**ABSTRACT**

**Objective:** Gastric acid secretory capacity in different anatomical regions, including the postprandial acid pocket, was assessed in *H. pylori* positive and negative volunteers in a Western population.

**Design:** We studied 31 *H.pylori* positive and 28 *H.pylori* negative volunteers, matched for age, gender and BMI. Jumbo biopsies were taken at 11 pre-determined locations from the gastroesophageal junction and stomach. Combined high resolution pHmetry (12 sensors) and manometry (36 sensors) was performed for 20 minutes fasted and 90 minutes postprandially. The squamocolumnar junction was marked with radio-opaque clips, and visualised radiologically. Biopsies were scored for inflammation and density of parietal, chief and G cells immunohistochemically.

**Results:** Under fasting conditions, the *H.pylori* positives had less intragastric acidity compared to negatives at all sensors >1.1cm distal to the peak lower oesophageal sphincter (LES) pressure ( $p<0.01$ ). Postprandially, intragastric acidity was less in *H.pylori* positives at sensors 2.2, 3.3 and 4.4cm distal to the peak LES pressure ( $p<0.05$ ), but there was no significant differences in more distal sensors. The postprandial acid pocket was thus attenuated in *H.pylori* positives.

The *H.pylori* positives had a lower density of parietal and chief cells compared to *H.pylori* negatives in 10 of the 11 gastric locations ( $p<0.05$ ). 17/31 of the *H.pylori* positives were CagA seropositive and showed a more marked reduction in intragastric acidity and increased mucosal inflammation.

**Conclusion:** In population volunteers, *H.pylori* positives have reduced intragastric acidity which most markedly affects the postprandial acid pocket.

**SUMMARY BOX****WHAT IS ALREADY KNOWN?**

1. There is a negative association between *H. pylori* infection and both gastroesophageal reflux disease and oesophageal adenocarcinoma.
2. The mechanism of this negative association is unclear but might be related to *H. pylori* reducing gastric acidity.
3. The gastric acid which refluxes into the oesophagus originates from the proximal gastric acid pocket.

**NOVEL FINDINGS:**

1. In population volunteers, intragastric acidity was less in those with *H. pylori* infection and this was most marked in the proximal stomach close to the gastroesophageal junction.
2. The density of parietal cells and chief cells was reduced in *H. pylori* positives compared to negatives.
3. The reduction in intragastric acidity and severity of inflammation were more marked in CagA positive versus CagA negative *H. pylori* infected subjects.

**CLINICAL IMPLICATIONS:**

The reduced intragastric acidity close to the gastroesophageal junction in the *H. pylori* infected subjects provides a mechanism for the negative association between the infection and reflux disease and its complications.

## INTRODUCTION

*Helicobacter pylori* (*H.pylori*) is a common bacterial infection of the stomach present in the majority of the world's human population and resulting in varying degrees of inflammation of the underlying gastric mucosa. The infection is acquired in early childhood and usually persists indefinitely unless specifically eradicated. [1]

One of the major medical advances of the past 25 years has been the discovery that this common infection plays an important role in the aetiology of duodenal and gastric ulcers and also of gastric cancer.[2] Eradicating the infection produces a long-term cure for the majority of patients with peptic ulcers unrelated to NSAID therapy. There is also increasing evidence that eradication of the infection reduces the risk of gastric cancer.[3]

An unexplained observation regarding the infection is its negative association with gastroesophageal reflux disease (GERD) and its complications of Barrett's oesophagus and oesophageal adenocarcinoma, with these disorders being less than half as common in infected subjects. [4, 5] It has been postulated that this negative association may represent the gastric infection protecting against these oesophageal disorders. If so, the falling incidence of the infection in the general population might explain the rising incidence of these oesophageal diseases.

One mechanism by which the infection might protect against oesophageal disease is by reducing the ability of the gastric mucosa to secrete acid and pepsin which are the constituents of gastric juice which can induce oesophageal damage. The infection is known to exert varying effects on gastric secretory function. In subjects with duodenal ulcers, the infection produces a non-atrophic gastritis with well-maintained gastric secretory cell mass which secretes increased amounts of acid due to the infection inhibiting the gastrin-mediated negative feedback control of acid secretion.[6] In patients who develop gastric cancer, the infection induces an atrophic gastritis with loss of gastric secretory cells and thus reduced acid secretion. Only approximately 1 in 10 *H.pylori* infected subjects develop complicating ulcer disease or gastric cancer and relatively little is known about the effects of the chronic

1  
2  
3 infection on gastric secretory function in the 90% of infected subjects without these  
4 complications.[7] If the degree of reduction in oesophageal disease in the *H.pylori* infected  
5 population is due to the infection reducing gastric acid secretion, then this suppression of  
6 acid secretion would need to be apparent in the majority of infected subjects.  
7  
8

9  
10  
11 Recent evidence indicates that it is the acidity of the gastric contents close to the  
12 gastroesophageal junction (GEJ), referred to as the acid pocket, which refluxes and causes  
13 oesophageal damage.[8] It is also known that loss of gastric secretory cells due to *H.pylori*-  
14 induced atrophic gastritis does not occur uniformly throughout the stomach but may be more  
15 marked at the periphery of the acid secreting mucosa.[9] In assessing any potential  
16 protective effect of the infection against oesophageal damage, it is important to examine the  
17 structure and secretory function of different anatomical regions of the stomach as well as its  
18 overall secretory capacity.  
19  
20

21  
22 The aim of our study was to assess gastric secretory status in different anatomical regions  
23 of the stomach and in subjects representative of the majority of the *H.pylori* infected  
24 population.  
25  
26

## 27 28 29 30 31 32 33 34 35 **METHODS & MATERIALS**

### 36 37 38 ***Subjects***

39  
40 Study participants were volunteers from the general population of the West of Scotland.  
41 Subjects who were currently taking, or had recently taken, proton pump inhibitors, were  
42 currently using H<sub>2</sub> receptor antagonists or had ever received *H.pylori* eradication therapy  
43 were excluded. Recruitment was by general advertisement and from the NHS Scotland  
44 SHARE database.

## **Study design**

### **Study Day 1: Clinical measurements and Urea breath test**

The presence and severity of any gastrointestinal symptoms was assessed using the Short-Form Leeds Dyspepsia Questionnaire [10] and a medication history was recorded. Measurements of height, weight, waist and hip circumference were taken. Volunteers were tested for *H.pylori* infection by C<sup>14</sup> urea breath test. Fasting serum and plasma samples were stored at -20°C and later tested for *H.pylori* CagA IgG using ELISA (Genesis Diagnostics Ltd, Littleport, UK).

### **Study day 2: Upper gastrointestinal endoscopy**

Volunteers attended after an overnight fast for upper gastrointestinal endoscopy. They were offered topical lidocaine throat spray or conscious sedation with midazolam 1-3mg. Biopsies were taken using large capacity biopsy forceps (Radial Jaw™ 4; Boston Scientific, Hemel Hempstead, UK) with a jaw span of 8mm. Two junctional biopsies were taken perpendicular to the squamocolumnar junction (SCJ), one from lesser and one from greater curve, and targeted to include squamous mucosa at the proximal end. Three further junctional biopsies were taken longitudinally below the SCJ, aiming for end-to-end biopsies starting at 6, 12 and 18mm distal to the SCJ down the lesser curve. In addition, six further gastric biopsies were taken from gastric fundus, mid-body on greater curve, mid-body on lesser curve, distal body on greater curve, incisura angularis and antrum. Finally, two small metal radio-opaque clips were attached to the SCJ using a single use rotatable clip fixing device (QuickClip 2™; Olympus, Southend-on-Sea, UK).

### ***Biopsy specimen processing***

Biopsies were immediately placed onto non-adherent dental wax and oriented flat. More detailed information concerning the two-stage orientation method has been described elsewhere.[11] The specimens were later embedded in agar on the filter paper without

1  
2  
3 further manipulation. Staining was performed with conventional H&E, as well as monoclonal  
4  
5 antibodies to H<sup>+</sup>/K<sup>+</sup>ATPase, pepsinogen I and gastrin.  
6  
7

### 8 9 **Study Day 3: Combined manometry and pH study**

10  
11 The volunteers attended after an overnight fast for combined high resolution manometry  
12  
13 and pH studies. The combined probe was passed pernasally and positioned so that the  
14  
15 most proximal pH sensor was 5cm above the lower oesophageal sphincter (LES), with the  
16  
17 remaining eleven sensors lying across the sphincter and within the proximal stomach. The  
18  
19 relative positions of the 12 sensor pH catheter, 36 sensor manometer and SCJ is shown in  
20  
21 Fig 1. Manometry and pH data were recorded concurrently for a 20 minute fasting period.  
22  
23 Subjects then consumed a standardised meal over ten minutes [400g Waitrose spaghetti  
24  
25 bolognese ready meal and 100ml water (500kcal; 55.2g carbohydrate, 27.8g protein, 17.6g  
26  
27 fat)]. Following this, manometry and pH recordings were continued for a further 90 minutes.  
28  
29 An X-ray was taken before and after the meal to visualise the metal clips at the SCJ.  
30  
31

#### 32 33 *Equipment*

#### 34 35 **High-resolution pHmetry**

36  
37 pH recordings were taken using a high resolution pH catheter (Synectics Medical Ltd,  
38  
39 Enfield, UK). This was a custom-made pH probe composed of 12 antimony pH electrodes  
40  
41 with the most distal electrode situated 5mm from the tip of the catheter, with the other eleven  
42  
43 electrodes 35, 46, 57, 68, 79, 90, 101, 112, 123, 134 and 169mm proximal to the tip. The  
44  
45 probe was calibrated prior to each study using pH buffer solution (Synmed Ltd, Enfield, UK)  
46  
47 at pH 7.01 and pH 1.07. Recordings were captured using Polygram Net software (Synectics  
48  
49 Medical Ltd, Enfield, UK).

56  
57  
58  
59  
60

### High-resolution manometry

Manometry was performed using a high resolution solid-state catheter with 7.5mm spacing between 36 circumferential sensors (Given Imaging, Hamburg, Germany). Calibration was performed prior to each study and In vivo calibration was carried out on a weekly basis and applied to each study to compensate for thermal drift. Recordings were captured with ManoScan 360 high-resolution Manometry System and analysed with ManoView ESO v3.0.1 software (Given Imaging, Hamburg, Germany).

### Combined probe

The manometry and pH catheters were combined using two thin strips of Leukoplast Sleek waterproof tape (BSN Medical, Pinetown, SA) such that manometry sensor 25 was immediately adjacent to pH sensor 3.

### Data analysis

#### Intragastric acid

The 90 minute postprandial period was split into three 30 minute periods for analysis. The median pH for each of the 12 pH sensors was calculated for the twenty minute fasting period and the three 30 minute postprandial periods. Acid exposure at the GEJ was also examined by calculating the % of time pH <4.

#### Manometry

Manometric characteristics were analysed in detail during fasting and the same three postprandial periods. For each two minute period, one inspiratory point and one expiratory point was chosen from the longest period without interference from swallowing, coughing or transient lower oesophageal sphincter relaxations (TLESRs). The mean pressure in inspiration and expiration was calculated for each of the 36 sensors over the twenty minute fasting period and thirty minute postprandial periods. The peak LES pressure was taken as

1  
2  
3 the sensor showing the highest mean pressure. The position of the SCJ was derived from  
4 the position of the metal clips relative to the combined manometry and pH sensors seen on  
5 X-ray.  
6

8  
9

## 10 11 **Histopathological Assessment**

### 12 13 **A. Studies using Conventional H&E:**

14  
15 **Glandular height:** The vertical height of epithelium starting from lamina propria to tip of  
16 gland were measured in 3 well-oriented and representative fields and expressed as “Total  
17 Thickness of Epithelium”. To measure the “Glandular Height”, the same method was limited  
18 to areas of gland containing secretory cells, but not superficial foveolar epithelial cells. All  
19 results were expressed as median (IQR) in mm.  
20  
21  
22  
23

24  
25 **Inflammatory scoring:** The intensity of inflammatory infiltrate by polymorphonuclear (PMN)  
26 and mononuclear (MN) cells was scored semi-quantitatively (0=none; 1=mild; 2=moderate;  
27 3=severe) as recommended in the Updated Sydney Classification of Gastritis [12]. A  
28 combined inflammatory score was calculated as the sum of these two scores. Intestinal  
29 metaplasia (IM) was scored by estimating the proportion of epithelial surface covered by  
30 goblet cells.  
31  
32  
33  
34  
35  
36  
37  
38  
39

### 40 41 **B. Immunohistochemistry**

42 The oriented biopsies, double embedded in agar and paraffin, were cut in standard 4-  
43 micron thickness and immunostained individually for parietal cell, chief cell and G cells. For  
44 parietal cells, we used a commercial mouse monoclonal anti-H<sup>+</sup>/K<sup>+</sup> ATPase (Ab 2866,  
45 Abcam, Cambridge, UK) diluted at 1:20,000. For Chief cells, a mouse monoclonal anti-  
46 pepsinogen 1 antibody (Ab 50123, Abcam, Cambridge, UK) was used at dilution of 1:4000.  
47 The G cells were stained with anti-gastrin (Ab-16035, Abcam, Cambridge, UK) diluted at  
48 1:200. A Thermo Quanto Detection Kit (TL-125-OHD, Thermo Fisher, UK) was used as  
49 secondary antibody.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

### Quantification of Secretory Cells:

To calculate the density of parietal cells, chief cells and G cells, absolute number of stained cells were counted at a magnification of 125X in 3 well-oriented and representative fields (1 mm<sup>2</sup> each) and expressed as mean cell number per 1 mm<sup>2</sup> area in each patient. All selected areas must have had complete glands located in sagittal plane, in which the lamina propria was in bottom and luminal side of epithelium was in top.

### Statistical analysis

All continuous data are expressed as medians and interquartile ranges unless otherwise stated. Comparison of variables between groups was made using the Mann-Whitney *U* test. Biopsy inflammatory scores are presented as crosstabulations and compared using Fisher's exact test. Significance for all statistical tests was set as p value <0.05.

### Ethics

The study protocol was approved by the West of Scotland Ethics Committee and all volunteers provided informed written consent.

## RESULTS

Of the 137 subjects assessed for eligibility for the study, 49 were excluded due to current or recent use of proton pump inhibitor (PPI) therapy (n=9) or history of previous *H.pylori* eradication therapy (n=8) or declining to participate following full explanation of the study protocol (n=32). 88 subjects proceeded to the urea breath test of which 31 were *H.pylori* positive and all of these went on to complete the full study protocol. Of the 57 testing *H.pylori* negative, 28 went on to complete the study due to 1 withdrawing consent after the endoscopy and 28 not being selected to proceed in order to maintain matching of the positive and negative groups with respect to age, gender and body mass index (BMI) (Fig. S1).

1  
2  
3 The 31 *H.pylori* positive and 28 *H.pylori* negative subjects who completed the study were  
4 well matched with respect to age (55 vs 56 years;  $p=0.95$ ), gender (18/31 vs 18/28 males;  
5  $p=0.84$ ) and BMI (26.3 vs 26.8 kg/m<sup>2</sup>;  $p=0.72$ ). There were 7 current smokers in the *H.pylori*  
6 positive group compared to 1 current smoker in the *H.pylori* negative group ( $p=0.035$ ).  
7  
8

9  
10 The median dyspepsia score for *H.pylori* positives was 2.0 (range 0-9) compared to 0  
11 (range 0-3) for the *H.pylori* negative subjects ( $p=0.002$ ). 17/31 (54.8%) of the *H.pylori*  
12 positives were taking no medication compared to 10/29 (35.7%) of the *H.pylori* negative  
13 subjects. The most frequent medications were antihypertensives, statins, antidepressants  
14 and inhalers for asthma. No subject was taking medications known to affect gastric  
15 secretion.  
16  
17

18 At endoscopy, 4 *H.pylori* positive subjects had a hiatus hernia (2-4cm in length), 1 subject  
19 had LA Grade A reflux esophagitis, and one subject had 3cm of Barrett's mucosa. None of  
20 the *H.pylori* negatives had a hiatus hernia, although two subjects had reflux esophagitis (LA  
21 grade A and B).  
22  
23

### 24 **Gastroesophageal Acidity**

25 Under fasting conditions, the *H.pylori* positive subjects had less intragastric acidity  
26 compared to the *H.pylori* negatives at all sensors more than 1.1cm distal to the peak LES  
27 pressure (Table 1). The fall from neutral oesophageal pH to highly acidic intragastric pH  
28 also occurred more abruptly in the *H.pylori* negatives. At the sensor 3.3cm distal to the peak  
29 LES pressure, the median pH in the *H.pylori* negatives had fallen to 2.27 compared to 6.13  
30 in the positives ( $p<0.001$ ). The radio-opaque clips indicated that this pH sensor was 1.8cm  
31 distal to the SCJ.  
32  
33

34 Throughout the three postprandial periods, intragastric acidity was significantly less in the  
35 *H.pylori* positives at the pH sensors placed 2.2, 3.3 and 4.4cm distal to the peak pressure of  
36 the LES but no significant difference was detected by the more distal sensors placed at 5.5  
37 and 6.6cm distal to this reference point (Table 1). These three sensors detecting a

3 significant difference in gastric acidity between the two groups were those closest to the GEJ  
4  
5 with the most proximal of them being only 0.6cm distal to the SCJ (Fig. 2).  
6

7 The % of time pH<4 for each of the three postprandial periods was significantly greater in  
8  
9 the *H.pylori* negatives versus positive subjects for the electrodes extending 3cm distal to the  
10  
11 peak LES pressure, at the peak LES pressure and also extending 1.1cm above the peak  
12  
13 LES pressure (Table 2).

## **Gastric Histopathology**

### **A. Conventional H&E Staining**

#### **Inflammation**

The *H.pylori* positives had a greater combined inflammatory cell infiltrate at each of the 11 biopsy sites compared to the *H.pylori* negatives (Table 3). The increased combined inflammatory cell infiltrate in the *H.pylori* positives consisted of a mixture of PMN cells and MN cells and tended to be more intense close to the SCJ, lesser curve, distal stomach, incisura and antrum compared to the gastric fundus and mid-body ( $p<0.05$  for each). The *H.pylori* negatives had a MN cell infiltrate limited to the SCJ and also to a lesser extent at the antrum and angularis incisura but its intensity was less than that of the *H.pylori* positives at these sites. There was minimal evidence of PMN cell infiltrate at any location in the *H.pylori* negatives.

#### **Intestinal Metaplasia**

Intestinal metaplasia was identified in 14 of the 31 *H. pylori* positive subjects. In 7 of these it was limited to one or more of the biopsies from mid-body lesser curve, distal body greater curve, incisura angularis and antrum. In 3 of the subjects it was present in at least one of the above sites and also in the biopsies close to the SCJ. In a further 3 it was limited to the region close to the SCJ. In 1 subjects it was present in each biopsy except for one of the biopsies from the SCJ.

Intestinal metaplasia was identified in only four of the 28 *H.pylori* negative subjects. In three of these it was only seen in the biopsies across the SCJ and in the fourth subject it was only seen in the biopsy from the fundus.

#### ***Gastric Gland Height***

The height of the gastric secretory glands was significantly reduced in the *H.pylori* positive versus negative subjects throughout the gastric mucosa except for the biopsies taken across the SCJ (Table 4).

**Table 3:** Cross-tabulation table showing the number of subjects within the *H. pylori* negative (HP-) and positive (HP+) groups with each combined inflammatory score (0-6) at the 11 different gastric biopsy locations.

## **B. Immunohistochemistry**

### *Parietal and Chief Cell Density:*

The *H.pylori* positives had a significant reduction in density of both parietal and chief cells compared to *H.pylori* negatives, and this was seen at each of the 11 intragastric locations assessed except for the SCJ greater curve where the difference did not achieve statistical significance (Table 4). The degree of reduction was similar for the two cell types.

The depletion of both cells in the *H.pylori* positives versus negatives was more marked in the biopsies taken from the distal gastric mucosa (i.e. antrum, incisura angularis, and distal body greater curve) being reduced by 67-100% compared to that observed in the more central region of the oxyntic mucosa (fundus and mid-body) at 26-35% (Fig. 3). In addition, the length of mucosa extending distal to the SCJ which contained no detectable parietal cells was greater in the *H.pylori* positives versus negatives (1.5mm vs 1.0mm;  $p=0.013$ ). However, the degree of reduction in specialised cell density in the biopsies taken 6mm and 12mm distal to the SCJ (38-47%) was not dissimilar from that observed in the more central oxyntic mucosa (i.e. fundus and mid-body) (26-35%) (Fig. 3).

### **G Cell Density**

The density of G cells was reduced in the antrum of the *H.pylori* positive versus negative subjects [48 (IQR: 31-86) vs. 91 (64-129),  $p<0.001$ ], but the converse was seen with respect to the biopsies taken from the distal body region [0 (IQR: 0-32) vs 0 (0-0),  $p=0.007$ ].

### **Intragastric Acidity and Histology in CagA Positive *H.pylori* Subjects**

Seventeen of the *H.pylori* positives were CagA seropositive and fourteen CagA seronegative. The associations with reduced intragastric acidity in comparison with *H.pylori* negatives was more apparent for the CagA positives being significant for five of the six intragastric sites both fasting and after the meal in the CagA positives but in only two of the six intragastric sites for the CagA negatives and only under fasting conditions (Table 1 – supplement). There was a statistically significant difference between the CagA negative and

1  
2  
3 CagA positives for only two of the six sites during fasting and one of the six sites after the  
4 meal.  
5

6  
7 The CagA positives had a significantly greater combined inflammatory cell infiltrate  
8 evident at three of the eleven biopsy locations (6mm and 18mm distal SCJ, and distal body  
9 greater curve), compared to the CagA negatives (Table 2 – supplement). The reduction in  
10 parietal and chief cell density was significant at each intragastric location for both CagA  
11 positive and negative subjects with no apparent difference between these two groups.

## 18 19 **DISCUSSION**

20  
21 In our volunteers recruited from the general population of the West of Scotland, those  
22 with *H.pylori* infection had less intragastric acidity both under fasting conditions and following  
23 a meal compared to uninfected volunteers matched for age, gender and BMI. In addition,  
24 those with the infection had a reduced density of both acid secreting parietal cells and  
25 pepsin producing chief cells compared to those uninfected. These findings indicate that  
26 *H.pylori* infection within our Western population is associated with a less acidic and  
27 proteolytic intragastric environment.  
28  
29  
30  
31  
32  
33  
34

35  
36 The reduced intragastric acidity in the *H.pylori* positive subjects was apparent throughout  
37 the stomach under fasting conditions. After the meal, however, the reduced acidity in the  
38 *H.pylori* positives was evident within the first few centimetres distal to the GEJ but no  
39 significant difference in acidity was apparent in the main body of the stomach. There was  
40 also evidence of increased acidity after the meal in the *H.pylori* negatives right at the SCJ  
41 junction and extending 2cm above it indicating increased intrasphincteric acid reflux. We  
42 and others have previously reported that the proximal region of the stomach close to the  
43 GEJ largely escapes the buffering effect of ingested food and may remain highly acidic after  
44 a meal.[13,14,15] This phenomenon has been called the acid pocket and is thought to be  
45 important in GERD induced oesophageal damage after a meal when reflux is most common.

57  
58  
59  
60

1  
2  
3 It is therefore interesting that it is at this region close to the GEJ where the reduced acidity  
4 was most apparent in the *H.pylori* infected subjects.  
5  
6

7 What is the reason for the reduced acidity in the *H.pylori* positives after a meal, being  
8 most marked close to the GEJ? There was no evidence that the depletion in parietal cell  
9 density in the *H.pylori* positives was more pronounced over the few centimetres close to the  
10 GEJ compared to other regions in the stomach. Inflammation may also inhibit gastric  
11 secretory function [16] and this was slightly increased close to the GEJ and also in the distal  
12 stomach compared to the mid-body gastric mucosa. The elevation of intragastric pH  
13 following the meal in the *H.pylori* positives being most marked close to the GEJ may simply  
14 reflect the relative intragastric distribution of gastric juice and ingested food. Following a  
15 meal, the food occupies the centre of the stomach and the secreted gastric juice, the region  
16 close to the stomach wall which secretes it. Impaired acid secretion will elevate the pH of  
17 the gastric juice and this will be most apparent close to the stomach wall. In contrast, the  
18 central region of the stomach will reflect the pH of the food and thus will be relatively  
19 unaffected by changes in the acidity of secreted juice. The effect of *H.pylori* on intragastric  
20 pH after the meal being most evident close to the GEJ may be due to this region being close  
21 to the wall of the stomach.  
22

29  
30  
31  
32  
33  
34  
35  
36

37 Whatever the explanation for the changes in acidity between *H.pylori* positives and  
38 negatives being most marked close to the GEJ, after the meal, the observation is likely to be  
39 important with respect to the propensity of gastroesophageal reflux producing oesophageal  
40 damage. It is well recognised that gastric juice which refluxes into the oesophagus is that  
41 present close to the GEJ and also that reflux most commonly occurs during the postprandial  
42 period when TLESRs are most frequent. [17]  
43  
44  
45  
46  
47  
48  
49

50 The reduction in parietal cell density observed in the *H.pylori* positive subjects was  
51 associated with a similar reduction in chief cell density. This is consistent with the infection  
52 and inflammation causing a loss in gastric glands and also with the previous literature  
53 showing that the development of parietal and chief cells is intimately linked.[18] We did not  
54 measure the secretion of pepsin and other digestive enzymes produced by the chief cells but  
55  
56  
57  
58  
59  
60

1  
2  
3 their reduced density is likely to be associated with reduced secretory capacity after the  
4 meal. Reduction in gastric juice peptic activity has previously been reported in *H.pylori*  
5 infected subjects.[19] The peptic activity of the gastric juice is as important, and arguably  
6 more important than its acidity, with respect to the ability to damage oesophageal mucosa  
7 and therefore the reduction in both specialised cells is likely to represent a substantial  
8 reduction in the damaging capacity of reflux gastric juice in *H.pylori* infected subjects. [20]

60  
There was a reduction in the density of G cells in the antrum of the *H.pylori* positives  
indicating a depletion of antral as well as oxyntic glands. In contrast, G cell density in the  
distal body mucosa of the *H. pylori* positives was higher than in the *H. pylori* negative  
subjects. This can be explained by the distal acid secreting body mucosa, which does not  
have G cells, being replaced by an antral-like mucosa that contains G cells (a process that  
has been called "antralization"). This process can be associated with the development of  
pseudo-pyloric metaplasia, also called spasmolytic polypeptide expressing metaplasia  
(SPEM). [21-24] This is consistent with our observation that the reduction in parietal and  
chief cell densities in *H. pylori* positives was most pronounced in the distal body mucosa.  
Together these findings are likely to represent the previously reported proximal progression  
of the junction between the antrum and body type mucosa leading to shrinkage in the  
surface area of the stomach covered by oxyntic mucosa in *H. pylori* atrophic gastritis. [25]

There are few previous studies assessing gastric secretory function in *H.pylori* infected  
healthy volunteers in the Western world. In a retrospective analysis of 95 healthy, young  
male volunteers (age 19-26 years) Smith et al reported that the 8 seropositive for *H.pylori*  
had similar intragastric acidity to the other 87. [26] In a retrospective analysis of 136 healthy  
volunteers, Peterson et al reported reduced basal acid output but no significant difference in  
gastrin stimulated peak acid output or meal stimulated acid output assessed by intragastric  
titration in *H.pylori* seropositives.[27] In a prospective study of 206 healthy volunteers,  
Feldman et al. in 1996 reported reduced gastrin stimulated peak acid output and reduced  
basal pepsin output in those with *H.pylori* detected histologically in gastric biopsies.[28] In  
1998, our own group reported a reduced acid secretory response to gastrin stimulation in 20

1  
2  
3 *H.pylori* positive versus 24 *H.pylori* negative healthy volunteers.[29] Several studies in the  
4 Japanese population have reported reduced gastric secretory function in *H.pylori* positive  
5 healthy volunteers.[30,31]  
6  
7

8  
9 Our current study differs from previously published studies in a number of important  
10 respects. Firstly, we aimed to study subjects representative of the general population  
11 infected with *H.pylori* rather than asymptomatic healthy volunteers. Secondly, by using  
12 intragastric pH sensors, we avoided the use of non-physiological gastric stimuli, gastric  
13 aspiration or intragastric titration which may not be representative of the subjects usual  
14 gastric functioning. Thirdly, we focused on the middle-aged population rather than young  
15 students as the former is the population in whom reflux disease manifests itself. Finally, and  
16 probably most critically, we employed a technique which allowed us to assess the acidity in  
17 different regions of the stomach and in particular close to the GEJ.  
18  
19  
20  
21  
22  
23  
24  
25  
26

27 Our observation that gastric acidity was reduced most markedly close to the GEJ is  
28 interesting in the light of the previously reported but unexplained observations by Feldman et  
29 al in 1999. They observed that in healthy volunteers, eradication of *H.pylori* did not alter  
30 basal or meal-stimulated gastric acid secretion assessed by intragastric titration but did  
31 result in a 2-3 fold increase in gastroesophageal acid reflux.[32] In the light of our current  
32 study, the observed increase in gastroesophageal acid reflux may have been explained by  
33 the *H.pylori* infection reducing intragastric acidity close to the GEJ.  
34  
35  
36  
37  
38  
39  
40  
41

42 Is our finding of reduced gastric secretory function in the *H.pylori* infected population a  
43 peculiar feature of our West of Scotland population or relevant to the wider Western  
44 community? *H.pylori* induced atrophic gastritis and reduced acid secretory function is  
45 associated with gastric cancer and the prevalence of the two correlates at a population  
46 level.[33] The incidence of gastric cancer in Scotland is 9.7 /100,00py and similar to that of  
47 Western European and North American countries and substantially lower than that of  
48 Eastern European and Far Eastern countries.[34] This would suggest that our findings of  
49 reduced acid secretory function is representative of what is happening in Western countries.

54  
55  
56  
57  
58  
59  
60

1  
2  
3           Though our study demonstrates that the *H.pylori* infected general adult population has  
4 less intragastric acidity than the uninfected population, this association does not necessarily  
5 indicate that the reduced intragastric acidity is caused by the infection. However, causal  
6 association seems highly likely as *H.pylori* gastritis is recognised to cause loss of gastric  
7 glands and impaired secretory function. In addition, the more marked changes in gastric  
8 secretory function in those with the more virulent CagA strain supports it being caused by  
9 the infection. Confirming causality by an intervention study has potential problems as  
10 *H.pylori*-induced loss of gastric glands is generally regarded as being irreversible.  
11  
12

13           In summary, our current study indicates that *H.pylori* infected population volunteers have  
14 reduced intragastric acidity compared to uninfected controls and that this is most marked  
15 close to the GEJ. This observation may explain the negative association between the  
16 infection and GEJ disease and its complications.

**GRANT SUPPORT:**

This study was funded by a grant from NHS Greater Glasgow & Clyde Endowment Fund.

**AUTHOR DISCLOSURES:**

None to declare.

**AUTHOR CONTRIBUTIONS:**

**DRM:** Clinical investigations, manometry, pHmetry, data analysis and drafting manuscript.

**MHD:** Histological assessment, biopsy orientation, data analysis and drafting manuscript.

**AAW:** Recruitment of volunteers and assisting clinical investigations.

**CO:** Technical assistance in histology & scanning of histological slides.

**SAB:** Radiological assessment.

**JJG:** Histological assessment and drafting manuscript.

**KELM:** Conception of original idea, drafting manuscript and overall supervision.

**ABSTRACT**

**Objective:** Gastric acid secretory capacity in different anatomical regions, including the postprandial acid pocket, was assessed in *H. pylori* positive and negative volunteers in a Western population.

**Design:** We studied 31 *H.pylori* positive and 28 *H.pylori* negative volunteers, matched for age, gender and BMI. Jumbo biopsies were taken at 11 pre-determined locations from the gastroesophageal junction and stomach. Combined high resolution pHmetry (12 sensors) and manometry (36 sensors) was performed for 20 minutes fasted and 90 minutes postprandially. The squamocolumnar junction was marked with radio-opaque clips, and visualised radiologically. Biopsies were scored for inflammation and density of parietal, chief and G cells immunohistochemically.

**Results:** Under fasting conditions, the *H.pylori* positives had less intragastric acidity compared to negatives at all sensors >1.1cm distal to the peak lower oesophageal sphincter (LES) pressure ( $p<0.01$ ). Postprandially, intragastric acidity was less in *H.pylori* positives at sensors 2.2, 3.3 and 4.4cm distal to the peak LES pressure ( $p<0.05$ ), but there was no significant differences in more distal sensors. The postprandial acid pocket was thus attenuated in *H.pylori* positives.

The *H.pylori* positives had a lower density of parietal and chief cells compared to *H.pylori* negatives in 10 of the 11 gastric locations ( $p<0.05$ ). 17/31 of the *H.pylori* positives were CagA seropositive and showed a more marked reduction in intragastric acidity and increased mucosal inflammation.

**Conclusion:** In population volunteers, *H.pylori* positives have reduced intragastric acidity which most markedly affects the postprandial acid pocket.

**SUMMARY BOX****WHAT IS ALREADY KNOWN?**

1. There is a negative association between *H. pylori* infection and both gastroesophageal reflux disease and oesophageal adenocarcinoma.
2. The mechanism of this negative association is unclear but might be related to *H. pylori* reducing gastric acidity.
3. The gastric acid which refluxes into the oesophagus originates from the proximal gastric acid pocket.

**NOVEL FINDINGS:**

1. In population volunteers, intragastric acidity was less in those with *H. pylori* infection and this was most marked in the proximal stomach close to the gastroesophageal junction.
2. The density of parietal cells and chief cells was reduced in *H. pylori* positives compared to negatives.
3. The reduction in intragastric acidity and severity of inflammation were more marked in CagA positive versus CagA negative *H. pylori* infected subjects.

**CLINICAL IMPLICATIONS:**

The reduced intragastric acidity close to the gastroesophageal junction in the *H. pylori* infected subjects provides a mechanism for the negative association between the infection and reflux disease and its complications.

## INTRODUCTION

*Helicobacter pylori* (*H.pylori*) is a common bacterial infection of the stomach present in the majority of the world's human population and resulting in varying degrees of inflammation of the underlying gastric mucosa. The infection is acquired in early childhood and usually persists indefinitely unless specifically eradicated. [1]

One of the major medical advances of the past 25 years has been the discovery that this common infection plays an important role in the aetiology of duodenal and gastric ulcers and also of gastric cancer.[2] Eradicating the infection produces a long-term cure for the majority of patients with peptic ulcers unrelated to NSAID therapy. There is also increasing evidence that eradication of the infection reduces the risk of gastric cancer.[3]

An unexplained observation regarding the infection is its negative association with gastroesophageal reflux disease (GERD) and its complications of Barrett's oesophagus and oesophageal adenocarcinoma, with these disorders being less than half as common in infected subjects. [4, 5] It has been postulated that this negative association may represent the gastric infection protecting against these oesophageal disorders. If so, the falling incidence of the infection in the general population might explain the rising incidence of these oesophageal diseases.

One mechanism by which the infection might protect against oesophageal disease is by reducing the ability of the gastric mucosa to secrete acid and pepsin which are the constituents of gastric juice which can induce oesophageal damage. The infection is known to exert varying effects on gastric secretory function. In subjects with duodenal ulcers, the infection produces a non-atrophic gastritis with well-maintained gastric secretory cell mass which secretes increased amounts of acid due to the infection inhibiting the gastrin-mediated negative feedback control of acid secretion.[6] In patients who develop gastric cancer, the infection induces an atrophic gastritis with loss of gastric secretory cells and thus reduced acid secretion. Only approximately 1 in 10 *H.pylori* infected subjects develop complicating ulcer disease or gastric cancer and relatively little is known about the effects of the chronic

1  
2  
3 infection on gastric secretory function in the 90% of infected subjects without these  
4 complications.[7] If the degree of reduction in oesophageal disease in the *H.pylori* infected  
5 population is due to the infection reducing gastric acid secretion, then this suppression of  
6 acid secretion would need to be apparent in the majority of infected subjects.  
7  
8

9  
10  
11 Recent evidence indicates that it is the acidity of the gastric contents close to the  
12 gastroesophageal junction (GEJ), referred to as the acid pocket, which refluxes and causes  
13 oesophageal damage.[8] It is also known that loss of gastric secretory cells due to *H.pylori*-  
14 induced atrophic gastritis does not occur uniformly throughout the stomach but may be more  
15 marked at the periphery of the acid secreting mucosa.[9] In assessing any potential  
16 protective effect of the infection against oesophageal damage, it is important to examine the  
17 structure and secretory function of different anatomical regions of the stomach as well as its  
18 overall secretory capacity.  
19  
20

21  
22 The aim of our study was to assess gastric secretory status in different anatomical regions  
23 of the stomach and in subjects representative of the majority of the *H.pylori* infected  
24 population.  
25  
26

## 27 28 29 30 31 32 33 34 35 **METHODS & MATERIALS**

### 36 37 38 ***Subjects***

39  
40 Study participants were volunteers from the general population of the West of Scotland.  
41 Subjects who were currently taking, or had recently taken, proton pump inhibitors, were  
42 currently using H<sub>2</sub> receptor antagonists or had ever received *H.pylori* eradication therapy  
43 were excluded. Recruitment was by general advertisement and from the NHS Scotland  
44 SHARE database.

## **Study design**

### **Study Day 1: Clinical measurements and Urea breath test**

The presence and severity of any gastrointestinal symptoms was assessed using the Short-Form Leeds Dyspepsia Questionnaire [10] and a medication history was recorded. Measurements of height, weight, waist and hip circumference were taken. Volunteers were tested for *H.pylori* infection by C<sup>14</sup> urea breath test. Fasting serum and plasma samples were stored at -20°C and later tested for *H.pylori* CagA IgG using ELISA (Genesis Diagnostics Ltd, Littleport, UK).

### **Study day 2: Upper gastrointestinal endoscopy**

Volunteers attended after an overnight fast for upper gastrointestinal endoscopy. They were offered topical lidocaine throat spray or conscious sedation with midazolam 1-3mg. Biopsies were taken using large capacity biopsy forceps (Radial Jaw™ 4; Boston Scientific, Hemel Hempstead, UK) with a jaw span of 8mm. Two junctional biopsies were taken perpendicular to the squamocolumnar junction (SCJ), one from lesser and one from greater curve, and targeted to include squamous mucosa at the proximal end. Three further junctional biopsies were taken longitudinally below the SCJ, aiming for end-to-end biopsies starting at 6, 12 and 18mm distal to the SCJ down the lesser curve. In addition, six further gastric biopsies were taken from gastric fundus, mid-body on greater curve, mid-body on lesser curve, distal body on greater curve, incisura angularis and antrum. Finally, two small metal radio-opaque clips were attached to the SCJ using a single use rotatable clip fixing device (QuickClip 2™; Olympus, Southend-on-Sea, UK).

### ***Biopsy specimen processing***

Biopsies were immediately placed onto non-adherent dental wax and oriented flat. More detailed information concerning the two-stage orientation method has been described elsewhere.[11] The specimens were later embedded in agar on the filter paper without

1  
2  
3 further manipulation. Staining was performed with conventional H&E, as well as monoclonal  
4  
5 antibodies to H<sup>+</sup>/K<sup>+</sup>ATPase, pepsinogen I and gastrin.  
6  
7

### 8 9 **Study Day 3: Combined manometry and pH study**

10  
11 The volunteers attended after an overnight fast for combined high resolution manometry  
12  
13 and pH studies. The combined probe was passed pernasally and positioned so that the  
14  
15 most proximal pH sensor was 5cm above the lower oesophageal sphincter (LES), with the  
16  
17 remaining eleven sensors lying across the sphincter and within the proximal stomach. The  
18  
19 relative positions of the 12 sensor pH catheter, 36 sensor manometer and SCJ is shown in  
20  
21 Fig 1. Manometry and pH data were recorded concurrently for a 20 minute fasting period.  
22  
23 Subjects then consumed a standardised meal over ten minutes [400g Waitrose spaghetti  
24  
25 bolognese ready meal and 100ml water (500kcal; 55.2g carbohydrate, 27.8g protein, 17.6g  
26  
27 fat)]. Following this, manometry and pH recordings were continued for a further 90 minutes.  
28  
29 An X-ray was taken before and after the meal to visualise the metal clips at the SCJ.  
30  
31

#### 32 33 *Equipment*

#### 34 35 **High-resolution pHmetry**

36  
37 pH recordings were taken using a high resolution pH catheter (Synectics Medical Ltd,  
38  
39 Enfield, UK). This was a custom-made pH probe composed of 12 antimony pH electrodes  
40  
41 with the most distal electrode situated 5mm from the tip of the catheter, with the other eleven  
42  
43 electrodes 35, 46, 57, 68, 79, 90, 101, 112, 123, 134 and 169mm proximal to the tip. The  
44  
45 probe was calibrated prior to each study using pH buffer solution (Synmed Ltd, Enfield, UK)  
46  
47 at pH 7.01 and pH 1.07. Recordings were captured using Polygram Net software (Synectics  
48  
49 Medical Ltd, Enfield, UK).  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

### High-resolution manometry

Manometry was performed using a high resolution solid-state catheter with 7.5mm spacing between 36 circumferential sensors (Given Imaging, Hamburg, Germany). Calibration was performed prior to each study and In vivo calibration was carried out on a weekly basis and applied to each study to compensate for thermal drift. Recordings were captured with ManoScan 360 high-resolution Manometry System and analysed with ManoView ESO v3.0.1 software (Given Imaging, Hamburg, Germany).

### Combined probe

The manometry and pH catheters were combined using two thin strips of Leukoplast Sleek waterproof tape (BSN Medical, Pinetown, SA) such that manometry sensor 25 was immediately adjacent to pH sensor 3.

### Data analysis

#### Intragastric acid

The 90 minute postprandial period was split into three 30 minute periods for analysis. The median pH for each of the 12 pH sensors was calculated for the twenty minute fasting period and the three 30 minute postprandial periods. Acid exposure at the GEJ was also examined by calculating the % of time pH <4.

#### Manometry

Manometric characteristics were analysed in detail during fasting and the same three postprandial periods. For each two minute period, one inspiratory point and one expiratory point was chosen from the longest period without interference from swallowing, coughing or transient lower oesophageal sphincter relaxations (TLESRs). The mean pressure in inspiration and expiration was calculated for each of the 36 sensors over the twenty minute fasting period and thirty minute postprandial periods. The peak LES pressure was taken as

1  
2  
3 the sensor showing the highest mean pressure. The position of the SCJ was derived from  
4 the position of the metal clips relative to the combined manometry and pH sensors seen on  
5 X-ray.

## 10 **Histopathological Assessment**

### 11 **A. Studies using Conventional H&E:**

12  
13 **Glandular height:** The vertical height of epithelium starting from lamina propria to tip of  
14 gland were measured in 3 well-oriented and representative fields and expressed as “Total  
15 Thickness of Epithelium”. To measure the “Glandular Height”, the same method was limited  
16 to areas of gland containing secretory cells, but not superficial foveolar epithelial cells. All  
17 results were expressed as median (IQR) in mm.  
18  
19

20  
21 **Inflammatory scoring:** The intensity of inflammatory infiltrate by polymorphonuclear (PMN)  
22 and mononuclear (MN) cells was scored semi-quantitatively (0=none; 1=mild; 2=moderate;  
23 3=severe) as recommended in the Updated Sydney Classification of Gastritis [12]. A  
24 combined inflammatory score was calculated as the sum of these two scores. Intestinal  
25 metaplasia (IM) was scored by estimating the proportion of epithelial surface covered by  
26 goblet cells.

### 40 **B. Immunohistochemistry**

41 The oriented biopsies, double embedded in agar and paraffin, were cut in standard 4-  
42 micron thickness and immunostained individually for parietal cell, chief cell and G cells. For  
43 parietal cells, we used a commercial mouse monoclonal anti-H<sup>+</sup>/K<sup>+</sup> ATPase (Ab 2866,  
44 Abcam, Cambridge, UK) diluted at 1:20,000. For Chief cells, a mouse monoclonal anti-  
45 pepsinogen 1 antibody (Ab 50123, Abcam, Cambridge, UK) was used at dilution of 1:4000.  
46 The G cells were stained with anti-gastrin (Ab-16035, Abcam, Cambridge, UK) diluted at  
47 1:200. A Thermo Quanto Detection Kit (TL-125-OHD, Thermo Fisher, UK) was used as  
48 secondary antibody.

### Quantification of Secretory Cells:

To calculate the density of parietal cells, chief cells and G cells, absolute number of stained cells were counted at a magnification of 125X in 3 well-oriented and representative fields (1 mm<sup>2</sup> each) and expressed as mean cell number per 1 mm<sup>2</sup> area in each patient. All selected areas must have had complete glands located in sagittal plane, in which the lamina propria was in bottom and luminal side of epithelium was in top.

### Statistical analysis

All continuous data are expressed as medians and interquartile ranges unless otherwise stated. Comparison of variables between groups was made using the Mann-Whitney *U* test. Biopsy inflammatory scores are presented as crosstabulations and compared using Fisher's exact test. Significance for all statistical tests was set as p value <0.05.

### Ethics

The study protocol was approved by the West of Scotland Ethics Committee and all volunteers provided informed written consent.

## RESULTS

Of the 137 subjects assessed for eligibility for the study, 49 were excluded due to current or recent use of proton pump inhibitor (PPI) therapy (n=9) or history of previous *H.pylori* eradication therapy (n=8) or declining to participate following full explanation of the study protocol (n=32). 88 subjects proceeded to the urea breath test of which 31 were *H.pylori* positive and all of these went on to complete the full study protocol. Of the 57 testing *H.pylori* negative, 28 went on to complete the study due to 1 withdrawing consent after the endoscopy and 28 not being selected to proceed in order to maintain matching of the positive and negative groups with respect to age, gender and body mass index (BMI) (Fig. S1).

1  
2  
3 The 31 *H.pylori* positive and 28 *H.pylori* negative subjects who completed the study were  
4 well matched with respect to age (55 vs 56 years;  $p=0.95$ ), gender (18/31 vs 18/28 males;  
5  $p=0.84$ ) and BMI (26.3 vs 26.8 kg/m<sup>2</sup>;  $p=0.72$ ). There were 7 current smokers in the *H.pylori*  
6 positive group compared to 1 current smoker in the *H.pylori* negative group ( $p=0.035$ ).  
7  
8

9  
10 The median dyspepsia score for *H.pylori* positives was 2.0 (range 0-9) compared to 0  
11 (range 0-3) for the *H.pylori* negative subjects ( $p=0.002$ ). 17/31 (54.8%) of the *H.pylori*  
12 positives were taking no medication compared to 10/29 (35.7%) of the *H.pylori* negative  
13 subjects. The most frequent medications were antihypertensives, statins, antidepressants  
14 and inhalers for asthma. No subject was taking medications known to affect gastric  
15 secretion.  
16  
17

18 At endoscopy, 4 *H.pylori* positive subjects had a hiatus hernia (2-4cm in length), 1 subject  
19 had LA Grade A reflux esophagitis, and one subject had 3cm of Barrett's mucosa. None of  
20 the *H.pylori* negatives had a hiatus hernia, although two subjects had reflux esophagitis (LA  
21 grade A and B).  
22  
23

### 24 **Gastroesophageal Acidity**

25 Under fasting conditions, the *H.pylori* positive subjects had less intragastric acidity  
26 compared to the *H.pylori* negatives at all sensors more than 1.1cm distal to the peak LES  
27 pressure (Table 1). The fall from neutral oesophageal pH to highly acidic intragastric pH  
28 also occurred more abruptly in the *H.pylori* negatives. At the sensor 3.3cm distal to the peak  
29 LES pressure, the median pH in the *H.pylori* negatives had fallen to 2.27 compared to 6.13  
30 in the positives ( $p<0.001$ ). The radio-opaque clips indicated that this pH sensor was 1.8cm  
31 distal to the SCJ.  
32  
33

34 Throughout the three postprandial periods, intragastric acidity was significantly less in the  
35 *H.pylori* positives at the pH sensors placed 2.2, 3.3 and 4.4cm distal to the peak pressure of  
36 the LES but no significant difference was detected by the more distal sensors placed at 5.5  
37 and 6.6cm distal to this reference point (Table 1). These three sensors detecting a

## **Gastric Histopathology**

### **A. Conventional H&E Staining**

#### **Inflammation**

The *H.pylori* positives had a greater combined inflammatory cell infiltrate at each of the 11 biopsy sites compared to the *H.pylori* negatives (Table 3). The increased combined inflammatory cell infiltrate in the *H.pylori* positives consisted of a mixture of PMN cells and MN cells and tended to be more intense close to the SCJ, lesser curve, distal stomach, incisura and antrum compared to the gastric fundus and mid-body ( $p < 0.05$  for each). The *H.pylori* negatives had a MN cell infiltrate limited to the SCJ and also to a lesser extent at the antrum and angularis incisura but its intensity was less than that of the *H.pylori* positives at these sites. There was minimal evidence of PMN cell infiltrate at any location in the *H.pylori* negatives.

#### **Intestinal Metaplasia**

Intestinal metaplasia was identified in 14 of the 31 *H. pylori* positive subjects. In 7 of these it was limited to one or more of the biopsies from mid-body lesser curve, distal body greater curve, incisura angularis and antrum. In 3 of the subjects it was present in at least one of the above sites and also in the biopsies close to the SCJ. In a further 3 it was limited to the region close to the SCJ. In 1 subjects it was present in each biopsy except for one of the biopsies from the SCJ.

Intestinal metaplasia was identified in only four of the 28 *H.pylori* negative subjects. In three of these it was only seen in the biopsies across the SCJ and in the fourth subject it was only seen in the biopsy from the fundus.

#### **Gastric Gland Height**

The height of the gastric secretory glands was significantly reduced in the *H.pylori* positive versus negative subjects throughout the gastric mucosa except for the biopsies taken across the SCJ (Table 4).

## **B. Immunohistochemistry**

### *Parietal and Chief Cell Density:*

The *H.pylori* positives had a significant reduction in density of both parietal and chief cells compared to *H.pylori* negatives, and this was seen at each of the 11 intragastric locations assessed except for the SCJ greater curve where the difference did not achieve statistical significance (Table 4). The degree of reduction was similar for the two cell types.

The depletion of both cells in the *H.pylori* positives versus negatives was more marked in the biopsies taken from the distal gastric mucosa (i.e. antrum, incisura angularis, and distal body greater curve) being reduced by 67-100% compared to that observed in the more central region of the oxyntic mucosa (fundus and mid-body) at 26-35% (Fig. 3). In addition, the length of mucosa extending distal to the SCJ which contained no detectable parietal cells was greater in the *H.pylori* positives versus negatives (1.5mm vs 1.0mm;  $p=0.013$ ). However, the degree of reduction in specialised cell density in the biopsies taken 6mm and 12mm distal to the SCJ (38-47%) was not dissimilar from that observed in the more central oxyntic mucosa (i.e. fundus and mid-body) (26-35%) (Fig. 3).

### **G Cell Density**

The density of G cells was reduced in the antrum of the *H.pylori* positive versus negative subjects [48 (IQR: 31-86) vs. 91 (64-129),  $p<0.001$ ], but the converse was seen with respect to the biopsies taken from the distal body region [0 (IQR: 0-32) vs 0 (0-0),  $p=0.007$ ].

### **Intragastric Acidity and Histology in CagA Positive *H.pylori* Subjects**

Seventeen of the *H.pylori* positives were CagA seropositive and fourteen CagA seronegative. The associations with reduced intragastric acidity in comparison with *H.pylori* negatives was more apparent for the CagA positives being significant for five of the six intragastric sites both fasting and after the meal in the CagA positives but in only two of the six intragastric sites for the CagA negatives and only under fasting conditions (Table 1 – supplement). There was a statistically significant difference between the CagA negative and

1  
2  
3 CagA positives for only two of the six sites during fasting and one of the six sites after the  
4  
5 meal.

6  
7 The CagA positives had a significantly greater combined inflammatory cell infiltrate  
8  
9 evident at three of the eleven biopsy locations (6mm and 18mm distal SCJ, and distal body  
10  
11 greater curve), compared to the CagA negatives (Table 2 – supplement). The reduction in  
12  
13 parietal and chief cell density was significant at each intragastric location for both CagA  
14  
15 positive and negative subjects with no apparent difference between these two groups.  
16  
17

## 18 19 **DISCUSSION**

20  
21 In our volunteers recruited from the general population of the West of Scotland, those  
22  
23 with *H.pylori* infection had less intragastric acidity both under fasting conditions and following  
24  
25 a meal compared to uninfected volunteers matched for age, gender and BMI. In addition,  
26  
27 those with the infection had a reduced density of both acid secreting parietal cells and  
28  
29 pepsin producing chief cells compared to those uninfected. These findings indicate that  
30  
31 *H.pylori* infection within our Western population is associated with a less acidic and  
32  
33 proteolytic intragastric environment.  
34

35  
36 The reduced intragastric acidity in the *H.pylori* positive subjects was apparent throughout  
37  
38 the stomach under fasting conditions. After the meal, however, the reduced acidity in the  
39  
40 *H.pylori* positives was evident within the first few centimetres distal to the GEJ but no  
41  
42 significant difference in acidity was apparent in the main body of the stomach. There was  
43  
44 also evidence of increased acidity after the meal in the *H.pylori* negatives right at the SCJ  
45  
46 junction and extending 2cm above it indicating increased intrasphincteric acid reflux. We  
47  
48 and others have previously reported that the proximal region of the stomach close to the  
49  
50 GEJ largely escapes the buffering effect of ingested food and may remain highly acidic after  
51  
52 a meal.[13,14,15] This phenomenon has been called the acid pocket and is thought to be  
53  
54 important in GERD induced oesophageal damage after a meal when reflux is most common.  
55  
56  
57  
58  
59  
60

1  
2  
3 It is therefore interesting that it is at this region close to the GEJ where the reduced acidity  
4 was most apparent in the *H.pylori* infected subjects.  
5  
6

7 What is the reason for the reduced acidity in the *H.pylori* positives after a meal, being  
8 most marked close to the GEJ? There was no evidence that the depletion in parietal cell  
9 density in the *H.pylori* positives was more pronounced over the few centimetres close to the  
10 GEJ compared to other regions in the stomach. Inflammation may also inhibit gastric  
11 secretory function [16] and this was slightly increased close to the GEJ and also in the distal  
12 stomach compared to the mid-body gastric mucosa. The elevation of intragastric pH  
13 following the meal in the *H.pylori* positives being most marked close to the GEJ may simply  
14 reflect the relative intragastric distribution of gastric juice and ingested food. Following a  
15 meal, the food occupies the centre of the stomach and the secreted gastric juice, the region  
16 close to the stomach wall which secretes it. Impaired acid secretion will elevate the pH of  
17 the gastric juice and this will be most apparent close to the stomach wall. In contrast, the  
18 central region of the stomach will reflect the pH of the food and thus will be relatively  
19 unaffected by changes in the acidity of secreted juice. The effect of *H.pylori* on intragastric  
20 pH after the meal being most evident close to the GEJ may be due to this region being close  
21 to the wall of the stomach.  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36

37 Whatever the explanation for the changes in acidity between *H.pylori* positives and  
38 negatives being most marked close to the GEJ, after the meal, the observation is likely to be  
39 important with respect to the propensity of gastroesophageal reflux producing oesophageal  
40 damage. It is well recognised that gastric juice which refluxes into the oesophagus is that  
41 present close to the GEJ and also that reflux most commonly occurs during the postprandial  
42 period when TLESRs are most frequent. [17]  
43  
44  
45  
46  
47  
48

49 The reduction in parietal cell density observed in the *H.pylori* positive subjects was  
50 associated with a similar reduction in chief cell density. This is consistent with the infection  
51 and inflammation causing a loss in gastric glands and also with the previous literature  
52 showing that the development of parietal and chief cells is intimately linked.[18] We did not  
53 measure the secretion of pepsin and other digestive enzymes produced by the chief cells but  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 their reduced density is likely to be associated with reduced secretory capacity after the  
4 meal. Reduction in gastric juice peptic activity has previously been reported in *H.pylori*  
5 infected subjects.[19] The peptic activity of the gastric juice is as important, and arguably  
6 more important than its acidity, with respect to the ability to damage oesophageal mucosa  
7 and therefore the reduction in both specialised cells is likely to represent a substantial  
8 reduction in the damaging capacity of reflux gastric juice in *H.pylori* infected subjects. [20]  
9

10  
11  
12  
13  
14  
15 There was a reduction in the density of G cells in the antrum of the *H.pylori* positives  
16 indicating a depletion of antral as well as oxyntic glands. In contrast, G cell density in the  
17 distal body mucosa of the *H. pylori* positives was higher than in the *H. pylori* negative  
18 subjects. This can be explained by the distal acid secreting body mucosa, which does not  
19 have G cells, being replaced by an antral-like mucosa that contains G cells (a process that  
20 has been called “antralization”). This process can be associated with the development of  
21 pseudo-pyloric metaplasia, also called spasmolytic polypeptide expressing metaplasia  
22 (SPEM). [21-24] This is consistent with our observation that the reduction in parietal and  
23 chief cell densities in *H. pylori* positives was most pronounced in the distal body mucosa.  
24 Together these findings are likely to represent the previously reported proximal progression  
25 of the junction between the antrum and body type mucosa leading to shrinkage in the  
26 surface area of the stomach covered by oxyntic mucosa in *H. pylori* atrophic gastritis. [25]

38

39  
40 There are few previous studies assessing gastric secretory function in *H.pylori* infected  
41 healthy volunteers in the Western world. In a retrospective analysis of 95 healthy, young  
42 male volunteers (age 19-26 years) Smith et al reported that the 8 seropositive for *H.pylori*  
43 had similar intragastric acidity to the other 87. [26] In a retrospective analysis of 136 healthy  
44 volunteers, Peterson et al reported reduced basal acid output but no significant difference in  
45 gastrin stimulated peak acid output or meal stimulated acid output assessed by intragastric  
46 titration in *H.pylori* seropositives.[27] In a prospective study of 206 healthy volunteers,

1  
2  
3 *H.pylori* positive versus 24 *H.pylori* negative healthy volunteers.[29] Several studies in the  
4 Japanese population have reported reduced gastric secretory function in *H.pylori* positive  
5 healthy volunteers.[30,31]  
6  
7

8  
9 Our current study differs from previously published studies in a number of important  
10 respects. Firstly, we aimed to study subjects representative of the general population  
11 infected with *H.pylori* rather than asymptomatic healthy volunteers. Secondly, by using  
12 intragastric pH sensors, we avoided the use of non-physiological gastric stimuli, gastric  
13 aspiration or intragastric titration which may not be representative of the subjects usual  
14 gastric functioning. Thirdly, we focused on the middle-aged population rather than young  
15 students as the former is the population in whom reflux disease manifests itself. Finally, and  
16 probably most critically, we employed a technique which allowed us to assess the acidity in  
17 different regions of the stomach and in particular close to the GEJ.  
18  
19  
20  
21  
22  
23  
24  
25  
26

27 Our observation that gastric acidity was reduced most markedly close to the GEJ is  
28 interesting in the light of the previously reported but unexplained observations by Feldman et  
29 al in 1999. They observed that in healthy volunteers, eradication of *H.pylori* did not alter  
30 basal or meal-stimulated gastric acid secretion assessed by intragastric titration but did  
31 result in a 2-3 fold increase in gastroesophageal acid reflux.[32] In the light of our current  
32 study, the observed increase in gastroesophageal acid reflux may have been explained by  
33 the *H.pylori* infection reducing intragastric acidity close to the GEJ.  
34  
35  
36  
37  
38  
39  
40  
41

42 Is our finding of reduced gastric secretory function in the *H.pylori* infected population a  
43 peculiar feature of our West of Scotland population or relevant to the wider Western  
44 community? *H.pylori* induced atrophic gastritis and reduced acid secretory function is  
45 associated with gastric cancer and the prevalence of the two correlates at a population  
46 level.[33] The incidence of gastric cancer in Scotland is 9.7 /100,00py and similar to that of  
47 Western European and North American countries and substantially lower than that of  
48 Eastern European and Far Eastern countries.[34] This would suggest that our findings of  
49 reduced acid secretory function is representative of what is happening in Western countries.

55  
56  
57  
58  
59  
60

1  
2  
3        Though our study demonstrates that the *H.pylori* infected general adult population has  
4 less intragastric acidity than the uninfected population, this association does not necessarily  
5 indicate that the reduced intragastric acidity is caused by the infection. However, causal  
6 association seems highly likely as *H.pylori* gastritis is recognised to cause loss of gastric  
7 glands and impaired secretory function. In addition, the more marked changes in gastric  
8 secretory function in those with the more virulent CagA strain supports it being caused by  
9 the infection. Confirming causality by an intervention study has potential problems as  
10 *H.pylori*-induced loss of gastric glands is generally regarded as being irreversible.  
11  
12

13        In summary, our current study indicates that *H.pylori* infected population volunteers have  
14 reduced intragastric acidity compared to uninfected controls and that this is most marked  
15 close to the GEJ. This observation may explain the negative association between the  
16 infection and GEJ disease and its complications.

## FIGURE LEGENDS

**Fig 1.** Schematic diagram of the relative positions of the 12 sensor pH catheter, 36 sensor manometer and SCJ (identified by attached metal clip)

**Fig 2.** Median pH for 0-30 minute period after meal relative to LES and SCJ in *H.pylori* positive (HP+) and negative (HP-) subjects

**Fig 3.** Relative reduction in parietal and chief cell densities at different gastric locations in *H.pylori* infected versus non-infected

**Note:** At the GE junction and distal stomach these cells are reduced by 80% whereas in the mid-body reduction was about 30%. Biopsy locations: **JG:** across SCJ above greater curve; **JL1:** across SCJ above lesser curve; **JL2:** 6mm distal SCJ; **JL3:** 12mm distal SCJ; **JL4:** 18mm distal SCJ; **BG3:** Fundus; **BL:** mid-body lesser curve; **BG2:** mid-body greater curve; **BG1:** distal body greater curve; **IA:** incisura angularis; **Ant:** antrum.

**Supplement Fig 1.** Flow diagram showing progress of study participants through each stage

**GRANT SUPPORT:**

This study was funded by a grant from NHS Greater Glasgow & Clyde Endowment Fund.

**AUTHOR DISCLOSURES:**

None to declare.

**AUTHOR CONTRIBUTIONS:**

**DRM:** Clinical investigations, manometry, pHmetry, data analysis and drafting manuscript.

**MHD:** Histological assessment, biopsy orientation, data analysis and drafting manuscript.

**AAW:** Recruitment of volunteers and assisting clinical investigations.

**CO:** Technical assistance in histology & scanning of histological slides.

**SAB:** Radiological assessment.

**JJG:** Histological assessment and drafting manuscript.

**KELM:** Conception of original idea, drafting manuscript and overall supervision.

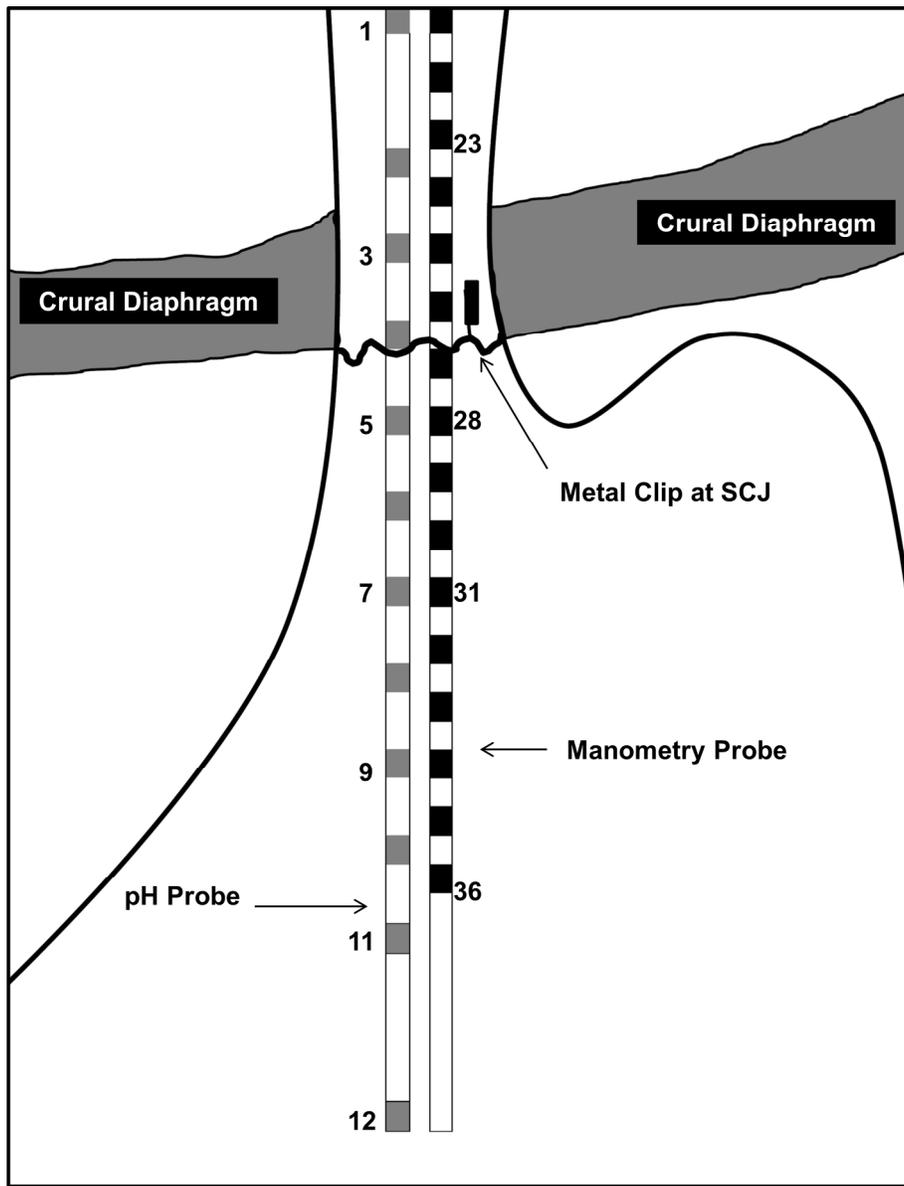

Fig 1. Schematic diagram of the relative positions of the 12 sensor pH catheter, 36 sensor manometer and SCJ (identified by attached metal clip)

175x224mm (300 x 300 DPI)

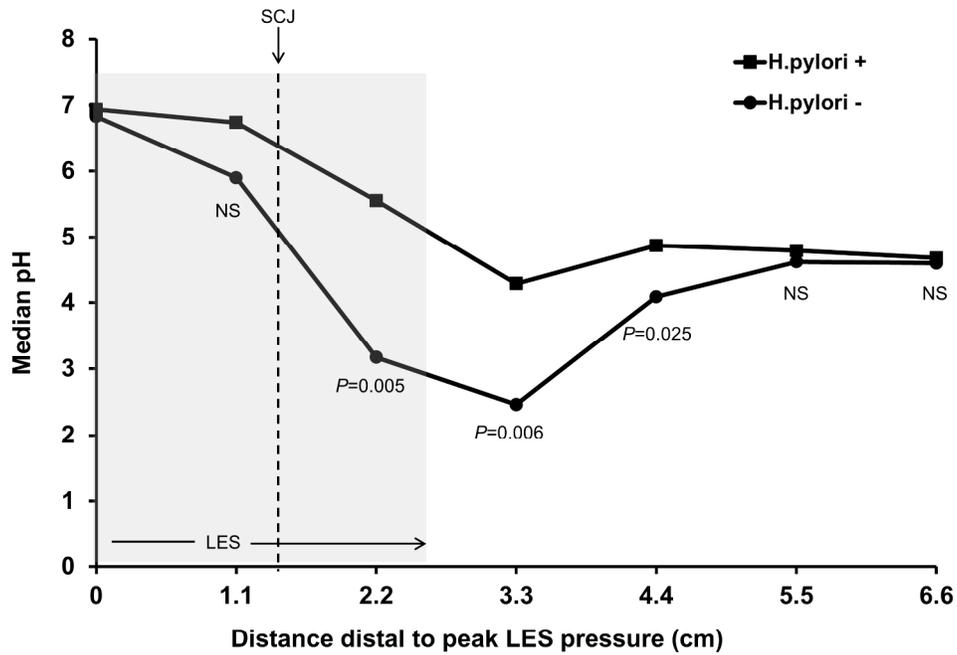

Fig 2. Median pH for 0-30 minute period after meal relative to LES and SCJ in H.pylori positive (HP+) and negative (HP-) subjects

228x176mm (300 x 300 DPI)

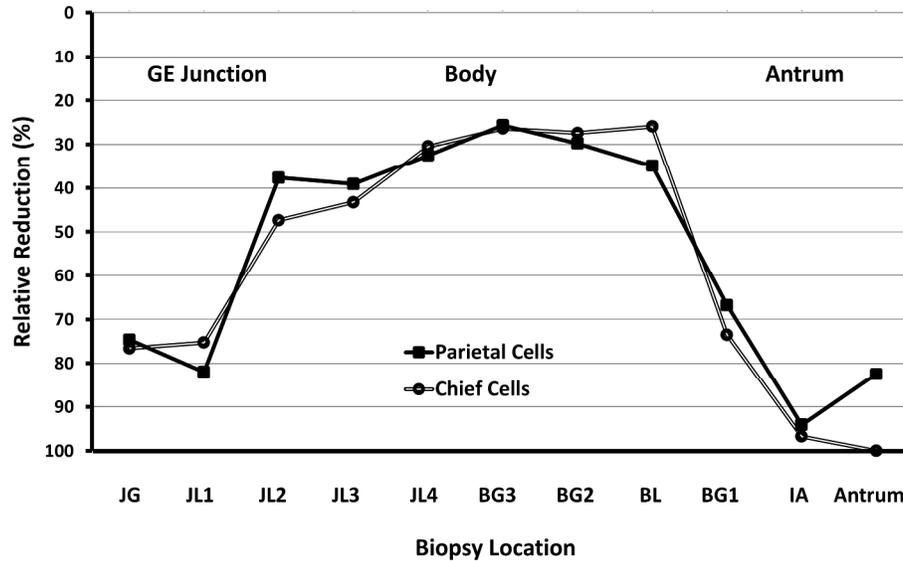

Fig 3. Relative reduction in parietal and chief cell densities at different gastric locations in *H.pylori* infected versus non-infected. Note: At the GE junction and distal stomach these cells are reduced by 80% whereas in the mid-body reduction was about 30%. Biopsy locations: JG: across SCJ above greater curve; JL1: across SCJ above lesser curve; JL2: 6mm distal SCJ; JL3: 12mm distal SCJ; JL4: 18mm distal SCJ; BG3: Fundus; BL: mid-body lesser curve; BG2: mid-body greater curve; BG1: distal body greater curve; IA: incisura angularis; Ant: antrum.

254x190mm (300 x 300 DPI)

**Table S1:** Median (IQR) pH in *H.pylori* negatives (n=28), *H.pylori* positive CagA negatives (n=14) and *H.pylori* positive CagA positives (n=17) during 20 minute fasting and three 30 minute postprandial periods. **Note:** \*Indicates statistically different from *H.pylori* negatives. ‡Indicates statistically different from *H.pylori* positive CagA negatives ( $p < 0.05$ ).
