Circumstances in Development and Social Class Differences in Adulthood Depression

**Evidence from the National Child
Development Study**

Context

⌘ Increasing

⌘ Inequality of mental health morbidity by
Social Class

⌘ Variation evident by

☑ Age

☑ Sex

☑ Geography

⌘ Impact on primary care facilities

Some Risk Factors...

- ⌘ **Low Birth Weight**
- ⌘ **Bottle-fed in infancy**
- ⌘ **Lower IQ**
- ⌘ **Lack of social or parental support**
- ⌘ **Poor quality housing in childhood**
- ⌘ **Low income or financial insecurity**
- ⌘ **Poor physical health**
- ⌘ **Low educational achievement**

Research Question

Which risk factors for depression during development influence the social class gradient of depressive tendency in adulthood?

- ⌘ *Are class differences in risk factors a sufficient explanation?*
- ⌘ *What are the most influential determinants of poor mental health?*

National Child Development Study (NCDS, 1958 cohort)

- ⌘ All those living in Great Britain born between 3rd-9th March 1958 (N=18,000)
- ⌘ Data collected at birth, 7, 11, 16, 23, 33 & 42 years of age
- ⌘ Rich data on multiple aspects of life at each 'sweep'

Malaise Inventory

- ⌘ Population measurement of ‘depressive tendency’
- ⌘ Simple sum of a 24 question inventory of dichotomous questions (‘Yes’=1 ‘No=0’)
- ⌘ Measured in NCDS at 23, 33 & 42
- ⌘ Inventories with less than 21 responses not used, those with 22-24 responses treated for missing values

Distribution

Sex Differences

Class & Age Variation

Changing depressive states

Depressed (D) or Not Depressed (N) at 23 33 42	%	Grouped %	Further %
D D D	1.56	1.56	17.14
D D N	0.73	3.96	
D N D	1.40		
N D D	1.84		
N N D	7.11	11.62	
N D N	1.64		
D N N	2.87		
N N N	82.86	82.86	82.86
Total	100	100	100

Regression Analysis - method

- ⌘ Multiple linear regression models fitted
- ⌘ Control variables from infancy, childhood & adulthood
- ⌘ Regressions initially performed on each separate age survey (23, 33, 42)
- ⌘ Final regressions combined all survey inventories & adjusted additionally for age

Regression Analysis - controls I

⌘ Sex

⌘ Birth weight

⌘ Breastfeeding

⌘ Ethnicity

⌘ Parity

⌘ Family Size

⌘ Geographical Region

⌘ Housing Tenure (age 7, 11, 16)

Regression Analysis - controls II

- ⌘ Crowding (age 7, 11, 16)
- ⌘ Health Abnormality (age 7, 16)
- ⌘ Maths ability (age 7, 11, 16)
- ⌘ Reading ability (age 7, 11, 16)
- ⌘ Financial Hardship in family (age 11, 16)
- ⌘ Parental divorce (up to ages 7, 11, 16)
- ⌘ Geographical mobility (birth to 16)
- ⌘ Parental interest in education (ages 7, 11, 16, both maternal & paternal)

Regression Analysis - results I

⌘ Crude Linear Regressions

⌘ Significant increases in mean malaise score with SES ($p < 0.001$)

⌘ Malaise score increased by 0.51, 0.76 and 1.15 points for each respective SES group

⌘ Significantly higher malaise among women ($p < 0.001$)

Regression Analysis - results II

⌘ Adjusted Linear Regressions

⌘ Non Significant differences in malaise scores between SES groups ($p > 0.05$)

⌘ Significantly higher malaise among women persists ($p < 0.001$)

⌘ Factors with most explanatory power include maths score, financial hardship & parental interest in education

Conclusions

- ⌘ Significant gradient with social class
- ⌘ Episodic in nature
- ⌘ Large and persistent gender difference
- ⌘ Gradient can be eliminated by relatively few factors: thus differences can be explained by differentials in risk factors between SES groups
- ⌘ Factors in infancy, childhood & adolescence all play a role
