
21 are mainly distributed around  $3.1 \text{ nm}$  and  $41.8 \text{ nm}$ . As the calcination temperature  
22  
23 increases, the pore size of the  $\text{Co}_3\text{O}_4$  product increases, which is consistent with the  
24  
25 results observed in the SEM. The results of various characterizations show that the  
26  
27 calcination temperature has a significant effect on the structure and morphology of  
28  
29  $\text{Co}_3\text{O}_4$  nanospheres formed by self-assembly of nanoparticles, especially with MOF as  
30  
31 a self-sacrificing template.

### 3.2. Gas sensing properties

< Fig. 4 >

50 The gas sensing performance of as prepared  $\text{Co}_3\text{O}_4$  samples were evaluated through  
51  
52 testing the working temperature, response value, response/recovery time, stability and  
53  
54 selectivity. The working temperature is an important indicator to measure the  
55  
56 performance of gas sensors, which is of great significance for the practical application  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 of sensors. Fig. 4 depicts the response of three  $\text{Co}_3\text{O}_4$  samples to 100 ppm n-butanol  
2  
3 over a range of 100°C-220°C. From 100°C to 140°C, the response of these three sensors  
4  
5 increases with the increment of operating temperature until the maximum response at  
6  
7 140°C is obtained. The  $\text{Co}_3\text{O}_4$ -400 sample exhibits the highest response of 53.78 for  
8  
9 100 ppm n-butanol at 140°C, comparing with 33.40 for  $\text{Co}_3\text{O}_4$ -300, and 13.86 for  
10  
11  $\text{Co}_3\text{O}_4$ -500. Subsequently, when the operating temperature increases, the response  
12  
13 decreases gradually. This phenomenon can be attributed to the following reasons [12].  
14  
15 At first, when the operating temperature is relatively low, most target gas is inactive,  
16  
17 as well as there is not enough activation energy to react with the surface-adsorbed  
18  
19 oxygen species, which leads to a low response. As the temperature increases, the gas  
20  
21 molecules obtain enough energy to overcome the activation energy barrier, so the  
22  
23 response enhances. Then, when the temperature exceeds the optimum reaction  
24  
25 temperature, the desorption rate of the gas molecules on the surface of sensing  
26  
27 materials is greater than the corresponding adsorption rate, which causes the response  
28  
29 value diminish greatly. Therefore, the sensor exhibits the response characteristics of  
30  
31 "increase-maximum-decrease" [45]. The optimal operating temperature can be  
32  
33 determined to be 140°C, which is critical for subsequent gas-sensitive performance  
34  
35 tests.

50 < Fig. 5 >  
51

52 The transient sensing curves of the three sensors for 100ppm n-butanol at the  
53  
54 optimum operating temperature are shown in Fig. 5(a). All the sensors show similar  
55  
56 response and recovery processes. Fast response and recovery processes are very  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 important for the practical application of gas sensors. The response and recovery time  
2 are calculated and labeled in Fig. 5(b, c, d). The response times of  $\text{Co}_3\text{O}_4$ -300,  
3  $\text{Co}_3\text{O}_4$ -400, and  $\text{Co}_3\text{O}_4$ -500 are 152s, 99s, and 153s, respectively, and the recovery  
4 times are 37s, 50s, and 53s, respectively. Comparing with  $\text{Co}_3\text{O}_4$ -300 and  $\text{Co}_3\text{O}_4$ -500,  
5  $\text{Co}_3\text{O}_4$ -400 has a much shorter response time, but its recovery time is slightly longer  
6 than that of  $\text{Co}_3\text{O}_4$ -300.

12  
13  
14  
15

16  
17 < Fig. 6 >  
18

19  
20 Fig. 6 (a) is the typical dynamic sensing transient curves of  $\text{Co}_3\text{O}_4$  sensors at  
21 different n-butanol concentrations (3ppm-100ppm). All the sensors showed good  
22 response, and the response value enhanced with the increment of n-butanol  
23 concentration. The relationship of response values and n-butanol concentrations for  
24 three samples are displayed in Fig. 6(b). When the concentration of n-butanol is 3ppm,  
25 the response of  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 are 1.87, 8.74 and 1.94,  
26 respectively. It is obvious that  $\text{Co}_3\text{O}_4$ -400 has the lowest detection limit in the three  
27 sensors. Meanwhile, the  $\text{Co}_3\text{O}_4$ -400 exhibits the highest response value at each  
28 n-butanol concentration. It can also be observed in Fig. 6(b) that the response value of  
29 the  $\text{Co}_3\text{O}_4$ -400 sample increases significantly in the concentration range from 3 ppm  
30 to 20 ppm, and then it gets saturated. The linear relationship between n-butanol  
31 concentration and the response values in the range from 3 ppm to 20 ppm is shown in  
32 Fig. 6(c). The theoretical detection limits for n-butanol in  $\text{Co}_3\text{O}_4$  samples can be  
33 evaluated through linear extrapolation, the calculating of the LOD is  $\text{LOD} = 3 \times$   
34 (Standard Deviation/Slope) , which are calculated to be 215 ppb, 150 ppb, and 190  
35  
36  
37

65

1 ppb, respectively [46]. The above results indicate that the  $\text{Co}_3\text{O}_4$ -400 sample owns  
2  
3 excellent sensitivity for n-butanol, which means that it has great application potential  
4  
5  
6 in low concentration n-butanol sensing.  
7

8  
9 Stability (repeatability) is crucial for a sensor in the commercial application. To test  
10  
11 the stability of  $\text{Co}_3\text{O}_4$  sensors, they were measured over 6 periods (a period means a  
12  
13 complete cycle of response and recovery procedures to 100 ppm n-butanol). The  
14  
15 sensing transient curves are shown in Fig. 6(d). During 6 periods, the instantaneous  
16  
17 response values of the sensors have no obvious change, which proves the good  
18  
19 reversibility and repeatability of the  $\text{Co}_3\text{O}_4$  sensors prepared in our work.  
20  
21  
22  
23  
24

25 Selectivity is another important factor for the practical application of gas sensors.  
26  
27 The response of all  $\text{Co}_3\text{O}_4$  samples toward 100 ppm VOCs mixture (including  
28  
29 n-butanol, formaldehyde, methanol, ethanol, acetone, isopropanol, ammonia, xylene,  
30  
31 toluene, benzene, sulfur dioxide and nitrogen Dioxide) is shown in Fig. 6(e). The  
32  
33  $\text{Co}_3\text{O}_4$ -400 sample not only shows the highest response to all the VOCs, but also  
34  
35 exhibits the best selectivity to n-butanol. The response value of  $\text{Co}_3\text{O}_4$ -400 to  
36  
37 n-butanol is 1.3-5.5 times than other VOCs. Among them, only xylene could make  
38  
39 interference with n-butanol, which may be due to similar optimal operating  
40  
41 temperature and chemical reactivity energy. Moreover, in order to evaluate the  
42  
43 selectivity of all  $\text{Co}_3\text{O}_4$  sensors to oxidizing gases (such as  $\text{SO}_2$  and  $\text{NO}_2$ ), the  
44  
45 responses of the  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500 sensors to 100 ppm  $\text{SO}_2$  and  
46  
47  $\text{NO}_2$  were tested. As shown in Fig. 6(e),  $\text{Co}_3\text{O}_4$ -300,  $\text{Co}_3\text{O}_4$ -400 and  $\text{Co}_3\text{O}_4$ -500  
48  
49 sensors show extremely low response to  $\text{SO}_2$  and  $\text{NO}_2$  at the optimal operating  
50  
51  
52  
53  
54  
55  
56

61  
62  
63  
64  
65

1 temperature as 140°C. It means all  $\text{Co}_3\text{O}_4$  sensors exhibit the best selectivity to  
2  
3  
4 n-butanol among all examined gases at the operating temperature at 140°C.  
5

6 The selectivity of  $\text{Co}_3\text{O}_4$ -400 to n-butanol has been analyzed in details. The reasons  
7  
8 for the selectivity of  $\text{Co}_3\text{O}_4$ -400 to n-butanol include two points: (i) The polarity of  
9  
10 hydroxyl group (-OH) is stronger than amino group (-NH<sub>2</sub>), aldehyde (-CHO),  
11  
12 carbonyl group (-C=O) and phenyl group. For containing hydroxyl group, the polarity  
13  
14 of n-butanol is stronger than ammonia, formaldehyde, acetone, xylene, toluene and  
15  
16 benzene. That means n-butanol has a very strong ability to provide electrons. And the  
17  
18 large intrinsic crystal defects and rich oxygen vacancies of  $\text{Co}_3\text{O}_4$ -400 make it prefer  
19  
20 to bound extra electrons as free carries, so it shows good selectivity to n-butanol.  
21  
22 Furthermore, the excellent electron donor characteristics of n-butanol causes it react  
23  
24 with the adsorbed oxygen species at the relatively low concentration, exhibiting  
25  
26 relatively high response. (ii) The diffusivity determines the residence time of the  
27  
28 detected gas on the surface of gas sensor. And the longer residence time can improve  
29  
30 the response of gas sensors to the detected gas. Comparing with ethanol and methanol,  
31  
32 n-butanol has a lower diffusivity for its higher molecular weight. Hence, the residence  
33  
34 time of n-butanol on  $\text{Co}_3\text{O}_4$ -400 is longer than other detected gases, which endows  
35  
36 n-butanol higher response.  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 Long-term stability as a significant impact on the durability of sensors has been  
51  
52 tested. In order to evaluate the influence of the external environment on the stability  
53  
54 of the gas sensor, the  $\text{Co}_3\text{O}_4$ -400 sensor was placed in the air for 45 days. After 45  
55  
56 days, the response value of  $\text{Co}_3\text{O}_4$ -400 to n-butanol still can achieve 46.65, which was  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 86.74% of the initial value, and show good response-recovery performance, indicating  
2  
3 that the stability of  $\text{Co}_3\text{O}_4$ -400 is splendid. Then, the response of the  $\text{Co}_3\text{O}_4$ -400 to  
4  
5  
6 100 ppm n-butanol at  $140^\circ\text{C}$  was continuously tested for 30 days , as shown in  
7  
8  
9 Fig.6(f). Within 30 days, the response of the  $\text{Co}_3\text{O}_4$ -400 sensor fluctuated slightly.  
10  
11 After the 75 days' test, the response value of the  $\text{Co}_3\text{O}_4$ -400 is tested to be 40.30,  
12  
13 retaining 74.93% without significant reduction, further indicating that it has good  
14  
15 long-term stability and guarantees its service life. Furthermore, the  $\text{Co}_3\text{O}_4$ -400 sensor  
16  
17 synthesized in this work is compared with the reported  $\text{Co}_3\text{O}_4$  sensors. The results are  
18  
19 listed in Table 1. It can be seen from this, the gas sensor prepared in this work can  
20  
21 effectively enhance the response of n-butanol and reduce the operating temperature.  
22  
23 Considering the response and the optimal operating temperature, the unique 3D  
24  
25 porous structure  $\text{Co}_3\text{O}_4$  nanospheres gas sensor shows superior gas sensing properties  
26  
27 and has great practical application potential.

### 39 3.3. Gas sensing mechanism 40

41 < Fig. 7 >  
42  
43

44 The reaction process of the target gas on the surface of the material plays an  
45  
46 important role in the sensing process. In order to further study the electronic states of  
47  
48 the surface elements, the XPS analysis of  $\text{Co}_3\text{O}_4$  samples was performed. Fig. 7(a)  
49  
50 shows the high-resolution spectrum of Co 2p, in which there are two characteristic  
51  
52 peaks and two satellite peaks. Both the positions and distributions of the Co 2p XPS  
53  
54 peaks in all the  $\text{Co}_3\text{O}_4$  samples are similar. Two characteristic peaks at 779.8 eV and  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 794.9 eV belong to the Co 2p<sub>3/2</sub> and Co 2p<sub>1/2</sub> spin-orbital peaks of Co<sub>3</sub>O<sub>4</sub>, respectively,  
2  
3 and their corresponding satellite peaks are at 789.7 eV and 804.6 eV. The difference  
4  
5  
6 between Co<sup>2+</sup> and Co<sup>3+</sup> peaks can be observed after curve-fitting, as shown in Fig.  
7  
8  
9 7(a). Fig. 7 (b-d) show the high resolution XPS spectra of O1s for Co<sub>3</sub>O<sub>4</sub> samples.  
10  
11 These spectra can be divided into three fitted peaks, corresponding to O<sub>L</sub>, O<sub>V</sub> and O<sub>C</sub>,  
12  
13 respectively. O<sub>L</sub> refers to the lattice oxygen species, which contributes little to the gas  
14  
15 response for its stability. O<sub>V</sub> means that there are oxygen vacancies on the surface of  
16  
17 samples, which can provide active sites for the gas adsorption and reaction on the  
18  
19 surface of sensing materials. O<sub>C</sub> represents the chemically adsorbed oxygen species,  
20  
21 such as O<sub>2</sub><sup>-</sup>, O<sup>-</sup>, O<sup>2-</sup>. When the calcination temperature is 300°C, 400°C, and 500°C,  
22  
23 the corresponding O<sub>V</sub> contents are 25.69%, 53.75%, and 35.76%, respectively.  
24  
25  
26  
27  
28  
29  
30  
31 Obviously, Co<sub>3</sub>O<sub>4</sub>-400 has the highest oxygen vacancy content, which leads to its  
32  
33 highest response to 100 ppm n-butanol at 140°C. Heat treatment is one of the common  
34  
35 methods for the controllable defect generation of nanomaterials, and it can be adjusted  
36  
37 by controlling the calcination temperature and the atmosphere. The defects due to heat  
38  
39 treatment are mainly the result of the release and recovery of O atoms in the material  
40  
41 lattice. Therefore, in the presence of oxygen, the oxygen vacancy concentration will  
42  
43 have a high point [53]. The presence of surface oxygen vacancies plays a crucial role  
44  
45 in chemical sensing. Positively charged oxygen vacancies tend to trap electrons,  
46  
47 effectively separating electron-hole pairs and improving sensing performance. The  
48  
49 oxygen vacancy content of Co<sub>3</sub>O<sub>4</sub>-300 is 25.69 %, which is lower than 35.76 % of  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 due to the fact that the specific surface area of  $\text{Co}_3\text{O}_4$ -300 is much larger than that of  
2  
3  
4  $\text{Co}_3\text{O}_4$ -500.

5  
6 The other major factor affecting gas sensing performance is specific surface area  
7  
8 and pore size. In general, a large specific surface area enables the sensing material to  
9  
10 adsorb more oxygen species. The  $\text{Co}_3\text{O}_4$ -400 sample has a specific surface area of  
11  
12  $39.3 \text{ m}^2/\text{g}$ . Meanwhile, the porous structure of  $\text{Co}_3\text{O}_4$ -400 provides a large amount of  
13  
14 exposed area for gas sensing, which is conducive to improving its sensing  
15  
16 performance of n-butanol. According to surveys, the average pore size of many metal  
17  
18 oxide sensing materials is around 25 nm [8, 25, 48, 50]. The unique porous structure  
19  
20 of the product and the appropriate pore size facilitate the penetration of gas molecules  
21  
22 into the interior of the sensing material. This allows the hole accumulation layer to be  
23  
24 formed on both the outer layer and the inner layer of the materials, resulting in a low  
25  
26 initial resistance in the air.  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 Furthermore, the good catalytic activity of  $\text{Co}_3\text{O}_4$  also plays a positive role in  
37  
38 improving gas sensitivity, in which  $\text{Co}^{3+}$  is capable of oxidizing reductive gases [29].  
39  
40 During the catalytic process, the reductive gas reacts with oxygen ions adsorbed on  
41  
42 the  $\text{Co}^{3+}$  active site, causing a change in resistance and generating  $\text{Co}^{2+}$ . Then  $\text{Co}^{2+}$   
43  
44 can be oxidized to active  $\text{Co}^{3+}$  by the gaseous oxygen molecule in the air. In the target  
45  
46 gas,  $\text{Co}^{3+}$  in  $\text{Co}_3\text{O}_4$  can promote the oxidation reaction of n-butanol, improving the  
47  
48 sensing performance. In summary, the excellent gas sensing performance of the  
49  
50  $\text{Co}_3\text{O}_4$ -400 material for n-butanol can be attributed to the following three factors: (i)  
51  
52 abundant oxygen vacancies; (ii) the unique porous structure with a large specific  
53  
54  
55  
56

65

1 surface area; (iii) Catalytic activity of Co<sub>3</sub>O<sub>4</sub> for n-butanol.

2  
3  
4 < Fig. 8 >

5  
6 The sensing characteristics of MOS-based gas sensors are affected by the surface  
7 reaction of the sensor layer. The sensing mechanism of p-type semiconductor oxide  
8 Co<sub>3</sub>O<sub>4</sub> is closely related to the change of resistance. However, the change in resistance  
9 is mainly due to the change in the concentration of holes in the surface region [54]. As  
10 shown in Fig. 8, when the Co<sub>3</sub>O<sub>4</sub> sensor is exposed to the air, oxygen molecules are  
11 adsorbed on the surface of Co<sub>3</sub>O<sub>4</sub>, and electrons (e<sup>-</sup>) are trapped from the conduction  
12 band to form different oxygen species (such as O<sub>2</sub><sup>-</sup>, O<sup>-</sup>, O<sup>2-</sup>). O<sup>-</sup> is formed between  
13 100°C and 300°C [55]. The optimum operating temperature of the Co<sub>3</sub>O<sub>4</sub> sensor in  
14 this work is 140°C, so the main oxygen species is O<sup>-</sup> (Eq. (1)). With the changing of  
15 adsorbed oxygen species, the electron depletion layer of Co<sub>3</sub>O<sub>4</sub> is generated and the  
16 hole concentration is increased to form the hole accumulation layer [56]. Since the  
17 majority carrier of Co<sub>3</sub>O<sub>4</sub> is hole, the resistance of Co<sub>3</sub>O<sub>4</sub> in the air is low. When the  
18 n-butanol gas is injected, the adsorbed oxygen species (O<sup>-</sup>) react with the reductive  
19 n-butanol (Eq. (2)). The electrons generated in this process return to the conduction  
20 band of Co<sub>3</sub>O<sub>4</sub>, causing the electron-hole pairs recombine, the hole accumulation layer  
21 shrink, and the resistance of materials increase. The recovery process is just the  
22 reversible process of the above reaction. When the n-butanol gas is removed, the  
23 oxygen molecules again capture electrons from the conduction band, reducing the  
24 resistance to its initial value.

60 Eq. (1)

#### 4. Conclusion

The porous structure  $Co_3O_4$  was successfully prepared by the precursor derivatization strategy of metal-organic framework and applied to gas sensing. Through performance test, the  $Co_3O_4$ -400 exhibits the best gas sensitivity. At the optimum testing temperature, the response to 100 ppm n-butanol is 53.78 and the theoretical limit of detection is 150 ppb.  $Co_3O_4$ -400 also owns good stability and reproducibility. After six consecutive cycles of testing, there was no significant change in the response curve to n-butanol. After left in the air for 45 days, the response value of  $Co_3O_4$ -400 to n-butanol was tested to be 46.65, which was 86.74% of the initial value. Even in the following 30-day long-term test, the response value was still stable, retaining 74.93% of the initial value. The unique spherical porous microstructure make  $Co_3O_4$ -400 have a large specific surface area and a suitable pore size. The larger specific surface area can adsorb a large amount of gas, and the proper pore size is conducive to the diffusion of gas molecules into the sensing material, thereby helping to improve the gas sensing performance. Additionally, the abundant oxygen vacancies generated by the heat treatment provide a large number of active sites and also help to improve the sensing performance. Our work provides a strategy for developing p-type semiconductor metal oxide sensors with high response, low detection limit and low temperature.
