Universität Bremen

**Strukturelle und funktionelle Analyse
ausgewählter High Mobility Group Gene des
Haushundes**

Dissertation

Zur Erlangung des Grades eines Doktors der
Naturwissenschaften

- Dr. rer. nat -

Dem Promotionsausschuss Dr. rer. nat
im Fachbereich Biologie / Chemie der Universität Bremen

vorgelegt von Jan Thies Soller

1. Gutachter: Prof. Dr. Jörn Bullerdiek
2. Gutachter: Prof. Dr. Ingo Nolte

Hiermit erkläre ich, Jan Thies Soller, geboren am 04.11.1973, dass für das Verfassen der vorliegenden Dissertation „Strukturelle und funktionelle Analyse ausgewählter High Mobility Group Gene des Haushundes“ folgende drei Aussagen zutreffen:

1. Ich habe die Arbeit ohne unerlaubte fremde Hilfe angefertigt.
2. Ich habe keine anderen als die von mir angegebenen Quellen und Hilfsmittel benutzt.
3. Ich habe die den benutzten Werken wörtlich oder inhaltlich entnommenen Stellen als solche kenntlich gemacht.

Bremen, 2010

Jan Thies Soller

“Fast is fine, but accuracy is everything.”

Wyatt Earp

Abkürzungsverzeichnis

aa	Aminoacid (Aminosäure)
AAV	Adeno-assoziiertes Virus
AGER	Advanced Glycosylation End Product-specific Receptor
as	Antisense
AuNP	Goldnanopartikel
AX	Ampicillin-X-Gal
BAC	Bacterial Artificial Chromosome
bp	Basenpaare
BrdU	Bromodeoxyuridin
cDNA	Komplementäre DNA
CDS	Kodierende Sequenz
CFA	canines Chromosom (<i>Canis familiaris</i>)
Contig	Set von zusammenhängenden DNA Sequenzen in einem Alignment
Da	Dalton (1 Da = 1 u atomare Masseneinheit)
DMEM	Dulbecco's Modified Eagle Medium
DNA	Desoxyribonukleinsäure
DNase	Desoxyribonuklease
dNTP(s)	Desoxyribonukleotidtriphosphat(e)
EB	Elutionspuffer
<i>E. coli</i>	<i>Escherichia coli</i>
EDTA	Ethylendiamin-Tetraacetat
et al.	et alia
FKS	Fötales Kälberserum
g	Gramm
h	Stunde
GFP	Grün fluoreszierendes Protein
d _h	Hydrodynamischer Durchmesser
HMG	High mobility group Protein
HMGA	High mobility group Protein A
HMGA1a	High mobility group Protein A1 Isoform a
HMGA1b	High mobility group Protein A1 Isoform b

HMGA1c	High mobility group Protein A1 Isoform c
HMGA2	High mobility group Protein A2
HMGB1	High mobility group Protein B1
HSA	humanes Chromosom (<i>Homo sapiens</i>)
IRES	Interne ribosomale Eintrittsstelle
kb	Kilobasenpaare
kDa	Kilodalton
LacZ	β -Galactosidase
LB	Luria Bertami
M	Molar
MAP	Mitogen-activated Protein
MCS	Multiple Cloning Site
min	Minute
miRNA	micro RNA
μ Ci	Mikrocurie
μ l	Mikroliter
ml	Milliliter
mM	Millimolar
M-MLV	Moloney Murine Leukemia Virus
MMU	murines Chromosom (<i>Mus Musculus</i>)
mRNA	Messenger Ribonukleinsäure
NCBI	National Center for Biotechnology Information
ng	Nanogramm
nm	Nanometer
NOD-Scid	Non-obese Diabetic – Severe Combined Immunodeficiency
ORF	Open Reading Frame
pAAV	AAV-Genom kodierendes Plasmid
PCR	Polymerasekettenreaktion
PBS	Phosphat Buffered Saline (phosphatgepufferte Salzlösung)
rAAV	rekombinantes Adeno-assoziiertes Virion
RACE	Rapid Amplification of cDNA ends
RAGE	Receptor for Advanced Glycation End Products
RNA	Ribonukleinsäure
RNAi	RNA Interferenz

rpm	Rounds per Minute
RT	Raumtemperatur
RT	Reverse Transkriptase
s	Sekunde
SDS	Natriumdodecylsulfat
siRNA	small interfering RNA
SSC	Standard Saline Citrate Buffer
THADA	Thyroid Adenoma associated
u	Unit
UTR	Nichttranslatierte Region
V	Volt
vg	Virusgenom(e)
v/v	Volumen zu Volumen in Prozent
X-Gal	5-Brom-4-Chloro-3-Indolyl-Beta-D-Galactopyranosid
syn.	Synonym

1. Einleitung

In der Tumorgenetik werden viele Experimente zur Erforschung neuer Medikamente und Therapiekonzepte mit Hilfe von Nagetiermodellen entwickelt.

Allerdings hat die Erforschung des Nagetiermodells seine Grenzen, weil Nagetiere eine Physiologie und einen Zellstoffwechsel besitzen, die nicht ohne weiteres mit denen des Menschen vergleichbar sind. Die dadurch gewonnenen Erkenntnisse lassen sich somit nicht uneingeschränkt auf humane Tumorerkrankungen übertragen.

Der Hund gilt schon seit langem als Tiermodell zur Erforschung und Entwicklung von Medikamenten und Therapien in der Humanmedizin. Das Herzkreislauf-, das Nerven-, das Urogenitalsystem und der Bewegungsapparat beider Spezies sind in großen Teilen in ihrer Anatomie und Physiologie sehr ähnlich (Hongo et al. 1997; McMurray et al. 2006; Shelton & Engvall 2005; Ostrander & Giniger 1997). Bei der Entwicklung neuer therapeutischer Ansätze in der Tumorforschung hat sich der Hund gegenüber anderen Tiermodellen bewährt. Insbesondere die Pathogenese humaner und caniner Tumoren sind vergleichbar (Khanna et al. 2006). Am häufigsten treten bei Hunden verschiedene Tumor-Erkrankungen wie Lymphome und Karzinome auf. Es wird geschätzt, dass einer von drei Hunden ab einem Alter von zwei Jahren tödlich an Krebs erkrankt (Withrow & Vail 2007).

Die Gemeinsamkeiten bei der Pathogenese von Tumorerkrankungen zwischen Mensch und Hund umfassen Resistenzen gegen Therapeutika, das Auftreten von Tumor-Rezidiven und Metastasierungsmuster, die in den herkömmlichen Tiermodellen, wie z.B. bei Nagetieren, nicht vergleichend erforscht werden können (Khanna & Hunter 2005).

Zwischen Hunden und Menschen besteht eine enge Lebensgemeinschaft. In den USA leben in 40 % aller Haushalte Hunde, während in Deutschland in 13 % der Haushalte ein Hund gehalten wird. Die Anzahl der Tiere wird in den USA auf bis zu 72 Millionen geschätzt, in Deutschland leben ca. 5 Millionen Hunde (Olson 2007; Ohr & Zeddies 2006). Die Wahrscheinlichkeit einer spontanen Bildung von Tumorerkrankungen beim Hund in seinem natürlichen Lebensraum, d.h. im Lebensumfeld seines Besitzers, steigt mit dem voranschreitenden Lebensalter. Sie leiden häufig an den gleichen Tumorerkrankungen wie sie auch bei Menschen vorkommen. Hunde haben im Vergleich zum Menschen eine etwa doppelt so hohe

Wahrscheinlichkeit an Krebs zu erkranken. Ihr kürzeres Lebensalter macht klinische Studien im Rahmen eines überschaubaren Zeitraums erst möglich (Knapp & Waters 1997).

Die Bereitschaft der Besitzer ist sehr hoch neue therapeutische Ansätze bei ihren erkrankten Hunden anzuwenden, auch im Vorzug gegenüber bereits etablierten aber wenig aussichtsreichen, konventionellen Therapien. Die Ergebnisse neuer Therapien liefern, im Zusammenhang mit klinischen Studien, wertvolle Erkenntnisse für die Zulassung neuer Medikamente und Therapeutika in der Humanmedizin (Paoloni & Khanna 2007).

Herkunft und die Entstehung (Ätiologie) humaner und caniner Tumoren sind vergleichbar. Faktoren wie z.B. Alter, Geschlecht, Ernährung, Größe und Gewicht, hormonelles Gleichgewicht und Umwelteinflüsse wie Schadstoffbelastungen, werden auch bei Hunden als Ursache von Tumorerkrankungen beschrieben (Paoloni & Khanna 2007). Dabei liegen auch häufig genetische Rassen-Prädispositionen vor. An malignen Lymphomen erkranken vorwiegend Golden Retriever; Berner Sennenhunde weisen eine hohe Inzidenzrate auf an einer besonders schweren Form der malignen Histiozytose oder des disseminierten histiozytischen Sarkoms zu erkranken (Olson 2007; Waters & Wildasin 2006; Nolte & Nolte 2001; Abadie et al. 2009).

Jede Hunderasse repräsentiert einen in sich abgegrenzten Genpool. Die gegenwärtig über 400 verschiedenen Hunderassen besitzen eine relativ hohe phänotypische Uniformität mit einem sehr geringen Grad genetischer Heterogenität und Variabilität (Wayne & Ostrander 1999). Zur selektiven Züchtung einer Hunderasse wurde eine kleine Gründerpopulation nahverwandter Individuen verwendet, in der üblicherweise die Inzucht gezielt eingesetzt wurde. Dies führte zur Ausprägung eines engen und isolierten Genpools. Innerhalb der Hundepopulation sind Kreuzungen der einzelnen Rassen häufig, wodurch genetische Prädispositionen für Tumorerkrankungen an die Nachkommen weitervererbt werden. Für die Humangenetik sind genetische Prädispositionen für bestimmte Tumorarten von besonderem Interesse, da sie die Möglichkeit bieten seltene, vererbare Tumorerkrankungen zu erforschen (Kuska 1999; Ostrander & Giniger 1997).

Die Sequenzierung des caninen Genoms im Jahr 2005 bietet die Möglichkeit auf molekular-genetischer Ebene die Pathogenese und das Metastasierungsmuster von Tumoren *in vivo* zu erforschen (Lindblad-Toh et al. 2005). Es stellte sich heraus,

dass die Organisation des caninen Genoms bezüglich der Reihenfolge der Gene auf den verschiedenen Chromosomenabschnitten (Syntenie) von Menschen und Hunden bis zu 95 % identisch sind (Fleischer et al. 2008).

Bereits im Jahre 2000 wurden bei über 370 der beschriebenen caninen Erbkrankheiten genetische Ausprägungen einzelner Genloci oder polygene Faktoren entdeckt, die auch in der menschlichen Population auftreten. Von diesen 370 untersuchten Erbkrankheiten beim Hund zeigen etwa die Hälfte ähnliche klinische Befunde wie sie auch bei humanen Erkrankungen auftreten. Bei über 40 caninen Erkrankungen liegen dieselben homologen Genmutationen vor, die auch bei den humanen Erkrankungen vorliegen (Ostrander et al. 2000; Patterson 2000).

Zuvor etablierte Therapien gegen humane Tumorerkrankungen finden auch in der Veterinärmedizin bei Hunden zahlreiche Anwendungen, wie beispielsweise die Behandlung von malignen Lymphomen mit entsprechenden chemotherapeutischen Protokollen (Withrow & Vail 2007).

Die Erforschung der Tumorbilogie des Prostatakarzinoms bildet in dieser Arbeit einen besonderen Schwerpunkt. In vielen Ländern weltweit ist das Prostatakarzinom bei Männern die häufigste diagnostizierte Tumorerkrankung (Boyle & Levin 2008). Während beim Menschen die Heilungschancen eines nicht-metastasierenden Prostatakarzinoms hoch sind, verläuft die Erkrankung beim Hund in den meisten Fällen tödlich. Außerdem erkranken Rüden eher selten an Prostatakarzinomen. Im Rahmen vergleichender Untersuchungen in der Tumormedizin gehört der Hund, neben den Primaten, zu den wenigen Säugetieren bei denen eine spontane Bildung von Prostatakarzinomen diagnostiziert wird. Eine Ausnahme bilden die spontanen Entwicklungen von Prostata-Tumoren bei speziellen Zuchtstämmen von Ratten beobachtet. Das canine Prostatakarzinom zeigt ein dem Menschen vergleichbares Metastasierungsmuster. Beide Spezies weisen einen ähnlichen anatomischen Aufbau der Prostata auf (Leroy & Northrup 2009; Waters et al. 1998; Nolte & Nolte 2001).

Genomische Charakterisierungen dienen als Ausgangspunkt für funktionelle Analysen von tumorrelevanten Genen. Unter diesen Aspekten werden in dieser Arbeit die caninen Gene der evolutionär stark konservierten HMGA Familie charakterisiert. Weiterführend wird zur Inhibierung der Expression von HMGA Genen in einer caninen Prostatakarzinomzelllinie ein gentherapeutischer Ansatz entwickelt. Zur Aufklärung weiterer tumorrelevanter Gene, wie z.B. *Interleukin-1*,

TNF- α und *RAGE*, werden canine BAC Klone, genomische DNA, RNA und FISH-Analysen verwendet. Diese sind für zukünftige vergleichende Studien im Rahmen einer vergleichenden Onkologie zwischen Mensch und Hund unerlässlich.

Bei vielen humanen Tumoren beobachtet man eine erhöhte Expression von HMGA Proteinen. Im Gegensatz dazu ist die Expression von HMGA in adulten, bereits ausdifferenzierten Zellen gering. Eine Überexpression von HMGA Proteinen geht oft einher mit einer malignen neoplastischen Transformation mit ungünstigen Prognosen für den weiteren Krankheitsverlauf (Fusco & Fedele 2007). Das humane *HMGAI* Gen ist auf dem Chromosom 6 auf der Bande p21 lokalisiert (Johnson et al. 1989; Friedmann et al. 1993). Das verwandte HMGA2 Protein wird durch ein Gen auf Chromosom 12 auf der Bande q14-15 kodiert (Schoenmakers et al. 1995; Wanschura et al. 1995).

Eine stark erhöhte *HMGAI* mRNA Expression wurde bei einer Vielzahl von menschlichen Tumoren gemessen, wie z.B. Mamma-, Cervix-, Schilddrüsen- und Prostata-Tumoren (Flohr et al. 2003; Bandiera et al. 1998; Bussemakers et al. 1991; Chiappetta et al. 1998). Beobachtet wurde eine erhöhte Transkription von *HMGAI* in Karzinomen der Mamma, der Lunge und des Pankreas (Rogalla et al. 1997; Meyer et al. 2007; Abe et al. 2000).

Ein weiteres Protein der HMG Familie, das mit seiner Funktion als architektonischer Transkriptionsfaktor den HMGA Proteinen ähnelt, ist das High Mobility Protein B1 (HMGB1, syn. Amphoterin) (Reeves & Adair 2005). HMGB1 kann aktiv von Monozyten ausgeschüttet werden und wirkt als proinflammatorisches Zytokin (Andersson et al. 2002). Als extrazelluläres Protein ist HMGB1 ein Ligand des Rezeptors RAGE („Receptor for Advanced Glycation Endprodukts“) (Vazzana et al. 2009). RAGE ist auf der Zellmembran lokalisiert und steuert zusammen mit HMGB1 die Aktivierung der Signaltransduktion mit Hilfe von MAP-Kinasen. Es spielt eine wichtige Rolle bei Entzündungsreaktionen, Proliferationen und Metastasierungsprozessen (Rouhiainen et al. 2004). Durch die Applikation von rekombinanten RAGE Proteinen, denen die Cytosol- und Transmembran-Domäne fehlt, konnte die Signaltransduktion inhibiert und das Wachstum von Tumorzellen stark reduziert werden (Taguchi et al. 2000). Dieses RAGE Protein besteht nur aus einer extrazellulären Domäne und wird als trunkeerte, lösliche („soluble“) sRAGE Variante bezeichnet. Beim Menschen konnten bereits viele natürlich existierende sRAGE Varianten nachgewiesen werden. Sie agieren als

kompetitive Inhibitoren des membrangebunden Rezeptors. Eine Störung des Gleichgewichts zwischen membrangebundenen und löslichen RAGE Varianten konnte bei Alzheimer Erkrankung oder rheumatischer Arthritis, sowie verschiedenen Tumoren nachgewiesen werden (Lue et al. 2005; Pullerits et al. 2005; Sparvero et al. 2009). Bei Tumoren wird ein Zusammenhang zwischen einer aberranten Expression des sRAGE und des HMGB1 Proteins bei Chondrosarkomen diskutiert (Takeuchi et al. 2007).

Die aberrante Expression von Zytokinen vor allem Interleukin-1 (IL-1 α and IL-1 β) und des Tumornekrosisfaktor alpha (TNF- α) spielt eine wichtige Rolle bei der Einleitung von Entzündungsreaktionen und der Immunantwort. Basenpaarsubstitutionen innerhalb der Gensequenzen dieser Zytokine wurden bei vielen Krankheiten wie Alzheimer, Parkinson und nicht-kleinzelligen Bronchialkarzinom beschrieben (McGeer & McGeer 2001; Mattila et al. 2002; Zienolddiny et al. 2004). Die humane Langerhans-Zell-Histiozytose zeichnet sich durch eine hohe Produktion von Interleukin-1 und des TNF- α in den Langerhans-Zellen und T-Zellen aus (Arico 2006). Es handelt sich hierbei um eine Autoimmunkrankheit, die durch eine Autophagozytose der Erythrozyten charakterisiert ist. In den betreffenden Organen, wie z.B. Lunge, Leber, Milz und Skelett, treten Neoplasien auf, die in kürzester Zeit in benachbarte Gewebe infiltrieren und metastasieren. Die Krankheit tritt hauptsächlich bei Kindern bis zu einem Alter von drei Jahren, aber auch jungen Erwachsenen auf, und endet meistens tödlich (Egeler et al. 1999; Tazi et al. 1999). Die molekularen Mechanismen der Pathogenese dieser Erkrankung und Therapiekonzepte sind weitestgehend unerforscht (Allen 2008). Die maligne Histiozytose ist bei Berner Sennenhunden eine häufig auftretende Erkrankung. Diese Rasse besitzt eine deutliche Prädisposition zur Ausbildung dieser Tumorerkrankung (Ramsey et al. 1996; Nolte & Nolte 2001). Viele klinische und pathologische Eigenschaften der caninen malignen Histiozytose ähneln der menschlichen Langerhans-Zell-Histiozytose (Affolter & Moore 2002). Zur Aufklärung der molekulargenetischen Pathogenese der humanen Langerhans-Zell-Histiozytose dient somit der Berner Sennenhund als Tiermodell.

Die vorliegende Arbeit gliedert sich in die folgenden inhaltliche Abschnitte:

Der erste Abschnitt behandelt die molekulargenetische Charakterisierung und chromosomale Lokalisation des caninen *HMGAI* Gens, sowie gesamt-genomische und vergleichende Analysen des caninen Gens mit denen anderer Säugetierspezies. Mit Hilfe einer spontan immortalisierten caninen Prostata-Adenokarzinomzelllinie wurde zur Erforschung des caninen Prostatakarzinoms ein Nagetiermodell etabliert. Diese Zelllinie wurde verwendet, um mit deren Hilfe *HMGA* anti-sense kodierende Adeno-assoziierte Viren (AAVs) zu konstruieren. Diese stellen einen gentherapeutischen Ansatz zur Inhibierung der nativen *HMGA* Überexpression dar. Desweiteren wird eine alternative Transfektions-Methode beschrieben, bei der DNA Moleküle mit Hilfe von Gold-Nanopartikeln effizient in Zellen eingebracht wurden.

Der zweite Abschnitt befasst sich mit der molekulargenetischen Charakterisierung des caninen *RAGE* Gens. Dazu wurde in ausgewählten gesunden Geweben sowie in Tumorgeweben die *RAGE* Expression untersucht. Das Verhältnis der Expression von membrangebundenen und löslichen *RAGE* Varianten wurde analysiert. Zudem wurden weitere canine und humane *RAGE* Varianten molekulargenetisch charakterisiert.

Bei vielen Neoplasien beobachtet man häufig eine Überexpression von Zytokinen, deren Folge wiederum zu aberranten Inflammations- und Immunantworten führen.

Der dritte Abschnitt beinhaltet das Screening nach Basenpaarsubstitutionen, den „Single Nucleotide Polymorphisms“, in den kodierenden Regionen der *IL-1* und *TNF- α* cDNA Sequenzen. Es wurden RNAs von verschiedenen Hunderassen isoliert, die unterschiedliche Rassen-Prädispositionen zur Ausprägung der malignen Histiozytose aufweisen. Des Weiteren wurde eine vergleichende Analyse und eine Zusammenstellung der *IL-1*, *TNF- α* Gene und Proteine bei verschiedenen Säugetieren durchgeführt.

2 Material und Methoden

2.1. Entnahme von Gewebeproben

Die canine Gewebekbank war die Grundlage für die Isolierung von RNA und DNA des Haushundes. Sie wurde an der Kleintierklinik der Tierärztlichen Hochschule Hannover entwickelt und aufgebaut. Diverse Gewebearten von verschiedenen Hunderassen wurden unmittelbar während Operationen oder Sektionen gesammelt. Je nach Menge des Ausgangsmaterials wurden ca. 0,5 g bis 2 g Frischgewebe in 2 ml Kryogefäße überführt und sofort in flüssigem Stickstoff (-196°C) eingefroren. Die gesammelten Gewebeproben wurden in einem -80°C Gefrierschrank zur späteren Isolierung von Nukleinsäuren überführt und aufbewahrt.

2.2 Zellkultur und Zelllinien

Die folgenden adhärenenten Zelllinien wurden vom Zentrum für Humangenetik der Universität Bremen für diese Arbeit zur Verfügung gestellt:

Die Zelllinie ZMTH3 wurde aus einer caninen Gewebeprobe eines pleomorphen Adenoms hergestellt. Die ursprünglichen Gewebe der Zelllinien MTH52c und MTH53a waren ein Klein-Zell Karzinom bzw. Mamma Gewebe ohne Befund. Die Zelllinie CT1258 wurde direkt aus dem Gewebe eines caninen Prostata Adenokarzinoms etabliert. Die aufgeführten Zelllinien sind spontan immortalisiert, das bedeutet diese Zellen haben die Fähigkeit erlangt sich unendlich zu teilen, ohne dass diese Eigenschaft künstlich induziert wurde. Die Kultivierung der caninen Zellen erfolgte in 25 cm² Kulturflaschen mit 5 ml Medium 199 supplementiert mit 20 % (v/v) fötalem Kälberserum (FKS) bei 37°C und 5 % CO₂ Atmosphäre.

Für die Produktion der rekombinanten Adeno-Assoziierten- Viren (AAV) wurde die Zelllinie AAV-(HEK)-293 (Stratagene) aus humanen embryonalen Nierenzellen kultiviert. Die Titrierung der rAAV-LacZ Viren erfolgte mit der humanen Fibrosarkom Zelllinie HT1080 (Stratagene). Die Kultivierung der humanen Zelllinien erfolgte in 75 cm² bis 150 cm² Kulturflaschen mit 15 ml bzw. 30 ml DMEM mit 10 % (v/v) FKS (37°C, 5 % CO₂).

2.3 DNA Isolierung und Aufreinigung

2.3.1 Plasmid Präparation aus *E.coli*

Die Isolierung der Plasmid-DNA für Bakteriensuspensions-Kulturen erfolgte nach dem „QIAprep Spin Miniprep Kit“ Protokoll (Qiagen, QIAprep Miniprep Handbook, Seiten 22 bis 23). Die Plasmide wurde nach der Aufreinigung mit 50 µl EB Puffer (10 mM Tris-HCl, pH 8,5) aus der Säule eluiert. Für größere Bakterienkulturen (≥ 250 ml) LB Medium wurde, analog zum „QIAprep Spin Mini Kit“, das Protokoll für „DNA-Purification Using Plasmid Midi and Maxi Kits“ (Qiagen) verwendet (QIAGEN Plasmid Purification Handbook, Seiten 19 bis 23). Das DNA Pellet wurde anschließend in 100 µl bis 500 µl EB Puffer gelöst und die Konzentration photometrisch gemessen.

2.3.2 BAC DNA Präparation

BAC DNA Präparationen wurden mit Hilfe des „QIAGEN Plasmid Maxi Kit“ (QIAGEN) durchgeführt. Zuerst wurde eine Vorkultur in 10 ml LB Medium für 8h bei 37°C im Schüttelschrank (300 rpm) inkubiert. Diese Vorkultur wurde in 500 ml LB Medium gegeben und es erfolgte eine Inkubation des Ansatzes über Nacht im Schüttelschrank bei 37°C. Die anschließende BAC DNA Extraktion erfolgte nach Angaben des Herstellers (QIAGEN Plasmid Purification Handbook, Seiten 47-51, Protocol „Very Low-Copy Plasmid/Cosmid Purification“). Das DNA Pellet wurde in EB Puffer gelöst und die Konzentration und Reinheit bestimmt.

2.3.3 AAV Plasmid Präparation

Zur Herstellung rekombinanter AAVs (Stratagene) wurden die Plasmide pAAV-MCS, pAAV-LacZ und die Plasmide pAAV-Helper und pAAV-RC, welche die Gene für die infektiösen Virionen kodieren, mit Hilfe des „QIAGEN EndoFree Maxi Kit“ (Qiagen) isoliert. Eine Vorkultur wurde selektiv in 5 ml Ampicillin-LB Medium angesetzt und für 6-8 h bei 37°C im Schüttelschrank (300rpm) inkubiert. Anschließend wurden 250 ml Ampicillin-LB Medium mit 500 µl Vorkultur inokuliert und nach dem Hersteller-Protokoll aufgearbeitet (QIAGEN Plasmid Purification Handbook, Seiten 20-23, Protocol EndoFreePlasmid Maxi DNA Purification Using QIAGEN Plasmid Midi and Maxi Kits). Das DNA Pellet wurde

anschließend in 100 µl bis 250 µl TE Puffer (10 mM Tris-HCl, 1 mM EDTA, pH 7,5) gelöst und die photometrisch gemessen.

2.3.4 DNA Isolierung aus Blut und Gewebe

Die Isolierung genomischer DNA erfolgte nach den Angaben des Herstellers (Qiagen, QIAamp DNA Mini Kit). Aus 250 µl EDTA-Vollblut wurde die DNA nach dem „Blood and Body Fluid Spin“ Protokoll, Seiten 27-29, isoliert. Für eine DNA-Isolierung aus Gewebeproben wurde 25 mg frisches oder gefrorenes Gewebe abgewogen, mechanisch zerkleinert und in ATL Puffer und Proteinase K lysiert („Tissue Protocol, Seiten 33-35“). Die DNA aus Zellkultur Proben wurde nach dem Protokoll „Protocol for cultured cells, Seite 49“ isoliert. Mundschleimhaut und Speichelproben („Buccal Swabs“) wurden von den Wattestäbchen in PBS Puffer gelöst und anschließend die DNA nach dem Protokoll „DNA Purification from Buccal Swabs, Seiten 37-39“ aufgereinigt.

2.4 Polymerase Chain Reaction (PCR)

Die Amplifikation der DNA Fragmente erfolgte mit Oligonukleotiden (Primer) entsprechend der Protokolle des Herstellers der Firma Invitrogen (Basic Protocol) oder Promega (GoTaq DNA Polymerase). Die Annealing Temperaturen der Primer variierten gemäß der Nukleotidsequenz der Zielgene, (siehe entsprechende Publikationen). Die PCR Reaktionen wurden in dem Thermoblock T-Gradient (Biometra) durchgeführt. Nach den Angaben des Protokolls „QIAquick Spin Handbook, Seite 18, QIAquick PCR Purification Kit Protocol“ (Qiagen) wurden die PCR-Produkte aufgereinigt.

2.5 Agarose-Gelelektrophorese

Zum Auftrennen der DNA Moleküle wurden abhängig von der zu erwartenden Größe des DNA Amplikons, ein 1,5 % oder 4 % (bei DNA-Molekülen < 300 bp) Agarosegel vorbereitet. Dazu wurde die entsprechende Menge Agarose in 100 ml TAE (40 mM Tris-Acetat, 1mM EDTA, pH 8,0) Puffer bei konstanter Temperatur (bis ca. 100°C) gelöst. Zur Detektion der DNA Banden wurden anschließend 1 µl

Ethidiumbromid (10 mg/ml) in das noch flüssige Agarosegel gegeben. Die Proben wurden mit 6x Farbbeladungspuffer gemischt und in das Gel pipettiert. Die Trennung der DNA Fragmente erfolgte im elektrischen Feld (5 V x Länge der Elektrophoresekammer in cm) in 500 ml TAE Puffer.

2.6 PCR Klonierung

Die PCR Fragmente (Amplikon-Bande) wurden mit einem sterilen Skalpell aus dem Agarosegel (1,5 %) herausgeschnitten und in ein 1,5 ml Reaktionsgefäß überführt. Anschließend erfolgte eine Elution der DNA aus dem Agarosegel mit Hilfe des Protokolls „QIAquick Gel Extraction Kit Protocol using a micro centrifuge“ auf den Seiten 23 - 27 des QIAquick Spin Handbook (Qiagen). Die PCR Fragmente wurden mit Hilfe des Enzyms T₄-DNA Ligase (3 U) in den Vektor „pGEM-T Easy“ nach Angaben des Herstellers (Promega) kloniert. Die Ligations-Reaktion erfolgte mit 4 µl PCR-Eluat und 50 ng Vektor DNA (siehe „Technical Manual, pGEM-T and pGEM-T Easy Vector Systems“, Seite 8: „Protocol for Ligations Using the pGEM-T and pGEM-T Easy Vectors and the 2X Rapid Ligation Buffer“). Anschließend erfolgte eine Transformation des Vektorsystems zur Vervielfältigung der Plasmid DNA in thermokompetente *E. coli* DH5α (Invitrogen).

2.7 Klonierung rekombinanter AAV Expressionsplasmide

Eine PCR zur Amplifikation von *HMGA* Genen wurde mit Adapter-Primern durchgeführt, die am 5' Ende des Oligonukleotids mit einer entsprechenden Erkennungssequenz für eine spezifische Restriktionsendonuklease modifiziert waren. Als Template für die PCR Reaktion diente cDNA. Nach einer Aufreinigung des PCR Produktes (siehe 2.4.) wurden die DNA Fragmente (Inserts) mit den entsprechenden Restriktionsendonukleasen *Bam*HI und *Eco*RI geschnitten. Für das pAAV-MCS Plasmid erfolgte in einem separaten Ansatz eine Restriktionsendonuklease-Reaktion mit den identischen Enzymen. Die gerichtete Ligationsreaktion erfolgte mit Hilfe der T₄-DNA Ligase (Fermentas) nach Angaben des Herstellers: „DNA Insert Ligation into Vector DNA“ (www.fermentas.com/techinfo/). Das molare Verhältnis von Vektor- zu Insert-DNA betrug 1:3. Anschließend wurde eine Transformation der rekombinanten pAAV-*HMGA* antisense Vektoren zur Vervielfältigung der Plasmid DNA in thermokompetente *E. coli* XL10 Gold (Stratagene) durchgeführt.

2.8 Transformation rekombinanter Plasmide in *E. coli*

Die rekombinanten Plasmide (siehe 2.6) wurden in thermokompetente Bakterienzellen transformiert. Dabei wurden *E. coli* DH5 α mit 4 μ l Ligationsansatz nach dem Protokoll von Invitrogen „Library Efficiency DH5 α Competent Cells, Cat. No. 18263-012“, Seiten 1-4 transformiert. 100 μ l bis 250 μ l Bakteriensuspension (in SOC Medium) wurden auf LB-AX-Agar ausplattiert (2 % LB-Medium, 100 μ g/ml Ampicillin und 50 μ g/ml X-Gal) und für 12 h bei 37°C inkubiert. Eine Auswahl geeigneter Klone wurde durch eine „Blue-White“ Kolonie-Selektion ermöglicht. Analog zu dem DH5 α Protokoll erfolgte die Transformation der *E. coli* XL10 Gold Zellen (siehe 2.6) mit Hilfe des Protokolls von Stratagene „XL-10 Gold Ultracompetent Cells“, Seiten 1-2. Es wurden 250 μ l Bakteriensuspension (in NZY⁺ Medium) auf LB-Ampicillin-Agar Platten (2 % LB-Medium, 100 μ g/ml Ampicillin) ausgestrichen.

2.9 DNA Restriktionsendonuklease Verdau

Zum Nachweis einer erfolgreichen Insertion eines DNA Fragments in die verschiedenen Expressions- bzw. Sequenzierungsvektoren wurde ein Restriktionsendonuklease Verdau der Plasmid-DNA angesetzt. Dabei wurde 1 μ g bis 3 μ g photometrisch quantifizierte Plasmid-DNA mit ausgewählten 5 U Enzymen und Puffern nach Protokoll des Herstellers (Invitrogen, Fermentas) über Nacht bei 37°C im Wasserbad inkubiert. Anschließend erfolgte die Auftrennung der geschnittenen Plasmid-DNA in einem 1 %, ethidiumbromidhaltigem Agarosegel (siehe 2.5).

2.10 Sequenzierung und *in silico* Auswertung

Die verschiedenen PCR Amplikons, Vektor Inserts und rekombinante Plasmide wurden von der Fa. MWG-Biotech sequenziert. Es wurden 1,2 μ g DNA-Plasmid oder 20 ng/bp PCR-Fragmente zur Sequenzierung entnommen und versendet. Die *in silico* Auswertung bzw. Sequenzanalyse erfolgte zunächst in den NCBI Datenbanken mit Hilfe des Blast-Programms. Die weitere Analyse und Bearbeitung der DNA Sequenzen, wie z.B. die Generierung von DNA Contigs und von

Homologie-Alignments, erfolgte mit Hilfe der Lasergene-Suite Software 5.0 bis 7.0 (DNAS^tar).

2.11 RNA Isolierung

Canine Gewebep^roben wurden gesammelt und sofort bei -196°C in flüssigem Stickstoff eingefroren (siehe 2.1) und mit einer bestimmten Menge Lysisreagenz (Trizol LS oder RLT Puffer, siehe unten) versetzt und homogenisiert. Für die Isolierung von Gesamt-RNA aus Zellkulturen (z.B. CT1258) wurde das Medium entfernt und mit 1x PBS (ohne Mg²⁺) gewaschen. Das Lysisreagenz wurde direkt auf den Zellmonolayer gegeben und die Zellen wurden durch mehrmaliges Auf- und Abpipettieren homogenisiert.

2.11.1 RNA Isolierung mit Trizol[®] LS

Aus den Kryogefäßen wurden ca. 50 mg bis 100 mg Gewebematerial entnommen und mit 750 µl Trizol[®]-LS-Reagenz (Fa. Invitrogen) versetzt. Im Gegensatz zu Trizol[®] sind bei Trizol[®]-LS die chemischen Komponenten wie Phenol und Guaninthiocyanat höher konzentriert. Mit einem Skalpell wurde die Probe zerkleinert und mit einer Pipettenspitze oder Kanüle (0,9 mm Durchmesser, 2,5 ml Einwegspritze) suspensiert, passiert und homogenisiert. Für die Lysierung von Zellen in Kultur wurden direkt 750 µl Trizol[®]-LS-Reagenz in die Zellkulturflasche gegeben und die Zellen wurden in durch mehrmaliges Auf- und Abpipettieren homogenisiert. Die weitere Aufarbeitung und Isolierung und Aufbereitung der RNA erfolgte nach den Angaben des Herstellers mit Chloroform und Ethanol (Invitrogen, TRIzol[®] LS Reagent Protocol). Nach der Trocknung des RNA Pellets wurde sie in nukleasefreiem Wasser gelöst, die Konzentration der Gesamt-RNA photometrisch bestimmt und die RNA bei -80°C eingefroren.

2.11.2 RNA Isolierung mit RNeasy

Die Isolierung von Gesamt RNA aus Gewebe und Zellkultur erfolgte mit Hilfe der Protokolle „Purification of RNA from Animal Tissues“ (Seiten 39 bis 44) oder „Purification of Total RNA from Animal Cells Using Spin Technology“ (Seiten 25 bis 30) aus dem RNeasy Mini Handbook, 04/2006 (Qiagen). Die Homogenisierung der Gewebep^roben (bis zu 30 mg) erfolgte mit Hilfe des Protokolls „Purification of RNA or Multiple Analytes from Animal and Human Tissues“ (Seiten 10 bis 17) aus dem TissueLyser Handbook (Qiagen). Zellen in Monolayer ($\leq 5 \times 10^6$ Zellen)

wurden zunächst mit 1 ml TrypLE (Gibco) versetzt; nach der Inkubation (1 bis 2 min) wurde das TrypLE mit 1 ml Medium (10 bis 20 % v/v FKS) inaktiviert. Die vereinzelt Zellen wurden in ein 1,5 ml Eppendorfreaktionsgefäß überführt und mit 1x PBS gewaschen. Die Homogenisierung der Zellen erfolgte in der entsprechenden Menge RLT Puffer mit Mercaptoethanol durch die Anwendung von QIAshredder Säulen (Qiagen, Schritt 3a, Seite 29 RNeasy Mini Handbook).

Für größere Gewebemengen und Zellkulturmaterial ($\leq 250\text{mg}$ bzw. $> 5 \times 10^6$ Zellen) wurde die gesamte RNA mit Hilfe des Protokolls „RNeasy Midi/Maxi Protocol for Isolation of Total RNA from Animal Tissues“ (Seiten 41 bis 44) aus dem RNeasy Midi/Maxi Handbook (Qiagen) durchgeführt.

Nach dem ersten Waschschrift wurde auf die Säule eine DNase I / Puffer Lösung (RNase-Free DNase Set, Qiagen) pipettiert (siehe Appendix RNeasy Protokolle), um eine Kontamination der RNA mit genomischer DNA auszuschließen. Die Gesamt-RNA wurde mit nukleasefreiem Wasser eluiert, die Konzentration der RNA photometrisch gemessen und die RNA bei -80°C eingefroren.

2.12 cDNA Synthese

2.12.1 3'RACE cDNA Synthese

Für die Charakterisierung caniner Transkripte wurde für die cDNA Synthese ein 3'RACE Adapter Primer AP2 (AAGGATCCGTCGACATC(T)₁₇) verwendet. Die cDNA Synthese wurde gemäß den Angaben des Herstellers (Invitrogen) mit 5 µg Gesamt-RNA und 200 U Superscript RT durchgeführt, siehe „Superscript Reverse Transcriptase Protocol, review 260903“. Die Inkubation, zum Aufschmelzen potentieller Sekundärstrukturen der RNA, erfolgte bei 65°C für 5 min, die eigentliche Synthese der cDNA erfolgte bei 42°C für 50 min. Für die reverse Transkription langer (> 1000 bp) und GC-reicher Sequenzen wurde die Reaktion mit Trehalose (0,6 M) substituiert. Die Synthese der cDNA erfolgte für 2 min bei 60°C und 2 min 50°C in zehn nacheinander abfolgenden Zyklen. Nach der Erststrang-Synthese wurden 2 U RNase H zu der Probe gegeben (Inkubation bei 37°C für 15 min), um die RNA aus dem DNA/RNA Hybridmolekül enzymatisch abzubauen. Insgesamt wurde 1 µl cDNA Lösung für spätere PCR Reaktionen (siehe 2.4) eingesetzt.

Für die Real-Time PCR (siehe 2.13) wurden 250 ng Gesamt-RNA zusammen mit genspezifischen Primern für die 3'RACE cDNA Synthese eingesetzt. Die Synthese

erfolgte mit dem M-MLV Enzym (Invitrogen) nach den Angaben des „M-MLV Reverse Transcriptase Protocol, review 091002“. Der Reaktionsansatz wurde für 50 min bei 37°C inkubiert.

Die cDNA wurde bis zur weiteren Verwendung bei -20°C gelagert.

2.12.2 5'RACE cDNA Synthese

Zur Charakterisierung der Nukleotide am 5'Ende der mRNA wurde eine 5'RACE cDNA Synthese nach dem Protokoll "5' RACE System for Rapid Amplification of cDNA Ends" handbook, 12/2004" (Invitrogen) durchgeführt. Für die cDNA Synthese wurden genspezifische Primer und das Enzym Superscript RT verwendet.

2.13 Northern Blot

RNA Gelelektrophoresen, der Aufbau der Blotting Apparatur und der Transfer der Gesamt-RNA auf die Hybridisierungsmembran (Nylon TransferMembran Hybond™-N+, Amersham Pharmacia Biotech) wurden nach Angaben des Protokolls von Stratagene des „Northern Transfer Protocol“, Messenger RNA Isolierung Kit, Instruction Manual, Seiten 13 bis 15 durchgeführt. Hybridisierungssonden wurden durch die Amplifikation von cDNA mit genspezifischen Primerpaaren generiert (siehe 2.4 bis 2.6). Anschließend wurden die PCR Produkte in das pGEM-T Easy Vektor System kloniert und sequenziert.

Die aufgereinigte Sonden-DNA (50 ng/μl) wurde mit dem radiaktiven Nukleotid dCTP markiert (Amersham Pharmacia Biotech), welches als α-Phosphat ein Isotop ³²P trägt. Die folgenden Arbeiten zur radioaktiven Markierung der Sonden-DNA wurden mit Hilfe des Random Primed Labeling Kit (Roche) durchgeführt. Nicht eingefügte dNTPs wurden mit Hilfe von Sephadex G-50 Säulen (Amersham Pharmacia Biotech) entfernt.

Die Prähybridisierung der Northern Blot Membran erfolgte mit Hilfe der PERFECTHYB PLUS (Sigma-Aldrich) Lösung für 30 min. Die Hybridisierung der Membran erfolgte für 2,5 h bei 68°C im Hybridisierungs-Ofen unter konstanten Mischbewegungen. Anschließend wurde die Membran für 5 min bei RT in 2x SCC/0,1 % SDS gewaschen. Anschließend erfolgte ein zweiter Waschschrift für 20 min bei 68°C in 0,5x SCC/0,1 % SDS, der einmal wiederholt wurde. Die Auswertung, d.h. die Visualisierung der Nukleotidbanden des Northern-Blots erfolgte im Storm 860 Phosphorimager (Molecular Dynamics).

2.14 Quantitative Real-Time PCR

Nach der RNA Isolierung mit anschließendem DNaseI Verdau wurden pro Ansatz 250 ng RNA in einer cDNA Synthese mit M-MLV Enzym und genspezifischen Primern eingesetzt (siehe 2.12.1). Parallel erfolgte eine Synthesereaktion unter gleichen Bedingungen an einem Oligonukleotid-Standard in definierter Menge und kovalent gebundenen Fluoreszenzfarbstoffen (5'-FAM / 3'-TAMRA). Die eigentliche absolute Real-Time PCR erfolgte mit dem „Applied Biosystems 7300 Real-Time PCR System“ mit „TaqMan Universal PCR Master Mix“ (Applied Biosystem) nach den Angaben des Herstellers. Das PCR Programm bestand aus einer initialen Denaturierung für 10 min bei 95°C, anschließend in 50 Zyklen 15 s bei 95°C und 60 s bei 60°C.

2.14.1 Bestimmung des rAAV Titers

Der genomische rAAV Titer (vg/ml) wurde mit Hilfe einer CMV Promoter spezifischen quantitativen Real-Time PCR bestimmt. Für die folgende Real-Time PCR musste das AAV Virion zunächst aufgebrochen bzw. die ssDNA freigesetzt werden. Es wurden 40 µl aufgereinigtes Virus Eluat (siehe 2.17), 160 µl H₂O und 200 µl NaOH für 30 min bei 56°C inkubiert. Anschließend wurde die Lösung mit 190 µl HCl neutralisiert. Die Probe wurde für die Real-Time PCR 1:100 verdünnt und 3 µl Template wurde in die PCR Reaktion eingesetzt. Zehn Verdünnungen (10¹ bis 10⁶ Moleküle / 3 µl Template) eines universellen AAV Oligonukleotid-Standards wurden parallel in weiteren PCRs eingesetzt. Mit dem bereits verwendeten PCR-System (siehe 2.14) erfolgte anschließend die eigentliche Real-Time PCR (Applied Biosystems, 7300 Real-Time PCR System). Die Amplifikation erfolgte für 2 min bei 50°C, 10 min bei 95°C und weiter für 45 Zyklen mit 15 s bei 95°C und 60 s bei 60°C.

2.15 BAC Screening

Für das BAC-Screening wurden PCR Sonden auf den caninen RPCI-81 BAC/PAC Filter (BACPAC Resources) hybridisiert. Die Sonden wurden mit genspezifischen Primern an caniner DNA amplifiziert. Der PCR Ansatz wurde auf ein 1,5 % Agarosegel aufgetragen. Nach einer Gelelektrophorese wurden die DNA Fragmente

aus der Agarose eluiert (Qiagen, „QIAquick Gel Extraction Kit Protocol using a micro centrifuge“ auf den Seiten 23 - 27 des QIAquick Spin Handbook). Nach der erfolgreichen Klonierung der PCR-Produkte in das pGEM-T Easy Vektor System wurden sie sequenziert. 250 ng Sonden-DNA wurde gemäß des Hersteller Protokolls mit 250 μCi ($\alpha^{32}\text{P}$)dCTP makiert (Roche, Random Primed Labeling Kit). Die Aufreinigung der Sonden DNA erfolgte mit Sephadex G-50 Säulen (siehe auch 2.13). Zur Hybridisierung der Sonde wurde das Protokoll „Hybridisation of High Density Filters“ nach Angaben des Herstellers (BACPAC Resources) durchgeführt. Die BAC-Filter wurden unter Verwendung des Storm 860 Phosphorimager (Molecular Dynamics) ausgewertet.

Der BAC Klon, mit der Sequenz des *THADA* Gens, wurde mit genspezifischen Primern an der „*Canis familiaris* DogBAC library“ (Institute of Animal Genetics, Nutrition and Housing, Universität Bern, Schweiz) detektiert.

Die PCR gescreenten BAC-Klone wurden für das chromosomale Mapping caniner Gene mit Hilfe der Fluoreszenz-*in-situ*-Hybridisierung (FISH) Methode verwendet (siehe 3. Ergebnisse).

2.16 Transfektion rekombinanter Plasmide in eukaryotische Zellen

2.16.1 Fugene HD Transfektion caniner Zelllinien (transient)

Wie im Abschnitt 2.7 wurden eGFP-C1 (Invitrogen) Expressionsvektoren konstruiert, in deren MCS (Multiple Cloning Site) die kodierenden Sequenzen von HMG-GFP Fusionproteine ligiert wurden. Die Transfektion der rekombinanten eGFP-C1-HMG Plasmide erfolgte mit Hilfe der Reagenz Fugene HD (Roche) in canine Zelllinien (z.B. MTH53a) (Protokoll: „FuGENE HD Transfection Reagent 11/2007“). Dazu wurden $2,5 \times 10^4$ Zellen in 1 ml 199er Medium (20 % FKS) ausgesät. Zum Ansetzen der Transfektions-Lösung wurden 2 μg Plasmid und 3 μl Fugene HD in 100 μl serumfreiem Medium verdünnt. Nach einer Inkubation für 15 min bei Raumtemperatur wurde die Transfektions-Lösung auf die Zellen gegeben und der Ansatz für 72 h (37°C, 5 % CO_2) inkubiert. Die Auswertungen der Transfektionseffizienz und die Lokalisation des GFP Fusionsproteins in der Zelle erfolgten durch Fluoreszenzmikroskopie (Carl Zeiss MicroImaging).

2.16.2 Herstellung rekombinanter AAVs (Adeno-assoziierte Viren)

Nach der Konstruktion rekombinanter *HMGA* antisense pAAV Vektoren (siehe 2.7.) erfolgte eine Kalziumphosphat Transfektion der AAV-293 Zellen (siehe Anleitung des Handbuchs von Stratagene „AAV Helper-Free System instruction manuals, 2004“. Es wurde jeweils das pAAV-LacZ (10 µg) oder die verschiedenen antisense Vektoren pAAV-asHMGA (pro Variante 10 µg) zusammen mit den beiden Virusproteinen kodierenden Plasmiden (je 10 µg) pAAV-Helper und pAAV-RC transfiziert (Tabelle 1.1). Nach 72 h wurden die Viren nach Angaben des Herstellers geerntet und der primäre Stock aufgereinigt (siehe 2.17).

Tabelle 1.1 Konstruktion rekombinanter AAVs

Insert	Orientierung	Rekombinanter pAAV Vektor	pAAV-RC	pHelper	Rekombinanter rAAV Virus-Vektor
<i>HMGA2 short</i>	<i>antisense</i>	<i>pAAV-asHMGA2short</i>	+	+	<i>rAAV-asHMGA2short</i>
<i>HMGA2 long</i>	<i>antisense</i>	<i>pAAV-asHMGA2long</i>	+	+	<i>rAAV-asHMGA2long</i>
<i>HMGA1 short</i>	<i>antisense</i>	<i>pAAV-asHMGA1short</i>	+	+	<i>rAAV-asHMGA1short</i>
<i>HMGA1 long</i>	<i>antisense</i>	<i>pAAV-asHMGA1long</i>	+	+	<i>rAAV-asHMGA1long</i>
<i>LacZ ORF</i>	<i>sense</i>	<i>pAAV-LacZ</i>	+	+	<i>rAAV-LacZ</i>

(Modifiziert nach Pöhler 2006; Bünger 2007)

2.17 Aufreinigung des primären AAV Stocks

Die AAV-293 Zellen wurden mit pAAV-asHMGA1 short, pAAV-asHMGA2short sowie mit den langen *HMGA* (Insert > 1000 bp) antisense Plasmiden pAAV-asHMGA1long und pAAV-asHMGA2long wie in Abschnitt 1.16.2 transfiziert. Die konstruierten AAVs enthalten *HMGA1* oder *HMGA2* in langer oder kurzer Variante in antisense Orientierung, sowie das β -Galactosidase Gen (rAAV-LacZ) in sense Orientierung. Die hergestellten Viren wurden sowohl mit ViraKit (Virapur) Filtrationseinheiten und mit ViraTrap Heparin-Agarose-Säulen (Omega Bio-Tek) aufgereinigt.

2.17.1 ViraKit AAV Aufreinigung

Die transfizierten AAV-293 Zellen wurden nach 72 h Inkubation wie im Abschnitt „Preparing Viral Stocks“ des Handbuchs „AAV Helper-Free System instruction manuals, 2004“ von Stratagene geerntet und aufbereitet. Konfluente Zellen von zwölf 75 cm² Kulturflaschen wurden abgeschabt und in 50 ml Zentrifugationsröhrchen überführt. Diese Zellsuspension bildete den primären AAV Stock. Im weiteren Verlauf wurden die Zellen durch mehrmalige Ethanol/Trockeneis- und 37°C Wasserbad-Inkubationen aufgeschlossen („Freeze & Thaw“). Dadurch wurden die rekombinanten AAVs aus den Zellen freigesetzt. Nach einer Zentrifugation (3500 rpm, 30 min) wurde der Überstand mit DNaseI (10 u/ml) bei 37°C, für 30 min inkubiert. Mit Hilfe der Filtrationseinheiten wurde der Überstand aufgereinigt (Protokoll: „ViraKit AAV – Instruction Booklet for Purification Kit, 2005“, Seiten 6 bis 9). Das Virus Eluat konnte für 4 Wochen bei 4°C gelagert werden oder nach Zusatz von Glycerin (10 % v/v) bei -80°C zur permanenten Lagerung eingefroren werden.

2.17.2 ViraTrap Aufreinigung

Nach dem Ablauf der Inkubationszeit zur Herstellung der rekombinanten AAVs wurden die adhärennten Zellen mit 10 ml 1x PBS gewaschen. Anschließend wurden die Zellen von insgesamt 3 bis 4 Zellkulturflaschen abgeschabt und in einem 50 ml Röhrchen gesammelt. Nach einer Zentrifugation (3500 rpm, 15 min) wurde das Pellet in 3 ml ViraTrap-Binding-Puffer resuspendiert und nach Zugabe von 3 µl ViraTrap-Nuclease (Benzoase 25 u/µl) bei 37°C für 1h im Schüttelschrank (≤ 300 rpm) lysiert. Die weitere Aufreinigung erfolgte nach dem Protokoll des Herstellers „ViraTrap AAV (AAV2) Purification Kit“ über vorgefertigte Heparin-Agarose Säulen. Das aufgereinigte Virus-Eluat konnte für längere oder kürzere Zeit gelagert werden (siehe 2.17.1)

2.18 Funktionstest und Titerbestimmung der rAAV-LacZ

Die Funktionalität und Infektiösität der konstruierten rAAVs wurden mit Hilfe des Kontroll- und Titer-Virus rAAV-LacZ getestet. HT1080 Zellen (3×10^5 Zellen) wurden in 12well Mikrotiterplatten ausgesät („AAV Helper-Free System Instruction Manual, 2004“ (Stratagene), Seiten 32 bis 34). Sowohl der Titer des LacZ-Virus des Primär-Stocks, als auch des aufgereinigten Virus (siehe 2.17) wurde nach dem Protokoll des AAV Helper-Free System Handbuchs „Viral Titer Measurement of Recombinant pAAV-LacZ-AAV“, Seiten 36 bis 37 bestimmt. Nach einer Infektion und 24 h langer Inkubation der HT1080 Zellen mit rAAV-LacZ wurden die Zellen wie auf Seite 3 „Staining transfected cells in a tissue culture dish“ des „*In Situ* β -Galactosidase Staining Kit Protokolls (Stratagene) beschrieben, behandelt. Die Inkubation der Staining-Solution erfolgte für 12 h bei 37°C und 5 % CO₂. Abschließend erfolgte die Auswertung am Lichtmikroskop.

2.19 Infektion der CT1258 Zellen mit rAAVs und Proliferationstest

Die canine Prostatakarzinom-Zelllinie CT1258 wurde mit rekombinanten AAVs infiziert, die entweder den β -Galactosidase ORF in sense oder *HMGAI* und *HMGAI2* Transkripte in antisense Orientierung exprimieren. Die Auswirkung einer rAAVs Infektion auf das Proliferationsverhalten der CT1258 Zellen wurde mit dem Kit „Cell Proliferation ELISA, BrdU Kit (colorimetric), Instruction Manual 11/04“ (Roche) gemessen. Es wurden $2,5 \times 10^3$ Zellen pro Well in 96-well Mikrotiterplatten ausgesät (200 μ l Medium 199, 10 % FKS). Nach 2h wurden rAAV-Lösungen verschiedener Konzentrationen von Virusgenomen pro Zelle (vg/Z) in die einzelnen Wells hinzugegeben. Es wurden acht Wells pro Virus-Art, Kombination und Konzentration pipettiert, auf jeweils zwei unterschiedlichen 96-well Platten. Kreuzkontaminationen konnten vermieden werden, indem alle Experimente auf separaten Platten durchgeführt wurden. Als Kontrolle diente der Lösungspuffer ohne Virus. Nach einer Inkubationszeit von ca. 60 h (37°C, 5 % CO₂) wurden 20 μ l BrdU Lösung (Roche) in die jeweiligen Wells hinzu gegeben. Nach einer weiteren 12 h Inkubation erfolgte die Auswertung des Proliferationstests („Cell Proliferation ELISA, BrdU Kit (colorimetric), Instruction Manual 11/04“ (Roche), Seiten 13 bis 14) beschrieben. Die Messung der Absorption erfolgte bei 370 nm / 492 nm im Synergy HT Multiplate Reader (BIO-TEK) alle 5 min, für insgesamt 30 min.

2.20 Statistik

Die statistischen Analysen wurden mit Hilfe eines einfachen ANOVA Test durchgeführt. Dabei wurde die GraphPad Prism Software (GraphPad) verwendet. Zur Darstellung der Signifikanz wurde der p-Wert berechnet. Lagen die Werte ≤ 1 %, wurde die Nullhypothese verworfen und die Ergebnisse wurden als signifikant bewertet.

3. Ergebnisse

3.1 Strukturelle und funktionelle Analyse des caninen *HMGA1*

Dieser Abschnitt beinhaltet die molekulargenetische Charakterisierung der caninen *HMGA* Gene. Mit Hilfe einer rekombinanten *HMGA* antisense AAV Applikation, an einer spontan immortalisierten, caninen Prostata-Adenokarzinom-Zelllinie, sollen neue therapeutische Ansätze zur Inhibierung der endogenen *HMGA* Expression etabliert werden.

3.1.1 The canine *HMGA1*

I. Murua Escobar et al., Gene 2004

Die humanen mRNA Sequenzen des architektonischen Transkriptionsfaktors *HMGA1* bildeten die Grundlage für die Charakterisierung der orthologen caninen *HMGA1* Transkripte. Es wurden von zwölf verschiedenen Hunderassen die Gesamt-RNA aus Testis-Gewebe Proben isoliert. Die isolierten caninen RNAs wurden als Template (Matrize) für eine 3'RACE cDNA Synthese mit einem poly-T-Adapter Primer eingesetzt. Mit Hilfe der humanen *HMGA1* Sequenz wurden Primer für eine PCR hergestellt, die es ermöglichten den gesamten ORF der caninen Sequenz zu amplifizieren, zu klonieren und zu sequenzieren. Nach der Sequenzierung der caninen *HMGA1* Amplikons wurden vergleichende Similaritäts- und Homologie-Studien durchgeführt.

Das gesamte canine *HMGA1* Transkript besteht aus sieben verschiedenen Exons. Im Gegensatz dazu besitzt das humane Transkript acht Exons. Wie auch bei der humanen mRNA sind beide *HMGA1* Spleiß-Varianten vorhanden. Das canine *HMGA1a* besitzt 1836 bp und das *HMGA1b* 1803 bp. Die charakteristischen 33 bp langen „gaps“ der *HMGA1* mRNA, die Deletionen darstellen, sind ebenfalls in der *HMGA1b* mRNA des Hundes nachweisbar. In beiden Spezies sind diese stark konserviert. Die Homologie der vollständigen caninen *HMGA1a* und *HMGA1b* mRNAs zu den humanen *HMGA1* Transkripten zeigt einen Homologie SI Wert von 80,6 %. Unterteilt man den gesamten caninen *HMGA1* ORF in die Regionen 5'UTR, CDS und 3'UTR, betragen die Homologie SI Werte 95,6 %, 95,1 % und 74,7 %. Das canine *HMGA1a* Protein (11,7 kDa) setzt sich aus 107 Aminosäuren

zusammen. Das canine HMGA1b Protein (10,7 kDa) besteht aus 96 Aminosäuren. Die Aminosäure Sequenzen der HMGA1 Proteine beider Spezies sind identisch. Ebenfalls wurden die kodierenden Sequenzen (CDS) von *HMGA1a* und *HMGA1b* von zwölf unterschiedlichen Hunderassen sequenziert und auf mögliche SNPs (Single Nucleotide Polymorphisms) untersucht. In 11 von 12 Rassen sind die HMGA1 Transkripte identisch oder weisen synonyme Basenpaarsubstitutionen auf. Die canine cDNA-Sequenz von *HMGA1b* eines Teckels wies einen SNP auf, der zur Missense-Mutation innerhalb der kodierenden Region im 7. (6.) Exon führte (geänderte Exon-Nummerierung, siehe 3.1.2). Diese Punktmutation wurde exklusiv für die Spleiß-Variante *HMGA1b* beschrieben, denn *HMGA1a* zeigte keine Basenpaarsubstitutionen. Dieses Ergebnis lässt auf eine Heterozygotie beider Allele schließen.

Die *HMGA1* Expressionsanalysen an verschiedenen Gewebeproben zeigten auf, dass das Gen in allen Geweben exprimiert wird. Allerdings zeigten sich im Vergleich zur endogenen Kontrolle *GAPDH* nur schwache Signale.

3.1.2 “Best friends” sharing the *HMGA1* gene: comparison of the human and canine *HMGA1* to orthologous other species.

II. Murua Escobar et al., J Hered. 2005

Die Charakterisierung der caninen HMGA1 Gene und Proteine und ihr Vergleich zu acht weiteren Spezies konnte aufzeigen, dass humane und canine HMGA1 Proteine zu 100 % identisch sind. Es wurden die caninen mRNAs und Protein Sequenzen des Hundes und des Menschen mit denen der anderen Spezies verglichen.

Zudem wurden die verschiedenen *HMGA1* Transkripte aus der NCBI Datenbank in einer Übersichts-Darstellung verglichen. Nur der Hund besitzt eine *HMGA1* Exon Anzahl und Anordnung, die zur humanen Transkript-Organisation identisch ist. Der Mensch besitzt insgesamt sieben verschiedene *HMGA1* Spleißvarianten mit unterschiedlichen Exonkombinationen, die beim Hund fehlen. Die Homologie SIs der caninen *HMGA1* CDS im Vergleich zu den anderen Spezies variiert zwischen 72 % (Huhn) und 95,7 % (Pferd und Schwein). Die abgeleiteten Aminosäure Sequenzen der caninen Proteine variieren zwischen 67,7 % (Huhn) und Rind (99%). Alle untersuchten Spezies weisen die *HMGA1a* und *HMGA1b* Isoformen, den 33 bp Gap und die vier Exons der kodierenden Sequenz auf. Die AT-Hooks von HMGA1 sind bei den untersuchten Spezies hoch konserviert.

3.1.3 Genomic characterisation, chromosomal assignment and in vivo localisation of the canine High Mobility Group A1 (*HMGA1*) gene

III. Beuing et al., *BMC Genet.* 2008

Das Ziel dieser Arbeit war die vollständige Charakterisierung des caninen *HMGA1* Gens. Dabei konnte die genomische Organisation, einschließlich der Grenzen und Längen der Exons und Introns des caninen *HMGA1*, bestimmt werden. Die genomische Struktur des caninen *HMGA1* Gens kann für vergleichende Analysen homologer *HMGA1* Sequenzen des Menschen herangezogen werden. Vergleichende Gen-Analysen können zu wichtigen Erkenntnissen in der Tumorforschung beitragen, da sie auf evolutionär-konservierte Gen- und Protein-Strukturen bzw. -Funktionen hinweisen.

Der Genort des caninen *HMGA1* konnte mit Hilfe einer BAC Sonde und der FISH Methode auf dem caninen Chromosom (CFA) 12 lokalisiert werden. Zudem konnten umfangreiche *in silico* Analysen mit Hilfe des vollständig sequenzierten Genoms des Hundes große Bereiche des caninem *HMGA1* dem CFA 12 zugeordnet werden. Das canine *HMGA1* Gen besteht insgesamt aus sieben Exons und sechs Introns und umspannt eine Sequenzlänge von 9524 bp. Die vergleichenden Homologie SI Werte und Ähnlichkeiten zwischen den humanen und caninen *HMGA1* Genen betragen insgesamt 62,8 %. Im Detail lagen die Homologie SI Werte der Exons beider Spezies zwischen 74,6 % und 97,8 % und die der Introns zwischen 58,9 % und 92,4 %. Es konnte bei den vergleichenden *in silico* Analysen des *HMGA1* aufgezeigt werden, dass der Hund und die Maus kein Exon 4 besitzt. Dadurch ist ein Unterschied beider Spezies in Bezug zur Struktur und Funktion der 5'UTR der mRNA erkennbar. Es wurde deshalb in dieser Arbeit empfohlen die Nomenklatur der caninen Exons und Introns, die bereits in einer vorherigen Publikation (siehe 3.1.1) beschrieben wurde, zu ändern bzw. zu ergänzen. Exon 5 wird folglich als Exon 4 bezeichnet. Aufgrund des sehr hohen GC Gehaltes und einer Vielzahl von „Repeats“ konnten nur 311 bp des caninen Introns 2 sequenziert und beschrieben werden.

Die Transfektion eines *HMGA1a*-GFP Expressionsvektors in canine MTH53a Zellen konnte aufzeigen, dass das Fusionsprotein innerhalb des Zellkerns lokalisiert

ist. Wie auch bei dem humanen HMGA1 Protein, lässt sich daher auch für das canine HMGA1 eine Funktion als architektonischer Transkriptionsfaktor ableiten. Wie bereits in 3.1 beschrieben, wurde bei einer Teckel Probe eine Transition in Folge einer Punktmutation beschrieben. Diese liegt innerhalb der CDS von *HMGA1* und führt zu einem Aminosäureaustausch im Protein. Diese Punktmutation wurde bei 55 Teckeln mit Hilfe eines PCR-Screenings analysiert, um zu klären, ob sich diese Transition innerhalb einer Population manifestiert hat. Es wurden allerdings keine weiteren Punktmutationen innerhalb dieser Teckel Population gefunden.

3.1.4 Expression of the high mobility group A1 (*HMGA1*) and A2 (*HMGA2*) in canine lymphoma: Analysis of 23 cases and comparison to control cases

VI Joetzke et al., Vet Comp Oncol 2010

Die Expression von *HMGA* Genen in caninen hämatopoetischen Tumoren wurde bisher nicht untersucht. In dieser Studie wurden von 23 an Non-Hodgkin Lymphomen erkrankten Hunden und 4 gesunden Hunden Lymphknoten Gewebe gesammelt. Nach der RNA Isolierung wurde die cDNA synthetisiert. Es wurden 19 multizentrische und 4 intestinale B- und T-Zell-Lymphome auf die Gen-Expression von *HMGA1* und *HMGA2* untersucht. Bei multizentrischen Lymphomen sind unterschiedliche Organe betroffen, wie z.B. Lymphknoten, Leber und Milz.

Im Rahmen dieser Arbeit wurde zur relativen Quantifizierung der *HMGA1* und *HMGA2* Transkripte eine quantitative Real-time PCR etabliert. Als endogene Amplifikations-Kontrolle diente die Expression des Haushalts-Gen *β -Glucuronidase* (*GUSB*). In 15 caninen B-Zell Lymphom Proben wurde eine 4,79-fache bis 12,14-fache Überexpression für das *HMGA1* Gen im Vergleich zum endogenen *GUSB* Gens gemessen. Dagegen war in 3 caninen T-Zell Lymphomen eine nur gering erhöhte *HMGA1* Expression nachzuweisen (1,09- bis 1,53-fach).

Die relativen Expressionsraten von *HMGA1* Transkripten innerhalb der multizentrischen Lymphome waren, im Vergleich zu der gesunden Kontrollgruppe, nur gering erhöht (0,94- bis 1,0-fach). Im Gegensatz zur *HMGA1* Expression wurde eine 21,98-fache bis 317,66-fache Überexpression in den T-Zell Lymphomen und bei den B-Zell Lyphomen eine geringe *HMGA2* Expression (0,03- bis 5,33-fach) gemessen.

3.1.5 Establishing an *in vivo* model of canine prostate carcinoma using the new cell line CT1258

IV. Fork et al., BMC Cancer. 2008

In vitro Studien an Zelllinien sind unerlässlich zur Untersuchung der Tumorentstehung in der Prostata. Bisher gab es nur wenige geeignete canine Zelllinien von Prostata-Tumoren, die für Fragestellungen in Bezug zur Pathogenese von Prostata-Tumoren genutzt werden konnten. In dieser Arbeit wurde die canine, spontan immortalisierte Zelllinie CT1258 subkutan und intraperitoneal in 19 immundefiziente NOD-Scid Mäusen injiziert. Dieses Experiment sollte aufzeigen, ob die Zelllinie CT1258 *in vivo* die gleichen Charakteristika in Bezug zur Tumorgenese, Histologie und Metastasierung aufweist, wie das ursprüngliche canine maligne Prostata-Adenokarziom.

Die untersuchten Tumoren bestanden aus einer heterogenen Zell-Population. Die Zellen zeichneten sich durch zahlreiche strukturell unterschiedliche Mitosen aus. Dabei variierte die Form und Größe des Zellkerns (Anisokaryose) oder die Anzahl von verschieden großen Zellkernen (Anisozytosen). Ein ähnlicher histologischer Befund wurde auch für die intraperitoneal induzierten Tumore aufgezeigt. Insgesamt führte die Injektion von CT1258 zu einer massiven Penetration des entstehenden Tumors innerhalb der Bauchhöhle und des Mesenteriums mit ausgeprägter Aszites. Jedoch konnten keine Metastasierungen in den umliegenden Geweben entdeckt werden. In beiden Gruppen von induzierten Tumoren wurden die gleichen Zytogenetischen Marker detektiert wie im Ursprungs-Tumor. Für die *in vivo* Applikation der Zelllinie CT1258 wurde der gleiche histologische, zytologische und zytogenetische Befund erbracht wie zuvor beim ursprünglichen Adenokarziom. Aufgrund dessen eignet sich die Zelllinie CT1258 als Modell für die Erforschung der molekularen Mechanismen zur Pathogenese caniner Prostata-Karzinome.

3.1.6 Application of antisense *HMGA* AAVs suppresses cell proliferation in a canine carcinoma cell line

V Soller et al., in Vorbereitung 2010; (fertiges Manuskript)

In dieser Arbeit wurde ein gentherapeutischer Ansatz entwickelt, der mit Hilfe von Adenoassoziierten Viren (AAV) Vektorkonstrukte in CT1258 Zellen einbringt, welche verschiedene Konstrukte von *HMGA* antisense mRNAs transkribieren. Es wurde die canine Prostatakarzinom-Zelllinie CT1258 (siehe 3.3.4) verwendet, die die Gene *HMGA1a/b* und *HMGA2* stark exprimierten. Mit Hilfe der *HMGA* antisense Vektoren sollte eine Überexpression der sense *HMGA* mRNA in den CT1258 Zellen inhibiert werden. Der Effekt auf das Proliferationsverhalten der transduzierten CT1258 Zellen wurde anschließend untersucht. Zwei verschiedene antisense *HMGA1* und antisense *HMGA2* AAV Vektor-Varianten wurden konstruiert. Parallel wurde ein Kontroll-Virus eingesetzt, welches den ORF des β -*Galactosidase* Gens kodiert. Die Genome der verschiedenen AAV Vektoren (siehe Tabelle 1.1) kodieren entweder kurze („short“) Varianten der *HMGA* mRNA (rAAV-asHMGA1short und rAAV-asHMGA2short) oder lange („long“) Varianten der *HMGA* mRNAs (rAAV-asHMGA1long und rAAV-asHMGA2long). Die kurzen Varianten exprimieren die CDS von *HMGA* in antisense Richtung. Die langen Varianten exprimieren zusätzlich zu der kodierenden Sequenz große Teile der 3'UTR der *HMGA* mRNAs in antisense Orientierung. Das Proliferationsverhalten der CT1258 Zellen wurde nach einer Infektion mit den verschiedenen rAAVasHMGA Varianten und Kombinationen (rAAV-asHMGA1 und rAAV-asHMGA2) ausgewertet. Hierzu wurde mit Hilfe eines Immunoassays der Einbau des Basenanalogen BrdU (Bromdesoxyuridin) in die DNA der Zellen während der S-Phase gemessen. Es konnte gezeigt werden, dass Infektionen mit rAAV-asHMGA Vektoren nach 72h, im Vergleich zur nicht behandelten Kontrolle, zur Proliferationsabnahme in der CT1258 Zell-Population führen. Mit steigendem Virustiter nimmt die Proliferation im Vergleich zur unbehandelten Kontrolle stetig ab. Diese Abnahme wird besonders bei den antisense *HMGA1* AAV Varianten deutlich. Eine Infektion der CT1258 Zellen mit 1×10^4 vg/Zelle und $1,5 \times 10^4$ vg/Zelle rAAV-asHMGA1short Viren, führt zu einer Proliferationsabnahme von 21,6 % (von 55,9 % auf 34,3 %). Eine Infektion mit der gleichen Menge von rAAV-asHMGA1long verringerte die Proliferation um 34,6 % (von 35,4 % auf 0,8 %).

Ebenfalls zeigte sich ein deutlicher Effekt auf die Abnahme der Proliferation der CT1258 Zellen durch eine Kombination beider antisense *HMGA1* und *HMGA2* AAV Vektoren. Eine Infektion mit $1,5 \times 10^4$ vg/Zelle rAAV-LacZ Viren führte ebenfalls zu einem leichten Proliferationsrückgang von CT1258.

Somit wurde gezeigt, dass eine Applikation von AAV Vektoren, die *HMGA* mRNA in antisense Orientierung exprimieren, zur Verringerung der Proliferation in caninen CT1258 Zellen führt.

3.1.7 Co-transfection of plasmid DNA and laser-generated gold nanoparticles does not disturb the bioactivity of GFP-HMGB1 fusion protein.

XV Petersen et al., J Nanobiotechnology 2009

Lasergenerierte AuNPs (AG „JRG Nanoparticles, Research Cluster of Excellence Rebirth“ vom Laserzentrum Hannover e.V.) besitzen eine große Anzahl an positiven Ladungen bzw. eine hohe Elektronen-Akzeptanz. Aufgrund dieser Eigenschaft wurde die Interaktion von AuNPs mit einem Expressionsvektor analysiert, um festzustellen, ob AuNPs die biochemische Funktionalität von Biomolekülen verändern.

Der canine Expressionsvektor eGFP-C1-HMGB1 kodiert für ein rekombinantes GFP-HMGB1 Fusionsprotein. Es wurden jeweils 250 ng AuNP mit 1 µg eGFP-C1-HMGB1 Vektor-DNA für 24h Raumtemperatur in wässriger Lösung inkubiert. Dabei wurden vier verschiedene AuNPs-Suspensionen eingesetzt, deren Nanopartikel unterschiedliche hydrodynamische Durchmesser besaßen ($d_h = 14$ bis 89 nm). Nach Ablauf der Inkubationszeit wurden die unterschiedlichen AuNPs/DNA Lösungen, zusammen mit einem Transfektionsreagenz (FugeneHD, Fa Roche), in die canine MTH53a Zelllinie transfiziert. Nach 48h wurden die transfizierten Zellen mit Hilfe eines Fluoreszenz-Mikroskops ausgewertet. In allen untersuchten Ansätzen konnte erfolgreich nachgewiesen werden, dass die biologischen Eigenschaften des GFP-HMGB1 Fusionsproteins nicht durch lasergenerierte AuNPs beeinträchtigt wurden. Zudem wurde beobachtet, dass eine Inkubation mit den mittleren Au-NPs der Größen $d_h = 24$ nm und 59 nm die

Transfektionseffizienz des eGFP-C1-HMGB1 Vektors, im Vergleich zur Kontrolle ohne AuNPs, um 30 bis 50 % erhöht.

3.2 Die molekulargenetische Charakterisierung des caninen *RAGE* (Receptor for Advanced Glycation End Products)

Im vorherigen Kapitel wurde ein therapeutischer Ansatz zur Inhibierung der HMGA Expression in Tumorzellen sowie die genomische Charakterisierung des caninen *HMGA1* als Tumormarker vorgestellt. Im Folgenden Abschnitt wurde untersucht, inwiefern sich, ausgehend vom Primärtumor, Rückschlüsse auf die molekularen Mechanismen der Metastasierung gezogen werden können. Dazu wurden die genomische Struktur und die Expression des caninen *RAGE* Gens untersucht.

Der Rezeptor für „Advanced Glycation End Products“ *RAGE* (syn. *AGER*) ist ein Multiligand-Rezeptor, der auf der Zellmembran lokalisiert ist. Der Rezeptor interagiert unter anderem mit HMGB1. Als Ligand-Rezeptor-Komplex reguliert *RAGE*/HMGB1 Stoffwechselwege, die in einer Signalkaskade Zell-Wachstum und -Proliferation initiieren. Bei einer Vielzahl von Erkrankungen wird die *RAGE*-HMGB1 (Rezeptor-Ligand) Interaktion eine Schlüsselrolle in der Pathogenese zugeschrieben, wie z.B. der Alzheimer Krankheit, Diabetes, der Tumorangiogenese und Metastasierung.

3.2.1 Cloning and characterization of the canine receptor for advanced glycation end products

VII Murua Escobar & Soller et al., Gene 2006

Zur Charakterisierung des caninen *RAGE* Gens wurde aus caninem Lungengewebe die Gesamt-RNA isoliert. Diese wurde in eine 5' RACE und 3'RACE cDNA Synthese Reaktion eingesetzt und diente anschließend als Templates in verschiedenen PCRs mit Hilfe genspezifischer Primer. Die anschließend klonierten und sequenzierten PCR-Produkte wurden in einem Alignment zu einem Contig zusammengesetzt. Der gesamte ORF des caninen *RAGE* mit 1384 bp konnte konstruiert werden. Die *RAGE* cDNA Sequenz bildete die Grundlage für weitere PCRs zur Aufklärung der vollständigen Exon/Intron Organisation mit insgesamt 11 Exons und 2835 bp. Die Größe der Exons variiert zwischen 27 bp und 254 bp. Die Introns haben eine Länge von 94 bp bis 268 bp.

Die canine *RAGE* mRNA besitzt eine 5'UTR von 18 bp und eine CDS von 1215 bp. Die 3'UTR hat eine Länge von 151 bp und der Homologie-SI Wert der gesamten cDNA zwischen Mensch und Hund beträgt 80,9 %, während die CDS eine Sequenzhomologie von 82,9 % aufweist. Das abgeleitete canine Protein weist eine Übereinstimmung von 77,6 % zwischen beiden Spezies auf. Im Detail die SI-Werte zwischen Mensch und Hund in den funktionellen Domänen von *RAGE*: Extrazelluläre Domäne 78,2 %, Transmembran Domäne 78,9 % und die Cytosol Domäne 72,7 %. Im Northern Blot mit Gesamt-RNA aus verschiedenen caninen Geweben (Testis, Herz, Lunge, Muskel, Niere, Pankreas, Milz und Leber) konnte ausschließlich eine 1,4 kb große Bande in der Lungenprobe detektiert werden. Dieses Expressionsmuster ist homolog zum humanen *RAGE*. Zur Lokalisation bzw. zum Mapping des *RAGE* Gens im caninen Genom wurde eine DNA Sonde auf den caninen RPCI 81 BAC/PAC Filter hybridisiert. Der BAC 339-J10 Klon wurde identifiziert. Ein Teil der BAC-DNA wurde mit Hilfe einer PCR amplifiziert und anschließend durch eine Sequenzierung verifiziert. Die BAC DNA wurde in einem FISH Experiment verwendet, um das canine *RAGE* Gen auf CFA 12 zu lokalisieren.

3.2.2 Cloning, characterisation and comparative quantitative expression analysis of receptor for advanced glycation end products

VIII Sterenczak et al., Gene. 2009

Beim Menschen konnten bisher 19 verschiedene *RAGE* Spleiß-Varianten charakterisiert werden. Eine charakterisierte Spleißvariante kodiert für die s*RAGE* Protein Variante („solubles“ *RAGE*), deren carboxy-terminales Ende trunkiert ist und dadurch nicht in der Zellmembran verankert ist. Dennoch kann sie mit extrazellulären Liganden interagieren.

In dieser Arbeit wurde aus 17 caninen Tumoren, 7 verschiedenen gesunden Gewebeproben (u.a. aus Milz, Leber, Pankreas) und aus 4 caninen und 3 humanen Zelllinien die RNA isoliert. Insgesamt wurden 24 canine und 6 humane *RAGE* Transkripte gefunden. Diese kodieren für 16 verschiedene canine und 5 humane Spleiß-Varianten. Von diesen Transkripten wurden 14 verschiedene canine und 4 verschiedene humane *RAGE* Varianten neu beschrieben.

Demnach lassen sich die *RAGE* Transkripte in zwei verschiedene Gruppen aufteilen:

Die erste Gruppe besteht aus *RAGE* Transkripten, die den vollständigen ORF oder die solublen s*RAGE* Proteine kodieren. Die zweite Gruppe besteht aus Transkripten, die durch alternatives Exons/Intron Spleißen und Intron Insertionen charakterisiert sind und zu „non-sense“ Proteinen translatiert werden. In dieser Gruppe fällt im Besonderen eine *RAGE*-Variante mit einer Intron 1 Insertion (Intron 1 Variante) auf, die sich sowohl in normalen Geweben als auch im Tumoren detektieren lässt.

Real-time PCR Experimente konnten aufzeigen, dass in gesunden Lungen-, Hoden- und Schilddrüsengeweben überwiegend die komplette oder soluble *RAGE* Varianten exprimiert werden. In Tumoren wird dagegen überwiegend die Intron 1 Variante von *RAGE* exprimiert.

3.3 SNP Screening und Homologie Analysen caniner Zytokine

Ein weiterer Faktor der zur Entstehung invasiver Tumoren führen kann ist die durch die neoplastische Erkrankung bedingte Einleitung einer Inflammation (tumor-induzierte Inflammation) in umliegenden Geweben. Eine unkontrollierte Inflammation kann aber auch selbst der Auslöser einer malignen Transformation sein (inflammations-induzierter Tumor). Ein Mechanismus zur Tumorenstehung, oder Proliferation bereits vorhandener neoplastischer Gewebe, ist eine Überexpression von Zytokinen, die durch Zellen des Immunsystems während der Inflammation sezerniert werden. Die Zytokine fördern weitere Zellteilungen und die Bildung von neuen Blutgefäßen (Neoangiogenese).

Die Zytokine Interleukin-1 (IL-1 α und IL-1 β) und der Tumor-Nekrose-Faktor- α (TNF α) werden von Monozyten und Makrophagen sezerniert. Sie spielen eine wichtige Rolle in der Signal-Transduktion zur Einleitung von Entzündungsreaktion und Immunantworten des Körpers. Eine erhöhte Sezernierung von IL-1 α , IL-1 β und TNF α wird bei vielen Krankheiten des Menschen und des Hundes beobachtet, wie z.B. Tumor-, Autoimmun-, Alzheimer- und Parkinson-Erkrankungen sowie Sepsis.

3.3.1 Comparison of the human and canine IL-1 (α/β) and TNF α to orthologous other mammals

X Soller et al., J Hered. 2007

In dieser Arbeit wurden die humanen und caninen Nukleotid- und Aminosäuresequenzen IL-1 (IL-1 α und IL-1 β) und TNF α mit den bekannten Sequenzen anderer Säugetieren, wie z.B. mit denen der Maus, der Ratte, der Katze, des Schweins, des Rindes, des Pferdes und des Schafs, verglichen.

Vergleichende Sequenz-Analysen, d.h. die Berechnung der Homologie SIs, wurden erstellt und die Homologien und evolutionär-konservierte Regionen der Zytokine des Hundes, des Menschen und weiterer Säugetiere in einer Gesamtübersicht dargestellt. Die genomische Organisation, d.h. die Länge und die Anzahl der Exons der beschriebenen Zytokine variiert nur bedingt. Während bei allen untersuchten Säugetieren *IL-1* aus sieben Exons besteht, setzt sich das *TNF α* Transkript aus vier Exons zusammen. Es werden Abweichungen in der Anzahl der Nukleotide der einzelnen Exons zwischen den Arten beobachtet, die sich in unterschiedlichen Längen der kodierenden Sequenzen zeigen. Die vergleichenden Homologie SI der beschriebenen Zytokin CDS in Bezug zum Hund liegen zwischen 43,9 % (Maus, *IL-1 β*) und 93,43 % (Katze, *TNF α*). Bei den Proteinen liegen die Werte zwischen 57,1 % (Maus, *IL-1 β*) bis 94,4 % (Katze, *TNF α*). Auf der Ebene der funktionellen Domänen und Regionen der Proteine von IL-1 und TNF α besteht eine evolutionär-konservierte Homologie innerhalb der Säugetier-Ordnungen. So zeigt sich, dass z.B. die Calpain Erkennungssequenz von IL-1 α bei allen Säugetieren stark konserviert ist. Des Weiteren wurden in dieser Arbeit die Nukleotid-Sequenzen der caninen Zytokine *IL-1* (*IL-1 α* und *IL-1 β*) und *TNF α* vollständig charakterisiert. Die Charakterisierung caniner Zytokine und die vergleichenden Homologie-Analysen innerhalb der Säugetiere zur Darstellung evolutionär-konservierter Gen- und Protein-Regionen, ermöglichen neue Strategien für experimentelle und therapeutische Ansätze.

3.3.2 Cytokine Genes Single Nucleotide Polymorphism (SNP) Screening Analyses in Canine Malignant Histiocytosis

IX Soller et al., Anticancer Res. 2006

Der Hund als Modeltier in der Tumorforschung kann hier zur Erforschung der malignen Histiocytose beitragen, weil der Berner Sennenhund (BSH) eine Rassendisposition für diese Erkrankung aufweist. In dieser Arbeit wurden von 17 verschiedenen Hunden (15 BSHs, ein Collie und ein West Highland Terrier) Gewebeproben der Lunge, Milz, Testis und der Haut gesammelt. Nach der RNA Isolierung folgte die cDNAs Synthese für die Zytokin Transkripte *TNF α* , *Interleukin-1- α* (*IL-1 α*) und *Interleukin-1- β* (*IL-1*). Es erfolgte eine PCR, anschließend wurden die Amplikons in pGEM-T Easy Vektoren kloniert, sequenziert und auf Single Nucleotide Polymorphisms (SNPs) untersucht. Von insgesamt 17 untersuchten Hunden zeigten 8 Zytokin Transkripte Basenpaarsubstitutionen. Diese führen zu Missense Mutationen innerhalb der Aminosäuresequenz der abgeleiteten Proteine *TNF α* , *IL-1 α* und *IL-1 β* . Eine BSH Lungenprobe zeigte eine Punktmutation in *TNF α* Exon 4, Codon 113 die zu einem Aminosäureaustausch führt (GAT \rightarrow GGT, Asp \rightarrow Gly). Für das *IL-1 α* Gen wurde die vollständig kodierende Sequenz (CDS), sowie die alternative Spleiß-Variante *IL-1 α Exon 5 del* amplifiziert. Nach einer Sequenzierung der CDS des *IL-1 α* Gens konnte eine Punktmutation in Exon 3 Codon 23 (TTC \rightarrow TCC, Ser \rightarrow Pro) und Exon 4 Codon 47 (TGC \rightarrow CGC, Cys \rightarrow Arg) nachgewiesen werden.

Innerhalb der Isoform von *IL-1 α Exon 5 del* wurde bei einem West Highland Terrier eine Punktmutation im Exon 4 Codon 43 (CTT \rightarrow CCT, Leu \rightarrow Pro) gefunden. Bei *IL-1 β* Transkripten von drei verschiedenen Leberproben wurden Basenpaarsubstitutionen in den caninen Exons gefunden. In zwei Proben (BSH) wurde je eine Punktmutation in der CDS von Exon 5 Codon 113 (GAT \rightarrow GGT, Asp \rightarrow Gly) bzw. Codon 124 (CAG \rightarrow AAG, Gln \rightarrow Lys) entdeckt. Die dritte Probe (BSH) zeigte zwei Basenpaarsubstitutionen die das Exon 7 betreffen: Codon 228 (TCT \rightarrow CCT, Ser \rightarrow Pro) und Codon 234 (TAC \rightarrow CAC, Tyr \rightarrow His). *In silico* Analysen ergaben, dass die entdeckten Basenpaarsubstitutionen innerhalb der funktionellen Domänen der Zytokine liegen.

3.4 Charakterisierung weiterer caniner Gene

3.4.1 A domain of thyroid adenoma associated gene (THADA) conserved in vertebrates becomes destroyed by chromosomal rearrangements observed in thyroid adenomas

XIII Drieschner et al., Gene 2007

In benignen menschlichen Schilddrüsenadenomen beobachtet man häufig Translokationen in der chromosomalen Region 2p21. Dort wurde das *THADA* Gen (365 kb) mit Hilfe der FISH Analyse lokalisiert. Der Bruchpunkt liegt im Intron 28. Die CDS der *THADA* Variante 1 kodiert für eine abgeleitete Sequenz von 1953 Aminosäuren. Bis auf die COG5543 Domäne konnten keine bekannten Homologien menschlicher Protein-Domänen oder -Regionen nachgewiesen werden. Es handelt sich hierbei um ein Protein Cluster, das bereits bei Pilzen beschrieben wurde. Die Funktion der COG5543 Domäne (COG: „Cluster of Orthologous Groups“) wurde bisher noch nicht aufgeklärt.

In dieser Arbeit wurden die cDNA Sequenzen des *THADA* Gens des Hundes, des Huhns, der Grünen Meerkatze (Altweltaffen) und der Maus sequenziert und charakterisiert sowie die Aminosäuresequenzen *in silico* abgeleitet.

In der evolutionär am höchsten konservierten Protein-Region aller Spezies wurde eine Ähnlichkeit von 78,6 % aufgezeigt, die der menschlichen *THADA* Region von 1033 aa bis 1415 aa entspricht. In dieser Region befindet sich bei allen fünf untersuchten Spezies die hochkonservierte COG5543 Domäne. Weitere Strukturen, die bei allen *THADA* Proteinen der verschiedenen Spezies gefunden wurden, konnten als ARM- Wiederholungsmotive (Arginine Rich Motifs z.B. „Armadillo- und HEAT-Repeats“) identifiziert werden. Diese werden als eine Familie rechtsdrehender Superhelices zusammengefasst. Funktionelle *in silico* Analysen ergaben, dass das *THADA* Protein eine hohe Homologie zum CAND1 Protein (Cullin-Associated Neddylation-Dissociated Protein 1) aufweist (E-value: 0,00025). CAND Proteine besitzen ebenfalls Abfolgen von ARM Motiven.

3.4.2 Chromosomal assignment of canine *THADA* gene to CFA 10q25

XIV Soller et al., Mol Cytogenet 2008

Für die Lokalisation des caninen *THADA* Gens wurden, mit Hilfe der ermittelten („predicted“) caninen *THADA* Sequenz aus der NCBI Datenbank, PCR-Primer hergestellt. Die PCR wurde an caniner DNA etabliert, das PCR Fragment kloniert, sequenziert und verifiziert. Mit Hilfe dieser etablierten PCR wurde die „*Canis familiaris* DogBAC library“ (Institute of Animal Genetics, Nutrition and Housing, Universität Bern, Schweiz) auf das Vorhandensein positiver BAC Klone überprüft. Mit einer zweiten semi-nested PCR wurden diese BAC Klone verifiziert. Der Klon „DogBAC library ID S011P24K05RE“ wurde für ein FISH Mapping verwendet. Das canine *THADA* konnte im Genom des Hundes auf dem Chromosom (CFA) 10 lokalisiert werden. Der canine Genlocus auf Chromosom 10 Bande q25 ist homolog zum menschlichen Chromosom 2 Bande p21.

Der Grund für die Lokalisation des caninen *THADA* war die Fragestellung, ob dieses Gen auch durch homologe Translokations Ereignisse bei Schilddrüsenerkrankungen des Hundes betroffen ist. Diese wurden bereits für die Bruchpunktregion auf Chromosom 2 Bande p21 bei menschlichen Schilddrüsenadenomen beschrieben. In dieser Arbeit wurde nachgewiesen, dass für canine Schilddrüsenadenome das *THADA* Gen nicht durch Translokationen betroffen ist. Abschließend ist darauf hinzuweisen, dass bei Hunden im Vergleich zum Menschen bösartige Erkrankungen der Schilddrüse vorherrschen. Es wird eine wesentlich höhere Anzahl an Karzinomen anstatt Adenomen der Schilddrüse beobachtet. Weitere Analysen könnten aufklären, ob das canine *THADA* als Kandidaten-Gen eine wichtige Rolle bei einer malignen Transformation des caninen Schilddrüsenadenoms spielt.

4. Diskussion

Obwohl die Medizin in den vergangenen Jahrzehnten Fortschritte in der Behandlung und Heilung von Tumorerkrankungen zu verzeichnen hat, ist Krebs nach wie vor die Hauptursache aller Todesfälle. Während in den USA die Todesrate an Herz-Kreislaufkrankungen von 1950 bis 2002 um ca. 40% zurückging, blieb die Anzahl tödlicher Tumorerkrankungen nahezu unverändert (Olson 2007).

Der Hund als Tiermodell kann die bisherigen Forschungen über die genetischen Ursachen der Tumorgenese beim Menschen ergänzen und vervollständigen.

Das Ziel dieser Arbeit ist die strukturelle Charakterisierung und funktionelle Analyse der caninen *HMGA* und weiterer Gene, die auch bei menschlichen Erkrankungen, vor allem in der Tumorgenese eine große Rolle spielen. Im Rahmen des Tiermodells Hund hilft die molekulargenetische Charakterisierung der caninen Gene und Genprodukte die Grundlagen für neue potentielle Therapieansätze zu entwickeln, die zu nützlichen Erkenntnissen in klinischen Studien und zur Entwicklung neuer Medikamente für die Humanmedizin führen.

Die HMGA Proteine sind kleine, chromatin-assoziierte nicht-Histon Proteine, die bei einer Vielzahl von regulativen Prozessen in der Genexpression eine wichtige Rolle als architektonische Transkriptionsfaktoren spielen. Reeves und Beckerbauer beschrieben bereits 2001, dass HMGA Proteine die Transkription von über 45 eukaryotischen und retroviralen Genen regulieren. Sgarra et al. haben in einer umfangreichen elektronischen Datenbank ein molekulares Proteom Netzwerk beschrieben, welches die bekannten HMGA Partner auflistet. Neben der Transkriptionsregulation sind die nativen HMGA- und post-transkriptional modifizierten Proteine (Phosphorylierung, Methylierung und Acetylierung) in der Organisation des Chromatins, der DNA Reparatur, der RNA Prozessierung, sowie der Interaktion mit anderen Enzymen, wie z.B. p53 beteiligt (Sgarra et al. 2009).

Die „High Mobility Group A“ (HMGA) Familie besteht aus vier Proteinen HMGA1a (11,7 kDa), HMGA1b (10,6 kDa), HMGA1c (19,7 kDa) und HMGA2 (12 kDa). Diese Proteine werden durch zwei verschiedene Gene kodiert, wobei das *HMGA1* Gen durch alternatives Spleißen drei verschiedene Protein-Isoformen kodiert (Reeves & Beckerbauer 2001).

4.1 Das canine *HMGA1*

Im Jahr 2004 wurde die canine *HMGA1* mRNA Sequenz vollständig sequenziert, die Exon Organisation aufgeklärt sowie mit den humanen und verschiedenen Nagetier *HMGA1* Sequenzen verglichen (Murua Escobar et al. 2004).

Die kodierende Sequenz (CDS) des caninen *HMGA1* zeigt eine Homologie zu den Exons 5 bis 8 der menschlichen CDS auf. Beide Sequenzen sind auf der Ebene der Nukleotidsequenz zu 95,1 % identisch mit der gleichen Anzahl an Basenpaaren für *HMGA1a* mit 324 bp und *HMGA1b* mit 291 bp. Bei allen untersuchten Hunden konnte die 33 bp Deletion von *HMGA1b* homolog zur humanen *HMGA1b* Sequenz nachgewiesen werden. Damit weisen beide Arten dieselbe *HMGA1b* Spleißvariante auf (Murua Escobar et al. 2004).

Neben der Charakterisierung der caninen mRNA wurden die CDS von *HMGA1a/b* von zwölf verschiedenen Hunderassen auf Punktmutationen untersucht. Eine Teckel-Probe zeigte eine Transition (A→G) in Exon 6, Codon 64.. Diese Punktmutation führt zu einer Missense Mutation (Thr→Ala) außerhalb der AT-Hook Domäne von HMGA1. Zur Evaluation des gefundenen SNP wurde aus 55 Teckel-Proben gesammelt die Region des Exon 6 amplifiziert. Die darauffolgenden Sequenzierungen zeigten, dass keiner der untersuchten Teckel ein Träger dieser Missense Mutation war. Die zuvor in einer Teckel Probe gefundene Basenpaarsubstitution spielt keine größere Rolle in der *HMGA1* Pathogenese (Beuing et al. 2008).

Ein Vergleich der caninen *HMGA1(a/b)* CDS mit sieben verschiedenen kodierenden Regionen von *HMGA1* anderer Säugetiere ergibt, dass die Sequenzen des Schweins (*Sus scrofa*) und des Pferdes (*Equus caballus*) eine leicht höhere Ähnlichkeit zur caninen *HMGA1* CDS als zu der des Menschen aufweist (Murua Escobar et al. 2005). Die SI-Homologie Werte von Hund zu Schwein, bzw. zum Pferd, zeigt eine Ähnlichkeit von 95,7 %. Die SI-Homologie der caninen *HMGA1* Sequenzen zu denen der Nagetiere liegen zwischen 90,1 % bis 92,6 %.

Die SI-Homologien der caninen *HMGA1* CDS zu Nicht-Säugetieren, wie dem Krallenfrosch (*Xenopus laevis*), liegen bei 90,4 % für *HMGA1a* bzw. dem Huhn (*Gallus gallus*) bei 72,0 % für *HMGA1b* (Murua Escobar et al. 2005). In allen Spezies besteht die mRNA aus vier proteinkodierenden Exons. Des Weiteren existiert bei allen Spezies im ersten kodierenden Exon die spezifische 33 bp

Deletion der *HMGAI1b* Spleiß-Variante. Die abgeleiteten Proteinsequenzen besitzen alle 107 Aminosäuren für HMGA1a und 96 Aminosäuren für HMGA1b.

Die Aminosäuresequenzen des Menschen, des Hundes und des Pferdes sind zu 100 % identisch. Trotz höherer Sequenz-Ähnlichkeit auf Nukleotid-Ebene zeigt die Aminosäuresequenz von HMGA1 des Schweins eine SI-Homologie von 99 % zu den humanen und caninen Proteinen. Insgesamt liegt die Sequenzähnlichkeit der abgeleiteten Aminosäuresequenzen von HMGA1a und HMGA1b zwischen 69,7 % (*Gallus gallus*) und 100 % (*Homo sapiens*, *Canis lupus familiaris* und *Equus caballus*). Die SI-Homologie der caninen HMGA1 Proteine zu denen der Nagetiere, wie Maus, Ratte und Hamster liegen zwischen 95,8 % bis 98,1 %. Es zeigt sich, dass die Aminosäuresequenzen der verschiedenen Säugetiere eine höhere Sequenzähnlichkeit zum Krallenfrosch mit 97,2 % aufweisen, als zum Vertreter der evolutionär näher verwandten Vögel, wie dem Huhn mit 69,7 %. Die funktionellen AT-Hooks der HMGA1 Proteine sind evolutionär konserviert, d.h. in diesen Domänen gibt es nur sehr wenige Aminosäure-Austausche zwischen den verschiedenen Arten.

Das canine *HMGAI* Gen besteht aus 7 Exons und 6 Introns und hat eine Anzahl von insgesamt 9524 Basenpaaren. Die Sequenzähnlichkeit des caninen *HMGAI* zum menschlichen Gen hat eine SI-Homologie von 62,8 %. Die SI-Homologien der einzelnen Exons liegen zwischen 74,6 % und 97,8 %, während die der Introns beider Arten zwischen 58,9 % und 92,4 % liegen. *In silico* Analysen mit Sequenzen aus der NCBI Datenbank (AY366395, NW_876254) und sequenzierten PCR Amplikons des BAC Klons MGA572P20K12RG zeigten, dass das orthologe humane Exon 4 beim Hund fehlt.

Erst im Rahmen der vollständigen Sequenzierung des caninen *HMGAI* Gens wurde festgestellt, dass die veröffentlichte canine mRNA Sequenz (NM_001003387) einer neuen Exon Nummerierung bedarf. Da die canine mRNA Sequenz kein Exon besitzt, welches homolog zum menschlichen Exon 4 ist, wurde die bekannte Bezeichnung der caninen Exons geändert. Das im Jahr 2004 bezeichnete canine *HMGAI* Exon 5 wird seit der Charakterisierung des vollständigen caninen *HMGAI* Gens im Rahmen der numerischen Reihenfolge als Exon 4 bezeichnet. Diese Exon 4 Deletion beim Hund ist ebenfalls für die *Hmgal* Sequenz der Maus charakteristisch. Dadurch sind die Strukturen der 5'UTRs des Hundes und der Maus im Vergleich zur menschlichen Sequenz betroffen (Beuing et al. 2008; Murua Escobar et al. 2004;

Friedmann et al. 1993). Jedoch zeigen NCBI Datenbank-Analysen, dass der Mensch insgesamt 7 verschiedene *HMGAI* Spleißvarianten (SPV) besitzt, die allerdings nur für die Protein Isoformen HMGA1a und HMGA1b kodieren (NCBI 2010a). Die Maus besitzt insgesamt 14 *Hmgal* Spleißvarianten, die für insgesamt fünf (*a* bis *e*) verschiedene Protein Isoformen kodieren (NCBI 2010b). Beim Hund konnten bisher die zwei *HMGAI* Spleißvarianten *HMGA1a* und *HMGA1b* beschrieben werden, die für die entsprechenden Protein Isoformen kodieren und direkt zu den SPV 1 (NM_145899.2) und SPV 2 (NM_002131.3) des Menschen homolog sind.

Das menschliche *HMGAI* Gen ist auf dem Chromosom 6 Bande p21 lokalisiert (Friedmann et al. 1993). Innerhalb dieser chromosomalen Region wurden überwiegend 3'-stromabwärts, seltener 5' stromaufwärts des *HMGAI* Genlocus, Bruchpunkte gefunden. Diese führen bei benignen mesenchymalen Tumoren wie z.B. in chondroiden Lungenhamartomen, Polypen der Gebärmutter Schleimhaut, Lipomen, Uterus Leiomyomen (Kazmierczak et al. 1998; Kazmierczak et al. 1999; Williams et al. 1997; Tallini et al. 2000) zu chromosomalen Rearrangierungen. Bei 25 % aller chondroiden Lungenhamartomen findet man innerhalb des *HMGAI* Genlocus (Xiao et al. 1997) aberrante Translokationen. Die chromosomalen Aberrationen innerhalb des *HMGAI* Genlocus gehen einher mit einer Überexpression des HMGA1 Proteins in diesen mesenchymalen Tumoren (Reeves et al. 2001). Das canine *HMGAI* Gen befindet sich auf dem Chromosom 12 (Beuing et al. 2008). Diese Region ist aber nur selten ein Ausgangspunkt für chromosomale Rearrangierungen bei caninen Tumoren (Reimann et al. 1999; Thomas et al. 2007), so dass chromosomale Aberrationen, die den Genlocus des caninen *HMGAI* betreffen, für die Pathogenese caniner Neoplasien nur eine untergeordnete Rolle spielen.

Eine Vielzahl von malignen epithelialen Tumoren ist durch eine Überexpression von *HMGAI* charakterisiert, die nicht als Ursache von chromosomalen Translokationen innerhalb des Gens oder des Promotors erklärt werden können. Eine Überexpression von *HMGAI* wurde in humanen Karzinomen des Pankreas, des Gebärmutterhalses, des Dickdarms, der Schilddrüse, der Leber und der Prostata beobachtet (Abe et al. 2000; Mellone et al. 2008; Huang et al. 2009; Chiappetta et al. 1998; Martinez Hoyos et al. 2009; Chang et al. 2005; Tamimi et al. 1993). Bei Hunden mit B-Zell-Lymphomen konnte eine signifikant erhöhte Expression von *HMGAI* Transkripten beobachtet werden. Dagegen gibt es Hinweise, dass *HMGAI*

bei B-Zell-Lymphomen im Gegensatz zu T-Zell-Lymphomen viel höher exprimiert wird (Joetzke et al. 2010). Lymphome gehören zu den häufigsten Tumoren bei Hunden (MacEwen 1990). Obwohl bereits eine Reihe von prognostischen Markern für maligne Lymphome beim Hund beschrieben wurden wie z.B. histologischer Differenzierungsgrad und Ki-67 Proliferation, stellen sich abschließende Diagnosen zur Einteilung der Schwere bzw. Prognosen über den Verlauf der Erkrankung als weithin ungenau dar. Molekulare Marker wie *HMGAI* könnten zu neuen Erkenntnissen sowohl in der Pathogenese des caninen Lymphoms, als auch in der vergleichenden Onkologie führen.

4.2 Inhibierung der HMGA Transkription

Bereits im Jahr 1995 konnte eine viral induzierte, onkogene Transformation von Ratten Schilddrüsenzellen, mit Hilfe eines *HMGA2* antisense Vektors, unterdrückt werden. Im Vergleich zur unbehandelten Kontrolle wurde die Proliferation der antisense behandelten Tumorzellen stark inhibiert. Northern- und Western-Blots der behandelten Schilddrüsenzellen zeigten im Vergleich zur Kontrolle neben einer starken Abnahme von *HMGA2* Transkripten bzw. Proteinen, auch eine deutliche Reduktion von *HMGAI* Transkripten und Proteinen (Berlingieri et al. 1995).

Fünf Jahre später gelang es der derselben Arbeitsgruppe mit einem adenoviralen *HMGA1* antisense Vektor (Ad-Yas), das Wachstum eines artifiziell induzierten Schilddrüsenkarzinoms bei athymischen Mäusen stark zu reduzieren. Zudem konnte die Apoptose mit Hilfe des rekombinanten Ad-Yas Virus bei Lungen-, Schilddrüsen-, Dickdarm- und Brust-Karzinom-Zelllinien eingeleitet werden. Ein Adenovirus, welches ein LacZ Gen transkribierte, diente als Kontrolle und zeigte keine inhibierende Wirkung auf das Wachstum der Tumorzellen (Scala et al. 2000).

In der vorliegenden Arbeit wurden analog zu den oben beschriebenen Ergebnissen canine AAV *HMGA* antisense Vektoren konstruiert. Die canine Adenokarzinomzelllinie CT1258 wurde mit den rekombinanten antisense *HMGA* Viren infiziert (Soller et al 2010). Die verwendete Zelllinie wurde ursprünglich aus einem stark metastasierenden Adenokarzinom der Prostata etabliert (Winkler et al. 2005). Der originale Tumor und die Zelllinie besitzen eine sehr hohe *HMGA2* Expression. Eine absolute Real-time PCR quantifizierte für das Adenokarzinom $4,2 \times 10^6$ und für die Zelllinie CT1258 $11,9 \times 10^6$ *HMGA2* Transkripte pro 250 ng Gesamt-RNA. Im Vergleich dazu wurden bei nicht-neoplastischen Geweben von

Hunden ca. 1 bis 5×10^2 Transkripte pro 250 ng Gesamt-RNA gemessen (Winkler et al. 2007). Durch die Infektion der Zelllinie mit einer Kombination aus beiden langen AAV HMGA antisense Vektoren (rAAV-asHMGA1long und rAAV-asHMGA2long) konnte die Proliferation im Vergleich zur Kontrolle (gesetzt auf 100 %) auf 1 % verringert werden. Die Applikation der „langen“ AAV HMGA antisense Vektoren führen, im Gegensatz zu den „kurzen“ antisense Varianten, zu einer stärkeren Abnahme der Proliferation. Sie tragen Teile der 3'UTR Regionen der *HMGA* Gene. Die rAAV-asHMGA2long Variante kodiert zusätzlich zur CDS ca. 1000 bp oder 32 % der caninen *HMGA2* 3'UTR (insgesamt 3085 bp) in antisense Orientierung. In diesem Anteil der 3'UTR befindet sich die erste *let-7* Bindungsstelle #1169. Luziferase-Reporter Experimente zeigten, dass durch diese einzelne Bindungsstelle in der 3'UTR die Expression von *HMGA2* um über 50 % reduziert wurde (Lee & Dutta 2007). Die rAAV-asHMGA1long Variante kodiert die vollständige 3'UTR in antisense Orientierung und beinhaltet sowohl die Bindungsstellen für *let-7* als auch für *mir-16* (s.o.). Die Expression der antisense mRNA wird durch die stromaufwärts gelegene CMV Promotor Sequenz des rekombinanten AAV Genoms gesteuert. Die antisense *HMGA* Transkripte lagern sich an den endogenen *HMGA* Transkripten von CT1258 an und formen doppelsträngige RNA Komplexe, wodurch die Translation der nativen *HMGA* mRNAs blockiert wird. Bei der Genregulation, vor allem bei der genomischen Prägung („Imprinting“), spielt die Expression von endogener antisense mRNA bei höheren Eukaryoten eine wichtige Rolle. Bei Menschen und Mäusen existieren stromabwärts des väterlich vererbten *IGF2r* Gens nicht methylierte „CpG-Inseln“, die als Promotorsequenz für die Expression von antisense *IGF2r* RNA funktionieren (Kumar & Carmichael 1998). Ein weiteres Beispiel zeigt die Transkriptionsregulation der Gene für die Synthese des Myosins in Herzmuskelzellen durch antisense *MyHC* RNA (Haddad et al. 2003; Luther et al. 2005). Die besondere Wirksamkeit der langen antisense AAVs könnte durch die Einleitung des RNA-Interferenz Signalweges erklärt werden. Das Dicer Enzym schneidet die dsRNA *HMGA* Moleküle in 20 bis 25 bp große siRNAs, die bedingt durch die vorhandene 3'UTR der antisense Konstrukte, *let-7* bzw. *mir-16* miRNA ähnliche Sequenzeigenschaften haben könnten. Die durch das Dicer Enzym entstehenden doppelsträngigen RNA Oligos (dsRNA) sind vollständig revers-komplementär zu den endogenen *HMGA* Transkripten, so dass sie im Rahmen des

RNAi Stoffwechsels abgebaut werden. Dieser Mechanismus ist auch vergleichbar mit der *in vitro* Synthese und *in vivo* Applikation von esiRNA (endoribonuclease prepared siRNA) (Yang et al. 2002). Tatsächlich konnte bei Säuger-Zelllinien, die durch das RNA-Virus Influenza A infiziert wurden, eine Beteiligung des Dicer Enzyms und des RNAi Stoffwechsels bei der anti-viralen unspezifischen Immunantwort nachgewiesen werden (Matskevich & Moelling 2007).

Die Reduzierung der Proliferation ist deutlich abhängig vom infektiösen Titer, d.h. je höher die Konzentration an Virusgenomen pro Zelle (vg/Z), desto stärker ist die Abnahme der Proliferation. Des Weiteren zeigen die *HMGAI* antisense AAVs im Vergleich zu den *HMGAI2* antisense Vektoren eine höhere Inhibition des Zellwachstums der CT1258. Der rekombinante AAV-as*HMGAI1*long Vektor führte zu einer Reduktion der Proliferation auf bis zu 0,8 % ($1,5 \times 10^4$ vg/Zelle) im Vergleich dazu AAV-as*HMGAI2*long 20,3 % ($1,5 \times 10^4$ vg/Zelle).

Eine Überexpression von *HMGAI* wurde zuvor bei menschlichen Prostatatumoren beschrieben und geht einher mit hohem Metastasierungspotential und steigenden Tumorgrad (Tamimi et al. 1993; Tamimi et al. 1996). Nicht-metastasierende Prostatatumorzellen von Ratten („G Dunning rat prostate cancer cells“), die eine geringe Anzahl an *HMGAI* Transkripten aufwiesen, wurden mit einem *HMGAI1a* CDS Expressionsvektoren transfiziert. Dadurch wurde die Proliferation der Zellen *in vitro* und eine Zunahme des Tumolvolumens *in vivo* im Vergleich zu den nicht transfizierten Zellen signifikant erhöht. cDNA Microarray Analysen von *HMGAI* transfizierten Zellen weisen eine 8-fach erhöhte Expression des *MMP-2* (Matrix Metalloproteinase 2) Gens auf (Takaha et al. 2004).

Die CT1258 Zelllinie weist einen stark rearrangierten Karyotyp mit komplexer Chromosomenaberration auf. Intraperitoneale und subkutane Injektion (1×10^6 und 1×10^5 bzw. 5×10^5 Zellen) von CT1258 in NOD-SCID Mäuse zeigten eine hohe Tumorigenität der Zelllinie (Fork et al. 2008).

Die durch die Zelllinie induzierten Tumore zeigten die gleichen histopathologischen und karyotypischen Veränderungen wie das ursprüngliche Adenokarzinom. Die auffälligsten Translokationen von CT1258 bilden die klonalen Fusionen der akrozentrischen Chromosomen CFA 4 und 5 und CFA 1 und CFA 2 zu dem sogenannten Markerchromosom. Während in 50 % aller Metaphasen das Fusionschromosom 4 und 5 vorhanden war, konnte das Markerchromosom in jeder Metaphase nachgewiesen werden (Winkler et al. 2005). Die Fusion von

akrozentrischen Chromosomen ist ein charakteristisches Merkmal von Karyotypveränderungen in caninen Tumoren (Reimann et al. 1999), wobei neben den Chromosomen 4, 5, 25 und X, die Chromosomen 1 und 2 am häufigsten davon betroffen sind. Entscheidend dabei ist das insgesamt vervielfältigte Chromosomenmaterial der tetraploiden CT1258 Zelllinie (Fork et al. 2008; Winkler et al. 2005).

Auf den ersten Blick ist die Überexpression der *HMGA* Gene bei CT1258 nur bedingt zu erklären. Die Genloci von *HMGAI* und *HMGAI2* des Hundes liegen auf CFA 12 und 10 in der Nähe der Zentromere. CT1258 ist charakterisiert durch komplexe Chromosomen-Rearrangierungen. Bei den bisher identifizierten Markerchromosomen sind die Chromosomen 1, 2, 4 und 5 involviert. Jedoch können die Chromosomen 10 und 12 durchaus an der Entstehung der anderen komplex rearrangierten Fusionschromosomen beteiligt gewesen sein. Die Rearrangierungen können einen Einfluss auf die *HMGA* Genloci haben. Auch Mikrodeletionen, die die transkriptionsregulativen Sequenzen innerhalb der 3'UTR betreffen, können nicht ausgeschlossen werden.

Zudem könnte durch das vermehrte Vorhandensein von Chromosom 2 in der Zelllinie das canine Gen *Lin-28a* überexprimiert sein. Das *Lin-28a* kann als RNA-Bindungs-Protein die Reifung der pre-miRNA von *let-7* blockieren (Viswanathan et al. 2009).

Die Applikation von Adeno-assoziierten Virus *HMGA* Antisense-Vektoren ist ein geeigneter gentherapeutischer Ansatz zur Inhibierung der Proliferation der caninen Prostataadenokarzinomzellen. Trotzdem ist die Methode sehr aufwendig d.h. Kosten und Zeit intensiv. Die Produktion und Ernte der rekombinanten AAVs kann stark innerhalb der einzelnen Chargen variieren. Zudem können starke qualitative und quantitative Unterschiede zwischen infektiösen und genomischen Titer entstehen, die die Transfektionseffizienzen beeinflussen (Rohr et al. 2005).

Eine alternative Strategie zur Transfektion von caninen Zellen kann eine Applikation von Gold-Nanopartikeln und rekombinaten caninen Transkriptionsvektoren sein. Gold Nanopartikel spielen bei vielen biomedizinischen Anwendungen eine immer wichtigere Rolle, wie z.B. Cell Imaging Techniken, Diagnostikverfahren und Drug Targeting. In dieser Arbeit wurden Gold Nanopartikel (AuNPs) mit Hilfe einer Femtosekunden Laser-Ablationstechnik ohne die Verwendung von Chemikalien und Vorläufermolekülen hergestellt. Erste

Ergebnisse deuten darauf hin, dass sich Säugetierzellen effizient transformieren lassen (Petersen et al. 2009).

SNPs innerhalb der kodierenden Sequenz sind von *HMGA2* in der menschlichen Population selten. Von 87 verschiedenen, gesunden Individuen konnten zeigte ein Transkript einen Aminosäureaustausch innerhalb der CDS (von Ahsen et al. 2006). In einer genomweiten Assoziationsstudie (GWAS) wurden die Genome erkrankter Individuen mit Prostatatumoren und gesunde Individuen miteinander genotypisiert. Dabei wurden in sieben Loci neun verschiedene SNPs m menschlichen Genom entdeckt, die signifikant im Zusammenhang zur Pathogenese von vererbaren Prostatakarzinomen stehen. Ein SNP (rs7578597) wurde auf dem HSA 2p21 gefunden, innerhalb des Intron 30 des *THADA* Gens (Eeles et al. 2009). Ein weiterer SNP im Exon 24 von *THADA* ist assoziiert mit Diabetes Typ 2 (Zeggini et al. 2008). Der Genort von *THADA* ist häufig ein Hotspot für chromosomale Rearrangierungen bei Schilddrüsenadenomen (Rippe et al. 2003). Der Genort des caninen *THADA* liegt auf CFA 10 Bande q25. Die abgeleiteten Aminosäuresequenzen und Proteindomänen sind bei Menschen und Hunden stärker konserviert als zwischen Menschen und Nagetieren (Drieschner et al. 2007; Soller et al. 2008). Chromosomale Aberrationen des CFA 10 sind eher selten und bisher sind noch keine chromosomalen Rearrangierungen bei caninen Schilddrüsenadenomen bekannt die den Genort des caninen *THADA* betreffen (Mayr et al. 1991; Reimann et al. 1996).

4.3 Inflammation und Angiogenese bei Tumorerkrankungen

Die vorherigen Abschnitte beinhalteten die molekularen Entstehungsmechanismen von Tumoren ausgehend von der klonalen Aberration und erhöhten Proliferation einer einzelnen Zelle oder einer Zellpopulation in einem Gewebeverband, welche sich zu Tumorzellen entwickeln. HMGA Proteine spielen als architektonische Transkriptionsfaktoren für die maligne Transformation eine entscheidende Rolle, wenn sie in einer gesunden Körperzelle überexprimiert werden. Daneben gibt es aber auch weitere Ereignisse, die es Tumorzellen ermöglichen sich in einem Organismus zu etablieren bzw. zu wachsen und schließlich zur Bildung von Metastasen führen. Im folgenden Abschnitt soll im Rahmen der Inflammation und

Neoangiogenese die Funktion weiterer humaner und caniner Genprodukte während einer Tumorerkrankung untersucht werden.

Der Rezeptor für „Advanced Glycation End Products“ RAGE ist ein Mitglied der Immunoglobulin-Familie und ein transmembranes Zelloberflächenprotein, das als Multiligand-Rezeptor nicht-enzymatisch glykolysierte Moleküle wie „Advanced Glycation End Products“ (AGE) bindet. Neben den TLR 2 und TLR 4 („Toll-like“ Rezeptoren) ist RAGE ein wichtiger Rezeptor für HMGB1 (van Beijnum et al. 2008).

Das RAGE Protein und seine vielfältigen Isoformen sind bei der Pathogenese verschiedener Erkrankungen bedeutend wie z.B. bei Störungen des Immunsystems, bei Sepsis, Morbus Alzheimer, Diabetes bedingter Arteriosklerose, rheumatoide Arthritis, Multiple Sklerose, Wundheilungsstörungen und Tumorerkrankungen (Schmidt et al. 2001; Liliensiek et al. 2004; Yan et al. 1997; Emanuele et al. 2005; Park et al. 1998; Pullerits et al. 2005; Sternberg et al. 2008; Goova et al. 2001; Bhawal et al. 2005).

Innerhalb der Klasse der Säugetiere sind die genomische Exon/Intron Organisation, die Nukleotidsequenzen der Transkripte und die abgeleiteten Aminosäuresequenzen der Proteine von RAGE und HMGB1 beim Menschen und Hund evolutionär konserviert. Das humane und canine HMGB1 haben eine identische Aminosäuresequenz. Die SI-Homologien zwischen dem humanen und caninen RAGE Proteinen betragen 77,6 %. Die SI-Homologien von RAGE zwischen Hund und Nagetieren bzw. Rindern liegen zwischen 73,5 % bis 77,7 %. Der Rezeptor besteht aus drei verbundenen Immunoglobinen (Ig-Klassen: V-C-C'), der extrazellulären Domäne, einer Transmembran- und einer Cytosol-Domäne. HMGB1 bindet am Rezeptor die Ig-V-Domäne. Diese Domäne ist zwischen Mensch und Hund mit einer SI-Homologie von 85,7 % am stärksten evolutionär konserviert. Die hohe Ähnlichkeit des humanen und caninen RAGE/HMGB1 Komplexes und der beteiligten Ligand/Rezeptor-Domänen lassen Therapieansätze, die für das Tiermodell Hund entwickelt werden, besser auf den Menschen übertragen als experimentelle Erkenntnisse, die mit Hilfe anderer Tiermodelle erlangt werden (Murua Escobar et al. 2003; Murua Escobar et al. 2006).

Eine Vielzahl experimenteller Therapieansätze konnte belegen, dass die von RAGE vermittelte Signaltransduktionskaskade durch trunkierte, soluble RAGE Proteinisoformen kompetitiv inhibiert werden kann. Dieses sRAGE Protein besitzt

nur die extrazelluläre V-C-C'-Domäne, während die Transmembran- und Cytosol-Motive fehlen. Durch die Applikation von sRAGE wird das Wachstum und die Metastasierungen von Tumorzellen deutlich reduziert (Huttunen & Rauvala 2004).

Zurzeit sind beim Menschen 19 verschiedene endogene Spleiß-Varianten bekannt, die entweder N- oder C-terminal trunkeerte Proteine kodieren (Malherbe et al. 1999; Schlueter et al. 2003; Yonekura et al. 2003; Park et al. 2004; Ding & Keller 2005; Hudson et al. 2008). Ihre zellbiologischen Funktionen sind bisher wenig charakterisiert worden. Es wird diskutiert, ob die Protein-Isoformen eine Funktion innerhalb eines komplexen Netzwerks der Selbst-Regulation haben sowie für die Besetzung der RAGE Moleküle innerhalb der Zellmembran verantwortlich sind. Eine weitere wichtige Funktion der sRAGE Isoformen liegt in der kompetitiven Inhibition des vollständig, membrangebunden Rezeptors und im Zusammenspiel der Aufrechterhaltung der Homöostasen zwischen Ligand, Rezeptor und solublen Protein Konzentrationen im inter- und intrazellulären Raum. Soluble RAGE Isoformen konnten im Blutplasma und in verschiedenen Geweben nachgewiesen werden. Erkenntnisse, die die Regulation bzw. das Verhältnis der verschiedenen solublen RAGE Isoformen und membrangebundenen RAGE Proteine auf Transkript-Ebene beschreiben, sind selten (Vazzana et al. 2009).

Für den Hund konnte Sterenczak et al. 2009 14 neue RAGE Spleiß-Varianten aus gesunden und neoplastischen Geweben und Zelllinien beschreiben, die bisher noch in keiner Spezies entdeckt wurden. Daneben wurden vier neue Spleiß-Varianten aus humanen Zelllinien entdeckt. Wie in Kapitel 3.3.2 beschrieben, ergaben sich zwei Gruppen von abgeleiteten RAGE Isoformen. Die erste Gruppe kodierte vollständige oder soluble RAGE Proteine, die zweite Gruppe N-terminal trunkeerte Proteine mit fehlender Ligand-bindender Ig-V Domäne.

Die CDS der N-terminal trunkeerten Protein-Gruppe sind durch Insertionen des Intron 1 gekennzeichnet („*RAGE Intron 1 ins*“ Variante). Sie haben ihre Funktion als kompetitive Inhibitoren verloren. Dieses Expressions-Verhältnis zwischen den *RAGE Intron 1 ins* Varianten und den Ligand-bindenden *RAGE* Transkripten ist in gesunden und neoplastischen Geweben und Zelllinien gemessen worden. In den gesunden Geweben der Lunge, des Hodens und der Schilddrüse ist die Menge der Ligand-bindenden Transkripte signifikant höher als die *RAGE Intron 1 ins* Varianten. Im Gegensatz weist die Mehrheit der untersuchten Tumorproben und Zelllinien eine weitaus größere Menge an N-terminal trunkeerten *RAGE Intron 1 ins*

Transkripten auf. Diese vergleichende Studie zur Charakterisierung der Transkription einer Vielzahl von verschiedenen *RAGE* Varianten beim Hund und beim Menschen trägt zum Verständnis bei, inwieweit eine Deregulierung bzw. Aberration der Spleiß-Varianten eine Rolle bei der Pathogenese von Tumorerkrankungen, Angiogenese und chronischer Inflammation spielen (Sterenczak et al. 2009). Unter dem Aspekt der Tumorenstehung und Metastasierung zeigt eine Studie, die das Verhältnis zwischen den unterschiedlichen *RAGE* Isoformen und HMGB1 beschreibt, dass die Expression von endogenen sRAGE (esRAGE) ein geeigneter Tumormarker zur Klassifizierung der Malignität von Chondrosarkomen ist (Takeuchi et al. 2007).

Gerade der Zusammenhang zwischen chronischer Inflammation und die Entstehung von Tumoren lässt sich durch den *RAGE*/HMGB1 Komplex besonders eingängig darstellen. Bei chronischer Inflammation können absterbende Zellen ein durch einen verminderten Sauerstoffpartialdruck gekennzeichnetes Mikroumfeld entstehen lassen (Hypoxie). Im Gegensatz zur Apoptose können nekrotische Zellen durch passive Diffusion Chromatin-assoziiertes HMGB1 in den extrazellulären Raum abgeben (Scaffidi et al. 2002).

Der *RAGE*/HMGB1-Komplex vermittelt eine Signaltransduktion über die GTPase CDC42/Rac oder über diverse MAP-Kinasen, die zur NF κ B abhängigen Transkription pro-inflammatorischer Gene führt (weiterführende Übersichtsartikel siehe Riehl et al. 2009). Tumorzellen sezernieren in einem hypoxischen Umfeld angiogenetische Faktoren und Zytokine wie z.B. VEGF, TNF α , IL-8, IL-6, und IL-1 (Shweiki et al. 1992; Bates & Mercurio 2003; Sparmann & Bar-Sagi 2004; Germano et al. 2008; Shchors et al. 2006). In einer positiven Rückkopplung exprimieren diese Zellen weitere *RAGE*-Rezeptoren (van Beijnum et al. 2008). Das proinflammatorische Milieu lockt Makrophagen an, die wiederum HMGB1 in den intrazellulären Raum aktiv sezernieren, dadurch wird in einer sich selbstverstärkenden inflammatorischen Kaskade weitere Zytokine ausgeschüttet (Andersson et al. 2002). Wachstumsfaktoren fördern die vermehrte Bildung von Blutgefäßen (Angiogenese), die den wachsenden Tumor versorgen. Am Anfang dieser aus dem Gleichgewicht geratenen Stoffwechsellkaskade stehen der Ligand HMGB1 und sein Rezeptor *RAGE* (Schlueter et al. 2005).

Während der Einleitung der Inflammation und der Initiierung der Immunabwehr führt eine durch *RAGE* oder TLR vermittelte Signalkaskade zur Aktivierung von

NF κ B (Huttunen et al. 1999; Yang et al. 1999; Kawai & Akira 2007). Dabei spielt NF κ B eine wichtige Schlüsselrolle bei der unspezifischen bzw. angeborenen Immunabwehr, da es als Transkriptionsfaktor die Transkription proinflammatorischer Zytokine induziert. Monozyten und Makrophagen erkennen durch einen rezeptorvermittelten Mechanismus pathogen-assoziierte molekulare Muster. Sie aktivieren über den Transkriptionsfaktor NF κ B die Sezernierung der Zytokine IL1 und TNF α .

Gerät diese multifaktoriell beeinflusste Immunantwort aus dem Gleichgewicht, kommt es zur Signaltransduktion vermittelter, permanenter Aktivierung des Transkriptionsfaktors NF κ B. Die endogene negative Rückkopplung gerät in diesem proinflammatorischen Umfeld außer Kontrolle, so dass dies zu chronischen Veränderungen des Gewebes führt. Eine hohe Konzentration an Zytokinen führt zu einer Aktivierung endothelialer Zellen der Blutgefäße. Über die Wachstumsfaktoren VEGF und TGF β bilden sich in den Tumoren Einsprossungen neuer Kapillaren in den Tumor (Neoangiogenese). Die gebildeten Blutgefäße versorgen den wachsenden Tumor mit Nährstoffen. Dies gilt als Voraussetzung für die weitere Tumor-Proliferation und schließlich für die Bildung von Metastasen (McMahon 2000; Pardali & Moustakas 2007).

Vergleichende Analysen der Aminosäuresequenzen der Zytokine IL-1 und TNF α zwischen verschiedenen Säugetierarten zeigen hohe Sequenzhomologien innerhalb der funktionellen Proteindomänen. Die „Calpain Cleavage Site“ bei IL-1 α oder das β -Faltblatt-Motiv bei IL-1 β sind bei beiden Spezies hoch konserviert (Soller et al. 2007). Die SI-Homologie zwischen humanen und caninen IL-1 α beträgt 68,5 %, zwischen Maus, Mensch und Hund liegen die SI-Homologien bei 60,1 % bzw. 57,1 %. Für das IL-1 β beträgt die SI-Homologie zwischen der humanen und caninen Aminosäuresequenz 62,8 %. Im Gegensatz zu IL-1 α teilen sich Mäuse und Menschen eine leicht höhere SI-Homologie von 66,4 %. Dagegen ist die Aminosäuresequenz von TNF α zwischen Mensch und Hund im Vergleich zu sieben weiteren Säugetieren, mit Ausnahme der Katze, am stärksten evolutionär konserviert. Die SI Homologie von Mensch zu Hund bzw. Katze beträgt 91 %, von Mensch zu Maus 77,8 %. Die genomische Organisation aller drei Zytokine ist zwischen den Säugetieren nahezu identisch. Eine Ausnahme bildet eine Spleiß-Variante von IL-1 α , die bisher nur bei Hunden, Katzen und Schweinen entdeckt

wurden. Parallel zu den normal Transkripten fehlt hier die Calpain-cleavage site (Straubinger et al. 1999; Soller et al. 2007).

4.4 Maligne Histiozytose und Langerhans-Zell Histiozytose

Menschen und Hunde teilen sich viele Gemeinsamkeiten in Bezug auf molekular genetische Stoffwechselwege bei inflammatorischen Prozessen. Es gibt bemerkenswerte Ähnlichkeiten bei der Dysfunktion des Immunsystems bei verschiedenen Erkrankungen, wie z.B. die Langerhans' Zell Histiozytose (LCH) und maligne Histiozytose (MH) (Affolter & Moore 2002). In neueren Untersuchungen wird diese Erkrankung als disseminiertes histiozytäres Sarkom bezeichnet (Abadie et al. 2009). Die MH oder LCH Erkrankung bildet sich spontan aus aberrant proliferierenden Histiozyten oder Langerhansschen Zellen. Als Folge ändert sich das Verhalten der Zellen, d.h. sie wandern wie Metastasen in umliegende Gewebe und initiieren unter anderem die Phagozytose der Erythrozyten (Kannourakis & Abbas 1994). Die Pathogenese der malignen Histiozytose ist noch weitgehend unerforscht. Während der Erkrankung sezernieren Histiozyten und T-Zellen große Mengen von Zytokinen in die betroffenen Gewebe (Egeler et al. 1999). In einer Studie konnten in einigen Zytokin-Transkripten bei insgesamt 17 untersuchten Hunden Punktmutationen innerhalb der CDS gefunden werden, die zu Aminosäureaustauschen der abgeleiteten Proteine führen (Soller et al. 2006). Die *IL-1 α* CDS eines Berner Sennenhundes (BSH Probe Nr. 2) zeigte auf Codon 23 eine Basenpaarsubstitution, dadurch wird im abgeleiteten Protein die native polare Aminosäure Serin zu unpolaren Prolin translatiert. Dieses Transkript zeigte eine zweite Basenpaarsubstitution (ebenfalls Probe Nr.2). Die Aminosäure Cystein auf der Position 47 wurde durch die positiv geladene Aminosäure Arginin substituiert. Cysteine bilden innerhalb der Vorstufe des *IL-1 α* Proteins Disulfidbrücken aus und interagieren mit der DNA des Zellkerns. Bei diesem Individuum konnte auch ein Aminosäureaustausch in der abgeleiteten membrangebunden Domäne des *TNF α* gefunden werden. Zwei BSHs (Proben Nr. 1 und 4) zeigten Basenpaarsubstitutionen, die zu Aminosäureaustauschen innerhalb der β -Faltblattmotive von *IL-1 β* führten. Ein weiterer BSH zeigte einen Austausch der Aminosäure Asparagin zu unpolarem Glycin. Dieser Aminosäureaustausch liegt innerhalb der ICE-Domäne des Proteins. Alle *IL-1 β* Basenpaarsubstitutionen wurden in Leberproben von drei verschiedenen Berner Sennenhunden detektiert.

SNPs innerhalb der Promotorsequenzen der untersuchten Zytokine sind mit der Pathogenese menschlicher Erkrankungen wie Morbus Alzheimer, Sepsis, rheumatoide Arthritis und Tumoren assoziiert (Dennis et al. 2004; Correa et al. 2005; Zienolddiny et al. 2004). SNP Screenings bei BSHs im Rahmen der Pathogenese der malignen Histiozytose sind bisher selten. Die in dieser Studie gefundenen Basenpaarsubstitutionen innerhalb der CDS von *TNF α* und *IL-1* zeigen erste Hinweise auf einen molekulargenetischen Hintergrund der Pathogenese dieser Erkrankung bei Hunden (Soller et al. 2006).

Die humane LCH wird durch eine unkontrollierte, klonale Proliferation antigen-präsentierender Zellen verursacht, den Histiozyten oder Langerhans' Zellen. Die Langerhans' Zellen bilden sich aus myeloiden Vorläuferzellen und sie haben die gleichen Eigenschaften, wie z.B. Zelloberflächenmarkerproteine wie bei unreifen dendritischen Zellen (DC). Sie exprimieren große Mengen an proinflammatorischen Zytokinen und diese Eigenschaft wird durch die Interaktion mit T-Zellen in einer positiven Rückkopplung weiter verstärkt (Egeler et al. 1999). Die canine MH oder das disseminierte histiozytäre Sarkom ist eine aggressive Multisystemerkrankung. Es bilden sich große Tumoren in verschiedenen Organen. Primäre Läsionen treten zunächst in der Milz, der Lunge und im Knochenmark auf, danach bilden sich sekundäre Läsionen in den Lymphknoten, in der Leber und in weiteren Organen (Affolter & Moore 2002).

Wie bei der LCH wird auch bei der MH eine aberrante Proliferation von DCs als die Ursache der Erkrankung angesehen. Die Zellen der humanen LCH als auch die caninen MH Zellen weisen beide die CD1a bis c Marker auf, die charakteristisch für unreife dendritische Zellen sind (Laman et al. 2003; Affolter & Moore 2002; Affolter 2004).

Der RAGE/HMGB1 Komplex spielt über den stromabwärts gelegenen MAPK und NF κ B Signaltransduktionsweg eine wichtige Schlüsselrolle bei der Reifung der DCs, in der Interaktion mit T-Zellen und der Fähigkeit zur Mobilität (Manfredi et al. 2008). Die Behandlung mit anti-RAGE Antikörper verhindert die Reifung der DCs der Milz bei Ratten (Zhu et al. 2009). Dendritische Zellen von *RAGE* Knock-out Mäusen verlieren die Fähigkeit zur Mobilität und verbleiben in einem unreifen („immature“) Zustand. Zudem verlieren sie die Eigenschaft T-Zellen zu aktivieren. Diese Eigenschaften zeigen auch die humanen LCH Zellen (Laman et al. 2003). Real-time Experimente an verschiedenen Gewebeproben (Lunge, Milz, Leber und

Lymphknoten) von MH erkrankten Hunden zeigten im Vergleich eine geringere *RAGE* Expression hauptsächlich in der Milz, aber auch in der Lunge als bei vergleichbaren nicht-neoplastischen Geweben (Sterenczak et al. 2010, in Vorb.). Interessanterweise zeigen humane Tumoren der Lunge, d.h. nicht-kleinzellige Bronchialkarzinome, ebenfalls eine erniedrigte *RAGE* Expression. Je höher das Grading bzw. die TNM-Klassifikation der malignen Tumoren, desto niedriger ist die mRNA und die Protein Konzentration von *RAGE* (Bartling et al. 2005).

RAGE wird in der Rhabdomyosarkom Zelllinie TE671/wt nicht transkribiert. NOD-SCID Mäuse, die mit dieser Zelllinie injiziert werden, entwickeln größere Tumore, als eine Vergleichs-Gruppe, die mit Zellen injiziert wurden, die zuvor stabil mit einem rekombinanten *RAGE* Expressionsvektor transfiziert wurde (Riuzzi et al. 2007). Die Autoren der Studie beschrieben eine Signaltransduktionkaskade, die über den *RAGE*/HMGB1 Komplex die MAP Kinase p38 aktiviert. Dadurch werden wiederum Transkriptionsfaktoren aktiviert, die die Expression von Genen steuern, welche für die Differenzierung von Myoblasten verantwortlich sind. Weiterhin hemmt MAPK p38 die unkontrollierte Proliferation von Myoblasten durch eine Inaktivierung der c-Jun N-terminalen Kinase (JNK). Dadurch wird die Expression von Zyklin D1 gestoppt (Lee et al. 2002). Die Phosphorylierung und Aktivierung von MAPK p38 und anderer Signaltransduktoren haben ebenfalls eine Bedeutung in der Reifung humaner dendritischer Zellen (Nakahara et al. 2006).

Abschließend betrachtet, bietet die molekularbiologische Erforschung der Pathogenese der humanen LCH und der caninen MH Einsichten in dem Gesamtkomplex chronischer Inflammation, durch die aberrante Expression von Zytokinen, der Tumorgenese und einer aberranten Immunantwort.

5. Zusammenfassung

Der „World Cancer Report 2008“ der Weltgesundheitsorganisation (WHO) berichtet von über 12,4 Millionen neuen Krebserkrankungen jährlich mit 7,6 Millionen Toten weltweit. In den vergangenen Jahrzehnten sind durch die moderne Medizin Fortschritte in der Behandlung und Heilung von Krebs erzielt worden, trotzdem gilt diese Krankheit nach wie vor als Hauptursache aller Todesfälle.

Das Tiermodell Hund kann für die Erforschung der Entstehung von Krebs beim Menschen zu neuen Ansätzen in der Therapie von Tumorerkrankungen und Entwicklung neuer Diagnose-Verfahren verhelfen sowie die bisherigen Nager-Tiermodelle für die Untersuchung der genetischen Ursachen von Krebs ergänzen. Die spontane Tumorenstehung, der gemeinsame Lebensraum von Hunden und Menschen unter denselben Umweltfaktoren, zeigen eine vielversprechende Übertragbarkeit der experimentellen Ergebnisse für die Humanmedizin. Die Anamnese und die Histologie von Tumoren beider Spezies sind einander sehr ähnlich. Tumorgenese und Tumorprogression verlaufen beim Hund in kürzester Zeit, so dass sich eine Vielzahl von übertragbaren Daten in einem überschaubaren Zeitrahmen sammeln lassen.

Einen besonderen Schwerpunkt der vorliegenden Arbeit bildet die Erforschung und vergleichende Tumorbiologie der caninen und humanen Prostatatumoren und weiterer Tumorerkrankungen, unter dem Aspekt der genomischen Charakterisierung der caninen Gene und Proteine HMGA1, HMGA2, THADA, RAGE, TNF α und IL-1 α/β .

Genomische Charakterisierungen stark evolutionär konservierter Gene sind die grundlegenden Maßnahmen für funktionelle und strukturelle Analysen tumorrelevanter Gene und Proteine. Darauf aufbauend ist ein gentherapeutischer Ansatz zur Inhibierung der Expression von *HMGA* Genen in einer caninen Prostatakarzinomzelllinie mit Hilfe von antisense Adeno-assoziierten Viren entwickelt worden. Zusätzlich konnte eine alternative Transfektionsmethode aufzeigen, dass sich eukaryotische Zellen besonders effizient mit Goldnanopartikeln transfizieren lassen.

Im Rahmen der Inflammation und Angiogenese während einer Tumorerkrankung wurde der canine Rezeptor für „Advanced Glycation End Products“ RAGE untersucht. Dabei zeigte sich eine hohe molekulargenetische Ähnlichkeit zwischen

dem humanen und caninen RAGE und den verschiedenen RAGE Isoformen und den beteiligten Ligand/Rezeptor-Domänen.

Eine aberrante Expression von Zytokinen, vor allem Interleukin-1 (IL-1 α and IL-1 β) und der Tumornekrosisfaktor alpha (TNF- α), spielen bei beiden Spezies eine wichtige Rolle bei der Einleitung von Entzündungsreaktionen und der Immunantwort.

Viele klinische und pathologische Eigenschaften, wie beispielsweise die Überexpression von Zytokinen bei der caninen malignen Histiozytose (MH), ähneln der humanen Langerhans-Zell-Histiozytose (LCH).

Die molekularbiologische Erforschung der Pathogenese der humanen LCH und der caninen MH bieten neue Einsichten im Zusammenhang zwischen Überexpression von Zytokinen, chronischer Inflammation, einer aberranten Immunantwort und der Tumorgenese. In diesem Zusammenhang wurden Basenpaarsubstitutionen und evolutionär konservierte Gensequenzen und Proteindomänen in caninen und humanen Zytokinen erforscht.

5. Summary

Medical advances due to scientific research made remarkable progress in the past decades fighting cancer. Nevertheless according to the United Nation's World Cancer Report 2008 tumour diseases are the leading cause of death with 7.6 million deaths and 12.4 million the new cancer cases a year.

According to cancer the dog as an animal model joins the popular rodent model in order to study and understand the molecular genetics of tumour diseases and to develop new therapeutic strategies against cancer. Canine tumour diseases are distinguished by spontaneous development and dogs and humans share striking similarities in the case of oncology.

The main part of this thesis comprises the comparative genomics and tumour biology of the human and canine tumour diseases focusing in particular prostate carcinomas by molecular characterisation of the genes and proteins HMGA1, HMGA2, THADA, RAGE, TNF α and IL-1 α/β .

Genomic characterisations of high evolutionary conserved genes are the fundamentals for functional and structural analysis of tumour relevant genes. According to this principle a gene therapeutic approach was developed in order to inhibit the *HMGA* expression of a canine prostate carcinoma cell line with the help of an adeno-associated virus vector. Furthermore an alternative method with gold nanoparticles was established for efficient transfection of eukaryotic cells.

In the context of inflammation and angiogenesis during a tumour disease the canine receptor for advanced glycation end products (RAGE) was analysed. The results showed highly conserved molecular similarities (N.B. ligand-receptor domains) between the human and canine RAGE and its isoforms.

In both species an aberrant expression of cytokines e.g. interleukin-1 (IL-1 α/β) and the tumour necrosis factor alpha (TNF α) plays an important role during the initiation of immune response and inflammation. In particular during the course of the Langerhans cell histiocytosis (LCH) large quantities of cytokines are produced. Interestingly most clinical and pathological features of the canine malignant histiocytosis resemble those of LCH in humans. Finally dogs could be used as an animal model to elucidate the molecular genetics of malignant histiocytosis as well as LCH. In this connection nucleic base pair substitution within evolutionary

conserved gene and amino acid sequences of canine and human cytokines were investigated.

7. Danksagung

Herrn Professor Dr. J. Bullerdiek danke ich für die Überlassung des Themas und die Diskussion dieser Arbeit. Ich danke ihm, dass ich diese Arbeit in dem Zentrum für Humangenetik in Bremen durchführen konnte sowie die damit verbundene wissenschaftliche Betreuung.

Herrn Professor Dr. I. Nolte danke für die vielen lehrreichen Jahre an der Klinik für Kleintiere in Hannover und für die Übernahme des Koreferats. Ich danke ihm besonders für die vielen Chancen, die er mir ermöglicht hat.

Herrn Dr. Hugo Murua Escobar danke ich für die geduldige Betreuung und zahlreichen wissenschaftlichen Gespräche und Anregungen.

Bedanken möchte ich mich auch bei Katharina „Kati“ Sterenczak und Saskia „Sassi“ Willenbrock, die mir mit ihren Erfahrungen immer tatkräftig zur Seite standen.

Mein besonderer Dank gilt auch den zahlreichen Kolleginnen und Kollegen, die mir mit ihrem Fachwissen, ihrer konstruktiven Kritik geholfen habe. Ich bedanke mich bei:

Dr. Nicola Reimann-Berg, PD Dr. Gazanfer Belge, Dr. Susanne Winkler, Andreas Richter, Siegfried Wagner, Merle Skischus und Norbert Drieschner.

Den Hannoveraner Kollegen vielen Dank für Verständnis und Unterstützung in der Klinik!

Schließlich möchte ich mich von ganzen Herzen bei meinen Eltern, meinem Bruder Sören Sönke und Senta Lück dafür bedanken, dass sie immer an das Zustandekommen dieser Arbeit geglaubt haben.

Mein Dank geht an meine liebe Freundin Sabine „Binchen“ Klein, die mich stets bestärkt hat. Sie hat mir die ganze Zeit den Rücken frei gehalten und daher widme ich ihr diese Arbeit.

8. Veröffentlichungen

Abstract

Due to the emerging advantages of numerous canine diseases as a genetic model for their human orthologs, the dog could join the mouse as the species of choice to unravel genetic mechanisms, e.g. of cancer predisposition, development and progression. However, precondition for such studies is the characterisation of the corresponding canine genes.

Human and murine HMGA1 non-histone proteins participate in a wide variety of cellular processes including regulation of inducible gene transcription, integration of retroviruses into chromosomes, and the induction of neoplastic transformation and promotion of metastatic progression of cancer cells.

Chromosomal aberrations affecting the human *HMGAI* gene at 6p21 were described in several tumours like pulmonary chondroid hamartomas, uterine leiomyomas, follicular thyroid adenomas and others. Over-expression of the proteins of *HMGAI* is characteristic for various malignant tumours suggesting a relation between high titer of the protein and the neoplastic phenotype.

In this study, we characterised the molecular structure of the canine *HMGAI* cDNA, its splice variants and predicted proteins HMGA1a and HMGA1b. Furthermore, we compared the coding sequence(s) (CDS) of both splice variants for 12 different breeds, screened them for single nucleotide polymorphisms (SNPs) and characterised a basic expression pattern.

1. Introduction

As witnessed by a number of recent articles (Kuska, 1996; Kingman, 2000; Ostrander et al., 2000; Vail and

MacEwen, 2000), a growing number of scientists predict that human genetics will focus on the dog in this century (Kuska, 1996). Due to the emerging advantages of numerous canine diseases as a genetic model for their human counterparts, the dog could join the mouse as the species of choice to unravel genetic mechanisms, e.g. of cancer predisposition, development and progression.

The proteins of the human *HMGAI* gene HMGA1a and HMGA1b are associated with various human diseases including cancer. Due to the similarities of various human and canine cancer entities, the characterisation of the canine *HMGAI* gene could open new fields for experimental and therapeutic approaches.

Four human members of the HMGA protein family are presently known: the HMGA1a, HMGA1b, HMGA1c and HMGA2 proteins, which can modify chromatin structure by bending DNA, thus influencing the transcription of a number of target genes. The human *HMGAI* gene on 6p21 encodes the well characterised

HMGA1a and HMGA1b proteins (formerly known as HMGI and HMGY) derived by alternative splicing and the barely characterised HMGA1c variant, while the HMGA2 protein is encoded by a separate gene on chromosome 12 (12q14–15) (for review, Reeves and Beckerbauer, 2001).

Expression of HMGA1 is detectable only at very low levels or is even absent in adult tissues, whereas it is abundantly expressed in embryonic cells (Chiappetta et al., 1996). In humans, 6p21 is often affected by aberrations leading to an up-regulation of *HMGAI* in benign mesenchymal tumours, e.g. lipomas, uterine leiomyomas, pulmonary chondroid hamartomas and endometrial polyps (Williams et al., 1997; Kazmierczak et al., 1998; Tallini et al., 2000). Transcriptional activation due to a chromosomal alteration of *HMGAI* is probably an early and often even primary event of cancer development. In contrast, *HMGAI* expression in malignant epithelial tumours seems to be a rather late event associated with an aggressive behaviour of the tumours. Thus, an over-expression of *HMGAI* was reported for a number of malignancies including thyroid, prostatic, pancreatic, cervical and colorectal cancer (Tamimi et al., 1993; Chiappetta et al., 1995, 1998; Fedele et al., 1996; Bandiera et al., 1998; Abe et al., 1999, 2000). The correlation between *HMGAI* expression and tumour aggressiveness in these malignancies has led to the conclusion that *HMGAI* expression may present a powerful prognostic molecular marker. The causal role of *HMGAI* expression in the progression of carcinomas has been elucidated by a set of *in vitro* experiments involving *HMGAI* sense and antisense transfection assays (Reeves et al., 2001). An experimental approach aimed at the down-regulation of HMGA protein in tumours has been presented by Scala et al. (2000) who were able to show that an *HMGAI* antisense strategy using an adenoviral vector treatment of tumours induced in athymic mice caused a drastic reduction in tumour size.

Recently, the canine *HMGAI* gene has been mapped to CFA 23. This cytogenetic assignment indicates that the canine *HMGAI* gene does not map to a hotspot of chromosomal breakpoints seen in canine tumours (Becker et al., 2003). However, despite the emerging role of *HMGAI* gene expression in malignancies, the molecular characterisation of the canine *HMGAI* gene had not been carried out before. The characterisation of the molecular structure could permit new therapeutic approaches using the dog as model organism.

In this study, we characterised the molecular structure of the canine *HMGAI* gene on cDNA level, its splice variants and proteins HMGA1a and HMGA1b, and a basic expression pattern. Furthermore, for 12 different canine breeds the coding sequence(s) (CDS) of both splice variants were characterised and screened for SNPs to find out if changes at protein level exist between the different breeds.

2. Materials and methods

2.1. Tissues

The tissues used in this study were provided by the Small Animal Clinic, Veterinary School, Hanover, Germany. The breeds represented were Alsatian, Bull Terrier, Collie, Dachshund, Doberman Pinscher, German Shorthaired Pointer, Golden Retriever, Jack Russell Terrier, Kangal, Munsterland, West Highland Terrier and Yorkshire Terrier. From each breed up to three samples of testis tissue were taken and used for analyses.

2.2. cDNA characterisation

Total RNA was isolated from 150 mg canine testis tissue using TRIZOL LS (Invitrogen, Karlsruhe, Germany) following the manufacturer's protocol. To avoid genomic DNA contamination a DNase digest of each sample was performed using DNA-free (Ambion, Huntingdon, Cambridgeshire, UK). cDNA was synthesised using 3'-RACE adaptor primer AP2 (AAGGATCCGTCGACATC(17)T), 5 µg total RNA and M-MLV (Invitrogen) reverse transcriptase according to the manufacturer's instructions. The polymerase chain reactions (PCRs) for the molecular cloning of the cDNA were done using the primer pairs Ex1up and Ex8lo (5' GCTCTTTTAAAGCTCCCCTGA 3'/5' CTGTCCAGTCCCAGAAGGAA 3') and primer pair Ex8up and 3'UTRlo (5' AGGGCATCTCGCAGGAGTC 3'/5' ATTCAAGTAACTGCAAATAGGA 3') which were derived from human cDNA sequences (accession no. X14957). The PCR products were separated on a 1.5% agarose gel, recovered with QIAEX II (QIAGEN, Hilden, Germany), cloned in pGEM-T Easy vector system (Promega, Madison, USA) and sequenced. The cDNA contig and the homology alignments were created with Lasergene software (DNASar, Madison, USA) and various sequences from the NCBI database (GenBank accession nos. X14957, X14958, NM_002131, NM_145899, NM_145900, NM_145901, NM_145902, NM_145903, NM_145904, NM_145905).

2.3. Characterisation of splice variants

The splice variants *HMGA1a* and *HMGA1b* were detected by amplifying a fragment spanning the CDS with primer pair Up (5' CATCCCAGCCATCACTC 3') and Lo (5' GCGGCTGGTGTGCTGTGTAGTGTG 3') using the canine testis cDNA samples as template. The primer pair was designed using the cDNA cloned as described in Section 2.2. The obtained PCR products were separated on a 4.0% agarose gel, recovered with QIAEX II (QIAGEN), cloned in pGEM-T Easy vector system (Promega) and sequenced. The contigs and the homology alignments were created with two sequences from the NCBI database (GenBank accession nos. X14957, X14958).

2.4. CDS comparison between breeds

The CDS of both splice variants were characterised for all breeds as described previously in Section 2.3. The contigs and the homology alignments were created using two sequences from the NCBI database (GenBank accession nos. X14957, X14958). In case of single nucleotide exchanges, the samples were sequenced again in both forward and reverse direction. Exchanges causing no amino acid (aa) substitution were not taken into account for further analyses. For all samples with aa substitutions the initial PCR was repeated and the exchange verified by sequencing the product in both forward and reverse direction. If possible, a restriction enzyme digestion was performed additionally.

2.5. Protein sequences

The canine HMGA1a and HMGA1b protein sequences were derived from the open reading frames (ORFs) of the characterised cDNA sequences described previously in Section 2.2. The protein homology alignments were created with two sequences from the NCBI database (GenBank accession nos. X14957, X14958).

2.6. Northern blot

Total RNAs were isolated from canine heart, lung, muscle, kidney and spleen tissue using RNeasy system (QIAGEN). An additional sample of total RNA was isolated from canine heart tissue by TRIZOL LS acid guanidine isothiocyanate–chloroform method (Invitrogen) in order to figure out whether this isolation method would lead to any difference in hybridisation. Further on poly A RNA was purified from canine spleen total RNA with OLIGOTEX (QIAGEN) and total RNA was prepared from human cultured fibroblasts by RNeasy system (QIAGEN). Spleen poly A RNA was placed on the blot in case that *HMGA1* was not detectable in the total RNA samples.

For Northern Blot hybridisation, 20 µg of total RNA from each sample with the exception of 10 µg of muscle and 3.6 µg of spleen poly A RNA were separated on a 1.2% denaturing agarose gel containing 0.65% formaldehyde. RNAs were transferred onto Hybond-N+ positive nylon membrane (Amersham Pharmacia Biotech, Freiburg, Germany) by capillary blot.

A 489-bp cDNA fragment derived from the canine HMGA1a sequence (exon 5/exon 8) served as a molecular probe for hybridisation. The probe was generated by PCR with the primer set Up and Lo (5' CATCCAGCCATCACTC 3'/5' GCGGCTGGTGTGCTGTGTAGTGTG 3') using the cloned cDNA described in Section 2.2. Probe labelling was performed by random primed labelling (Amersham Pharmacia Biotech) as described in the manufacturer's protocol with 50 µCi($\alpha^{32}\text{P}$)dCTP (Amersham Pharmacia Biotech). Purification of the labelled probe was performed

using Sephadex G-50 Nick Columns (Amersham Pharmacia Biotech) and the probe was stored at $-20\text{ }^{\circ}\text{C}$ before use.

Using the PERFECTHYB PLUS hybridisation solution (Sigma-Aldrich, Saint Louis, MO, USA) prehybridisation was carried out for 30 min and hybridisation for 2.5 h at $68\text{ }^{\circ}\text{C}$. The membrane was washed for 5 min at room temperature in $2\times\text{SSC}/0.1\%$ SDS, and twice for 20 min at $68\text{ }^{\circ}\text{C}$ in $0.5\times\text{SSC}/0.1\%$ SDS. Signals were visualised using a STORM phosphorimager (Molecular Dynamics, Sunnyvale, USA).

3. Results and discussion

3.1. The canine HMGA1 cDNA transcripts

For the human *HMGA1* gene various transcripts were described for both splicing variants (*HMGA1a* and *HMGA1b*) that differ in their 5'-UTR. The characterisation of the canine *HMGA1* cDNAs revealed that the complete canine *HMGA1* cDNA spans six exons and codes for two splicing variants *HMGA1a* with 1836 bp and *HMGA1b* with 1803 bp which are similar to the human transcripts (*HMGA1a* GenBank accession no. AY366390 and *HMGA1b* GenBank accession no. AY366392). The exon structure, the UTRs and the ORFs of both splice variants were defined and their homologies to their human counterparts analysed (Fig. 1, Table 1). The splicing variants showed the "typical" 33 bp gap which is conserved across various species such as human, mouse, hamster and rat (GenBank accession nos. BC013455, NM_016660, A7193763, NM_139327, A7511040). The homology of the canine cDNAs to their human counterparts is 80.6% for both splice variants. The 5'-UTR, CDS and the 3'-UTR showed homologies of 95.6%, 95.1% and 74.7%, respectively (Table 1). Homologies of the canine CDS with the CDS from mouse, hamster and rat on nucleotide level vary from 90.4% to 93.1%. The cDNA sequences were submitted to the NCBI database: *HMGA1a*, GenBank accession no. AY366390 and *HMGA1b*, GenBank accession no. AY366392.

3.2. The canine HMGA1a and HMGA1b proteins

The canine HMGA1a and HMGA1b protein sequences were deduced from the respective cDNA sequences. The canine HMGA1a protein is a 107-amino acid molecule with a calculated weight of 11,674.97 D and HMGA1b a 96-amino acid molecule with a calculated weight of 10,677.85 D (Fig. 2). Homology comparison to the human counterparts (GenBank accession nos. P17096, X14957) showed 100% homology of the molecules including the three "AT-hooks" and the acidic carboxy-terminal domain.

Comparison of the canine and human HMGA1a and HMGA1b proteins with the described mouse, rat and hamster molecules showed aa changes in positions 5, 34,

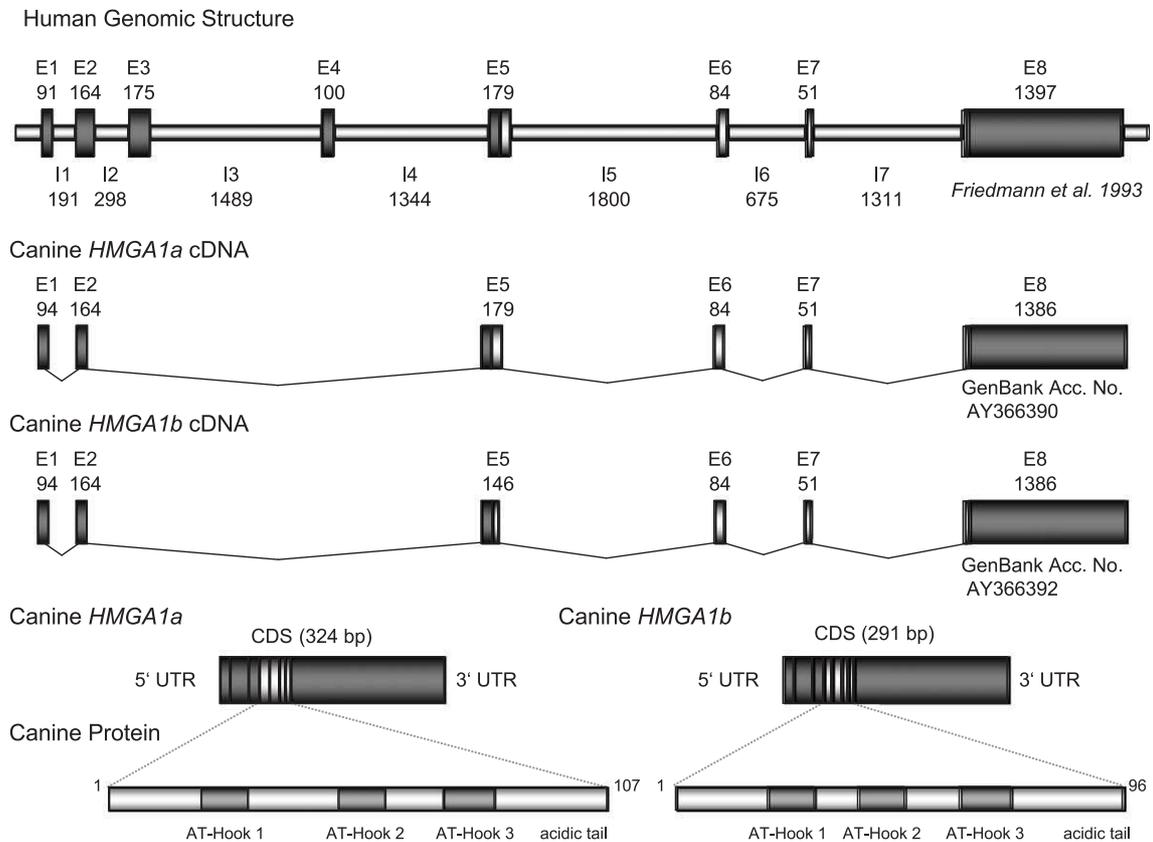

Fig. 1. Structure of the canine *HMGA1a* and *HMGA1b* transcripts and partial genomic structure.

69, 75 and 78 of *HMGA1a* and positions 5, 34, 58, 64 and 67 of *HMGA1b*, respectively (Fig. 2) (Johnson et al., 1988, 1989; Friedmann et al., 1993; Aldrich et al., 1999; Sgarra et al., 2000; Strausberg et al., 2002; Sgarra et al., 2003).

According to the definition of the AT-hooks (*HMGA1a*: I aa 21–31, II aa 53–63, III aa 78–89; *HMGA1b*: I aa 21–31, II aa 42–52, III aa 67–78) by Reeves and Nissen (1990) and Reeves (2000), none but the aa exchange at position 78

(*HMGA1a*) or 67 (*HMGA1b*), respectively, do affect the AT-hooks in either species. The exchange at position 78 leads to a difference in the third AT-hook of mouse and hamster when compared to the other species. According to the definition of the AT-hooks (*HMGA1a*: I aa 23–31, II aa 55–70, III aa 81–89; *HMGA1b*: I aa 23–31, II aa 44–59, III aa 70–78) by Huth et al. (1997), this aa exchange does not affect the third AT-hook. Following this definition, the second AT-hook is affected by the aa exchange at position 69 (*HMGA1a*) or 58 (*HMGA1b*), respectively.

The canine protein sequences were submitted to the NCBI database with GenBank accession nos. *HMGA1a* AY366390 and *HMGA1b* AY366392.

Due to the identical structure of the canine *HMGA* proteins to the respective human molecule, therapeutic approaches applied in dogs could be more suitable in terms of transferability for the development of human therapies than to approaches tested in other organisms.

3.3. *HMGA1a* and *HMGA1b* CDS comparison between canine breeds

For twelve different canine breeds the splicing variants *HMGA1a* and *HMGA1b* were detected by amplification of a fragment spanning the CDS using the canine testis cDNA samples as template. The comparison of the characterised protein coding sequences for these twelve canine breeds

Table 1

Detailed analysis of the canine *HMGA1a* and *HMGA1b* cDNA

Element of canine <i>HMGA1</i> cDNAs	Size in bp	Homology to human counterpart in %
Total cDNA <i>HMGA1a</i>	1836	80.6
Total cDNA <i>HMGA1b</i>	1803	80.6
5'-UTR	231	95.6
CDS <i>HMGA1a</i>	324	95.1
CDS <i>HMGA1b</i>	291	95.1
3'-UTR	1332	74.7
Exon 1	94	97.8
Exon 2	114	96.5
Exon 5 <i>HMGA1a</i>	179	93.9
Exon 5 <i>HMGA1b</i>	146	93.9
Exon 6	84	96.4
Exon 7	51	94.1
Exon 8	1386	75.4

Homology comparison of the cDNA elements of the canine *HMGA1* to its human counterpart (characterisation of the UTRs, the ORF and the exon sizes).

Fig. 2. Comparison of the canine, human, mouse, rat and hamster HMGA1a and HMGA1b proteins.

revealed one amino acid change in a single breed. Nucleotide exchanges causing no amino acid substitution were not taken into account in further analyses. Sample 2 (Teckel) showed in its *HMGA1b* transcript a nucleotide transition from A to G at the first base of codon 64 leading to an aa replacement from threonine to alanine and a new restriction recognition site for *AluI* causing four (58, 100, 158 and 176 bp) instead of three fragments (58, 100 and 334 bp) to appear in an *AluI* digest. (data not shown). The substitution was missing in the corresponding *HMGA1a* transcript of the dog suggesting a heterozygous genotype. A possible PCR artifact seems rather unlikely since the nucleotide transition was verified as described in Section 2.4. The CDS cDNA sequences of the twelve breeds were submitted to the NCBI database with GenBank accession nos. AY363606, AY363605, AY363607, AY363604, AY363608, AY363610, AY363609, AY363600, AY363603, AY363599, AY363601, AY363602, AY363994, AY363995, AY363611, AY363999, AY364000, AY364002, AY364001, AY363998, AY363996, AY363997, AY364003.

3.4. Canine HMGA1 expression analysis

Expression of human *HMGA1* is detectable at very low levels or is even absent in adult tissues whereas it is abundantly expressed in embryonic cells (Chiappetta et al., 1996). To elucidate a basic *HMGA1* gene expression pattern in dogs, a canine Northern blot was generated containing total RNA from canine spleen, heart, lung, muscle and kidney tissue samples. In order to detect a possible low level expression of *HMGA1* as reported in adult human tissues, a poly A RNA sample from canine spleen was additionally added to the blot. Hybridisation was performed with a $\alpha^{32}\text{P}$ -labelled canine *HMGA1a* cDNA

probe. Except for the kidney total RNA and one of two heart samples (Trizol method) all total RNA samples showed a weak signal of approximately 1.8 kb (Fig. 3, Trizol sample not shown), while the poly A RNA spleen sample revealed a distinct signal. After stripping, rehybridisation with a canine *GAPDH* probe showed signals corresponding to approximately 1.3 kb in all but the Trizol method (data not shown) samples, indicating a degradation of the Trizol-prepared RNA.

In humans, *HMGA1* expression in malignant epithelial tumours seems to be associated with an aggressive behaviour of the tumours. Over-expression of *HMGA1* was reported for a number of malignancies including thyroid, prostatic, pancreatic, uterus cervical and colorectal cancer (Tamimi et al., 1993; Chiappetta et al., 1995, 1998; Fedele et al., 1996; Bandiera et al., 1998; Abe et al., 1999, 2000). The correlation between *HMGA* expression and tumour

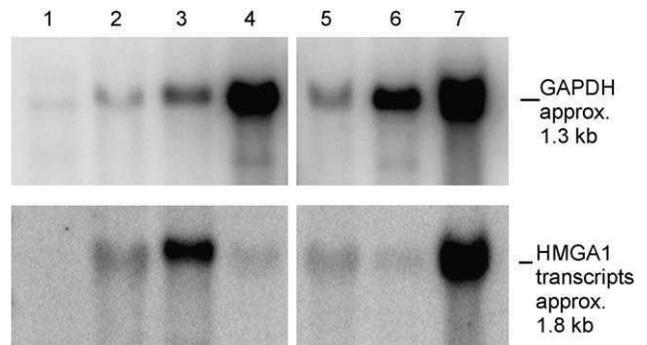

Fig. 3. Northern blot showing 1.8-kb *HMGA1* and 1.3-kb *GAPDH* transcripts. Lanes: (1) canine kidney total RNA, (2) canine spleen total RNA, (3) canine spleen poly A RNA, (4) canine heart total RNA, (5) canine lung total RNA, (6) canine muscle total RNA and (7) human fibroblasts total RNA.

aggressiveness in some of these malignancies has led to the conclusion that *HMGA* expression may present a powerful prognostic molecular marker.

So far no studies analysing the *HMGAI* expression pattern in canine tumours have been carried out. Since these tumours occur spontaneously in dogs as well as in humans a canine *in vivo* analysing system could have significant value for research and drug development.

The causal role of *HMGAI* expression in the progression of carcinomas has been elucidated by a set of *in vitro* experiments involving *HMGA1* sense and antisense transfection assays (Wood et al., 2000a,b; Reeves et al., 2001). A proof of concept for a therapy aimed at the down-regulation of *HMGA* protein in tumours has been presented by Scala et al. (2000) who were able to show that an *HMGAI* antisense strategy using an adenoviral vector treatment of tumours induced in athymic mice caused a drastic reduction in tumour size.

Due to the similarities of human and canine tumours, the transfer of such experimental approaches could benefit cancer research in either species.

The comprehension of the canine *HMGAI* gene and its gene products could be the precondition for future new experimental approaches and for evaluating the canine gene product as potential target for therapeutic strategies using the dog as model system.

Abstract

HMGA1 nonhistone proteins are reported to participate in various cellular processes including regulation of inducible gene transcription, integration of retroviruses into chromosomes, and the induction of neoplastic transformation and promotion of metastatic progression of cancer cells. Overexpression of *HMGA1* was shown to be characteristic for various malignant tumors, suggesting a relation between the neoplastic phenotype and a high titer of the protein. Also chromosomal aberrations affecting the human *HMGA1* gene at 6p21 were described in several tumors, e.g., uterine leiomyomas, pulmonary chondroid hamartomas, and follicular thyroid adenomas. We characterize the molecular structure of the canine *HMGA1* cDNA, its splice variants, and predicted proteins *HMGA1a* and *HMGA1b*. Furthermore, we compared the CDS of both splice variants for 12 different breeds, screened them for SNPs, characterised a basic expression pattern, and mapped the gene via FISH. Additionally, we compared the known human, canine, murine, rat, hamster, bovine, pig, *Xenopus*, and chicken *HMGA1* transcripts.

High mobility group proteins named according to their characteristic mobility in gel electrophoresis are small chromatin-associated nonhistone proteins, which can be subdivided into three families because of their functional sequence motives: the HMGA (functional motive “AT-hook”), HMGB (functional motive “HMG-box”), and HMGN (functional motive “nucleosomal binding domain”) protein families (for review see Bustin 2001). By binding DNA with their functional motives, the HMG proteins induce DNA conformation changes influencing the binding of various transcription factors and thus taking indirect influence on transcription regulation as so-called architectural transcription factors (for detail see Bustin and Reeves 1996).

The proteins *HMGA1a*, *HMGA1b*, and *HMGA2* of the human *HMGA* genes are associated with various human diseases, including cancer. Members of the human *HMGA1* protein family presently known are *HMGA1a* and *HMGA1b*, which by modifying chromatin structure take influence on transcription and up- and down-regulation of

a number of target genes, for example, *ATF2*, *IFN- β* , *NF- κ B*, *Interleukin-2 receptor*, *E-Selectin*, *Interleukin-4*, *Interferone-A*, *ERCC1*, and *Cyclin A* (Chuvpilo et al. 1993; Du and Maniatis 1994; Thanos and Maniatis 1992; Lewis et al. 1994; John et al. 1995, 1996; Klein-Hessling et al. 1996; Yie et al. 1997; Borrmann et al. 2003).

The expression pattern of the *HMGA* genes in human adult tissues shows only very low levels or even absent expression, whereas it is abundantly expressed in embryonic cells (Rogalla et al. 1996; Chiappetta et al. 1996). In humans the *HMGA1* gene is located on HSA 6p21, a region often affected by aberrations leading to an up-regulation of this gene in various benign mesenchymal tumors, for example, endometrial polyps, lipomas, pulmonary chondroid hamartomas, and uterine leiomyomas (Williams et al. 1997; Kazmierczak et al. 1998; Tallini et al. 2000). This suggests that transcriptional activation due to these chromosomal alterations is probably an early and often even primary event of cancer development. Recently, the canine *HMGA1* gene has been mapped to CFA 23. This cytogenetic assignment

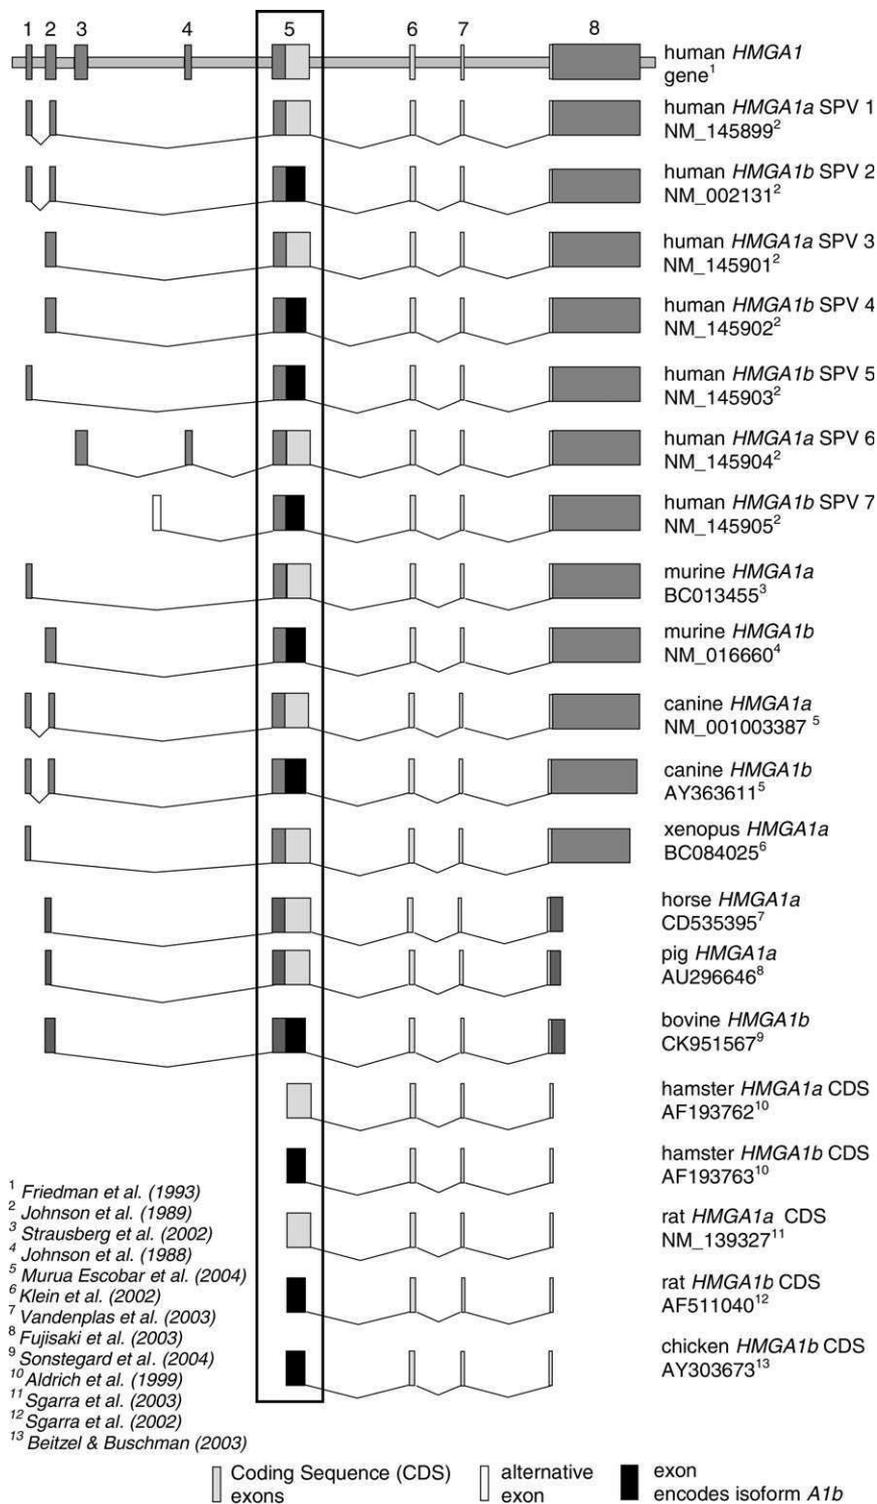

Figure 1. Species comparison of *HMGA1a* and *HMGA1b* transcripts. Exon 5 is enlarged by factor five for better visualization.

indicates that the canine *HMGA1* gene does not map to a hotspot of chromosomal breakpoints seen in canine tumours (Becker et al. 2003).

HMGA1 expression in human malignant epithelial tumors is reported to be associated with an aggressive behavior of the tumors. Overexpression of *HMGA1* was

detected in a number of malignancies, including thyroid, prostatic, pancreatic, uterine cervical, and colorectal cancer (Tamimi et al. 1993; Chiappetta et al. 1995; Fedele et al. 1996; Bandiera et al. 1998; Abe et al. 1999, 2000; Czyn et al. 2004; Takaha et al. 2004). The correlation between *HMGA* expression and tumor aggressiveness in some of these malignancies has led to the conclusion that *HMGA* expression may present a powerful diagnostic and prognostic molecular marker.

Due to the similarities of various human and canine cancer entities, the characterization of the canine *HMGA* genes could open new fields for experimental and therapeutic approaches. We recently characterized the canine *HMGA1a* and *HMGA1b* transcripts, deduced their proteins, evaluated them as targets for therapeutic approaches, and characterized a basic expression pattern in healthy tissues (Murua Escobar et al. 2004). Sequence comparison showed a 100% identity between the human and canine protein molecules. Although both species showed the identical two proteins, the number of found cDNA transcripts varies. For the human *HMGA1* seven different cDNA transcripts (Figure 1: SPV1–SPV7) were described (Johnson et al. 1988) of which SPV1 and SPV2 are the commonly found variants. The characterized dog variants showed the same composition structure as the mentioned human variants SPV1 and SPV2. Canine counterparts of the human transcript variants SPV3–SPV7 could not be detected using polymerase chain reaction (PCR) amplification approaches. Comparison of the human cDNAs to the known transcripts of other species shows that the dog is the only species showing similar transcripts to those commonly found in humans referring to exon structure and distribution. In detail, human and dog are the only known species showing the presence of exon one and two in both *HMGA1a* or *HMGA1b* transcripts, respectively (Figure 1). Both isoforms (*HMGA1a* and *HMGA1b*) were found in mouse (BC013455, NM_016660), hamster (AF1893762, AF193763), and rat (NM_139327, AF511040), of which for the last two species the described transcripts are limited to the protein coding sequences and the mouse transcripts show either exon one (*HMGA1a*) or exon two (*HMGA1b*) in the respective transcripts (Figure 1).

For the *HMGA1* transcripts of horse (CD535395), pig (AU296646), chicken (AY303673), bovine (CK951567), and *Xenopus* (BC084025), either the *HMGA1a* or the *HMGA1b* isoform are currently (2004) present at the NCBI database. For CDS (coding sequence) and protein identity analysis, we used the described sequences and deduced, if necessary, the corresponding parts for analyses. The in silico analyses were done using Lasergene software programs (DNASTAR, Madison). The coding sequence identities of the canine *HMGA1* transcripts to the sequences from other species vary between 72.0% (chicken AY303673) and 95.7% (pig AU296646, horse CD535395) (Table 1). Identity comparison of the deduced proteins revealed similarities between 69.7% (chicken AY303673) and 100.0% (human: P17096, X14957, horse CD535395) (Table 1). The proteins of all species showed strong conservation in the functional AT-Hook DNA binding domains. Common for all species analysed is that the protein coding sequences are composed of four

Table 1. *HMGA1* identity comparison (CDS and protein) of various species to the canine transcripts and proteins

Species	Isoform	Identity (%) to <i>C. familiaris</i>	
		CDS	Protein
Human (<i>H. sapiens</i>)	<i>HMGA1a</i>	95.1	100.0
Human (<i>H. sapiens</i>)	<i>HMGA1b</i>	95.1	100.0
Mouse (<i>M. musculus</i>)	<i>HMGA1a</i>	90.1	96.3
Mouse (<i>M. musculus</i>)	<i>HMGA1b</i>	90.1	96.9
Rat (<i>R. norvegicus</i>)	<i>HMGA1a</i>	90.4	96.3
Rat (<i>R. norvegicus</i>)	<i>HMGA1b</i>	90.4	95.8
Hamster (<i>C. griseus</i>)	<i>HMGA1a</i>	92.6	98.1
Hamster (<i>C. griseus</i>)	<i>HMGA1b</i>	92.6	97.9
Pig (<i>S. scrofa</i>)	<i>HMGA1a</i>	95.7	99.1
Horse (<i>E. caballus</i>)	<i>HMGA1b</i>	95.7	100.0
Cattle (<i>B. taurus</i>)	<i>HMGA1b</i>	94.4	99.0
Chicken (<i>G. gallus</i>)	<i>HMGA1b</i>	72.0	69.7
African clawed frog (<i>X. laevis</i>)	<i>HMGA1a</i>	90.4	97.2

exons (Figure 1). The described proteins of the different species are composed of 107 amino acids and 96 amino acids, respectively, for *HMGA1a* and *HMGA1b*. Also common for those species where both protein isoforms were described is that the difference between the splicing variants is the “typical” 33-bp deletion in the *HMGA1b* transcripts resulting in the lack of 11 amino acids.

Previous results describing the comparison of the protein coding sequences in 12 canine breeds revealed that the mentioned deletion is also conserved in the analyzed breeds. SNP screening in these breeds resulted in detection of one-amino-acid change in a single breed. A Teckel showed a nucleotide transition from A to G at the first base of codon 64 in its *HMGA1b* transcript leading to an amino acid replacement from threonine to alanine (Murua Escobar et al. 2004). As far as we know, no other canine *HMGA1* polymorphisms have been described. Summarizing the *HMGA1* transcript and protein comparison data emphasizes the relevance of the canine species as a model organism for the research and development of therapeutic approaches for human disorders.

Due to the mentioned properties of the *HMGA1* gene, its proteins *HMGA1a*/*HMGA1b*, and its reported role in development of cancer, future studies targeting *HMGA1* proteins could be of significant value.

Abstract

Background: The high mobility group A1 proteins (HMGA1a/HMGA1b) are highly conserved between mammalian species and widely described as participating in various cellular processes. By inducing DNA conformation changes the HMGA1 proteins indirectly influence the binding of various transcription factors and therefore effect the transcription regulation. In humans chromosomal aberrations affecting the *HMGA1* gene locus on HSA 6p21 were described to be the cause for various benign mesenchymal tumours while high titres of HMGA1 proteins were shown to be associated with the neoplastic potential of various types of cancer. Interestingly, the absence of HMGA1 proteins was shown to cause insulin resistance and diabetes in humans and mice.

Due to the various similarities in biology and presentation of human and canine cancers the dog has joined the common rodent animal model for therapeutic and preclinical studies. Accordingly, the canine genome was sequenced completely twice but unfortunately this could not solve the structure of canine *HMGA1* gene.

Results: Herein we report the characterisation of the genomic structure of the canine *HMGA1* gene consisting of 7 exons and 6 introns spanning in total 9524 bp, the *in vivo* localisation of the HMGA1 protein to the nucleus, and a chromosomal assignment of the gene by FISH to CFA12q11. Additionally, we evaluated a described canine *HMGA1* exon 6 SNP in 55 Dachshunds.

Conclusion: The performed characterisations will make comparative analyses of aberrations affecting the human and canine gene and proteins possible, thereby providing a basis for revealing mechanisms involved in HMGA1 related pathogenesis in both species.

Background

The high mobility group A (HMGA) proteins are small chromatin associated non-histone proteins named according to their characteristic motility in acid-urea polyacrylamide gel electrophoresis. The protein family consists of the three proteins HMGA1a, HMGA1b and HMGA2 which are encoded for by two different genes (HMGA1 and HMGA2). The functional motifs of these proteins, named AT-hooks, bind to the minor groove of DNA causing conformational changes of the DNA molecule. On genomic level these structural changes influence the binding of various transcription factors and thus indirectly influence the transcription regulation, which classifies the HMGA proteins as so called architectural transcription factors (for detail see [1]).

In previous studies we characterised the canine HMGA1 cDNAs and proteins and in comparative analyses of these molecules showed that they are highly conserved between different mammalian species. The observed number of amino acid changes seen across mammalian species (cattle, dog, hamster, horse, mouse, pig, and rat) vary between 0 to 3 when compared to the human molecules [2-10]. Interestingly, only the canine HMGA1 proteins are 100% identical to their respective human counterparts [11].

The HMGA1 proteins are well known to play a significant role in the pathogenesis of various diseases including cancer. In humans, chromosomal aberrations affecting the HMGA1 gene locus on HSA 6p21 were described for various benign mesenchymal tumours, e.g. endometrial polyps, lipomas, pulmonary chondroid hamartomas, and uterine leiomyomas [12-14]. The observed aberrations are supposed to lead to an up-regulation of the *HMGA1* gene in the affected tumours, as opposed to adult healthy tissues where *HMGA* gene expression is low or hardly measurable [9,15,16]. In malignant neoplasias *HMGA1* expression is reported to be associated with an aggressive behaviour of tumours. Accordingly, *HMGA1* overexpression was detected in various malignancies including thyroid, lung, prostatic, pancreatic, uterine cervical, and colorectal carcinoma [17-22]. Thus *HMGA* expression is supposed to present a powerful diagnostic and prognostic molecular marker due to the described correlation between *HMGA* expression and tumour aggressiveness.

Whilst overexpression of *HMGA1* is clearly associated with cancerogenesis the disruption of the *HMGA1* gene and thus induced loss of *HMGA1* expression shows significant pathogenic effects. Heterozygous and homozygous *Hmga1* knock-out mice develop cardiac hypertrophy combined with hematologic malignancies e.g. B cell lymphoma and myeloid granulocytic leukemia [23]. Additional research with *Hmga1* knock-out mice targeting diabetes presented by Foti et al. (2005) showed that loss

of *Hmga1* expression is clearly associated with significantly decreased insulin receptor expression and thus causes a characteristic diabetes type 2 phenotype in mice [24].

The various similarities in presentation and biology of numerous canine and human diseases including cancer suggest similar mechanisms to be involved in the respective pathogenic events. Accordingly, at least a dozen distinct canine cancers are hypothesized to be appropriate models for their human counterparts, among those osteosarcoma, breast carcinoma, oral melanomas, lung carcinomas and malignant non-Hodgkin's lymphomas [25].

The characterization of disease related genes and their protein biology will allow for comparative studies to reveal the molecular mechanisms involved therein and serve as a basis for future clinical studies.

Results and discussion

The *HMGA1* gene and its proteins HMGA1a and HMGA1b are described as regulating multiple cellular processes and are widely reported to be associated with various diseases including diabetes and cancer. In previous studies we characterised the canine *HMGA1* cDNAs and proteins completely and did comparative analyses of these molecules to the respective counterparts of different species and showed high evolutionary conservation. The fact that several canine and human cancer types show striking similarities in presentation and biological behaviour, e.g. spontaneous occurrence and metastasis patterns, strongly suggests similar mechanisms to be involved in the respective pathogenic events of both species. Thus, various canine tumours are currently used as models for several human cancer types. Accordingly, comprehension of the canine gene and its gene products is precondition for comparative analyses, allowing the revelation of molecular effects involved in these pathogenic presentations. Understanding and comparison of the respective genes will thus benefit both species. The exact mechanism for the emergence of the pathogenic effects caused by chromosomal aberrations affecting the human *HMGA1* gene in benign mesenchymal tumours, e.g. endometrial polyps, lipomas, pulmonary chondroid hamartomas, and uterine leiomyomas [12-14] are not completely understood. However, it is currently supposed that the aberration causes up-regulation of the *HMGA1* gene in the affected neoplasias. The principal aim of the study was to characterize the genomic structure of the canine *HMGA1* gene allowing the comparison of its genomic structure to the counterparts of other mammals and thus allowing a further evaluation of evolutionary conservation of the gene and a comparative analysis of chromosomal aberrations in both species. Additional aims were the *in vivo* localization of the canine HMGA1 protein and the evalu-

ation of a previously described point mutation which causes a disrupted protein.

Genomic structure, BAC Screening and FISH

A canine *HMGA1* genomic PCR reaction was established and used for screening of a canine BAC for identification of the canine *HMGA1* gene locus by FISH. The verified BAC 572 P20 K12 RC was used for FISH experiments. Ten well spread metaphases were analysed and showed signals on both chromatids of both chromosomes CFA 12q11 (Figure 1). The chromosomal localisation was done following the nomenclature established by Reimann et al. [26]. Existing painting probe based synteny studies and RH analyses [27] indicated that the canine CFA 12 shares homology with the human chromosome 6 on which the *HMGA1* gene is located at HSA 6p21. Chromosomal aberrations affecting CFA 12 are not or barely reported to be significantly associated with canine neoplasias [28,29]. While previous studies reported the localization of a *HMGA1* gene positive BAC to CFA 23 [30], the performed *in silico* analyses and the recently published canine genome assembly [31] support the herein described assignment of the canine *HMGA1* gene to CFA 12q11 by FISH described in this study. Comparative chromosomal *in silico* analyses using the "Evolutionary Highway" <http://evolutionhighway.ncsa.uiuc.edu/results.html> showed similar results.

The genomic structure of the canine *HMGA1* gene consists in total of the 7 exons and 6 introns. Overall the canine *HMGA1* gene spans 9524 bp. The exon/intron structure, size and the homologies to their human counterparts were analysed and defined (Figure 2, Table 1). The total identity to the corresponding human region is 62.8%. In detail, the identities of the exons vary between 74.6% and 97.8% to their human counterpart, while the introns show identities between 58.9% and 92.4% (for details see Table 1). The newly characterized sequences combined with the analyses performed *in silico* revealed that the exon 4, which exists in humans, is missing on genomic level in the canine genome. This exon 4 deletion also exists in the mouse genome and affects the respective mRNAs of both species in their 5' UTR. As the genomic characterization of the canine *HMGA1* gene was not available when the exons were named previously, the numbering at that time was based on the respective human exon numbers as defined by Friedmann et al. [32]. Consequently, as it is now known that the canine genomic sequence is lacking an equivalent to human exon 4, the previously used canine exon numbering should be revised with the then named canine exon 5 now being canine exon 4 and so on (Figure 2, Table 1). However, a part of intron 2 remains unsequenced due to an extensive CG repeat which also exists in the human counterpart (90%CG), and only the number of nucleotides (311 bp) could be identified. The genomic sequences were submit-

Intron 4 (5)	1761	51.1
Exon 5 (6)	84	96.4
Intron 5 (6)	584	57.5
Exon 6 (7)	51	94.1
Intron 6 (7)	1459	58.1
Exon 7 (8)	1386	75.4

Identity comparison of the genomic elements of the canine *HMGA1* gene with its respective human counterparts.

ing the protein coding region. A Dachshund sample showed a transition from A to G in exon 6 (according to revised exon numeration) leading to an amino acid exchange from threonine to alanine causing a mutated HMGA1 protein [9]. To elucidate if the observed exchange is frequently existent in the Dachshund population we screened 55 Dachshunds for the respective mutation (Figure 3). The results obtained by sequencing and restriction fragment analysis clearly showed that the previously found mutation is a rare event, as none of the screened 55 Dachshunds showed the mutation. Thus our findings suggest that the previously found aberrant *HMGA1* allele leading to a mutated protein form is unlikely to play a major role in *HMGA1* pathogenesis in Dachshunds.

In general, different species show significant differences considering the number and probability of described SNPs. This fact surely is directly dependent on total numbers of studies and sequencing reactions performed for the different species. While in 2001 Sachidanandam et al. [33] detected 1.42 million SNPs in the human genome with one SNP per 1.9 kb the currently estimated total number reported SNPs in the public databases is approx. 9 million for the human genome [34]. For the dog Lind-

blad-Toh et al. reported 2.5 million SNPs, whereas the probability differs depending on the breed between one SNP per 1500 bp and 900 bp [31]. Comparable to the human genome the total numbers of reported SNPs in the other different species is expected to increase significantly according to the performed research efforts, leading to increased knowledge of effects caused by SNPs in general.

HMGA1 in vivo localization

The *in vivo* localization of the canine *HMGA1* proteins via expression of a canine *HMGA1a*-GFP fusion protein showed that equivalently to its human counterpart the protein is located in the nucleus (Figure 4). Proteins of the *HMGA* family are described to be architectural transcription factors, and thus a localisation in the nucleus seems obvious. However, further localisation and function of these proteins seem to be very likely, due to the fact that application of recombinant *HMGA1* proteins to porcine cartilage cells *in vitro* showed significant increase of cell proliferation (Richter et al. accepted for publication). For a further member of the *HMG* proteins called *HMGB1* the existence of an extracellular function was recognised only a long time after its initial characterisation as an architectural transcription factor, revealing a direct influence of

Part of the canine *HMGA1a* gene

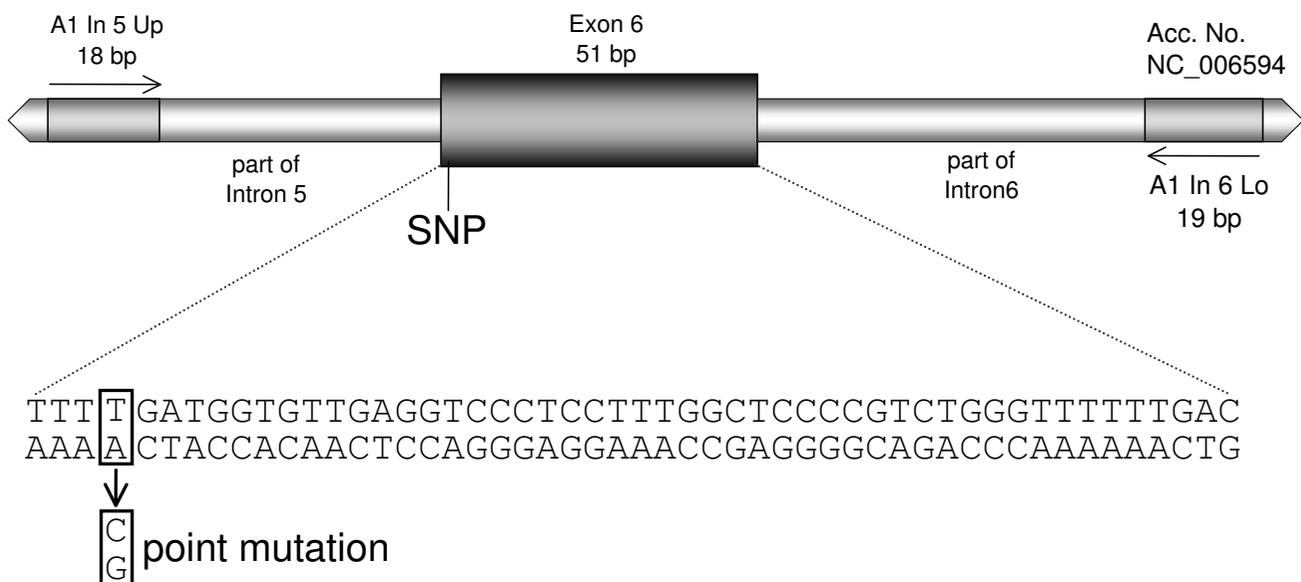

Figure 3
Position of the evaluated Dachshund point mutation. Strategic position of the evaluated point mutation screened in 55 Dachshunds.

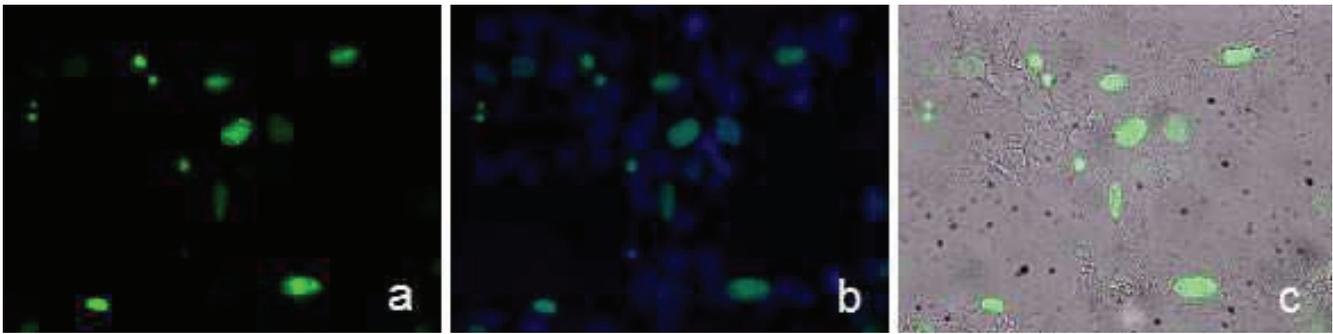

Figure 4

In vivo localisation of the canine HMGA1 protein. *In vivo* localization of a canine HMGA1a-GFP fusion protein in culture canine MTH53A cells, 24 h posttranslational. a) GFP expression in canine mammary cell line MTH53A, b) DAPI fluorescent staining of cell nuclei, merged GFP and DAPI image, c) merged GFP and transmitted light image (magnification $\times 400$).

extracellular HMGB1 on metastatic events [35-37]. Thus, we suppose that a similar mechanism could also exist for HMGA proteins and are currently working towards its identification.

Conclusion

Knowledge about the structure of genes and proteins is precondition to use them as potential therapeutic targets, markers or for revealing mechanisms involved in relevant pathogenic events. The canine and human HMGA genes and proteins have widely been shown to be involved in various diseases especially in cancer. Due to the numerous reasons for using the dog as a model system for human cancer research the characterisation of canine genes and proteins is of special interest. The performed characterisations of the canine HMGA1 gene and proteins will allow performing comparative analyses of aberrations affecting the human and canine genes and proteins as basis for revealing mechanisms involved in HMGA1 related pathogenesis in both species.

Methods

BAC library screening

A PCR reaction for the use in PCR-based screening of the *Canis familiaris* DogBAC library (Schelling et al., 2002) (Institute of Animal Genetics, Nutrition and Housing, University of Berne, Berne, Switzerland) for a BAC clone containing *HMGA1* was established using canine genomic DNA derived from blood. The primers A1In5up (5' GGCATCCGGTGAGCAGTG 3') and A1In6lo (5' CAGGCAGAGCACGCAGGAC 3') were designed using GeneBank sequences [AY366395](#) & [NW 876254](#). PCR parameters were: 95°C for 5 min, followed by 30 cycles of 95°C 30 sec, 59.3°C 30 sec, 72°C 30 sec, and a final elongation of 72°C for 10 min. The corresponding 201 bp PCR product was cloned into the pGEM-T Easy vector system (Promega, Mannheim, Germany) and verified by sequencing. The DNA contigs and alignments were done

with Lasergene software (DNASTAR, Madison, USA) and various sequences from the NCBI database ([AY366395](#), [NW 876254](#)). The verified BAC clone MGA 572 P20 K12 RC was used as probe for the following FISH experiments.

Slide Preparation

1 ml of canine whole blood was incubated for 72 h in Chromosome Medium B (Biochrom, Berlin, Germany). Subsequently, colcemide (0.1 $\mu\text{g}/\text{ml}$) (Biochrom, Berlin, Germany) was added for 2 hours. The cells were centrifuged at $135 \times g$ for 10 min and incubated for 20 min in 0.05 M KCl. Finally the cells were fixed with methanol/glacial acetic acid. This suspension was dropped on ice-cold slides and dried for at least 7 days at 37°C. The chromosomes were stained by GTG banding for karyotype description. Prior to use in FISH investigations, the slides were destained with 70% ethanol.

Fluorescence in situ Hybridization

MGA 572 P20 K12 RC BAC-DNA was digoxigenin labelled (Dig-Nick-Translation-Kit, Roche, Mannheim, Germany). The hybridization mixture contained 200 ng probe, 40 ng ssDNA, 600 ng sonicated dog DNA, $2 \times \text{SSC}$, $2 \times \text{SSPE}$, 50% formamide and 10% dextran sulfate. 50 μl of this mixture were applied to each slide and the cover slips were sealed with rubber cement. Probe and chromosomes were denatured at 75°C on an Eppendorf Thermocycler gradient, using the *in situ* adapter. Afterwards, the slides were incubated in a moist chamber at 37°C over night. Cover slips were carefully removed and the slides were incubated in $0.1 \times \text{SSC}$ at 61°C and $1 \times \text{PBS}$ at RT. Slides were then covered with 100 μl non fat dry milk (NFD) for 20 min. at 37°C in a moist chamber. For signal detection 100 μl NFD containing 3 μg of Anti-Digoxigenin-Rhodamine, Fab fragments (Roche, Mannheim, Germany), were added to each slide and again incubated for 20 min at 37°C in a moist chamber, followed by washes with $1 \times \text{PBS}$, 3×3 min. at RT. Slides were air dried

before chromosomes staining was performed with 25 µl of Vectashield Mounting Medium with DAPI (Vector Laboratories, Burlingame, CA, USA)

Ten well spread metaphases were examined indicating a signal on CFA 12q11 on both chromatids of both chromosomes CFA 12q11 (Fig. 1). The determination of chromosomes follows the nomenclature of the canine karyotype as described previously [26].

Genomic characterisation

For genomic characterisation of the canine *HMGA1* gene the missing parts were amplified by PCR on the screened BAC clone MGA 572 P20 K12 RC. For the missing part 1 a 858 bp fragment (bankit 1078968) was generated with primer pair A1_6640-6997_upa (5'-GGCGCGGCTCCAA-GAA-3'), A1_6_lo_2 (5'-CCAACAGAGCCCTGCAA-3'), a 1879 bp fragment (bankit 1078465 for the missing part 2 was generated by the primer pair A1_8864-10549_upa (5'-GTCTCACCGTCTGGAGAAT-3'), A1_8864-10549_loa (5'-TCACCGGAGGCTGCTT-3') and for the third missing part a 979 bp fragment (bankit 1078536) was generated with primer pair A1_11223-11834_upa (5'-CTGAGCCCATGCCAGATAA-3'), A1_11223-11834_loa (5'-AGAGATCCCTGCCGTAGT-3'). The obtained PCR products were separated on a 1.5% agarose gel, recovered with QIAquick Gel Extraction Kit (QIAGEN, Hilden, Germany), cloned in pGEM-T Easy vector system (Promega, Mannheim, Germany) and sequenced for verification. The final genomic canine *HMGA1* contig and the identity alignments were created with Lasergene software (DNASTar, Madison, USA) with the generated sequences from the cloned cDNAs described previously and various sequences from the NCBI database derived from the canine genome sequencing ([AY366394](#), [AY366395](#), [AY366396](#), [NM_001003387](#), [NW_876254](#)).

SNP screening

Genomic DNA was isolated from the collected 55 Dachshunds samples using the QiaAmp kit (QIAGEN, Hilden, Germany). A specific genomic PCR using the primer pair A1In5up (5' GGATCCGGTGAGCAGTG 3') and A1In6lo (5' CAGGCAGAGCACGCAGGAC 3') was established allowing the amplification of the complete exon 6 and flanking regions of intron 5 and 6, respectively (Figure 3). In detail the PCRs were performed in a 25 µl volume containing 0.5 µM of both primers (MWG Biotech, Martinsried, Germany), 0.1 mM of each dNTP (Invitrogen, Karlsruhe, Germany) 0.6 units Taq-DNA polymerase (Promega, Mannheim, Germany), 1.5 mM MgCl₂ (Promega, Mannheim, Germany), PCR buffer (Promega, Mannheim, Germany) and 2.5 µl template DNA, containing averaged 26.5 ng/µl.

After an initial denaturation step of 5 min at 95°C, the amplification followed in 30 cycles (30 sec. at 95°C, 30 sec at 59.3°C and 30 sec at 72°C). To complete, a final elongation step for 10 min. at 72°C completed the process. The obtained PCR products were purified using the QIAquick PCR Purification Kit (Qiagen, Hilden, Germany), directly sequenced by MWG Biotech (Martinsried, Germany), and additionally digested enzymatically with AluI (Fermentas, St. Leon-Rot, Germany). The occurrence of the described SNP creates a new restriction site for the enzyme AluI (5' AG▼CT 3'). Thus, a digestion with AluI cuts the 201 bp PCR product in two fragments of 69 bp and 132 bp, respectively allowing a verification of the sequencing results.

HMGA1 in vivo localisation

For the *HMGA1* *in vivo* localisation the protein coding sequence of the canine *HMGA1a* was amplified by PCR using primer pair EcoR1_IY-upATG (5'-CGGAATCCAC-CATGAGCGAGTCGAGCTCGA-3'), BamH1_IY-loSTOP (5'-CGGGATCCTCACTGCTCCTCTTCGGAGGACT-3'). The obtained PCR products were separated on a 1.5% agarose gel, recovered with QIAquick Gel Extraction Kit (QIAGEN, Hilden, Germany), ligated into the pEGFP-C1 vector plasmid (BD Bioscience Clontech) and sequenced for verification.

Cells from canine mammary tumour cell line MTH53a were cultivated using medium 199 (Invitrogen, Karlsruhe, Germany) supplemented with 20% FCS, penicillin, and streptomycin. The transfection was performed according to the manufacturer's instructions using 3 µl FugeneHD reagent (Roche, Mannheim, Germany) in 100 µl PBS (without Mg²⁺) containing 2 µg of recombinant pEGFP-C1-*HMGA1a*. After treatment, the cells were incubated for 48 hours in the culture media. The uptake and expression of DNA was verified by fluorescence microscopy.

Authors' contributions

CB: collected the Dachshund samples and performed the point mutation screening, JB: head of the centre for human genetics, took part in the conception design of the study, GD: constructed the screened BAC library, JTS: *in silico* analyses and construction of the *HMGA1* gene structure, MM: construction of expression vectors for the *in vivo* localisation, HME: principal study design, IN: head of the small animal clinic, took part in the conception design of the study, NR-B: karyotyping, AR: transfection of cells for *in vivo* localisation, CS: screening of the canine BAC library, SiW: molecular cloning of the newly characterised *HMGA1* fragments, SaW: supervision point mutation screening, SuW: performed the FISH experiments.

Abstract

Overexpression of high mobility group A (*HMGA*) genes was described as a prognostic marker in different human malignancies, but its role in canine haematopoietic malignancies was unknown so far. The objective of this study was to analyse *HMGA1* and *HMGA2* gene expression in lymph nodes of canine lymphoma patients. The expression of *HMGA1* and *HMGA2* was analysed in lymph node samples of 23 dogs with lymphoma and three control dogs using relative quantitative real-time RT-PCR. Relative quantity of *HMGA1* was significantly higher in dogs with lymphoma compared with reference samples. *HMGA2* expression did not differ between lymphoma and control dogs. With the exception of immunophenotype, comparison of disease parameters did not display any differences in *HMGA1* and *HMGA2* expression. The present findings indicate a role of *HMGA* genes in canine lymphoma. This study represents the basis for future veterinary and comparative studies dealing with their diagnostic, prognostic and therapeutic values.

Keywords

dogs, gene expression, *HMGA*, lymphoma, relative quantitative real-time RT-PCR

Introduction

The high mobility group A (*HMGA*) protein family consists of three members: *HMGA1a*, *HMGA1b* and *HMGA2*. These highly conserved,¹ small, chromatin associated non-histone proteins are encoded for by two different genes (*HMGA1* and *HMGA2*) and regulate gene expression by inducing genomic DNA conformation changes. These changes indirectly take effect on transcription regulation by influencing the binding of various transcription factors.² Although *HMGA* genes are abundantly expressed in embryonic cells, their expression in most human adult healthy tissues is low or even absent.³

The *HMGA* proteins are known to play a significant role in the pathogenesis of various diseases

including cancer. Re-expression of *HMGA1* was detected in various human malignancies including thyroid, lung, prostatic and colorectal carcinoma, as well as leukaemia and lymphoma,^{4–11} whereas *HMGA2* re-expression was described, for example, in leukaemia, mammary, non-small cell lung, oral squamous cell and thyroid carcinoma.^{12–16} In several of these malignancies *HMGA* overexpression has been reported to be associated with aggressive biologic behaviour.^{4,7,9–11,13,15} Furthermore, *HMGA1* and *HMGA2* have attracted interest as potential therapeutic targets and future influencers on the choice of therapy.¹⁷ Demonstration of *HMGA2* expression in canine prostate carcinoma tissue provided evidence that *HMGA* expression may also play a role in malignant tumours of dogs.¹⁸

The various similarities in biologic behaviour of many canine and human neoplastic diseases suggest similar mechanisms to be involved in the respective pathogenic events. Numerous canine malignancies are considered to be appropriate models for human oncology: among these, osteosarcoma, mammary carcinoma, oral melanoma, pulmonary carcinoma and non-Hodgkin's lymphoma.¹⁹

Lymphoma is one of the most common neoplastic diseases in the dog with an estimated annual incidence of 24–114 per 100 000 dogs.^{20,21} Furthermore, it belongs to the most chemoresponsive malignancies in dogs.¹⁹ Therefore, factors involved in the pathogenesis of canine lymphoma are of great interest for veterinarians as well as for comparative oncology. A wide variety of factors, for example, has been investigated for prognostic relevance,^{22–27} but there are still strong variations in outcome of canine lymphoma that cannot be completely predicted. Molecular markers may provide new insight into the pathogenesis of canine lymphoma and therefore might help in predicting outcome.

As a result of the reported role of *HMGA* re-expression in malignant tumours and its association with tumour aggressiveness in humans, the expression of the corresponding proteins is presumed to represent a powerful diagnostic and prognostic molecular marker. Therefore, it was the aim of the present study to analyse the *HMGA1* and *HMGA2* gene expression in canine lymphomas and to compare it with findings in a group of control cases.

Materials and methods

Patients

Dogs with cytologically or histologically confirmed lymphoma were included in the analysis. Dogs that had received chemotherapy prior to sampling were excluded, whereas those pretreated only with glucocorticoids were included. Control lymph node samples were acquired from dogs with clinically unaltered peripheral lymph nodes diagnosed with diseases other than haematopoietic neoplasia. Signed owner consent was obtained for every patient and the study design was reviewed and approved by the governmental animal care committee.

Staging and immunophenotyping

Clinical staging in dogs with lymphoma was performed according to the WHO clinical staging system²⁸ based on physical examination, complete blood count, serum biochemistry, thoracic and abdominal radiographs and bone marrow aspiration cytology. Flow cytometry was used to determine the immunophenotype of multicentric lymphoma cases as previously described.²⁹

Samples

Enlarged peripheral (multicentric lymphoma) or abdominal (intestinal lymphoma) lymph nodes were sampled via fine needle aspiration. Control samples were obtained from excised peripheral popliteal or superficial cervical lymph nodes within 20 min following euthanasia. All samples were immediately frozen in liquid nitrogen and stored at -80°C until RNA isolation.

RNA isolation and complementary DNA synthesis for transcript characterization

The samples were homogenized using the iron-beads QIAshredder homogenizer method (Qiagen, Hilden, Germany). Following, total RNA was isolated using the RNeasy Mini Kit according to the manufacturer's instructions (Qiagen, Hilden, Germany). In order to avoid genomic DNA contaminations, on-column DNase digestion with the RNase-Free DNase set (Qiagen, Hilden, Germany) was performed.

The respective complementary DNA (cDNA) syntheses were performed using 250 ng total RNA of each sample, the adaptor primer AP2: AAG GAT CCG TCG ACA TC(17)T and Quantiscript Reverse Transcriptase following the manufacturer's protocol (Qiagen, Hilden, Germany) with an integrated removal of genomic DNA contamination.

Quantitative real-time RT-PCR

For relative quantification of the *HMGA1* and *HMGA2* transcript levels, reverse transcription PCR (RT-PCR) amplifications were carried out using the Applied Biosystems 7300 real-time PCR System (Applied Biosystems, Darmstadt, Germany). Two

Table 1. Sequences of the primers and fluorogenic probes used in the RT-PCR procedures

Gene	Forward primer 5' → 3'	Reverse primer 5' → 3'	Fluorogenic probe 5' → 3'

GUSB, glucuronidase beta.

microlitres of each cDNA corresponding to 25 ng of total RNA was amplified in a total volume of 25 µL using universal PCR Mastermix (Applied Biosystems, Darmstadt, Germany) with 600 nM each of the respective forward and reverse primer (Table 1) and 200 nM of the respective fluorogenic probe (Table 1). PCR conditions were as follows: 2 min at 50 °C and 10 min at 95 °C, followed by 45 cycles with 15 s at 95 °C and 1 min at 60 °C.

For relative quantification based on the comparison of the *HMGA* expression with the expression of a housekeeping gene the canine glucuronidase beta transcript was chosen as endogenous control.³⁰ Two microlitres of each cDNA corresponding to 25 ng of total RNA was amplified with 600 nM of each primer (Table 1) and 200 nM fluorogenic probe (Table 1). The PCR was performed under the same conditions as the PCR reactions of the target genes.

All samples were measured in triplicate and for each run, non-template controls and no reverse transcriptase control reactions were included. Before performing the relative real-time quantifications, an absolute real-time PCR reaction was performed with all assays (results not shown), in order to ensure the comparability between the endogenous control and the respective target PCR reactions. All PCR reactions showed similar amplification efficiencies. To compare the gene expression levels based on the delta-delta-CT method, the expression in the control lymph node sample with the lowest variations between the three measurements of both *HMGA1* and *HMGA2* was used as a calibrator (expression level = 1).³¹

Statistical analysis

Expression levels of *HMGA1* and *HMGA2* were evaluated for statistically significant differences

between anatomic type (multicentric versus intestinal lymphoma, Mann–Whitney test), immunophenotype (B-cell versus T-cell, Mann–Whitney test), WHO-substage (substage a versus substage b, Mann–Whitney test) and WHO-stage (clinical stage 3 versus 4 versus 5, Kruskal–Wallis test and clinical stage 3 and 4 versus 5, Mann–Whitney test). A Mann–Whitney test was also used to compare expression levels in lymphomas with those in control dogs.

A *P*-value of <0.05 was considered to be statistically significant. Statistical analysis was performed using SPSS 15.0 statistics software (SPSS, Chicago, IL, USA).

Results

Patient population

Twenty-three dogs with lymphoma were included in the study. Control lymph node samples were obtained from three dogs that were euthanized because of a sarcoma of the liver, pneumonia and a mediastinal sarcoma, respectively. Patient characteristics are summarized in Table 2.

HMGA1 and *HMGA2* expression analyses

Lymph node expression of *HMGA1* was measured in all 23 dogs with lymphoma, whereas *HMGA2* expression was determined in 22 of the 23 lymphoma patients. Expression of both genes was analysed in three control lymph node samples.

HMGA expression in lymphoma samples and comparison to control

The median expression level of *HMGA1* in lymphoma samples (*n* = 23) was 6.88 (range

1.09–12.14), which was significantly higher than the expression measured in control samples (median 0.95, range 0.94–1.00, $P = 0.006$). *HMGA2* expression showed no significant difference between lymphoma-affected ($n = 22$; median 0.32, range 0.03–317.66) and control lymph nodes (median 0.52, range 0.33–1.00, $P = 0.738$).

HMGA expression in multicentric lymphoma

In a separate evaluation including only the dogs with multicentric lymphoma ($n = 19$), *HMGA1* was detected with a median relative quantity

of 7.20 (range 1.09–12.14). The median relative quantity of *HMGA2* in these dogs ($n = 18$) was 0.28 (range 0.03–317.66). The expression levels of *HMGA1* in the multicentric lymphoma cases were higher than in the control samples (median 0.95, range 0.94–1.00, $P = 0.001$, Fig. 1A). Expression of *HMGA2* did not differ significantly between multicentric lymphoma and control samples (median 0.52, range 0.33–1.00, $P = 0.534$, Fig. 1B).

HMGA1 and *HMGA2* expression levels in the dogs with multicentric lymphoma did not differ from those in dogs with intestinal lymphoma ($n = 4$ *HMGA1*: median 4.59, range 1.63–10.04, $P = 0.505$; *HMGA2*: median 7.02, range 0.14–138.69, $P = 0.118$).

In the dogs with multicentric lymphoma, clinical stage and clinical substage were not significantly associated with different *HMGA1* ($P = 0.340$ and $P = 0.482$, respectively) and *HMGA2* ($P = 0.964$ and $P = 0.126$, respectively) expression values. Comparison of a combined group of dogs in stages 3 and 4 with dogs in stage 5 also did not display any differences in *HMGA1* and *HMGA2* expression ($P = 0.940$ and $P = 0.965$, respectively).

Median relative *HMGA1* expression level in the multicentric lymphoma dogs with B-cell subtype ($n = 15$) was 7.42 (range 4.79–12.14). This was significantly higher than the respective relative quantity in the T-cell lymphoma cases ($n = 3$; 1.09, 1.50 and 1.53, respectively, $P = 0.002$, Fig. 2A). The relative quantity of *HMGA2* expression was on the other hand significantly higher in the T-cell subtype ($n = 3$; 21.98, 93.48 and 317.66, respectively) than in the B-cell lymphoma dogs ($n = 14$; median 0.17, range 0.03–5.33, $P = 0.003$, Fig. 2B).

Discussion

The present study aimed at the quantification of *HMGA1* and *HMGA2* expression in canine lymphoma and a comparison to control cases. It is the first report of *HMGA* expression analysis in canine haematopoietic malignancy. In the present population of dogs with lymphoma, *HMGA1* was overexpressed when compared with control dogs. In certain subtypes of human non-Hodgkin's lymphoma an alternative methodical approach using microarray technology indicated differences in

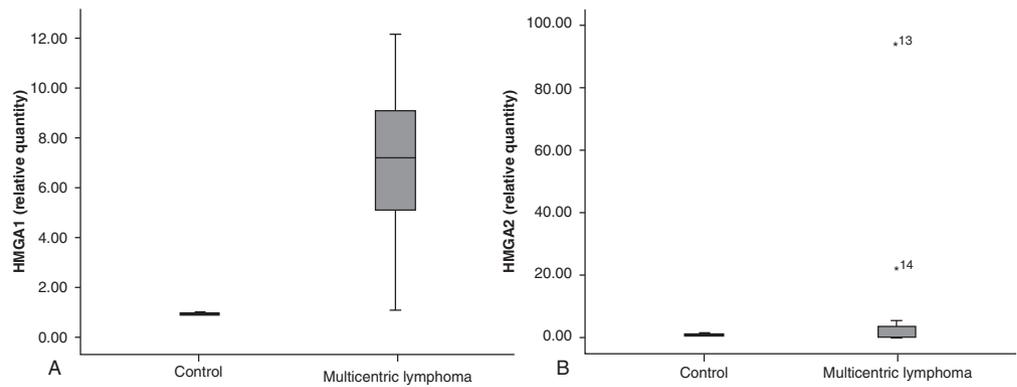

Figure 1. Relative quantity of *HMGA1* (A) and *HMGA2* (B) in dogs with multicentric lymphoma and control dogs. Boxplots graphs comparing multicentric lymphoma to control lymph nodes. (A) Median relative *HMGA1* quantity in multicentric lymphoma ($n = 19$): 7.20 (range 1.09–12.14), control samples ($n = 3$): 0.95 (range 0.94–1.00; $P = 0.001$); (B) median relative *HMGA2* quantity in multicentric lymphoma ($n = 18$): 0.28 (range 0.03–317.66), control samples ($n = 3$): 0.52 (range 0.33–1.00; $P = 0.534$).

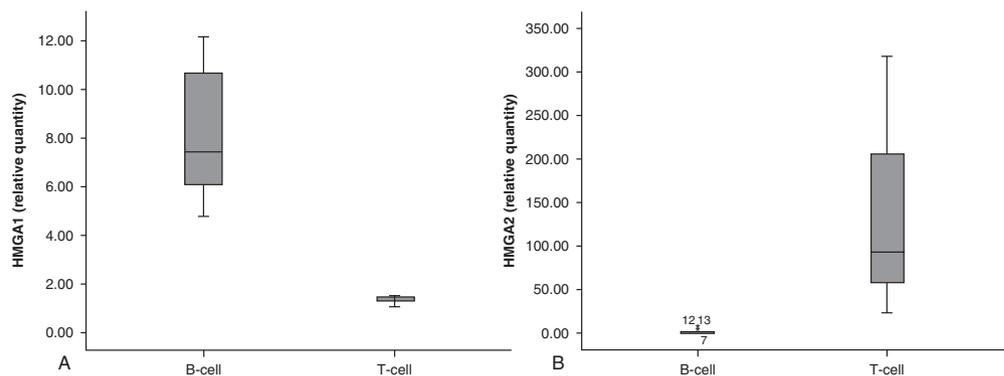

Figure 2. Relative quantity of *HMGA1* (A) and *HMGA2* (B) in multicentric lymphoma with different immunophenotype. Boxplots graphs comparing B-cell and T-cell lymphoma. (A) Median relative *HMGA1* quantity in B-cell lymphoma ($n = 15$): 7.42 (range 4.79–12.14), in T-cell lymphoma ($n = 3$): 1.50 (range 1.09–1.53; $P = 0.002$); (B) median relative *HMGA2* quantity in B-cell lymphoma ($n = 14$): 0.17 (range 0.03–5.33), in T-cell lymphoma ($n = 3$): 93.48 (range 21.98–317.66; $P = 0.003$).

HMGA1 expression levels as well. The expression was found to be significantly upregulated in the aggressive phase of follicular lymphoma compared with the indolent phase.¹⁰ Human mantle cell lymphomas with a high proliferative index as determined immunohistochemically via Ki-67 expression showed a 3.3-fold higher *HMGA1* expression than those with a low proliferative index.¹¹ Increased levels of HMGA1 proteins were also described in Burkitt's lymphoma cell lines with increased c-Myc protein.³² Furthermore, *HMGA1* overexpression has been shown in human leukaemias both of lymphoid and myeloid origin.^{6,8}

In addition, findings in mice emphasize the importance of *HMGA1* in haematopoietic malignancies. Induction of *HMGA1* overexpression in transgenic mice was found to be associated with the development of NK-cell lymphomas.³³ Interestingly, the loss of function of the *HMGA1* gene shows significant pathogenic effects, as well. Heterozygous and homozygous *HMGA1* knock-out mice develop cardiac hypertrophy combined with haematopoietic malignancies, for example, B-cell lymphoma and myeloid granulocytic leukaemia.³⁴

No significant difference in *HMGA2* expression levels between canine lymphoma and control lymph

node samples was detected in the study population. In human haematopoietic malignancies, both of lymphoid and myeloid origin, aberrant expression and/or chromosomal rearrangements affecting *HMGA2* have been described.^{35–38} Transgenic mice carrying a truncated *HMGA2* gene develop NK-cell lymphomas with a high frequency and thus show an association of *HMGA2* expression with haematopoietic neoplasia, as well.³⁹ Although increased *HMGA2* expression levels seem to play a role in several human myeloid neoplasias,^{14,38,40} findings in lymphoid malignancies are more heterogeneous. Significantly lower expression levels of *HMGA2* were found in the bone marrow of human acute lymphoblastic leukaemia (ALL) patients when compared with healthy bone marrow.³⁵ In contrast, there is a report of *HMGA2* locus rearrangement with overexpression of a *HMGA2* mRNA lacking a carboxy-terminal tail in a case of ALL.³⁷ Another paper showed *HMGA2* protein expression in bone marrow blasts associated with chromosomal translocation involving *HMGA2* in Richter transformation of a chronic lymphocytic leukaemia.³⁶

Despite the lack of significant differences in *HMGA2* expression between canine lymphoma and control lymph nodes in the present study, the *HMGA2* expression in canine lymphomas varied widely. This indicates that aberrant *HMGA2* expression may play a role in canine lymphoma but that its overexpression is not a consistent finding. The role of these expression differences in the respective pathogenesis remains to be investigated in future studies incorporating a larger study population. Interestingly, *HMGA2* expression levels were found to be significantly higher in T-cell than in B-cell lymphomas. The T-cell immunophenotype is observed less frequently in canine lymphoma, comprising approximately 19–33% of lymphoma cases.^{22,24,29} Consistent with these findings, T-cell lymphomas accounted for 17% of phenotyped lymphoma cases in the present study. A higher proportion of T-cell lymphomas may have resulted in a significant difference in *HMGA2* expression between multicentric lymphomas and control samples. Expression of *HMGA1* as well was significantly different between T-cell and B-cell lymphomas. In contrast to *HMGA2*, *HMGA1* was expressed

significantly higher in B-cell lymphomas. The known association of immunophenotype with prognosis of canine lymphoma^{22,24,25} in addition to the proven prognostic significance of *HMGA* expression in several human malignancies^{4,7,9,13,15} gives rise to the assumption that *HMGA* expression levels and especially the different expression of *HMGA1* and *HMGA2* may be associated with prognosis in canine lymphoma, as well. Further studies are needed to verify the present findings and to prove an association with prognosis. It is interesting, that there seems to be a low expression of *HMGA1* especially in the subgroup (T-cell lymphomas) with a significantly higher expression of *HMGA2*. When reviewing other studies about *HMGA* expression in different human tumours concurrent overexpression of *HMGA1* and *HMGA2* is found in some tumour types⁷ and overexpression of either *HMGA1* or *HMGA2* in others.^{41,42} In some human tumour entities, the expression profile of *HMGA* seems to be useful as a diagnostic tool to differentiate between histologically similar tumours.^{41,42} It is possible, that differential expression of *HMGA1* and *HMGA2* may be attributed to different roles they play in tissue differentiation and tumour pathogenesis. Whether it possesses diagnostic or prognostic importance in canine tumours and especially in canine lymphomas may become subject of future studies.

The present study has some limitations that need to be considered. Some subgroups within the study population were relatively small, which decreases the statistical significance of the results but reflects the epidemiological situation in the canine lymphoma population. The low number of control cases must be regarded as a limitation, as well. This group consisted of euthanized dogs with clinically unaltered peripheral lymph nodes and without haematopoietic neoplasia. Other neoplastic or non-neoplastic diseases were not excluded. It cannot be ruled out that the *HMGA* gene expression levels measured in the apparently unaltered peripheral lymph nodes of these dogs has been influenced by their respective disease or the postmortem sampling.

In the present study, overexpression of *HMGA* genes was demonstrated in dogs with lymphoma. The findings indicate that *HMGA* gene expression

may possess a role in the pathogenesis of canine lymphoma. Hence, the results of the present study may provide the basis for future veterinary and comparative studies on the diagnostic, prognostic and therapeutic use of *HMGA1* and *HMGA2*.

Abstract

Background: Prostate cancer is a frequent finding in man. In dogs, malignant disease of the prostate is also of clinical relevance, although it is a less common diagnosis. Even though there are numerous differences in origin and development of the disease, man and dog share many similarities in the pathological presentation. For this reason, the dog might be a useful animal model for prostate malignancies in man.

Although prostate cancer is of great importance in veterinary medicine as well as in comparative medicine, there are only few cell lines available. Thus, it was the aim of the present study to determine whether the formerly established prostate carcinoma cell line CT1258 is a suitable tool for *in vivo* testing, and to distinguish the growth pattern of the induced tumours.

Methods: For characterisation of the *in vivo* behaviour of the *in vitro* established canine prostate carcinoma cell line CT1258, cells were inoculated in 19 NOD.CB17-Prkdc^{Scid}/J (in the following: NOD-Scid) mice, either subcutaneously or intraperitoneally. After sacrifice, the obtained specimens were examined histologically and compared to the pattern of the original tumour in the donor.

Cytogenetic investigation was performed.

Results: The cell line CT 1258 not only showed to be highly tumourigenic after subcutaneous as well as intraperitoneal inoculation, but also mimicked the behaviour of the original tumour.

Conclusion: Tumours induced by inoculation of the cell line CT1258 resemble the situation in naturally occurring prostate carcinoma in the dog, and thus could be used as *in vivo* model for future studies.

Background

Only few species are known to spontaneously develop prostatic neoplasia; therefore the search for a suitable animal model for this disease is difficult. Currently, the dog is used as *in vivo* model for prostate malignancies in man, since it shows a similar metastatic pattern as well as age dependent development of malignant prostatic lesions [1-3]. Whereas prostate cancer is a frequent finding in man and even one of the leading causes of death in the Western world, it is less common in the dog. The prevalence is only 0.2%–0.6% [20]. Since this number is based on necropsy findings, the true number might be higher [4,5]. Although the relative number appears to be quite low, it results in an absolute count of estimated 60,000–180,000 affected dogs in the USA, 6,000–18,000 dogs in the UK, and 5,300–15,900 dogs in Germany, based on population.

Although there are some reports observing a permissive or protective effect of androgens [6-10], androgens do not seem to have an influence on development, growth, or metastasis in prostate carcinoma in dogs. Other than in human medicine, the diagnosis is usually made at a very late state of the disease, since for dogs no screening tests are available as there are for man [13]. Therefore treatment options for prostate cancer in the dog are limited and mostly remain to be palliative.

Despite the rather high incidence of prostate carcinoma in man, there are only three cell lines of human prostate carcinoma and their sub lines available. Thus, it is not surprising that there are only occasional reports about cell lines of canine prostatic carcinoma [11-13]. Hence the purpose of the present study was to establish an animal model, using the recently described cell line CT1258, which has been derived from a spontaneous canine prostate carcinoma [14,15]. Special attention was directed towards comparison of the clinical behaviour of the induced tumour in mice to the spontaneous tumour in the donor, as well as histological comparison. A comparison of the Ki67 index was performed in order to be able to address a potential change in proliferation. The Ki67 Index has been described to be associated with a poor outcome in human prostate cancer [18].

Methods

Donor

The cell line was derived from a prostatic tumour of a Briard, 10 years, male intact, which had been presented at the Small Animal Clinic of the University of Veterinary Medicine Hanover, Germany. The dog had a two week history of dyschezia, gain of abdominal girth, polydipsia, and loss of appetite. Clinical examination revealed an undulating and strained abdomen. Abdominal radiographs showed a highly reduced perceptibility of detail.

On abdominal ultrasound an enlarged prostate could be detected, which contained several cysts.

Explorative laparotomy was performed and about 3000 ml abdominal fluid were obtained; the prostate itself was highly enlarged and several miliary masses were found in the mesentery. There was no evidence of contact metastases to abdominal organs or distant metastases to the lung. Biopsies have been taken under general anaesthesia; the cytological diagnosis of a highly malignant adenocarcinoma of the prostate resulted in euthanasia *ad tabulam*. Prior to euthanasia, biopsies have been taken for further histological examination and for cell culture. Histological staining and immunohistochemical staining as well as cytogenetic analysis was performed as described below.

Cell line

The cell culture conditions, as well as the characteristics of the canine prostate carcinoma cell line CT1258 have been described previously [15].

Animals

This study involved 19 NOD-Scid mice (10 male, 9 female). All animals were bred and maintained in a protected environment at the Institute of Laboratory Animal Science of the Hanover Medical School. The mice were fed autoclaved food and water *ad libitum*, any manipulation was performed in a laminar flow hood. The animals were observed on a daily basis and sacrificed depending on the clinical condition and the size of detectable tumour, respectively. The tumours were allowed to grow up to a diameter of 10 mm. Additional criteria for euthanasia were ulceration of subcutaneous masses, a reduced level of activity of the mice, and the loss of appetite. The animals were humanely sacrificed by cervical dislocation after inhalation of > 70% carbon dioxide. The study was approved by the Lower Saxony State Office of Consumer Security and Food Safety (33-42502-05/950), the ethical approval was sought from the University of Veterinary Medicine Hanover.

Inoculation of Cells

The cells were harvested from the culture flasks with 1 ml of TrypLE Express (Invitrogen, Karlsruhe, Germany) and incubated at room temperature for 1 minute. L-199 medium (Invitrogen, Karlsruhe, Germany) supplemented with 20% FCS was added and the cells were centrifuged at 350 g for 15 minutes. The cell pellet was washed twice with PBS. The cells were resuspended in 200 µl PBS; immediately before application the suspension was aspirated into Insulin-Syringes (BD Micro-Fine, BD, Heidelberg, Germany) and inoculated either subcutaneously into the left flank of the animals or intraperitoneally.

For subcutaneous inoculation, the animals received 1×10^6 cells. For intraperitoneal application, mice received either 1×10^5 or 5×10^5 cells. The 19 NOD-Scid mice were subdivided into two groups: One group consisted of four female and five male mice, the animals received 1×10^6 cells subcutaneously each. The second group consisted of five male and five female animals, cells were inoculated intraperitoneally. Four of them (2 male, 2 female) received 1×10^5 cells; six animals (3 male, 3 female) received 5×10^5 cells, respectively.

Necropsy and histological staining

Necropsy was performed immediately after death had occurred. Lung, liver, spleen, kidneys, gonads, bowel, and detected masses were removed, fixed in 10% buffered formalin, paraffin embedded, sectioned, and stained with hematoxylin and eosin; immunohistochemical staining for Ki67 was performed, using the monoclonal antibody MIB-1 (Dianova, Hamburg, Germany) in a dilution of 1:100. The paraffin sections were pretreated in a microwave oven for 20 minutes in citrate buffer solution, pH 6. The secondary antibody was a biotinylated goat- α -mouse antibody, for detection, the Vectastain ABC-Kit (Vector Laboratories, Burlingame, USA) has been used. The Ki67 Index was determined by detecting the fraction of Ki67 positive stained cells in total 500 cells. This was performed in the original tumour, as well as in the induced tumours. Intestinal mucosa served as positive control. In addition, tumour samples of each mouse were obtained in liquid nitrogen for real time RT-PCR and in Hank's Medium for further *in vitro* culturing and Cytogenetic analysis. In order to address the growth pattern, the original canine tumour and the murine tumours have been classified based upon the presence of glandular, urothelial, squamoid, or sarcomatoid differentiation.

Cytogenetic analysis

For cytogenetic investigation, cells have been processed as described previously [15]. Tissue was transferred to liquid nitrogen immediately after dissection and stored at -70°C until examination.

Statistics

This study was intended to be descriptive rather than statistically significant. However, a paired student's t-test was performed. A P-value < 0.05 was considered to be significant.

Results

Pathological and histological examination

Original canine tumour

On histological examination the tumour showed to be consisting of poorly differentiated cells with numerous signs of malignancy. A strong anisocytosis, numerous cells with multiple nuclei, anisokaryosis, multiple mitotic fig-

ures, to some extent atypical mitotic figures, and a varying nucleus: plasma ratio could be detected. The tumour showed a compact growth with glandular differentiation. The Ki67 index was 43%.

Subcutaneous tumours

For analysis of duration until sacrifice of the mice, only those individuals were considered that were sacrificed due to tumour burden. All female mice and four of five male mice developed a detectable tumour mass after subcutaneous inoculation of 1×10^6 cells of the canine prostate carcinoma cell line CT1258 (Table 1). One mouse without detectable tumour growth was sacrificed due to bad clinical condition; necropsy revealed a mass of the thymus, histologically addressed as thymoma. In the remaining mice tumours were allowed to grow up to a size of 5–8 mm, which lasted 20 to 42 days (mean 25.37 days, median 22 days). Gender distribution showed a mean value of 28.75, median 26.5 days for female mice, and a mean and a median of 22 days for the males. None of the mice showed any signs of metastasis or of invasive growth pathologically or histologically; except for the mouse that did not develop any tumour mass, all animals remained in good clinical and nutritional condition.

Histology revealed a highly heterogeneous population of cells, numerous mitotic figures, anisokaryosis, anisocytosis, and several cells containing more than one nucleus; there was a variable nucleus: plasma ratio (Figures 1, 2). The centre of the obtained masses showed to be highly necrotic. Glandular differentiation was present. Immunohistochemistry revealed a strong positivity for the Ki67-antigen (Figure 3); the Ki67 index was between 41% and 48%, respectively

Intraperitoneal Tumours

The group was subdivided in two categories: Animals receiving 1×10^5 cells, consisting of two males and two females each, and animals receiving 5×10^5 cells, consisting of three males and three females each. The criteria for sacrifice were impairment of the general condition, worsening of the nutritional condition, and/or reduction of activity level. Weight gain was not a reliable factor due to the development of massive peritoneal effusion.

Table 1: Tumour growth after subcutaneous injection of 1×10^6 cells of CT1258.

	Mean [days]	No growth [No of animals]	Range [days]	SD
Male	22	1	20–24	1.63
Female	28.75	0	20–42	10.05
Total	25.38	1	20–42	7.58

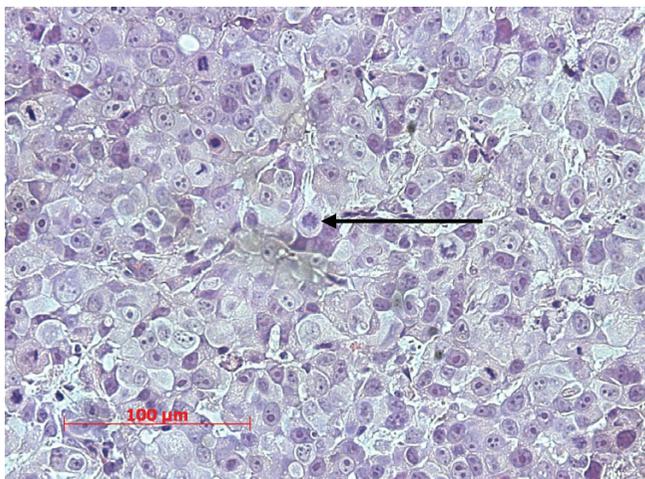

Figure 1
Subcutaneous mass with a high mitotic index. The arrow indicates an atypical mitotic figure.

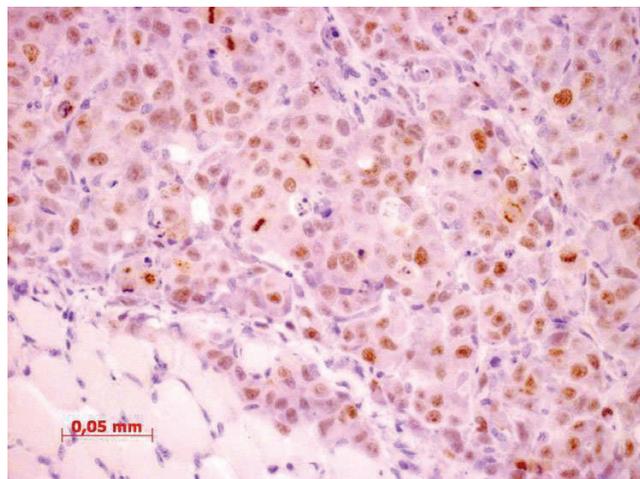

Figure 3
Ki67 staining of subcutaneous mass with a high amount of cells staining positively for Ki67.

In all mice receiving 1×10^5 cells tumour growth could be detected. The mean duration until sacrifice was 28 days. In one of three females and two of three males inoculated with 5×10^5 cells tumour growth could be detected, in this group the mean duration until sacrifice was 26 days (Table 2). Overall seven out of ten mice intraperitoneally inoculated with CT1258 developed tumour growth. Of those animals all but one male, which had received 5×10^5 cells, had an extended abdomen and proved to have peritoneal effusion. The male without obvious tumour growth had developed a thymoma, which was the cause

for the bad clinical condition. Six of these ten mice developed a mass at the injection site, although at inoculation a proper amount of time had elapsed until withdrawal of the needle. Necropsy showed a moderate to high tumour burden at the peritoneum and no visible signs of metastasis to the lungs (Figure 4). Histological examination of the obtained masses showed a similar pattern as the subcutaneous masses with a glandular differentiation (Figure 5); staining for Ki67 was strongly positive with a Ki67 index between 45% and 47%. Isolated populations of tumour cells could be detected in the lungs, but there was no sign

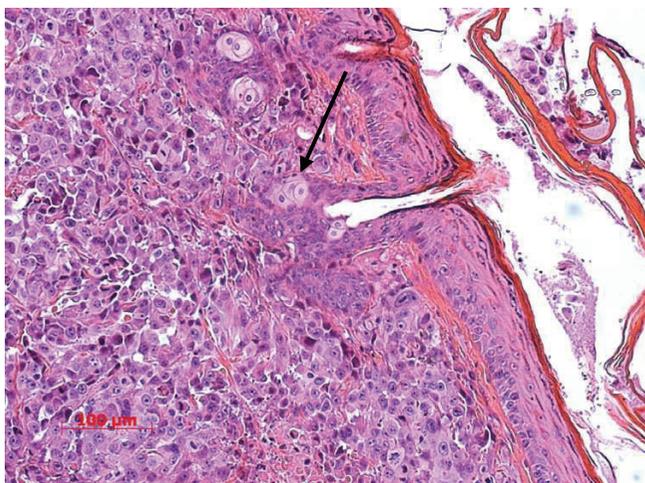

Figure 2
Subcutaneous mass with multiple mitotic figures and necrotic area; the large pale cells surrounding the hair follicle are part of the sebaceous gland and should not be mistaken as tumour cells (arrow).

Figure 4
Diaphragm after i.p. injection of 5×10^5 cells with a high tumour burden; see Figure 5 for histology; the thoracic aspect of the diaphragm is not affected.

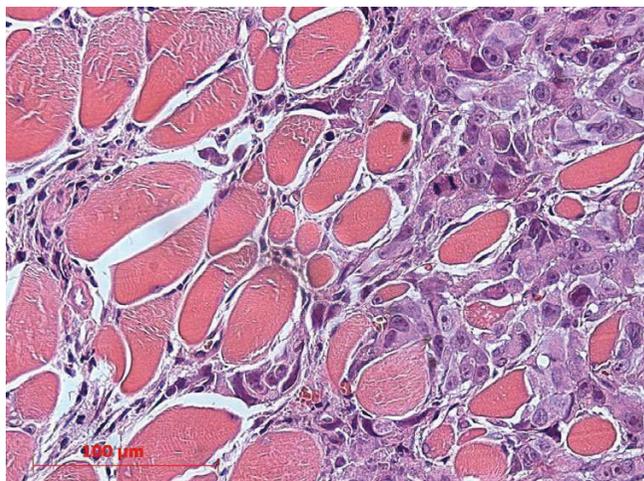

Figure 5
Diaphragmatic mass (see figure 4 for macroscopic appearance).

of vascularisation (Figure 6). In abdominal organs only peripheral tumour growth could be observed.

Cytogenetic Analysis

The cytogenetic investigation of intraperitoneal and subcutaneous tumours revealed the same markers that have been shown in analysis of the original tumour and of the cell line [15]. A hyperdiploid karyotype was present. Centromeric fusion between chromosomes 1 and 5 (der (1; 5)) and chromosomes 4 and 5 (der (4; 5)) were detected. A large biarmed marker (mar) was found (Figure 7, 8).

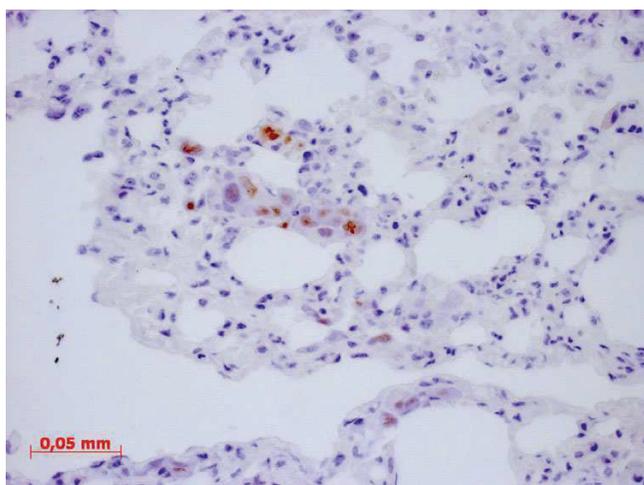

Figure 6
Ki67-staining of tumour cells in the lung; there is no evidence of vascularisation, therefore these cells are tumour emboli rather than metastasis.

Table 2: Tumour growth after intraperitoneal injection of 1×10^5 and 5×10^5 cells.

	Mean [days]	No growth [No of animals]	Range [days]	SD
Male	26.75	1	24–30	3.2
Female	27.67	2	24–30	3.21
1×10^5 cells	28	0	24–30	2.71
5×10^5 cells	26	3	24–30	3.46
Total	27.14	3	24–30	1.12

Discussion

Ideally a cell line should not only be immortalized spontaneously but also be tumourigenic in experimental animals. Another claim may be the mimicking of the original natural behaviour of the tumour in the host. This condition promotes the predictability of any results obtained with that very cell line. This is true especially for cell lines derived from nonhuman tumours if the origin may serve as a model itself.

This study reveals that the cell line CT1258 is highly tumourigenic in NOD-Scid mice. Local tumour growth occurred in 89% of the animals that had received cells subcutaneously; 86% of the animals that had been inoculated intraperitoneally and that had developed tumour growth also developed local tumour growth at the injection site. The latter was not desired, and since it is not known how many cells remained in the branch canal, the size of those accidental masses cannot be compared accurately. Focussing on the mice with cells inoculated i.p., 86% developed peritoneal effusion just as the donor did and all of them had multiple small nodules within the serous membranes of the peritoneum rather than one large mass. The excellent local tumour growth on one hand and the rapid development of pleural effusion on the other hand indicates that in studies to come the use of the cell line might be of a greater value in local administration rather than in systemic inoculation. Orthotopic implantation might be of great value, since this could enable the assessment of local growth and invasion as well as potential metastasis. Due to the lack of vascularisation, the tumour cells found in the lungs of the mice must be addressed as tumour cell embolism rather than metastasis. Since neither the mice nor the donor had evidence of lymphogenic or hematogenic metastasis, we conclude that time for metastasis exceeds the time limitation owed to local tumour growth. Whether this is due to the rapid growth rate or due to potentially little disposition of the cells to degrade extracellular matrix and therefore has a generally low tendency to metastasise remains unclear. The absence of bone metastasis is a remarkable fact, which is contrary to the high incidence of bone metastasis in

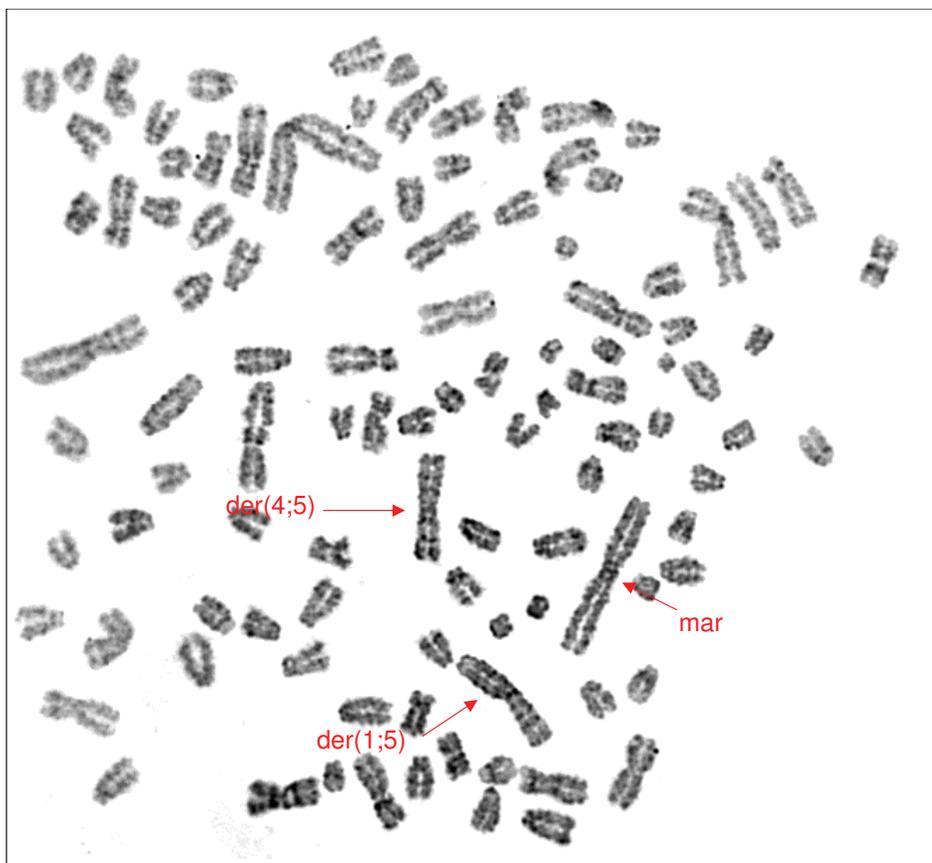

Figure 7

Metaphase spread from cells derived from the original canine tumour. The arrows indicate the derivative chromosomes der (1; 5), der (4; 5) and the marker chromosome mar, which consists of chromosome 1 and chromosome 2 material.

canine and human patients [5,19]. Potentially there was not enough time for bone metastasis to develop due to rapid local tumour growth, on the other hand, this particular tumour might have a reduced tendency for skeletal metastasis. At first glance this reduces the value of the present tumour model for comparative oncology, but this interesting feature might be used for further studies focussing on skeletal metastasis in particular, if the cause for the absence of metastasis to the skeleton in this otherwise highly malignant prostate carcinoma is detected. The tendency to show necrotic areas in the centre might be due to rapid tumour growth.

The number of cells obviously did not seem not to have a direct impact on tumour growth, since all mice that had been inoculated with 1×10^5 cells developed tumours, but 50% of the animals that received 5×10^5 cells did not; although this is not considered to be statistically significant, it suggests that an even lower number of cells might have been sufficient to induce a tumour. The difference

between male and female animals is not statistically significant.

The Ki67 indices in both, the original tumour and the experimentally induced tumours, were considered to be high. The difference between the original tumour on one hand and the subcutaneous and intraperitoneal masses on the other hand were statistically not significant. In human medicine a high Ki67 index has shown to be associated with a poor prognosis [20]. Considering the histological characteristics of the described tumour, the high Ki67 index is not a surprising finding. Comparison of the Ki67 index of the original tumour to the xenograft revealed no change in proliferation.

One limiting factor is that two of the nineteen mice in the study developed thymoma within the course of the study. This is a frequent finding in older NOD-Scid mice [16,17]. Therefore the animals must not be considered to be healthy.

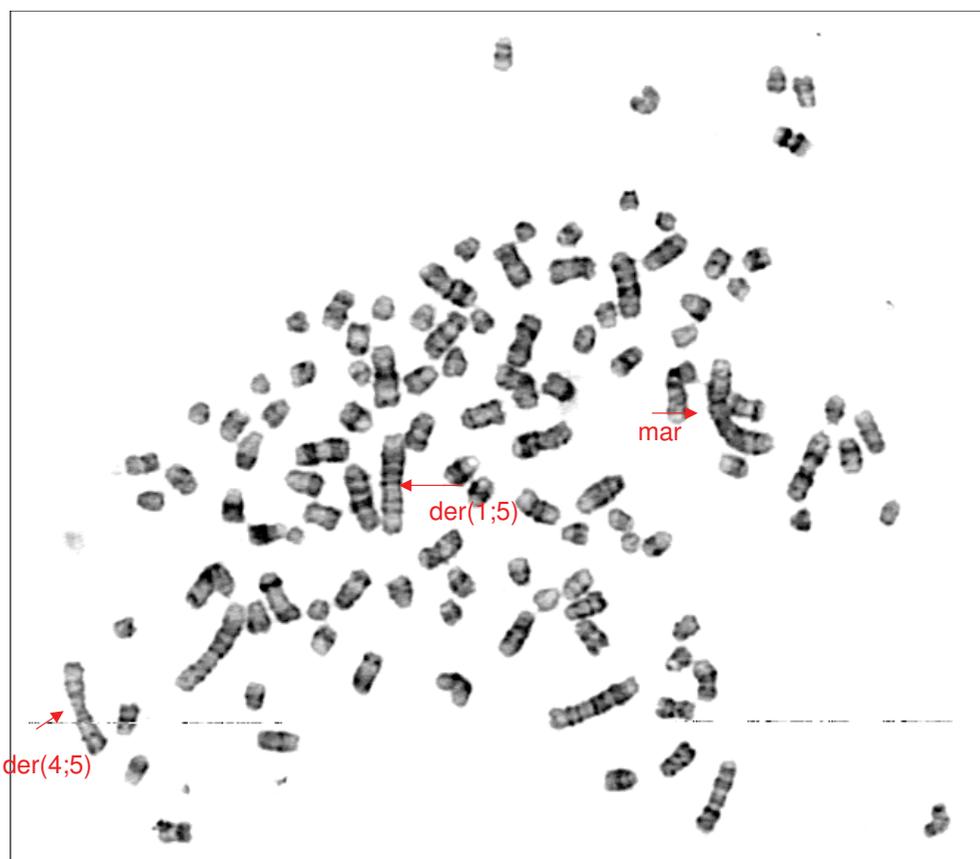

Figure 8

Metaphase spread from cells derived from a CT1258 induced tumour. The arrows indicate the derivative chromosomes der (1; 5), der (4; 5) and the marker chromosome mar, which consists of chromosome 1 and chromosome 2 material.

Conclusion

The canine prostate carcinoma cell line CT1258 demonstrated to be tumourigenic in the NOD-Scid mouse. Tumours induced in mice resembled the biological behaviour of the tumour from which the cell line was originally derived regarding growth pattern and histological appearance. Therefore we conclude that the use of this animal model will provide results with a high predictability towards clinical use in veterinary medicine and due to the correlation between canine and human prostate carcinoma in humans as well. The lack of skeletal metastasis is a potential field for further studies.

Competing interests

The authors declare that they have no competing interests.

Authors' contributions

MAMF was involved in study-design, implemented the *in vivo* tasks and the histopathology, and wrote the paper, HME was involved in study-design and coordination of *in vitro* work up, JTS and KAS assisted with dissection of the

animals and *in vitro* work up, SaW prepared the cells for inoculation, SuW was involved in study-design, NR-B was involved in chromosomal preparation, cytogenetic analyses and karyotyping, MD and HHJH were involved in study-design and supervising the *in vivo* work up, JB and IN incited the study and coordinated the operational procedure. All authors read and approved the final manuscript.

Abstract

Carcinomas of the prostate count to the most common neoplasms in men being one of the leading causes of cancer-related death. Besides men the dog is the only known species developing spontaneously carcinoma of the prostate. These in both species spontaneously appearing neoplasms show significant similarities in their biologic behavior e.g. their metastatic pattern and the expression of cancer related tumor markers. Proteins of the high mobility group A family (HMGA1 and HMGA2) were identified as tumor markers in both species. Accordingly their overexpression has been reported for a variety of cancers in both species showing a correlation of their overexpression and the malignant phenotype of the respective tumors. Herein we report that adeno-associated viruses (AAV)-2 carrying the mRNA of *HMGA1* or *HMGA2* in antisense orientation can significantly inhibit the proliferation of canine CT1258 prostate carcinoma cells *in vitro*, thus a suppression of HMGA expression represents a potential method for treatment of prostate carcinomas.

Introduction

In Europe prostate cancer is a leading cause of cancer related death among men with over 56,000 deaths per year in the European Union.¹ The worldwide incidence of registered prostate cancer accounts for 543,000 new cases each year, which is strongly related to Western lifestyle and an increasing risk of developing the disease at middle age (> 50 years). For men, the lifetime risk is about 10 % with a mortality rate of 3 %.^{2, 3}

Dogs are an animal model suited to elucidate the mechanisms of pathogenesis of human prostate carcinomas. First of all, except for humans dogs are the only known mammalian species that spontaneously develop carcinomas of the prostate with a considerably high frequency.⁴ As intensively outlined in the recent literature, dogs and humans share striking similarities in the field of oncology.^{5, 6} Also, canine cancer diseases are characterized by spontaneous development of neoplasias without the need for experimental induction or transplantation and artificially acquired immunodeficiency, respectively.⁷ Interestingly for cancer research, dogs are reported to develop cancer approximately twice as frequent as humans. Additionally the canine neoplasms show a faster progression of the tumors and their development when compared to their human counterparts and thus allow a better monitoring of the tumor related processes.⁸

Akin to human prostate adenocarcinomas their canine counterparts show local invasiveness and metastasize to the same organs, e.g. lungs and bones by bloodstream or lymph.⁴ As to age distribution, older individuals are prevalently affected by developing prostate cancer in both species, with an average age of 65 years in men⁹ which means a comparable age of 10 years in dogs.¹⁰

The high mobility AT-hook group of proteins (HMGA) consists of three members: HMGA1a, HMGA1b and HMGA2. HMGA proteins are characterized by three highly conserved DNA binding

domains called the “AT-hooks”.¹¹ The proteins HMGA1a and HMGA1b are isoforms coded by the same gene for alternative splicing variants. *HMGA1* is located on human chromosomal band 6p21.^{12, 13} The closely related HMGA2 protein is encoded by a different gene, which is located on 12q14-15^{14, 15}. These non-histone proteins are small secondary structured polypeptides which preferably bind to the minor groove of AT-rich B-form DNA and are defined as architectural nuclear factors, which are involved in chromatin dynamics. HMGA proteins influence the expression of a large number of genes by modifying chromatin structure.¹⁶⁻¹⁸

HMGA proteins are abundantly expressed during embryonic and fetal life. It has been proposed that HMGA2 mediates an embryonic chromatin conformation¹⁹ and accordingly HMGA2 has been implicated in the regulation of key developmental genes in pluripotent embryonic stem cells.²⁰

Overexpression of HMGA1 is reported in a diversity of human cancers, as for example cancers of breast, cervix, colon, thyroid, and prostate²¹⁻²⁴, whereas high levels of HMGA2 expression are observed in breast cancer, leukemia, non-small cell lung cancer, pancreatic cancer and squamous cell carcinomas of the oral cavity.²⁵⁻²⁹ In the latter cancer entity increased HMGA2 expression is correlated with epithelial-mesenchymal transitions and there is evidence that in case of malignant epithelial tumors HMGA proteins act by increasing tumor stemness of cancer cell populations, which is correlated with adverse prognosis.³⁰

As to comparative genomics we recently characterized the canine *HMGA1a* and *HMGA1b* transcripts and deduced their protein sequence, which showed a 100 % identity to its human counterpart whereas the coding sequence shows a 95 % identity in both splice variants.^{31, 32} To the best of our knowledge the complete canine *HMGA2* transcript was not characterized so far. In order to construct antisense *HMGA2* AAV vectors for the experimental

studies presented herein we have characterized the coding sequence.

Recently a new cell line was established from a canine prostate carcinoma.³³ Due to the similarities between human and canine prostate cancer, this new canine cell line provides a valuable tool in experimental cancer gene therapeutic approaches. Thereby an important aspect is that the original tumor as well as the derived cell line show high levels of *HMGA2* expression. The overexpression of *HMGA* genes in the canine cell line strongly correlates to the described malignancy of the carcinoma.³⁴

The aim of this study was to construct recombinant adeno-associated viruses encoding *HMGA1* and *HMGA2* antisense RNA and to analyze their effects on the proliferative behavior of canine carcinoma cells infected with the virus. AAV mediated gene therapy experiments show many advantages compared to the widely used adenoviral vectors, which induce host immune response to the target cells. Recombinant AAVs demonstrate long-term transgene expression and a minimal immune response.³⁵ Previous studies have shown that AAV vectors can be used successfully for the delivery of gene expression in sense and antisense orientation for up- and down regulation of target genes.³⁶⁻³⁹ In terms of suppression of *HMGA* expression, other studies conducted in athymic mice used adenoviral virus systems to deliver anti-sense *HMGA* cDNA to inhibit cell proliferation, malignant transformation and size of engrafted tumor.^{40, 41} In our study, we demonstrate the inhibition of cell proliferation in a canine prostate carcinoma cell line mediated by antisense *HMGA* mRNA recombinant AAVs (rAAV-asHMGA1, rAAV-asHMGA2).

Material and methods

Cell lines

The canine carcinoma cell line CT1258³³ was cultured in sterile flasks containing 5 ml of medium 199 with Earle's salts (Gibco, Invitrogen, Karlsruhe, Germany) with 20% heat inactivated and filtrated fetal bovine serum (FBS). 12 hours prior to infection with recombinant AAVs, 2500 CT1258 cells per well were seeded into 96 multiwell dishes and cultivated in 10 % FBS 199 medium.

For AAV production HEK-293 cells (AAV-293) were obtained from Stratagene's AAV-Helper-Free System. According to the manufacturer's protocol the cells were cultured in 10 % FBS D-MEM Medium (Biochrom AG, Berlin, Germany). All cell lines were cultivated in a 37°C incubator with 5 % CO₂ saturation.

AAV plasmids

The vector plasmid for generating the recombinant AAVs was obtained from Stratagene's AAV-Helper-Free System (Stratagene, La Jolla, USA). The kit includes the pAAV-MCS (AF396260) plasmid containing the ITR sequences, multiple cloning site (MCS), the CMV promoter and *hGH* poly A tail. The system also includes the pAAV-RC (AF369963) for AAV replication and the capsid genes, the pHelper (AF396965) which provides adenoviral helper function by coding for *E2A*, *E4*, and *VA* RNA genes; the pAAV-LacZ (AF369964) contains the CMV promoter, the ORF for the reporter gene *lacZ* and ITR sequences (Figure 1). Ultra competent the XL-10-Gold *E. coli* (Stratagene, La Jolla, USA) were used to amplify the AAV Helper-Free plasmids and recombinant AAV vectors. The AAV plasmids were harvested and purified with the EndoFree Plasmid Purification Kit (Qiagen, Hilden Germany).

Cloning of canine HMGA cDNA and construction of antisense RNA plasmid vectors

Total RNA was isolated from CT1258 canine carcinoma cell line using RNeasy Mini Kit (Qiagen, Hilden, Germany) following the manufacturer's protocol. In order to prevent genomic DNA contamination DNase I digestion was performed using RNase-Free DNase Set (Qiagen, Hilden, Germany). cDNA was synthesized using 3'RACE adapter primer AP2 (seq), 5µg of total RNA, and SuperScript II reverse transcriptase (Invitrogen, Karlsruhe, Germany) according to the manufacturer's instructions. The RT-PCRs for the molecular cloning the canine for the short cDNA fragments of *HMGA1a* (484 bp) and *HMGA2* (312 bp) were done using BamHI and EcoRI adapter primer pairs. For *HMGA1*, BamHI-IYup (enzyme recognition sites in minuscule) (5'-CGg gatccCTCGCGGCATCCCAGCCATCACT C-3'), EcoRI-IYlo (5'-CGgaattcGCGGCTGGTGTGCTGTGTAGTGTG -3') and for *HMGA2*, BamHI-ICup (5'-CGg gatccGTGAGGGCGCGGGCAGCCGTCC ACTTC-3'), EcoRI-IClo (5'-CGgaattcCTCTTCGGCAGACTCTTGTGAGGA TGTCT-3') were used. The primer for generating the long cDNA fragments of *HMGA1b* (1677 bp) were BamHI-IYup and EcoRI-A1-3'UTR (5'-CGgaattcATTCAAGTAACTGCAAATAGGA-3') and for *HMGA2* (1363 bp), BamHI-ICup and EcoRI-A2Ex5lo (5'-CGgaattcTTTCGCTCCTCTCACCTAAT-3').

A 1.5 % agarose gel electrophoresis was performed to separate the PCR products, the fragments were recovered with QIAquick Gel Extraction Kit (Qiagen, Hilden, Germany). The PCR products were cloned in the pGEM-T Easy Vector and sequenced in forward and reverse direction (MWG-Biotech AG, Ebersberg, Germany). The vector plasmid containing the *HMGA* (*HMGA1a* or *HMGA2*) cDNA was afterwards double-digested with *Bam*HI and *Eco*RI (Fermentas GmbH, St.Leon-Rot, Germany), and separated in a 1.5 % agarose gel, and the *HMGA* fragment was purified with QIAquick Gel Extraction Kit. In a

separate preparation the pAAV-MCS plasmid correspondently was digested with *Bam*HI and *Eco*RI and the assay was purified with QIAquick Nucleotide Removal Kit (Qiagen, Hilden, Germany). The *HMGA* fragment was ligated with T4-DNA Ligase (Fermentas GmbH, St Leon-Rot, Germany) at 25°C for 12 h into the *Eco*RI/*Bam*HI sites of the linearized pAAV-MCS (Stratagene, La Jolla, USA) plasmid to generate pAAV-HMGA in anti sense orientation relative to the CMV promoter (Figure 1). For validation the constructed pAAV-asHMGA vectors were confirmed by sequencing and restriction enzyme digestion.

rAAV vector construction, purification and titer measurement

Recombinant AAVs serotype 2 (AAV-2) were generated by transient transfection with CaCl₂/HBS buffer of AAV-293 cells with 10 µg of each of the three plasmids (pAAV-RC, pAAV-Helper, pAAV-asHMGA or pAAV-LacZ, respectively) according to the manufacturer's protocol (Stratagene, AAV-Helper-Free System). The AAV-2 primary stocks were purified using ViraTrap preequilibrated heparin agarose columns (Omega Bio-Tek, Doraville, USA) and stored in aliquots at -20°C. The virus genome titer (vg/ml) was determined by CMV promoter sequence specific quantitative RT-PCR (qRT-PCR) according to previously described methods^{42, 43}. For absolute quantification of vg/ml the qRT-PCR amplification was carried out using the Applied Biosystem 7300 Real-Time PCR System (Applied Biosystem, Darmstadt, Germany). The following primers were used in the qRT-PCR reactions: forward pAAV (5' GAGGTCTATATAAGCAGAGCTCGTTTAGT 3'), reverse pAAV (5' GGTGTCTTCTATGGAGGTCAAAACA 3') and the fluorogenic probe pAAV (5' 6-FAM-CAGATCGCCTGGAGACGCCATCC-TAMRA).

For each rAAV-asHMGA vector a simultaneous production of rAAV-LacZ vectors was performed in order to evaluate the quality and functionality of rAAV particles. Infections of HT1080 cells were performed followed by counting the induced X-Gal stained LacZ-forming units (Stratagene, AAV-Helper-Free-System and In Situ β-Galactosidase Staining Kit). Furthermore, additional quantitative real-time PCRs for titration of infectious rAAV-2 particles⁴⁴ were established using primers and probes mentioned above (data not shown).

Cell proliferation assay

2500 CT1258 cells per well were seeded into a 96 multi well plate in eight different wells in medium 199 (10 % FBS) at 37°C and 5 % CO₂. After 90 min the cells were infected with different quantities of AAV particles. Subsequently, the CT1258 cells were divided into different groups: group LacZ with 350, 1,000, 10,000, 15,000 vg/cell of rAAV-LacZ infected cells and an untreated control. Group asHMGA with 350, 1,000, 10,000, 15,000 rAAV-asHMGA virus genomes per cell (vg/cell) or a combination of both rAAV-asHMGA1 and asHMGA2 (175/175, 500/500, 5,000/5,000 and 7,500/7,500 vg/cell of rAAV-asHMGA1a/rAAV-asHMGA2) and an untreated control. In order to prevent cross-contamination each assay was performed on a separate multi well plate. BrdU was added after 60 h for an incubation time of 12 h. After 72 h of rAAV infection the incubation was stopped and prepared for cell proliferation assay as noted in the manufacturer's instruction. Quantification of the cell proliferation was performed by ELISA, BrdU colorimetric assay (Roche Diagnostics, Penzberg, Germany). The measurement of absorbance of the samples was done with the Synergy HT multititer plate reader (Biotek Inc., Winooski, USA) at 370 nm (reference wavelength 492 nm).

Statistical analysis

Statistical significance between the groups was tested using a one-way ANOVA using GraphPad Prism Software (GraphPad Software, La Jolla, USA). A *P*-value less than 0.01 was considered to be statistically significant. In Figure 2 the standard deviations of all assay controls were summarized for better presentation.

Results

The incorporation of BrdU as a synthetic analog of thymidine into newly synthesized DNA of replicating cells of the S-phase is used for the measurement of proliferation. The cells either served as a control or were treated with 350, 1,000, 10,000 or 15,000 vg/cell of rAAV-LacZ (Figure 2). For antisense *HMGA* AAV treatment the cells were also infected with 350, 1,000, 10,000 and 15,000 vg/cell of rAAV-asHMGA. A double virus infection using *HMGA1* and *HMGA2* anti-sense transcripts was done in a combination (50:50 ratios) of 350, 1,000, 10,000 and 15,000 vg/cell (Figure 2).

For comparability the absorbance were presented as percentage of proliferation. The proliferation rate of untreated cells was presumed to be 100 %, meaning that the quotient of the mean values from treated and untreated cells are expressed as the percentage of proliferation rates of cells exposed to rAAV vectors.

Both rAAV-LacZ and rAAV-asHMGA vectors showed a decrease in proliferation of the CT1285 cells (Figure 2). The effect of 15,000 rAAV-LacZ vg/cells is a decrease of 10.9 % compared to the untreated control, the *P*-value is <0.01.

A decrease in proliferation is shown for the CT1258 cells treated with the rAAV-asHMGA vectors. In detail the rAAV-asHMGA1short showed a 44.1 % decrease in proliferation at a titer of 10,000 vg/cell and respectively a 65.7 % decrease at a titer of 15,000 vg/cell. Whereas the rAAV-asHMGA2short showed a 36.1 % decrease of proliferation at titer of 15,000 vg/cell, the *P*-value are <0.01. The percentage of the decrease of CT1258 cell proliferation induced by the

vector combination of rAAV-asHMGA1 short and rAAV-asHMGA2 short is 61.7 % at a titer of 15,000 vg/cell in comparison to the untreated control, with a *P*-value of <0.01.

The inhibitory effect of proliferation is greater for the rAAV-asHMGA containing the CDS and parts of the 3'UTR sequence. For the rAAV-asHMGA1long virus vector the measured decrease of cell proliferation is 64.6 % at a titer of 10,000 vg/cell and 99.2 % at 15,000 vg/cell compared to the control, the *P*-values are <0.01.

The rAAV-asHMGA2long showed a 56.0 % decrease at a titer 10,000 vg/cell and 79.7 % decrease at 15,000 vg/cell, whereas in contrast a combination of both rAAV-asHMGA1long and rAAV-asHMGA2long showed a 96.8 % at titer 10,000 vg/cell and a 99.0 % decrease of proliferation compared to the untreated control. Statistical analyses using a one-way ANOVA revealed a highly significant decrease of cell proliferation (*P*<0.0001).

Discussion

In many benign mesenchymal tumors as for example uterine leiomyomas, lipomas, and pulmonary chondroid hamartomas^{14, 45-47}, a transcriptional reactivation of *HMGA* genes because of chromosomal rearrangements has been noted.

As to malignant tumors upregulation of *HMGA* protein expression seems to correlate to aggressiveness and severe prognosis of the disease, as has been shown e.g. for thyroid, breast, lung and prostate cancer. Previous *in-vitro* and *in-vivo* studies have shown that antisense *HMGA* vector transcripts induced by adenoviral vectors were able to reduce significantly protein synthesis of HMGA which in turn led to decreasing tumor growth and proliferation in transfected cancer cells and tissues of the thyroid.⁴⁰ In the present study the *in-vitro* infection of canine prostate carcinoma cells by combination of recombinant antisense *HMGA1* and *HMGA2* AAV-vectors also showed an inhibition of cell proliferation. Recently several studies on *HMGA2* transcription suppression were published concerning the regulation of *HMGA2* by microRNAs of the *let-7* family. In non-small cell lung cancer cell lines the inhibition of cell proliferation was achieved with the transfection of siRNA similar in sequence to the naturally occurring *let-7b*, *let-7e* and *let-7g* miRNAs.⁴⁸ The suppressive effect of *let-7* miRNAs on *HMGA2* expression is mediated through its capacity to bind to specific partial match sites within the 3'UTR of *HMGA2*. This effect would explain that in benign mesenchymal tumor entities translocations within the *HMGA2* gene locus can remove the recognition sites for miRNA *let-7*.⁴⁹ These studies strongly encourage the potential gene therapeutic approach of inducing antisense *HMGA* transcription for treating cancer because in many tumor entities e.g. lung cancers the transcription of *HMGA2* is up-regulated while the *let-7* expression is down-regulated.^{48, 50, 51}

Pancreatic adenocarcinomas showing an elevated expression of HMGA1 protein have a significantly

decreased median survival compared to patients without HMGA1 expression.

Additionally, application of *HMGA1* silencing siRNA *in vivo* led to the reduction of pancreatic adenocarcinoma cell line induced tumor volume in nude mice⁵².

In summary the infection of canine prostate carcinoma cells with the long rAAVasHMGA virus variants, encoding the CDS and 3'UTR in antisense orientation has led to the most promising effect of decreasing the cell proliferation to 4.5% compared to the untreated control. In mammals, insects, and fungi the existence of natural gene antisense transcripts has been reported to play an important role in gene regulation, e.g. circadian clockwork configuration, RNA processing and imprinting, most of all the regulation of the insulin like growth factor 2 receptor due to the transcription of antisense RNA from upstream control regions.^{53, 54} In this study a strong expression of anti-sense *HMGA* transcripts was mediated by the eukaryotic CMV promoter encoded by the AAV genome. These anti-sense *HMGA* transcripts are complementary to endogenous *HMGA* mRNA forming RNA duplexes. These double stranded RNAs are the key targets of the post transcriptional gene silencing machinery of the cell or RNA interference respectively.

In conclusion the repression of HMGA translation mediated by recombinant AAV carrying large *HMGA* RNA in antisense orientation could be a promising target for a gene therapeutic approach for treating prostate cancer.

Abstract

Ultrashort pulsed laser ablation in liquids represents a powerful tool for the generation of pure gold nanoparticles (AuNPs) avoiding chemical precursors and thereby making them especially interesting for biomedical applications. However, because of their electron accepting properties, laser-generated AuNPs might affect biochemical properties of biomolecules, which often adsorb onto the nanoparticles. We investigated possible effects of such laser-generated AuNPs on biological functionality of DNA molecules. We tested four differently sized and positively charged AuNPs by incubating them with recombinant eGFP-CI-HMGB1 DNA expression plasmids that code for eGFP fusion proteins and contain the canine architectural transcription factor HMGB1. We were able to show that successfully transfected mammalian cells are still able to synthesize and process the fusion proteins. Our observations revealed that incubation of AuNP with the plasmid DNA encoding the recombinant canine HMGB1 neither prevented the mediated uptake of the vector through the plasma membrane in presence of a transfection reagent nor had any effect on the transport of the synthesized fusion proteins to the nuclei. Biological activity of the recombinant GFP-HMGB1 fusion protein appears to have not been affected either, as a strong characteristic protein accumulation in the nucleus could be observed. We also discovered that transfection efficiencies depend on the size of AuNP. In conclusion, our data indicate that laser-generated AuNPs present a good alternative to chemically synthesized nanoparticles for use in biomedical applications.

Findings

Gold nanoparticles (AuNPs) are used widely for various biomedical applications including cell imaging [1], diag-

nostics [2], targeted drug delivery [3], and sensing [4]. Various methods have been established for AuNP generation. Many of these rely on several chemical reactions or gas

pyrolysis, showing the risk of impurities or agglomeration [5]. Laser ablation in liquids showed to be a powerful tool with many advantages, having almost no restriction in the choice of source material and the ability of yielding highly pure colloidal particles [6-11]. These pure AuNPs are characterised by their unique surface chemistry free of surfactants, a feature unattainable by other methods [12-14]. X-ray photoelectron spectroscopy of such AuNPs revealed the presence of the oxidation states Au⁺ and Au³⁺ at the AuNP surface [15]. In previous studies we demonstrated that unmodified DNA oligonucleotides adsorb easily onto these positively charged nanoparticles [16,17], probably via amino- and keto-groups, which interact with the electron accepting surface of the generated AuNPs. However, these findings raised the possibility that more complex biomolecules could also be attracted and bound to such nanoparticles' surfaces, if incubated intentionally or unintentionally with colloidal laser-generated gold nanoparticles, even if no additional conjugation is envisaged. Such binding could have a strong effect on the properties of biomolecules and should be characterised with a view of their potential toxicity [18].

We therefore decided to analyse the possible effects of laser-generated AuNPs on DNA functionality. For this reason we incubated the charged particles with recombinant eGFP-C1-HMGB1 expression plasmids and subsequently transfected them into mammalian cells. As the HMGB1 protein is normally highly abundant in the cell nuclei, we were able to show that the treated expression plasmids are still functional and suitable for use as transcription matrix, because the transfected cells were still able to synthesize the fusion proteins, to process them and to transport them to their biofunctional destination. The effect of four differently sized nanoparticles on the activity of the eGFP-C1-HMGB1 plasmid was investigated by fluorescence microscopy. We additionally performed a binding assay to investigate structural effects on the plasmid due to AuNP co-incubation.

Nanoparticle generation

AuNPs were generated by laser ablation in water, as recently reported in detail [17]. Briefly, the beam of a femtosecond laser system (Spitfire Pro, Spectra-Physics), delivering 120 fs laser pulses at a wavelength of 800 nm, was focused with a 40 mm lens on a 99.99% pure gold target placed at the bottom of a Petri dish filled with 2 mL of bidistilled water. A pulse energy of 200 μ J at 5 kHz repetition rate was employed for 12 min. According to observations of Kabashin et al. [9] the focal position was lowered from one generation experiment to the other (0 mm, -2 mm, -4 mm relative to the focus in air) in order to obtain colloidal suspensions containing AuNPs with mean hydrodynamic diameters of $d_h = 89$ nm, $d_h = 59$ nm and $d_h = 24$ nm. The remaining small particles were removed

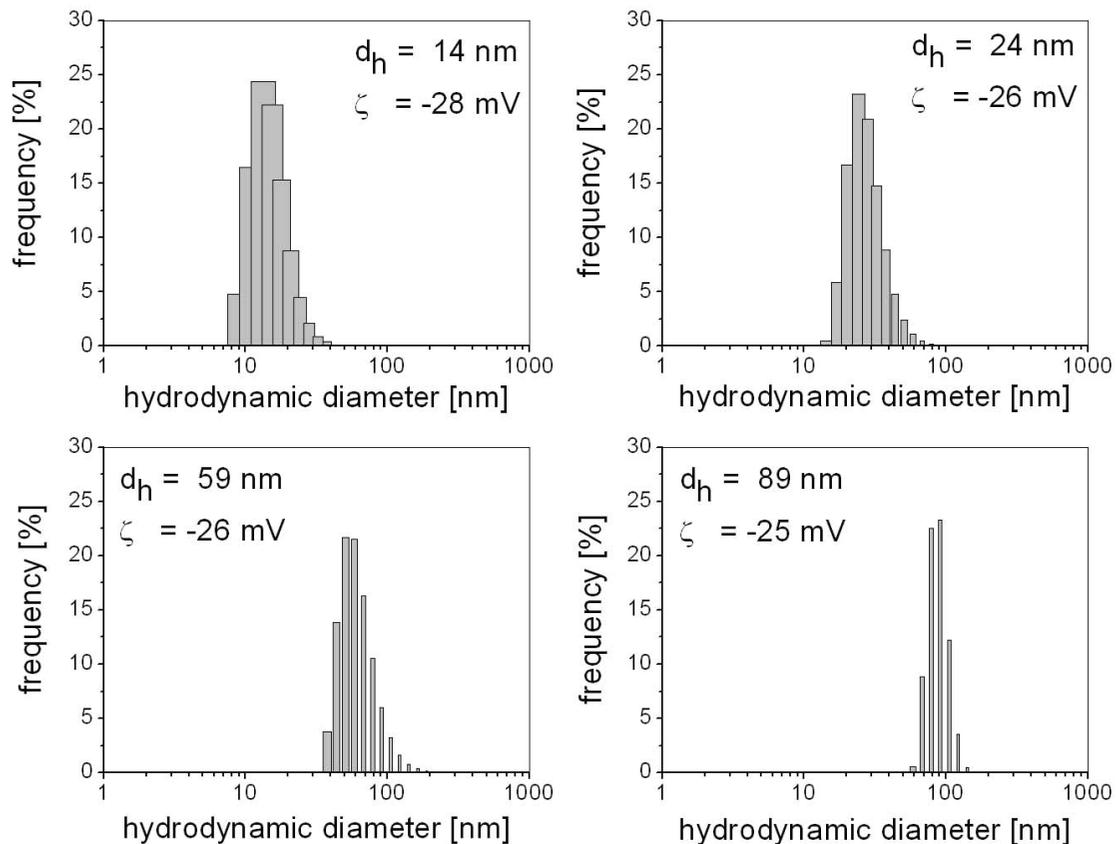

by centrifugation at 15000 rpm for 10 min. To generate 14 nm AuNPs, laser ablation was carried out at a focal position of -4 mm, followed by a second irradiation for 5 min at 1 mJ with an Nd-YLF laser system (pulse length: 27 ns, 1047 nm, 5 kHz), as was described recently [19,20]. Characterization of nanoparticle suspensions was performed by dynamic light scattering using a Malvern Zetasizer and by UV-Vis spectroscopy using a Shimadzu 1650. The hydrodynamic number distributions and the average zeta potential of the colloids are shown in Figure 1. The zeta potential seems to be independent of the nanoparticle size, which might be explained by a similar surface charge density.

The particle mass concentration in the suspensions was determined by weighing the sediment after water evaporation.

Au-NP and eGFP-C1-HMGB1 vector in vitro transfection assay

The synthesised Au-NP suspensions were sterilized by filtration through a 0.2 μ m filter device (Millex-GV Sterilizing Filter Unit, Millipore, Billerica, USA). Subsequently, 250 ng of each differently sized Au-NPs were incubated for 24 h at room temperature with 1 μ g of recombinant plasmid eGFP-C1-HMGB1 in a total volume of 47 μ l of ddH₂O. The time of co-incubation was intentionally kept that long as we aimed to investigate possible effects on the vector due to nanoparticle interferences. This was only possible as the circular double-stranded plasmid is not susceptible to rapid degenerative processes.

The recombinant plasmid encodes an eGFP-HMGB1 fusion protein. The HMGB1 coding sequence was derived from canine cDNA using PCR amplification (primer pair EcoRI_B15'CGGAATTCACCATGGGCAAAGGAGA3'/KpnI_B1 (5'GCGGTACCTTATTCATCATCATC-3'). The obtained PCR products were separated on a 1.5% agarose gel, recovered with QIAquick Gel Extraction Kit (QIAGEN, Hilden, Germany), cloned into the pEGFP-C1 vector plasmid (BD Bioscience Clontech) and sequenced. Twelve hours prior to transfection, 3×10^5 cells from canine mammary cell line MTH53a were seeded into 12 multi well plates. The cells were grown at 37°C and 5% CO₂ in medium 199 (Invitrogen, Karlsruhe, Germany) supplemented with 20% FCS, penicillin, and streptomycin. For transfection, 3 μ l aliquots of Eugene HD (FHD) reagent (Roche, Mannheim, Germany) were added to 47 μ l of different Au-NP/eGFP-C1-HMGB1 plasmid suspensions in a total volume of 50 μ l and incubated for 15 min. The three control sample sets were: (i) 1 μ g of eGFP-C1-HMGB1 DNA without nanoparticles, (ii) 250 ng of Au-NPs without any plasmid DNA, and (iii) a set of Au-NPs with DNA, but without the FHD.

**Figure 1**

Size distribution and surface charge of laser generated gold nanoparticles. Gold nanoparticles (Au-NP) were generated by laser ablation in water using a femtosecond laser system (Spitfire Pro, Spectra-Physics) delivering 120 fs laser pulses at a wavelength of 800 nm (working pulse energy: 200 μ J per pulse, beam diameter: 4 mm). In order to generate four suspensions containing differently sized nanoparticles, the focal position was lowered from one generation experiment to the other (0 mm, -2 mm, -4 mm relative to the focus in air) resulting in the colloidal suspensions containing nanoparticles with mean hydrodynamic diameters of $d_h = 89$ nm, $d_h = 59$ nm and $d_h = 24$ nm. For the generation of 14 nm sized nanoparticles, laser ablation was carried out at a focal position of -4 mm and then reirradiated for 5 min at 1 mJ with an Nd-YLF laser system (pulse length: 27 ns, 1047 nm, 5 kHz). The hydrodynamic size distribution was analysed by Dynamic Light Scattering.

Following 15 min incubation at 23 °C, the respective 50 μ l transfection mixtures were added to cell cultures. The cells were incubated for 48 hours in medium 199 (20% FCS) at 37 °C and 5% CO₂. The uptake of plasmid DNA and expression of the eGFP-C1-HMGB1 fusion protein were verified by fluorescence microscopy. All experiments were performed in quadruples.

Fluorescence microscopy

Transfected cells were washed with PBS, fixed in a 4% paraformaldehyde/PBS solution (pH 7.5) for 30 min at room temperature and washed again with PBS. Afterwards, the cells were incubated with 10 μ l of mounting medium containing DAPI (4',6-diamidino-2-phenylindole) for fluorescent visualization of nucleic DNA (Vecta

Laboratories, Burlingame, USA). Fluorescence microscopy was performed using the Carl Zeiss Axioskop 2 and images were recorded with the Axiovision Software. eGFP fluorescence was measured employing wavelength filter set 10 (Carl Zeiss MicroImaging, Göttingen, Germany), while DAPI fluorescence was measured employing wavelength filter set 2 (Figure 2A to 2M). Both fluorescence images were taken with a Zeiss 2-channel Axiocam MRm camera. Both images were then merged in a single image. Full colour images were taken with a Zeiss Axiocam HRC (Figure 2M and 2N). The uptake of plasmid DNA (efficiency of transfection) was estimated taking into account the quantity of cells within an ocular's visual field. Thus the estimation was done comparing the number of cells showing green fluorescence protein expression (green

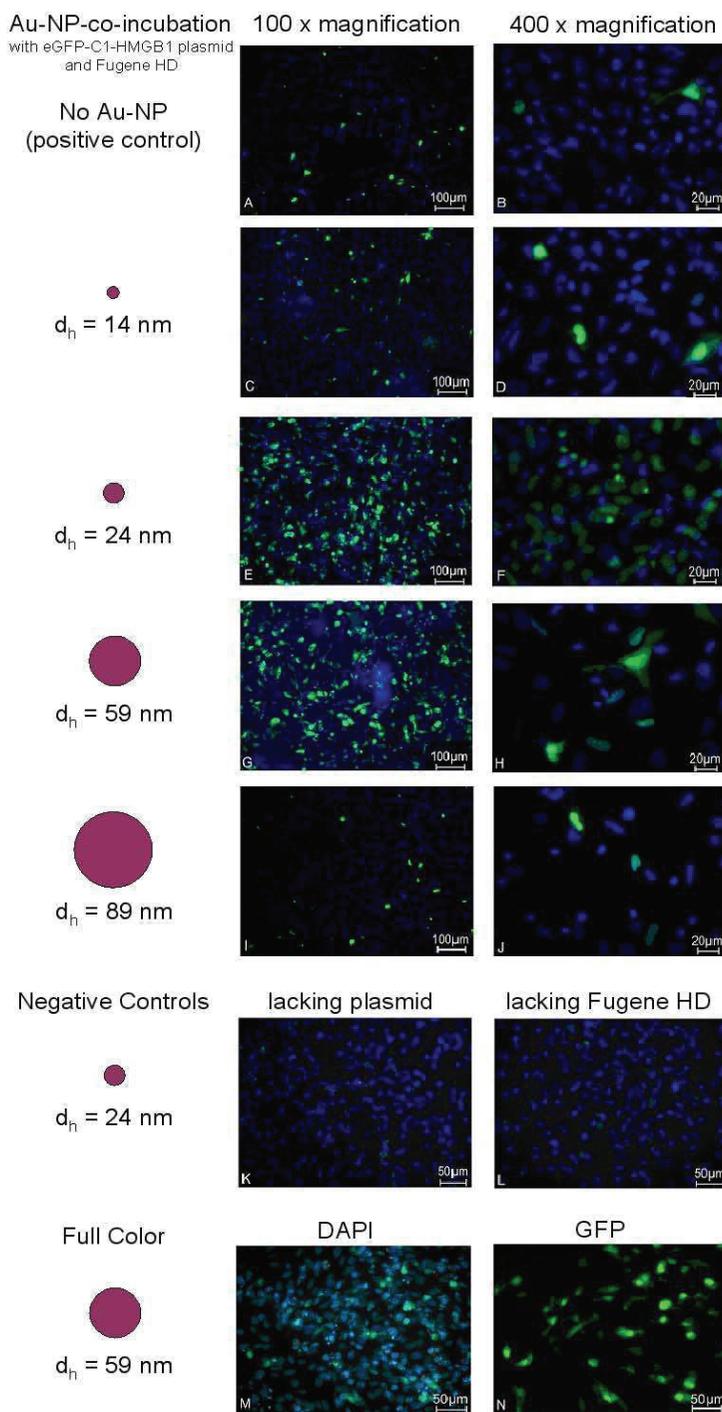

Figure 2
The effect of co-transfecting plasmid DNA and laser generated gold nanoparticles on the bioactivity of GFP-HMGB1 fusion protein. Images A to I (vertical) show a 100 fold magnification and B to J (vertical) a 400 fold magnification. Images A and B represent the positive control I: a transient transfection of MTH53a cells by Fugene HD reagent with the eGFP-C1-HMGB1 plasmid without Au-NP incubation. Cells in images C to J are treated like control I but include incubation of the plasmid with 14 nm sized Au-NP (C and D), 24 nm sized Au-NP (E and F), 59 nm sized nanoparticles (G and H) and 89 nm sized Au-NP (I and J), respectively. Image K and L represent the negative controls II and III. M and N are full color images of DAPI and GFP fluorescence.

Table 1: Summary of estimated transfection efficiencies

Size Au-NP (d_h)	Estimated Transfection Efficiency (%)	Figure
Positive controls	10 ± 2	A and B
14 nm	15 ± 5	C and D
24 nm	50 ± 5	E and F
59 nm	50 ± 10	G and H
89 nm	8 ± 3	I and J
Negative controls	-	K and L

Differently sized Au-NPs were incubated with plasmid DNA and transfected into the canine MTH53a cellline

staining) and cells showing blue DAPI fluorescence dye staining.

Co-transfection of plasmid DNA and laser-generated gold nanoparticles

As the HMGB1 protein is a transcription factor, it binds strongly to nuclear DNA. We therefore may assume that cell nuclei containing strong eGFP fluorescence represent successful functional transfection events. All cells transfected with AuNP-incubated plasmid DNA showed strong colocalised eGFP and DAPI staining (Figure 2), whilst the negative controls, cells treated with Au-NP and FHD (AuNP of $d_h = 24$ nm), showed no eGFP fluorescence (Figure 2K). We therefore conclude that co-incubation of AuNP with the plasmid DNA encoding the recombinant canine HMGB1 neither prevents the mediated uptake of the vector in presence of a transfection reagent nor has any visible effect on the transport and biological functionality of the synthesised fusion proteins.

By comparing fluorescence images of the cells co-incubated with the AuNPs of different sizes and to cells incubated without AuNPs, we were able to compare transfection efficiencies in each case. We estimate that the achieved efficiency of DNA transfection for the sample containing 14 nm AuNPs was approx. $15 \pm 5\%$ (Figure 2C and 2D).

The highest observed transfection efficiencies were achieved using 24 nm and 59 nm Au-NPs ($50 \pm 5\%$ and $50 \pm 10\%$ respectively, see Figure 2E to 2H). The Au-NPs showed size dependent effects concerning the observed transfection efficiencies (see Table 1). Exemplarily, Au-NPs of a medium size (d_h : 24 and 59 nm) showed the highest effects. Thus, the observed GFP fluorescence of the respective fusion proteins was so intense that it even leaked into the DAPI channel (Fig 2M and 2N respectively for AuNP of $d_h = 59$ nm). Further negative control samples containing DNA- co-incubated AuNPs missing FHD, showed no recombinant protein expression, proving that our AuNPs did not act as transfection reagent themselves. (Figure 2L). The cell population seems to go along with

transfection efficiency, as the observed seeding density was in all wells similar prior to transfection.

Shift assay

We performed binding experiments with plasmid DNA (eGFP-C1-HMGB1) and respective Au-NPs of different sizes and with various concentrations. We digested the co-incubated batches with a *NcoI* restriction enzyme (Fermentas, St Leon Rot, Germany) and separated the resulting DNA fragments in a 1.5% agarose gel. No significant shift alterations could be observed in the DNA mobility pattern. To ensure that this phenomenon is also valid in presence of proteins we added purified HMGB1 protein (Centre for Human Genetics, Bremen, Germany) to the

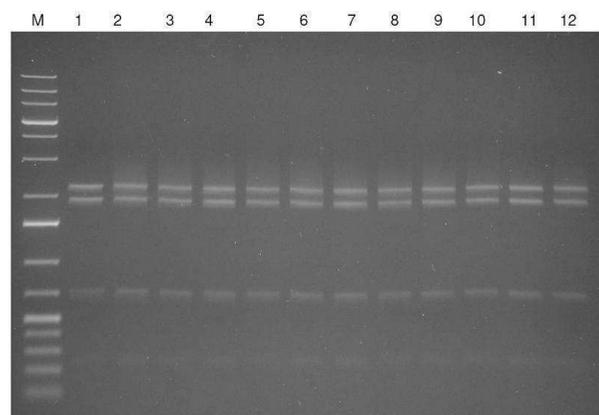

Figure 3
Au-NPs/DNA and HMGB1 protein mobility shift assay. M: GeneRuler 1 kb Plus (Fermentas), lane 1: 170 ng plasmid (*NcoI* digested); lane 2: 170 ng plasmid (*NcoI* digested) and 1.5 μ g HMGB1; lanes 3-6: 170 ng plasmid 170 (*NcoI* digested) and 1.5 μ g HMGB1 in 0.1 nM, 0.5 nM, 1.0 nM and 2.5 nM AuNPs suspensions, size d_h 24 nm; lane 7: 170 ng plasmid (*NcoI* digested) and 1.5 μ g HMGB1 and 90 ng pure Au suspension, size d_h 24 nm; lanes 8-11: 170 ng plasmid (*NcoI* digested) and 1.5 μ g HMGB1 in 0.1 nM, 0.5 nM, 1.0 nM and 2.5 nM AuNPs suspensions, size d_h 59 nm; lane 12: 170 ng plasmid (*NcoI* digested) and 1.5 μ g HMGB1 and 50 ng pure Au suspension, size d_h 59 nm.

batches. Akin to the DNA mobility pattern of digested Plasmid DNA and HMGB1 without Au-NPs (lane 2, Figure 3) we could not detect any significant change in the shift pattern (see lanes 3 to 12, Figure 3). Consequently the DNA/Au-NPs complexes serve as substrates for the DNA-binding protein HMGB1.

Conclusion

In conclusion, incubation of uncoated, positively charged AuNPs with a DNA plasmid that encodes recombinant eGFP-C1-HMGB1 fusion protein for 24 hours before cellular transfection does not seem to alter the protein expression and the protein functionality (DNA binding), while the presence of AuNPs seems to have a significantly positive effect on the transfection efficiencies. The observed effect was size-dependent: medium sized AuNPs enhanced transfection efficiency nearly 6 fold. These results support the hypothesis that laser-generated AuNPs present a good alternative to chemically synthesized nanoparticles and are especially suitable for biomedical applications.

Competing interests

The authors declare that they have no competing interests.

Authors' contributions

SP carried out the nanoparticle generation and partial drafting of the manuscript, JTS carried out the transfections, fluorescence microscopy analysis and partial drafting of the manuscript, SW performed cell culture and DNA preparation, AR generated the recombinant eGFP-C1-HMGB1 plasmid, SB principal study design, manuscript drafting and supervision of nanoparticle work, HME principal design, partial manuscript drafting and supervision of molecular and cell biologic work. IN and JB participated in the conception design of the study. All authors read and approved the final manuscript.

Abstract

Metastasis is one of the major problems when dealing with malignant neoplasias. Accordingly, the finding of molecular targets, which can be addressed to reduce tumour metastasising, will have significant impact on the development of new therapeutic approaches. Recently, the receptor for advanced glycation end products (RAGE)–high mobility group B1 (HMGB1) protein complex has been shown to have significant influence on invasiveness, growth and motility of tumour cells, which are essential characteristics required for metastatic behaviour. A set of in vitro and in vivo approaches showed that blocking of this complex resulted in drastic suppression of tumour cell growth.

Due to the similarities of human and canine cancer the dog has joined the common rodent animal model for therapeutic and preclinical studies. However, complete characterisation of the protein complex is a precondition to a therapeutic approach based on the blocking of the RAGE–HMGB1 complex to spontaneously occurring tumours in dogs. We recently characterised the canine *HMGB1* gene and protein completely. Here we present the complete characterisation of the canine *RAGE* gene including its 1384 bp mRNA, the 1215 bp protein coding sequence, the 2835 bp genomic structure, chromosomal localisation, gene expression pattern, and its 404 amino acid protein. Furthermore we compared the CDS of six different canine breeds and screened them for single nucleotide polymorphisms.

1. Introduction

The canine genome offers a wide field for genetic studies on various areas as e.g. phenotypic diversity, heredity and diseases including cancer. In terms of cancer, the canine model shows several advantages. First of all, the dog enjoys after the human the second best medical care of all species allowing a detailed surveillance of the cancer, progression, and therapy. The cancers seen in dogs are spontaneously developing as opposed to rodents with tumours being experimentally induced by carcinogen or transplanted to immunocompromised animals. Also, the canine cancers are more akin to human cancers than rodent tumours in terms of patient size and cell kinetics allowing better comparison of medical examinations as e.g. ultrasonography. It is generally believed that dogs develop cancer twice as frequently as humans, and it has been shown that the presentation, histology and biology of several canine cancers are similar to those in humans (Withrow and MacEwen, 1989, 2001; MacEwen, 1990). Most canine cancers progress more rapidly than their human counterparts permitting a better surveillance of the tumour state (Withrow and MacEwen, 2001). Additionally, dogs show similar characteristics of physiology and metabolism for most organ systems and drugs, which allows better comparability of modalities e.g. surgery, radiation, chemotherapy (Withrow and MacEwen, 2001), and new therapeutic approaches aimed at cancer treatment. At least a dozen distinct canine cancers are hypothesized to be appropriate models for their human counterparts (Patterson et al., 1982; Withrow and MacEwen, 1989; MacEwen, 1990; Knapp and Waters, 1997), among those osteosarcoma, breast carcinoma, oral melanomas, lung carcinomas and malignant non-Hodgkin's lymphomas (MacEwen, 1990).

Lately, the RAGE–HMGB1 protein complex has attracted significant interest in terms of metastatic behaviour of tumours. The receptor itself is a multiligand member of the immunoglobulin superfamily, which was shown to bind nonenzymatically glycosylated adducts, i.e. advanced glycation end products (AGE). It has been described to be involved in a variety of pathophysiological processes, e.g. immune/inflammatory disorders (Hofmann et al., 1999, 2002), Alzheimer's disease (Yan et al., 1997; Lue et al., 2001), abnormalities associated with diabetes, e.g. arteriosclerosis (Park et al., 1998) or impaired wound healing (Goova et al., 2001), and tumourigenesis (Taguchi et al., 2000; Huttunen et al., 2002). In terms of tumours and metastasis, the interaction with the extracellular ligand amphoterin, synonymously called HMGB1, was shown to have significant influence (Taguchi et al., 2000; Huttunen et al., 2002) by activating key cell signalling pathways such as MAP kinases and NF- κ B (Taguchi et al., 2000). Taguchi et al. (2000) were able to show that blocking of this complex by using a soluble variant of the receptor lacking the cytosolic and transmembrane domains strongly inhibited the metastatic behaviour of glioma cells in terms of invasive growth, motility and migration. To establish a therapeutic approach based on blocking of the RAGE–HMGB1 protein complex in canine tumours as preclinical approach for human neoplasias, the knowledge of the canine protein complex is precondition. Previously we characterised the canine HMGB1

gene and its protein (Murua Escobar et al., 2003). Here we present the complete characterisation of the canine RAGE gene including its mRNA, the genomic structure, chromosomal localisation, gene expression pattern, and its protein. Furthermore we compared the protein coding sequences (CDS) of six different canine breeds and screened them for single nucleotide polymorphisms (SNPs).

The complete characterisation of the canine RAGE–HMGB1 protein complex will serve as base for future clinical studies aimed at the development of blocking strategies to inhibit metastatic behaviour of canine and human tumours.

2. Methods and materials

2.1. Tissues

The tissues used in this study were provided by the Small Animal Clinic, University of Veterinary Medicine, Hannover, Germany. The breeds represented were Bernese Mountain Dog, Border Collie, Dachshund, Golden Retriever, Rottweiler, and Siberian Husky. From each breed up to three samples of lung tissue were taken and used for analyses.

2.2. Bacterial artificial chromosome (BAC) screening and fluorescence in situ hybridisation FISH

A canine genomic RAGE DNA probe was used for hybridisation of canine RPCI 81 BAC/PAC filter (BACPAC RESOURCES/Children's Hospital Oakland Research Institute, Oakland, USA). The 261 bp probe was generated by PCR with the primer set 480up and canisRlo623 (5' AGGGACTCT-TAGCTGGCACT 3'/5' GAAGGTGGGGTGGGGAGCTC 3') on genomic DNA prepared from a blood sample of a healthy dog. The obtained PCR product was separated on a 1.5% agarose gel, recovered with QIAEX II (QIAGEN, Hilden, Germany), cloned in pGEM–T-Easy vector system (Promega, Madison, USA) and sequenced for verification. The probe labelling was performed by random primed labelling (Roche Diagnostics, Mannheim, Germany) as described in the manufacturer's protocol with 250 ng probe and 250 μ Ci (α ³²P)dCTP (GE Healthcare, Freiburg, Germany). Purification of the labelled probe was done using Sephadex G-50 Nick Columns (Amersham Pharmacia Biotech, Freiburg, Germany) and the probe was stored at –20 °C before use.

The filters were placed in a minimum volume of Church Buffer (0.15 mM bovine serum albumin (BSA), 1 mM EDTA, 0.5 M NaHPO₄, 7% SDS) and transferred into hybridisation bottles. The filters were prehybridised at 65 °C for 1 h in 25 ml Church Buffer. Hybridisation was performed at 65 °C overnight (16–18 h) in the same solution. All further steps were performed according to manufacturer's protocol. Signals were visualised using a STORM imager (Molecular Dynamics, Sunnyvale, USA).

Metaphase preparations were obtained from blood samples of different dogs. The samples were stimulated with phytohemagglutinin (PHA) and cultured for 96 h at 37 °C. After incubation for 2 h with colcemide (0.1 μ g/ml), the lymphocytes

were harvested and slides were prepared according to routine procedures. Prior to FISH, chromosomes were stained using an adapted GTG-banding method. Chromosomal G-bands were identified according to Reimann et al. (1996). After recording the metaphases, the slides were destained in 70% ethanol for 15 min, air-dried and incubated at 60 °C overnight.

FISH was performed using the protocol of Fischer et al. (1996) with some modifications. BAC DNA was digoxigenin labelled (Dig-Nick-Translation-Kit, Roche Diagnostics, Mannheim, Germany). The hybridisation mixture contained 200 ng probe, 43.2 µg salmon sperm DNA, 800 ng sonicated dog DNA, 1× SSC, 1× SSPE, 50% formamide and 10% dextran sulfate. The chromosomes were counterstained with propidium iodide.

2.3. Genomic characterisation

For genomic characterization the canine *RAGE* gene was amplified by PCR using the screened BAC RP81339J10 (BACPAC RESOURCES/Children's Hospital Oakland Research Institute, Oakland, USA). A 1298 bp fragment spanning exon 1 to exon 6 was generated by the primer pair canisRup1/canisRlo623 (5' ATGGCAGCAGGGGCGGCAGC 3'/5' GAAGGTGGGGTGGGGAGCTC 3') and an additional 1403 bp fragment spanning exon 6 to exon 11 was generated with pair cEx6up/3046lo (5' CTCCCCACCCACCTTCTCC 3'/5' TCATGGCCCTGCTGCACCGCTCT 3') including the respective introns. The obtained PCR products were separated on a 1.5% agarose gel, recovered with QIAEX II (QIAGEN, Hilden, Germany), cloned in pGEM-T-Easy vector system (Promega, Madison, USA) and sequenced for verification. The final genomic canine *RAGE* contig and the identity alignments were created with Lasergene software (DNASTar, Madison, USA) using various sequences from the NCBI database (GenBank accession nos.: D28769, AB036432, NM_001136, BC020669, M91211) and the following described cDNA (see Section 2.4).

2.4. cDNA characterisation

Total RNA was isolated from 50 mg canine lung tissue using TRIZOL LS (Invitrogen, Karlsruhe, Germany) following the manufacturer's protocol. To avoid genomic DNA contamination a *DNase* digest of each sample was performed using *RNase*-Free *DNase* Set (Qiagen, Hilden, Germany). cDNA was synthesised using 3'-RACE adaptor primer AP2 (AAG-GATCCGTCGACATC(17)T), 5 µg total RNA, and SuperScript II (Invitrogen, Karlsruhe, Germany) reverse transcriptase according to the manufacturer's instructions. The PCRs for the molecular cloning of the cDNA were done using the primer pairs canisRup1/canisRlo623 (5' ATGGCAGCAGGGGCGGCAGC 3'/5' GAAGGTGGGGTGGGGAGCTC 3'), 480up/RAGElo1236 (5' AGGGACTCTTAGCTGGCACT 3'/5' TGTCTGTGGGCCCTCAAGG 3') and gene-specific primers cEx6up/cEx11up (5' CTCCCCACCCACCTTCTCC 3'/5' GAATCAGTCAGAGGAGCCCGAGG 3'). 3'RACE PCR was done using the adaptor primer AP2 specified above. The primers were derived from human cDNA sequences (GenBank

accession no. M91211). 5'RACE was performed using the primers 5'RACE Abridged Anchor Primer (5' GGCCAC-GCGTCTGACTAGTACGGGIIIGGGIIIGGGII 3'), Universal Amplification Primer (5' CTACTACTACTAGGCCACG-CGTCTGACTAGTAC 3'), and the gene-specific primers RAGElo1236 and canisRlo623 determined as above according to the 5'RACE System for Rapid Amplifications of cDNA Ends by Invitrogen. The PCR products were separated on a 1.5% agarose gel, recovered with QIAEX II (QIAGEN, Hilden, Germany), cloned in pGEM-T-Easy vector system (Promega, Madison, USA) and sequenced. The cDNA contig and the identity alignments were created with Lasergene software (DNASTar, Madison, USA) and various sequences from the NCBI database (GenBank accession nos.: D28769, AB036432, NM_001136, BC020669, M91211).

2.5. CDS comparison between breeds

The CDSs were characterised for all breeds as described previously in Section 2.2. The contigs and the identity alignments were created using several sequences from the NCBI database (GenBank accession nos.: D28769 AB036432, NM_001136, BC020669, M91211). In case of single-nucleotide exchanges, the samples were sequenced again in both forward and reverse direction. Exchanges causing no amino acid (aa) substitution were not taken into account for further analyses. For all samples with aa substitutions, the initial PCR was repeated and the exchange verified by sequencing the product in both forward and reverse direction.

2.6. Protein sequences

The canine *RAGE* protein sequence was derived from the ORF (open reading frames) of the characterised cDNA sequence described previously in Section 2.4. The protein homology alignments were created with four sequences from the NCBI database (GenBank accession nos.: BAA89369, NP_776407, AAA42027, AAH61182).

2.7. Northern Blot and RT-PCR

Total RNA was isolated from canine liver, kidney, heart, testis, lung, muscle, pancreas and spleen tissue using RNeasy midi system (QIAGEN, Hilden, Germany). For Northern Blot hybridisation 30 µg of total RNA from each tissue sample was separated on a 1.2% denaturing agarose gel containing 0.65% formaldehyde. RNA was transferred onto Hybond-N⁺ positive nylon membrane (Amersham Pharmacia Biotech, Freiburg, Germany) by capillary blot.

A 624 bp cDNA fragment derived from the canine *RAGE* sequence (exon 1/exon 5) served as a molecular probe for hybridisation. The probe was generated by PCR with the primer set canisRup1 and canisRlo623 (5' ATGGCAGCAGGGG-CGGCAGC 3'/5' GAAGGTGGGGTGGGGAGCTC 3') using the cloned cDNA described in Section 2.2. Probe labelling was performed by random primed labelling (Amersham Pharmacia Biotech, Freiburg, Germany) as described in the manufacturer's

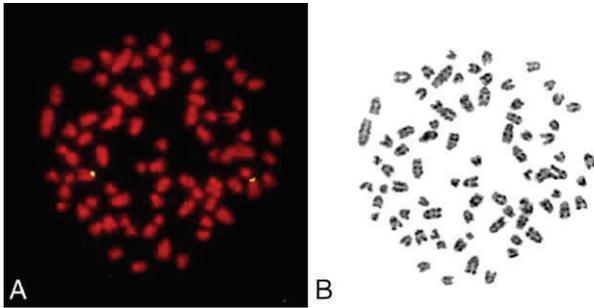

Fig. 1. An example of a metaphase spread after FISH with signals on both chromosomes 12 (A) and the same metaphase after GTG-banding (B).

protocol with 50 μCi ($\alpha^{32}\text{P}$)dCTP (Amersham Pharmacia Biotech, Freiburg, Germany). Purification of the labelled probe was performed using Sephadex G-50 Nick Columns (Amersham Pharmacia Biotech, Freiburg, Germany) and the probe was stored at -20°C before use.

Prehybridisation was carried out for 30 min and hybridisation overnight at 68°C using the PERFECTHYB PLUS hybridisation solution (Sigma-Aldrich, Saint Louis, MO, USA). The membrane was washed for 5 min at room temperature in $2\times\text{SSC}/0.1\%\text{SDS}$, and twice for 20 min at 68°C in $0.5\times\text{SSC}/0.1\%\text{SDS}$. Signals were visualised using a STORM phosphor-imager (Molecular Dynamics, Sunnyvale, USA).

RT-PCR was performed using all isolated tissue cDNAs with primer pair cEx6up/3046lo (5' CTCCCCACCCACCT-TCTCC 3'/5' TCATGGCCCTGCTGCACCGCTCT 3').

3. Results and discussion

The RAGE–HMGB1 protein complex has lately attracted significant interest of researchers working on cancer and other

diseases. Several publications demonstrate the involvement of the RAGE receptor in a variety of pathophysiological processes, e.g. immune/inflammatory disorders (Hofmann et al., 1999, 2002), Alzheimer disease (Yan et al., 1997; Lue et al., 2001), abnormalities associated with diabetes, e.g. arteriosclerosis (Park et al., 1998) and impaired wound healing (Goova et al., 2001). It has been shown that the specific RAGE-related diseases are caused by binding of different specific ligands to the receptor (for reviews, see Schmidt et al., 2001; Huttunen and Rauvala, 2004). In terms of tumourigenesis and metastasis, the interaction with the extracellular ligand amphoterin, synonymously called HMGB1, was shown to have significant influence by activating key cell signalling MAP kinase pathways (Huttunen et al., 2002; Taguchi et al., 2000). A set of in vivo and in vitro experiments showed that blocking of this complex strongly inhibited the metastatic behaviour of cancer cells in terms of invasive growth, motility and migration (Taguchi et al., 2000). Furthermore, deregulation of the *RAGE* gene expression level was associated with prostate cancer (Simm et al., 2004), with malignant potential of colorectal cancer (Sasahira et al., 2005) and non-small-cell lung cancer (Bartling et al., 2005).

To establish a therapeutic approach based on blocking of the RAGE–HMGB1 protein complex in canine tumours as a preclinical approach for human neoplasias, the knowledge of the canine protein complex is preconditioned.

3.1. Chromosomal localisation

A canine *RAGE* genomic DNA probe was generated and used for screening of a canine BAC for localisation of the canine *RAGE* gene locus by FISH. The verified BAC 339-J10 was used for FISH experiments. Twelve well-spread metaphases were

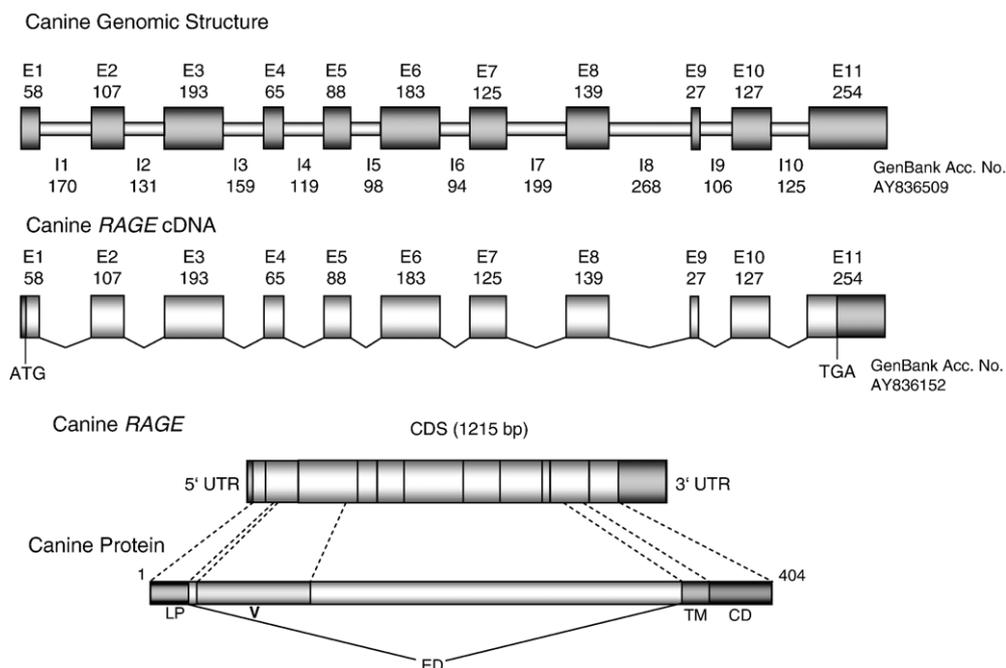

Fig. 2. Structure of the canine *RAGE* gene on genomic, cDNA and protein level.

examined for analyses, showing signals on both chromatides of both chromosomes CFA 12 (Fig. 1). The chromosomal localisation was done following the nomenclature established by Reimann et al. (1996). Presented synteny studies (Yang et al., 1999; Breen et al., 1999) showed that the canine CFA 12 shares homology to the human chromosome 6 where the *RAGE* gene is located at HSA 6p21.32. As far as we know, chromosomal aberrations affecting CFA 12 are not reported to be significantly associated with canine neoplasias.

3.2. Genomic structure

The genomic structure of the canine *RAGE* gene consists of eleven exons and ten introns. The complete canine gene spans 2835 bp. The exon/intron structure, size and the homologies to their human counterparts were analysed and defined (Fig. 2 and Table 1). The total identity to the corresponding human region shows 63.4%. In detail, the identities of the exons vary between 73.9% and 86.7% to their human counterpart, while the introns show identities between 43.4% and 71.0% (for details see Table

Table 1
Detailed analysis of the *RAGE* gene elements and the *RAGE* protein

Element	Size in bp	Identity to human counterpart in % (D28769)
Total genomic gene	2835	63.4
Total cDNA	1384	80.9
5'UTR	18	100

Cytosolic tail	43	72.7

Identity comparison of the canine *RAGE* genomic elements, cDNA elements, and protein to their human counterparts.

1). The genomic sequences were submitted to the NCBI database (GenBank accession no. AY836509).

3.3. The canine *RAGE* cDNA transcript

The complete canine *RAGE* cDNA consist of eleven exons spanning 1384 bp in total. The exon size varies between 27 bp to 254 bp composing all together a 5'UTR of 18 bp, a CDS of 1215 bp, and a 3'UTR of 151 bp (Fig. 2 and Table 1). Identity comparison to its human counterpart (GenBank accession no. D28769) revealed a total identity of 80.9% on nucleotide level varying in the exons from 73.9% (exon 11) to 86.7% (exon 2) (for details see Table 1). In humans several naturally occurring truncated *RAGE* transcripts have been described lacking the cytosolic and transmembrane domains named soluble *RAGE* variants (sRAGE) (Malherbe et al., 1999; Schlueter et al., 2003). These aberrant transcripts act as naturally occurring competitive inhibitors of the *RAGE* receptor taking effect on receptor efficiency. Detailed analysis of the aberrant transcript structure revealed the partial insertion of different genomic *RAGE* intron DNA fragments leading to the observed aberrant splicing products (Malherbe et al., 1999; Schlueter et al., 2003). In dogs, we could not detect corresponding aberrant splicing products using the experimental design developed previously in our group by Schlueter et al. (2003). However, the application of such soluble *RAGE* variants to block e.g. the HMGB1 protein drastically suppressed the growth of tumour cells in vitro and in vivo (for review see Huttunen et al., 2002). Treatment of mice with sRAGE completely suppressed diabetic atherosclerosis in a glycemia- and lipid-independent manner (Park et al., 1998). The total canine *RAGE* cDNA sequence was submitted to the NCBI database with GenBank accession no. AY836152 completing our previous submission of AY530943.

3.4. *RAGE* CDS comparison between different canine breeds

For six different canine breeds the protein coding sequences were characterised by amplification of a fragment spanning the CDS using the canine lung cDNA samples as template. Nucleotide exchanges causing no amino acid substitution were not taken into account in further analyses. The comparison of these six protein-coding sequences revealed one amino acid change. A Bernese Mountaindog sample showed a nucleotide transition from C (CGG) to T (TGG) at the first base of the CDS codon 364, leading to an aa replacement from arginine (R) to tryptophane (W). Possible PCR artefacts seem rather unlikely, since several clones were sequenced for verification. Polymorphisms causing mutations in the *RAGE* gene had been associated with various inflammatory diseases and diabetic syndromes such as rheumatoid arthritis, psoriasis, nephropathy, periodontitis, and microvascular diseases (Hudson et al., 1998, 2001; Kankova et al., 1999, 2001; Liu and Xiang, 1999; Poirier et al., 2001; Hofmann et al., 2002; Schmidt, 2002; Vasku et al., 2002). Considering the fact that canine breeds show breed-specific predispositions for various cancers and

other diseases, the detailed analyses of single breeds could be of significant value to unravel the disease associated mechanisms involved.

The CDS cDNA sequences of the six breeds were submitted to the NCBI database with GenBank accession nos. DQ125936, DQ125937, DQ125938, DQ125939, DQ125940, and DQ125941.

3.5. The canine RAGE protein

The canine RAGE protein sequence was deduced from the characterised cDNA sequence. The canine RAGE protein is a 404-amino-acid molecule with a calculated weight of 43 kDa (Fig. 1 and Table 1). Identity comparison of the canine molecule to its human counterpart (GenBank accession no. BAA89369) showed a total of 77.6% identity to the human protein including the described three extracellular (EC) immunoglobulin (Ig) type domains V, C, C', the hydrophobic transmembrane domain (TM), and the highly charged cytosolic tail including acidic carboxy-terminal domain (CD) (Neeper et al., 1992). The total canine extracellular domain shows 78.2%, the transmembrane domain 78.9%, and the cytosolic tail 72.7% identity to their human counterparts, respectively. The RAGE immunoglobulin type V domain was identified as HMGB1 binding domain. The identity comparison of this domain between dog and human showed 85.7% with 10 amino acid exchanges (Fig. 3). Recently, the motive

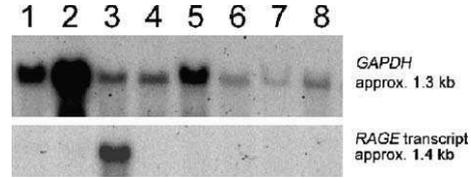

Fig. 4. Total RNA Northern blot showing 1.4 kb RAGE and 1.3 kb GAPDH transcripts. Lanes: (1) canine testis, (2) canine heart, (3) canine lung, (4) canine muscle, (5) canine kidney, (6) canine pancreas, (7) canine spleen, (8) canine liver.

of the human HMGB1 protein for binding the V domain of RAGE receptor was identified to consist of aa 150–183 including the HMG-Box-B and part of carboxy-terminal domain (Huttunen et al., 2002). We previously characterised the canine HMGB1 protein and comparison of the functional domains revealed that the canine amino acid sequence is identical to the human counterpart (Murua Escobar et al., 2003). Due to the high similarity of the canine and human RAGE–HMGB1 protein complexes in their interacting domains, therapeutic approaches applied in dogs could be more suitable in terms of transferability for the development of human therapies than approaches tested in other organisms.

Comparison of the canine RAGE protein with the described mouse (GenBank accession no. AAH61182), rat (GenBank accession no. AAA42027) and bovine (GenBank accession no.

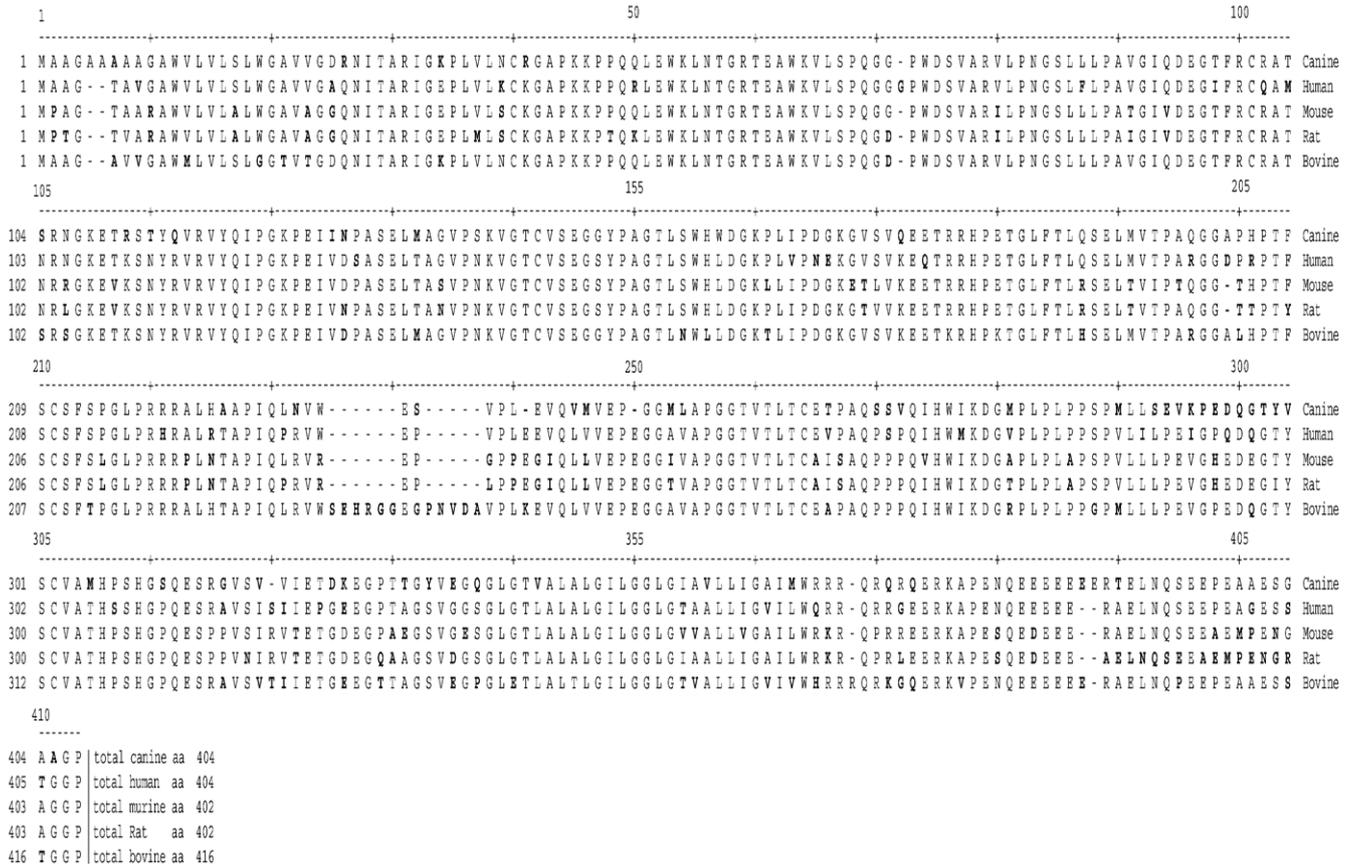

Fig. 3. Comparison of the canine, human, mouse, rat, and bovine RAGE proteins. The amino acid differences are shown as bold letters.

NP_776407) molecules showed identities of 73.5%, 72.8% and 77.7%, respectively (Fig. 3).

The canine RAGE protein sequence was submitted to the NCBI database with GenBank accession no. AAX38183.

3.6. Canine RAGE expression analysis

To elucidate the expression patterns of the canine *RAGE* gene, a canine Northern blot was performed using RNA from canine liver, kidney, heart, testis, lung, muscle, pancreas and spleen tissue samples as well as RNA from different canine cell lines and hybridised with a ³²P-labelled canine RAGE cDNA probe. Except for the lung tissue showing a clear approx. 1.4 kb signal, none of the samples revealed a distinct signal. After stripping and rehybridisation with a canine GAPDH probe, all samples revealed signals corresponding to approx. 1.3 kb demonstrating intact RNA (Fig. 4). For verification, performed RT-PCR using the same RNA revealed, additionally to a clear lung signal, very weak signals in spleen and heart tissue (data not shown). These results are in accordance to the gene expression pattern seen in humans. However, as mentioned before, aberrant transcripts like those found in humans could not be detected by RT-PCR. Lately, deregulation of the *RAGE* gene had been associated with various cancers and diseases e.g. up-regulation of the gene has been shown to be associated with prostate cancer development, human heart dysfunction, and inhibition of liver regeneration (Simm et al., 2004; Cataldegirmen et al., 2005; Ishiguro et al., 2005), while down-regulation of the *RAGE* gene has been shown to support non-small-cell lung carcinomas (Bartling et al., 2005). Additionally, *RAGE* gene expression has been associated with malignant potential of colorectal adenomas (Sasahira et al., 2005). As far as we know, in canine neoplasias, no *RAGE* expression analyses have been carried out. Considering the mentioned characteristics of canine neoplasias as model for human cancer, expression analyses done in canine tumours could be of significant value to further elucidate the role of *RAGE* in tumour and disease development.

4. Conclusions

As reviewed lately by Khanna and Hunter (2005), the dog is significantly helping to reveal characteristics of human tumour biology especially of metastasis due to the described similarities of the naturally occurring malignancies in both species. Accordingly, the development of new therapeutic approaches in animal model systems will be facilitated by the ongoing characterisation of model species specific molecular targets. Especially in points of transferability, the newly gained knowledge will be of great value. Due to the significant role of the RAGE–HMGB1 protein complex in cancer metastasis and the described various other diseases, the complete characterisation of the canine RAGE–HMGB1 protein complex will serve as basis for future clinical studies.

ABSTRACT

RAGE is a member of the immunoglobulin superfamily of cell surface molecules playing key roles in pathophysiological processes, e.g. immune/inflammatory disorders, Alzheimer's disease, diabetic arteriosclerosis and tumorigenesis. In humans 19 naturally occurring RAGE splicing variants resulting in either N-terminally or C-terminally truncated proteins were identified and are lately discussed as mechanisms for receptor regulation. Accordingly, deregulation of sRAGE levels has been associated with several diseases e.g. Alzheimer's disease, Type 1 diabetes, and rheumatoid arthritis. Administration of recombinant sRAGE to animal models of cancer blocked tumour growth successfully. In spite of its obvious relationship to cancer and metastasis data focusing sRAGE deregulation and tumours is rare. In this study we screened a set of tumours, healthy tissues and various cancer cell lines for RAGE splicing variants and analysed their structure. Additionally, we analysed the ratio of the mainly found transcript variants using quantitative Real-Time PCR. In total we characterised 24 previously not described canine and 4 human RAGE splicing variants, analysed their structure, classified their characteristics, and derived their respective protein forms. Interestingly, the healthy and the neoplastic tissue samples showed in majority RAGE transcripts coding for the complete receptor and transcripts showing insertions of intron 1.

1. Introduction

The receptor for advanced glycation end products (RAGE) is a member of the immunoglobulin superfamily of cell surface molecules which binds nonenzymatically glycosylated adducts like advanced

glycation end products (AGE). Acting as a multiligand receptor it has been described to interact with various ligands i.e. amphotericin also known as HMGB1 (Hori et al., 1995), amyloid beta (Yan et al., 1996), proteins of the S100/calgranulin family (Hofmann et al., 1999) and Mac-1 (Chavakis et al., 2003). The ligand-receptor-complexes regulate cell signalling pathways having influencing effect on cell growth and proliferation, i.e. p21ras, erk1/2 (p44/p42) MAP kinases, p38, SAPK/JNK Map kinases, rho GTPases, phosphoinositol-3 kinase, NFκB, and cAMP response element binding protein (CREB) (Neeper et al., 1992; Yan et al., 1994; Lander et al., 1997; Deora et al., 1998; Hofmann et al., 1999; Huttunen et al., 1999; Kislinger et al., 1999; Huang et al., 2001; Huttunen et al., 2002b). In terms of pathophysiological processes RAGE has been described to be involved in various diseases including diabetic arteriosclerosis (Park et al., 1998; Cipollone et al., 2003), impaired wound healing (Goova et al., 2001), Alzheimer's disease (Yan et al., 1996; Lue et al., 2001, 2005), immune and inflammatory disorders (Hofmann et al., 1999; Schmidt et al., 2001; Hofmann et al., 2002; Chavakis et al., 2004) and various cancers (Taguchi et al., 2000; Huttunen et al., 2002a; Bartling et al., 2005; Bhawal et al., 2005; Ishiguro et al., 2005). In humans 19 naturally occurring RAGE splicing variants resulting in either N-terminally or C-terminally truncated proteins were identified and are currently discussed as mechanisms for receptor regulation (hRAGEsec (Malherbe et al., 1999), sRAGE1,

sRAGE2, sRAGE3 (Schlueter et al., 2003), N-truncated and Secretory (Yonekura et al., 2003), $\Delta 8$ -RAGE (Park et al., 2004), RAGE Δ , NtRAGE Δ and sRAGE Δ (Ding and Keller, 2005b), RAGE_v4-RAGE_v13 (Hudson et al., 2007). The function of these variants was unclear, but lately the described truncated RAGE protein variants were supposed to act as competitive inhibitors of the receptor either by ligand binding or displacing the full-length receptor in the membrane (Ding and Keller, 2005a; Geroldi et al., 2005). Deregulations of the naturally occurring protein isoforms are supposed to have significant effect on RAGE mediated diseases. Accordingly, deregulations of sRAGE levels have been associated with several diseases e.g. Alzheimer's disease (Emanuele et al., 2005), Type 1 diabetes (Challier et al., 2005; Forbes et al., 2005; Katakami et al., 2005; Miura et al., 2007), Type 2 diabetes (Nakamura et al., 2006; Tan et al., 2006; Yamagishi et al., 2006; Humpert et al., 2007), atherosclerosis (Falcone et al., 2005; Koyama et al., 2005), rheumatoid arthritis (Moser et al., 2005; Pullerits et al., 2005), essential hypertension (Geroldi et al., 2005), and renal disease (Kalousova et al., 2006). On the other hand Taguchi et al. (2000) were able to show that blocking of the binding of the RAGE ligand HMGB1 to the receptor, by using RAGE variants lacking the cytosolic or transmembrane domains, strongly inhibited the metastatic behaviour of glioma cells in terms of invasive growth, motility and migration. The data clearly showed that the application of soluble RAGE variants drastically suppressed the growth of tumour cells *in vitro* and *in vivo* (for review see Huttunen and Rauvala, 2004). In spite of its obvious relationship to cancer and metastasis data focusing soluble RAGE deregulations or structural aberrations and tumours is currently rare. Only recently Takeuchi et al. reported a correlation between esRAGE, RAGE, and HMGB1 and staging of chondrosarcomas classifying esRAGE expression as tumourmarker for malignancy (Takeuchi et al., 2007).

As reviewed lately by Khanna and Hunter (2005) the dog is significantly helping to reveal characteristics of human tumour biology especially of metastasis due to various similarities of the malignancies seen in both species. Generally, in the case of cancer, in dogs we find naturally spontaneously developing neoplasias which are more similar to human cancers than induced tumours used in rodent model systems in terms of presentation, histology and biology (Withrow and MacEwen, 1989, 2001; MacEwen, 1990). Additionally, dogs show similar characteristics of physiology and metabolism for most organ systems and drugs, which allows better comparability of modalities e.g. surgery, radiation, chemotherapy (Withrow and MacEwen, 2001), and new therapeutic approaches aimed at cancer treatment.

In this study we screened a set of 14 different canine tumours, healthy tissues and various canine and human cancer cell lines for RAGE splicing variants and analysed their structures. Additionally, we analysed the ratio of the mainly found transcript variants using quantitative and relative Real-Time PCR.

2. Methods and materials

2.1. Tissues and cell lines

The analysed canine healthy (lung, ovar, pancreas, skin, spleen, testis, thyroid) and tumour tissues (adenoma of pancreas, colon cancer, fibrosarcoma, histiocytoma, insulinoma, liver adenoma, malignant histiocytosis, malignant lymphoma, mamma tumour, mastocytoma, melanoma, splenic hemangiosarcoma, testis tumour, thyroid carcinoma, vaginal tumour) were provided by the Small Animal Clinic, University of Veterinary Medicine, Hanover, Germany. The canine cell lines CT1258 (prostate cancer), MTH53A (non neoplastic tissue of the mammary gland), MTH52C (malignant small-cell carcinoma of the mammary gland), and ZMTH3 (pleomorphic adenoma of the mammary gland) and the human cell lines Hela (cervical cancer), Li14 (lipoma), and MCF7 (breast cancer) which were used in this

study, were provided by the Centre for Human Genetics, University of Bremen, Bremen, Germany.

2.2. RNA isolation and cDNA synthesis for transcript characterisation

The cultured cells were homogenized using QIAshredder spin columns (Qiagen, Hilden, Germany) while the used tissue samples were homogenized using the iron-beads QIAshredder homogenizer method (Qiagen, Hilden, Germany). Following, total RNA was isolated using the RNeasy Mini Kit according to the manufacturer's instructions (Qiagen, Hilden, Germany). To avoid genomic DNA contaminations, on-column DNase digestion with the RNase-Free DNase set (Qiagen, Hilden, Germany) was performed.

The respective total cDNA syntheses were performed using 5 μ g total RNA of each sample, the adaptor poly dT primer AP2: AAG GAT CCG TCG ACA TC(17)T, and MMLV reverse transcriptase following the manufacturer's protocol (Invitrogen, Karlsruhe, Germany). The respective cDNA syntheses were performed several times during the experiments.

2.3. PCR reactions

All performed PCR reactions were designed to amplify products spanning from exon 1 to exon 11 of the canine or human RAGE mRNA, respectively. The PCR reactions using the total poly dT primed cDNAs of the canine cell lines and tissue samples were performed either with the primer pair 1 (up 5'GAA GCC TGG GAA GGA ACG ATG3'/lo 5'GAG AGC AAG GGG GAA GAA AAG3') or pair 2 (up 5'CCT GGG TGC TGG TCC TCA GT3'/lo 5'TCA TGG CCC TGC TGC ACC GC TCT3'). The reactions using human templates were performed with the primer pair 5'CCT GGG TGC TGG TCC TCA GT3' as upper primer and the primer 5'TCA AGG CCC TCC AGT ACT ACT TC3' as lower primer for PCR reactions amplifying RAGE transcripts in human cell lines (Hela, Li14, MCF7).

The PCR reactions were performed with a "touch down" programme with the following conditions: initial denaturation at 95 °C for 5 min, followed by 10 cycles with 30 s denaturation at 95 °C, 1 min annealing by 70–60 °C with a decrease of 1 °C per cycle and an elongation at 72 °C for 1 min. The following 30 cycles were performed at 95 °C for 30 s, 60 °C for 1 min and 72 °C for 1 min, respectively.

2.4. Characterisation of RAGE transcript variants

The respective amplified PCR products were separated electrophoretically in 1.5% agarose gels and recovered using the QIAquick Gel Extraction Kit following the manufacturer's protocol (Qiagen, Hilden, Germany). The isolated fragments were cloned into the pGem-T-Easy vector system (Promega, Mannheim, Germany), transfected in thermocompetent DH5 α *E. coli* cells, and verified by sequencing (MWG, Ebersberg, Germany). The received sequence data was analysed using Lasergene software (DNASar, Madison, USA). The generated sequences were submitted to the NCBI database (GenBank accession nos: EU428788, EU428789, EU428790, EU428791, EU428792, EU428793, EU428794, EU428795, EU428796, EU428797, EU428798, EU428799, EU428800, EU428801, EU428802, EU428803, EU428804, EU428805, EU428806, EU428807, EU428808, EU428809, EU428810, EU428811, EU428812, EU428813, EU428814, EU428815, EU428816). The CDS and protein alignments were performed using various sequences from NCBI database (GenBank accession nos.: D28769, NM001048081; BAA89369, ABA18650).

2.5. Quantitative Real-time RT-PCR

2.5.1. RNA isolation and cDNA syntheses for qRT-PCR

Total RNAs from the homogenized cultured cells and tissue samples were isolated using the RNeasy Plus Mini Kit (Qiagen, Hilden,

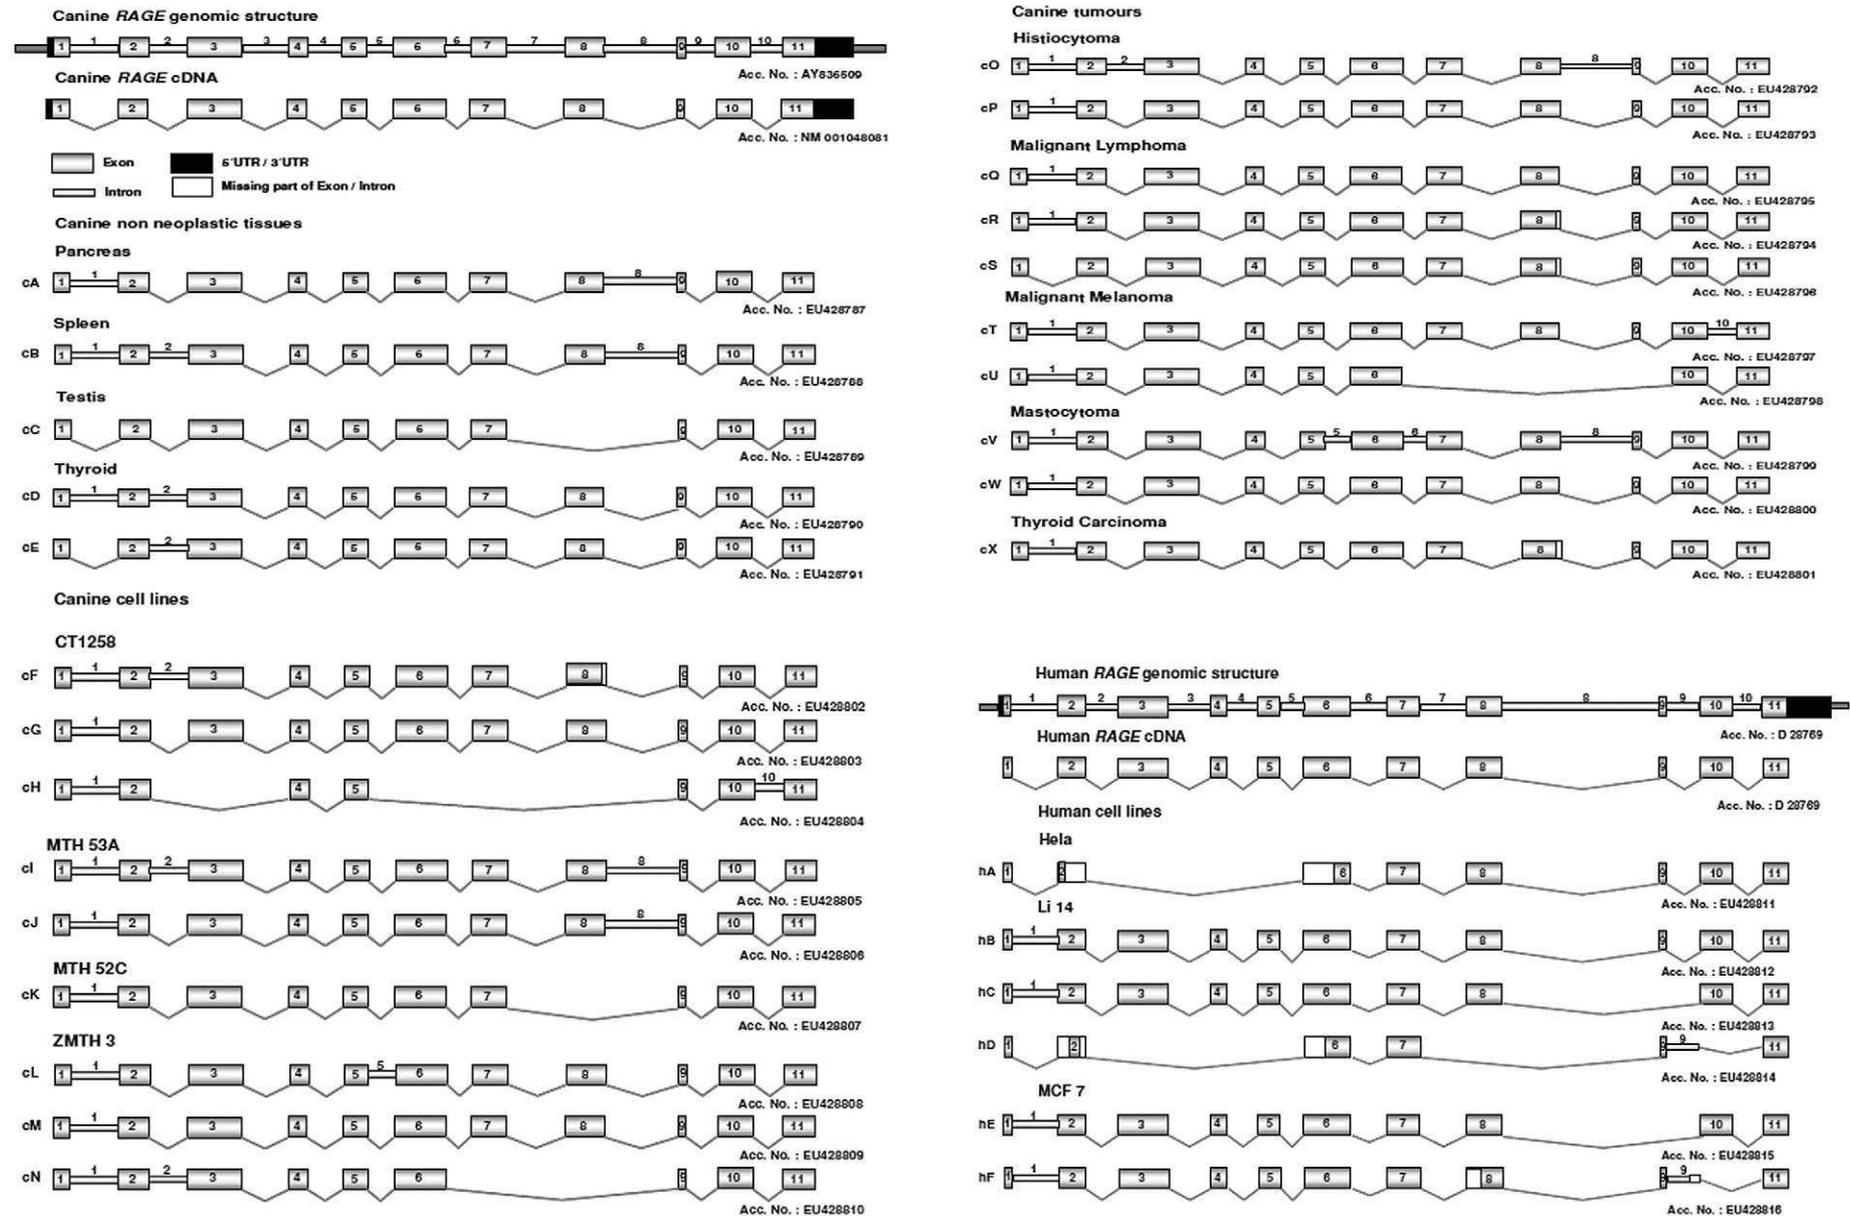

Fig. 1. *RAGE* transcript variants. Characterisation of *RAGE* transcript variants in canine non neoplastic tissues: pancreas, spleen, testis and thyroid (cA–cE), canine cell lines: CT1258, MTH 53A, MTH 52C and ZMTH3 (cF–cN), canine tumours: histiocytoma, malignant lymphoma, malignant melanoma, mastocytoma and thyroid carcinoma (cO–cX) and human cell lines: Hela, Li14 and MCF7 (hA–hF). The amplified PCR products range from the start codon in exon 1 till stop codon in exon 11. The RT PCR was performed with a poly dT primer. The transcript variants show different structural modifications like insertions of introns and deletions of both whole exons and parts of exons.

Table 1
Canine and human *RAGE* transcript variants

	Name (Fig. 1)	Structure insertion/deletion	Acc. No.	Putative protein (Fig. 2)/characteristic
<i>Non neoplastic canine tissues</i>				
Pancreas	cA	Insertion: intron1, intron 8	EU428787	J/non sense protein
Spleen	cB	Insertion: intron1, intron 2, intron 8	EU428788	I/non sense protein
Testis	cC	Deletion: exon 8	EU428789	A/soluble isoform, ligand binding
Thyroid	cD	Insertion: intron 1, intron 2	EU428790	C/membrane bound, no ligand binding
	cE	Insertion: intron 2	EU428791	F/membrane bound, no ligand binding
<i>Canine cell lines</i>				
CT1258	cF	Insertion: intron1, intron 2/deletion: 16 bp exon 8	EU428802	K/non sense protein
	cG	Insertion: intron 1	EU428803	E/membrane bound, no ligand binding
	cH	Insertion: intron 1/deletion: exon 3, exon 6, exon 7, exon 8	EU428804	No putative protein
MTH 53A	cI	Insertion: intron 1, intron 2, intron 8	EU428805	I/non sense protein
	cJ	Insertion: intron 1, intron 8	EU428806	J/non sense protein
MTH 52C	cK	Insertion: intron 1/deletion: exon 8	EU428807	M/non sense protein
ZMTH3	cL	Insertion: intron 1, intron 5	EU428808	D/membrane bound, no ligand binding
	cM	Insertion: intron 1	EU428809	E/membrane bound, no ligand binding
	cN	Insertion: intron 1, intron 2/deletion: exon 7, exon 8	EU428810	G/membrane bound, no ligand binding
<i>Canine tumours</i>				
Histiocytoma	cO	Insertion: intron 1, intron 2, intron 8	EU428792	I/non sense protein
	cP	Insertion: intron 1	EU428793	E/membrane bound, no ligand binding
Malignant lymphoma	cQ	Insertion: intron 1	EU428795	E/membrane bound, no ligand binding
	cR	Insertion: intron 1/deletion: 16 bp exon 8	EU428794	L/non sense protein
Malignant melanoma	cS	Deletion: 16 bp exon 8	EU428796	B/soluble isoform, ligand binding
	cT	Insertion: intron 1, intron 10	EU428797	No putative protein
	cU	Insertion: intron 1/Deletion: exon 7, exon 8, exon 9	EU428798	H/membrane bound, no ligand binding
Mastocytoma	cV	Insertion: intron1, intron 5, intron 6, intron 8	EU428799	No putative protein
	cW	Insertion: intron 1	EU428800	E/membrane bound, no ligand binding
Thyroid carcinoma	cX	Insertion: intron1/deletion: 16 bp exon 8	EU428801	L/non sense protein
<i>Human cell lines</i>				
Hela	hA	Deletion: 80 bp exon2, exon3, exon 4, exon 5, 120 bp exon6	EU428811	CC/membrane bound, no ligand binding
Li 14	hB	Insertion: intron 1	EU428812	AA/membrane bound, no ligand binding
	hC	Insertion: intron 1/deletion: exon 9	EU428813	BB/membrane bound, no ligand binding
	hD	Insertion: intron 9/deletion: 72 bp exon 2, exon 3, exon 4, exon 5	EU428814	No putative protein
MCF 7	hE	Insertion: intron 1/deletion: exon 9	EU428815	BB/membrane bound, no ligand binding
	hF	Insertion: intron 1, intron 9/deletion: 52 bp exon 8, 22 bp intron 9	EU428816	No putative protein

Detailed characterisation of the different respective *RAGE* transcript modifications and analyses of their derived protein isoforms.

Germany). This isolation method does not require an additional on column DNase digestion due to a direct removal of genomic DNA (gDNA) by a gDNA eliminating spin column.

The respective cDNA syntheses were performed using 250 ng total RNA of each sample, the gene specific lower primer 5' TTCTGTCCGACCTGTGTTTCAGCTT3', and Quantiscript Reverse Transcriptase following the manufacturer's protocol (Qiagen, Hilden, Germany) with an integrated removal of genomic DNA contamination.

For absolute and relative quantification of the *RAGE* transcript levels RT-PCR amplifications were carried out using the Applied Biosystems 7300 Real-Time PCR System (Applied Biosystems, Darmstadt, Germany). 2 µl of each cDNA corresponding to 25 ng of total RNA was amplified in a total volume of 25 µl using universal PCR Mastermix (Applied Biosystems) with 600 nM of each primer (forward primer 1: 5'GTCTGTGGGGAGCAGTAGTAGG3', forward primer 2: 5'TACTCTCCACCATTGTCCCATCT3', reverse primer: 5' TTCTGTCCGACCTGTGTTTCAGCTT3') and 200 nM fluorogenic probe (5' 6-FAM-AAGCCGCTGGTCTCAACTGTA-TAMRA 3'). PCR conditions were as follows: 2 min at 50 °C and 10 min at 95 °C, followed by 45 cycles with 15 s at 95 °C and 1 min at 60 °C. All samples were measured in triplicate and for each run non-template controls and no reverse transcriptase reactions were included. Expression levels of *RAGE* mRNA transcripts were calculated using an amplicon-

specific standard curve. For absolute quantification the transcript levels were normalised to total RNA concentration and expressed as copy number/250 ng total RNA. For relative quantification the healthy full length *RAGE* transcript was chosen as endogenous control. The calibrator sample was lung tissue to which all other samples were compared to determine the ratio of the relative expression level.

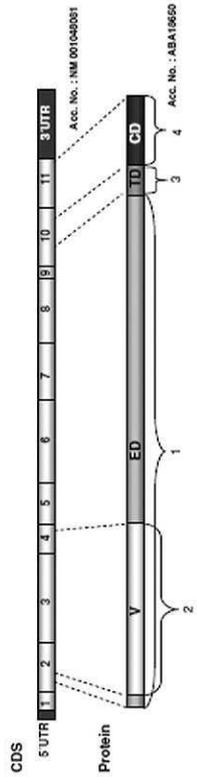

3. Results and discussion

3.1. Characterisation of *RAGE* transcript variants

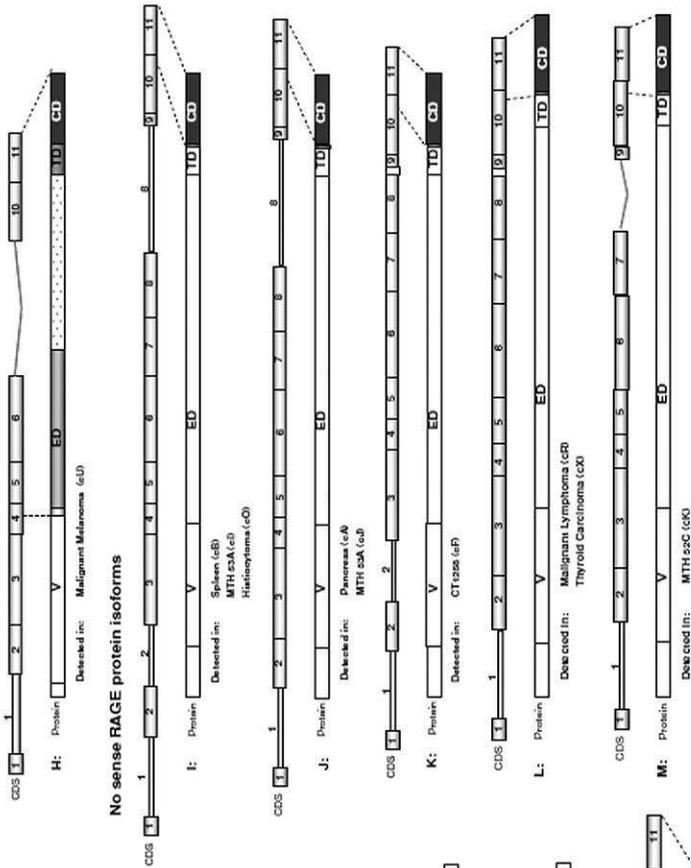

In humans 19 naturally occurring *RAGE* splicing variants resulting in either N-terminally or C-terminally truncated proteins were identified and are just recently discussed as mechanisms for receptor regulation (hRAGEsec, sRAGE1, sRAGE2, sRAGE3, N-truncated and Secretory, Δ8-RAGE, RageΔ, NtrRAGEΔ and sRAGEΔ, RAGE_v4 till RAGE_v13). The described truncated *RAGE* protein variants are discussed to act as competitive inhibitors of the receptor either by ligand binding or displacing the full-length receptor in the membrane. Deregulation of the naturally occurring protein isoforms is supposed to have significant effect on *RAGE* mediated diseases. Accordingly, deregulation of sRAGE levels has been associated with several diseases

Fig. 2. The canine *RAGE* CDS and protein structure. The different *RAGE* transcript variants characterised in canine non neoplastic tissues, cell lines, tumours and in human cell lines code for different putative protein structures: canine soluble *RAGE* protein isoforms with the ability to bind *RAGE* ligands without subsequent signalling in the cell (A, B), canine membrane bound *RAGE* isoforms without the competence of binding *RAGE* ligands (C–H), canine non sense *RAGE* protein isoforms (I–M) and human membrane bound *RAGE* protein isoforms (AA–CC).

Real Time Assay for absolute quantification of *RAGE* transcripts

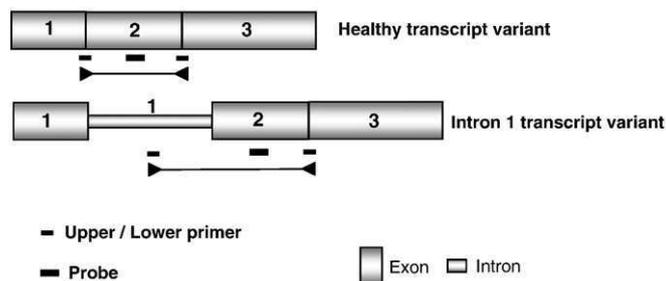

Fig. 3. Designed Real Time assay for absolute quantification of *RAGE* transcripts allowing differentiation of “healthy” and “intron 1” *RAGE* splicing variants. For the absolute quantification of healthy *RAGE* transcript the designed upper primer binds at the border of exon 1/exon 2, the probe anneals in exon 2 and the lower primer binds at the exon 2/exon 3 border avoiding measurement of genomic contaminations. The assay for measurement of the quantity of the intron 1 transcript variant consists of the same probe and lower primer like the healthy transcript detection, and the upper primer anneals in intron 1. Due to the upper and lower primer, transcripts which bear intron 1 but no genomic contaminations will be detected.

e.g. Alzheimer's disease, Type 1 diabetes, Type 2 diabetes, atherosclerosis, rheumatoid arthritis, essential hypertension, and renal disease. On the other hand blocking of the binding of the *RAGE* ligand HMGB1 to the receptor by using *RAGE* variants lacking the cytosolic or transmembrane domains, strongly inhibited the metastatic behaviour of glioma cells in terms of invasive growth, motility and migration (Taguchi et al., 2000). A recent study based on immunohistologic analyses reports a correlation of es*RAGE* and staging of chondrosarcomas classifying *RAGE* expression as tumourmarker for malignancy (Takeuchi et al., 2007).

In the herein screened canine 17 neoplastic and seven healthy tissue samples as well as the four canine and 3 human cell lines we found in total 24 canine and 6 human transcripts coding for 16 structural different canine and 5 different human forms. Fourteen of these found canine and four human forms were previously not described for any other species (Fig. 1, Table 1). In detail the transcripts detected in healthy tissues are characterised by various combinations of insertions of intron 1, 2 and 8 and by an observed deletion of the exon 8 (Figs. 1cA–cE). In canine cell lines the following events could be detected: various combinations of insertions of the introns 1, 2, 5, 8 and 10, a 16 bp partial deletion of exon 8, and complete deletions of the exons 3, 6, 7 and 8 (Figs. 1cF–cN). The neoplastic samples showed several insertions of introns 1, 2, 5, 6, 8 and 10, the partial 16 bp deletion of exon 8, and finally deletions of exons 7, 8 and 9 (Figs. 1cO–cX). The human cell lines showed insertion of intron 1, partial large deletions of parts of the exons 2, 6, and 8, complete deletions of the exons: 3, 4, 5, 8, and 9, and finally insertion of intron 9 with an additional deletion of parts of intron 9 (Figs. 1hA–hF).

These different transcript variants can be roughly classified into two groups. One group of splicing variants coding for full length *RAGE* transcripts or soluble *RAGE* variants which code for protein forms capable to bind extracellular ligands, and the other group showing various insertions of introns and alternative splicing of exons leading to mutated protein forms (Fig. 1, Fig. 2, Table 1). The recurrent remarkable modification in the latter group is the insertion of intron 1. This modification is seen in transcripts found in healthy tissues as well as in the cell lines and neoplastic samples. Depending on further modifications of the seen transcripts respective protein isoforms would result, missing the V – domain required for ligand binding or result in nonsense proteins (Fig. 2). Previously Yonekura et al. found a similar variant showing an insertion of intron 1 in a sample of human endothelial cells and pericytes (Yonekura et al., 2003). However, this reports the existence of these transcripts for the first time in neoplastic samples and cell lines.

3.2. Quantitative Real-Time PCR analyses

Following the assumption that the transcripts showing the intron 1 insertion are lost as competitive inhibitors we decided to quantify the ratio between these variants and variants coding for proteins capable to bind *RAGE* ligands in neoplastic canine samples providing naturally occurring tumour material. The designed assay discriminates genomic DNA detection, due to the position of the chosen primers (Fig. 3). The comparative quantification showed a diverse pattern (Table 2) in the analysed samples. Generally, in all screened tissue samples and cell lines, an expression of both forms could be detected varying from 1.38×10^3 (mastocytoma) to 6.53×10^8 (lung) transcripts for the normal splicing variant and 1.3×10^3 (mastocytoma) to 1.88×10^6 (lung) transcripts for the “intron 1” variant. In the screened healthy tissues the variant coding for a functional complete or soluble *RAGE* variant is significantly higher expressed in lung, testis and thyroid tissue showing in absolute numbers 6.53×10^8 , 6.27×10^5 and 1.02×10^7 more “healthy” transcripts than their respective “intron 1” variants. The pattern seen in the 17 tumour tissue samples and cell lines is quite different. The majority of samples showed a higher presence of the “intron 1” variant with the exception of a mastocytoma, which shows a similar level of both variants (1.3×10^3 “intron 1” to 1.38×10^3 “healthy”) and a testis tumour, which as only neoplastic sample showed a higher expression “healthy” variant (Table 2). In absolute numbers the “intron 1” variant outnumbered in the “healthy” variant 15 of the neoplastic samples with a range of 15 to 17 transcripts. The screened four cell lines showed uniformly a higher level of the intron 1 variant varying from 5.38×10^4 to 9.17×10^4 .

However, as lately discussed by Hudson et al. (2007), the wide diversity of seen *RAGE* transcripts and the obvious relationship of *RAGE* to several pathologic findings arise many new questions. The

Table 2

Absolute Real Time quantification transcript numbers of “healthy” and “intron 1” *RAGE* transcript variants in canine healthy tissues, neoplastic samples and cell lines

	Copy no./250 ng total RNA	
	Healthy transcript	Intron 1 transcript
<i>Non neoplastic canine tissues</i>		
Lung	6.53×10^8	1.88×10^6
Ovar	6.9×10^3	7.36×10^4
Pancreas	2.6×10^4	3.08×10^5
Skin	1.9×10^3	1.1×10^4
Spleen	7.1×10^3	8.26×10^4
Testis	6.27×10^5	5.6×10^4
Thyroid	1.02×10^7	1.9×10^5
<i>Canine cell lines</i>		
CT1258	2.98×10^3	5.38×10^4
MTH 53A	4.68×10^3	6.77×10^4
MTH 52C	9.3×10^3	9.17×10^4
ZMTH3	6.83×10^3	8.8×10^4
<i>Canine tumours</i>		
Adenoma of pancreas	4.26×10^3	5.5×10^4
Colon cancer	5.66×10^3	6.19×10^4
Fibrosarcoma	4.7×10^3	7.67×10^4
Histiocytoma	1.46×10^4	1.47×10^5
Insulinoma	1.7×10^4	2.6×10^5
Liver adenoma	3.9×10^3	2.9×10^4
Malignant histiocytosis	9.52×10^3	8.34×10^4
Malignant lymphoma	1.18×10^4	1.49×10^5
Malignant lymphoma	7.6×10^3	8.62×10^4
Malignant lymphoma	1.2×10^4	2.1×10^5
Mammatumour	1.5×10^4	5.29×10^4
Mastocytoma	1.38×10^3	1.3×10^3
Melanoma	4.77×10^3	4.14×10^4
Splenic hemangiosarcoma	2.17×10^4	1.07×10^5
Testis tumour	7.84×10^5	2.11×10^5
Thyroid carcinoma	5.16×10^4	1.53×10^5
Vaginal tumour	1.13×10^4	1.5×10^5

growing understanding of its biology combined with the accessibility of an adequate animal model – like the dog providing naturally occurring neoplastic samples – will be of great value to elucidate the pathologic events with RAGE involvement. The here newly described 24 canine and 4 human RAGE splicing variants as well as their respective derived protein forms will further help to understand the diversity of RAGE biology. The comparative quantitative Real-Time PCR analyses of both major RAGE transcript classes represent a first approach to analyse, if deregulation/structural aberrations of RAGE can be detected at RNA level and play a role in RAGE mediated pathologic events. Anyway, further studies will be needed, to confirm at protein level the qPCR data. We tested the commercially available RAGE antibodies for detection of recombinant canine protein but got unspecific results. This may be due to the fact that the identity of the canine RAGE protein to its human is just 77.6% (Murua Escobar et al., 2006).

However, studies done with human neoplasias using the herein generated data as basis should be a promising approach to answer the remaining questions.

Abstract. *In humans, malignant histiocytosis is a tumour-like disease characterised by increasing proliferation of macrophages and reinforced degradation of erythrocytes. High progression of this disease leads to an unfavourable prognosis for the patients, most of them children up to the age of three years. Histological and cytological findings have proposed an important role of aberrant expression of cytokines in histiocytosis. Due to the fact that Bernese Mountain Dogs (BMD) show a predisposition for spontaneously developing malignant histiocytosis, these dogs could possibly be used as a genetic model organism to elucidate the mechanisms of human malignant histiocytosis. Canine cytokine cDNA transcripts of TNF α , Interleukin-1- α (IL-1 α) and Interleukin-1-beta (IL-1 β) were screened for single nucleotide polymorphisms (SNPs). SNP screening in canine cytokine transcripts for malignant histiocytosis has not been carried out before. Total RNA was isolated from tissue samples from lung, spleen, testis, and skin of 17 different dogs (seven BMDs, one Collie and one West Highland Terrier). The corresponding cytokine cDNAs were amplified, sequenced and then screened for SNPs. The resulting effects on the protein sequence were analysed. Several BMDs and the West Highland Terrier showed SNPs in the coding sequences which led to missense mutations within the protein sequences of TNF α , IL1 α and IL1 β .*

Malignant histiocytosis (MH) and Langerhans cell histiocytosis (LCH) are neoplastic diseases which often spontaneously manifest in histiocytes also called Langerhans cells. These histiocytes rapidly change their behaviour to

proliferate like metastases with undetermined pathogenesis and heterogeneous diagnostic findings (1).

Due to aberrant immune response, these histiocytes, normally present in lung, liver, spleen, bones, brain, lymph nodes, skin and other epithelia, transform into highly mobile and infiltrating macrophages, which affect many different organs forming neoplasms with an enhancement of phagocytosis of erythrocytes. The clinical spectrum of this disease is wide with variable degrees of malignancy. However, histopathological findings of granulomas organised in clusters are uniform within the involved tissues (1, 2). The progressive course of histiocytosis is characterised by fast spreading symptoms and unfavourable prognosis, and is particularly often lethal in infants and children. Histiocytosis is not referred to as cancer by definition, although manifestations of this disease behave like tumour diseases, e.g. metastasising and an aggressive invasiveness of growth. Histiocytosis is defined as a disorder of the immune system with vague understanding of aetiology and pathogenesis (1).

As abundantly described in the literature, in many cases dogs and humans share the genetic pathways for the development of neoplastic diseases (3-5). Dogs can be used as an animal model to unravel the mechanisms of malignant histiocytosis as well as LCH. Most clinical and pathological features of canine histiocytosis resemble those of Langerhans cell histiocytosis in humans. In particular, there is a breeding predisposition for this disease observed in Bernese Mountain Dogs (BMD) (6-8). During the malignant histiocytosis disease, LCH cells and T cells produce large quantities of cytokines, raising a cytokine "storm" (9). Screening for single nucleotide polymorphism (SNP) within the nucleotide sequence of the responsible genes could be an instrument for revealing the cause of the disease. Cytokine genes are abundantly expressed in histiocytes and have been proposed to play a major role in pathogenesis. Due to the fact that the pro-inflammatory cytokines IL-1 (IL-1 α and IL-1 β) and the tumour necrosis factor- α (TNF α) are described to play a major role as

autocrine growth factors in many oncogenic malignancies (2, 10-12), it is interesting to focus on gene expression and SNP screening. Additionally, *IL-1 α / β* were also described to be involved in the regulation of the immune system, fever proteins and inflammatory processes (9, 13).

In order to clarify whether SNPs in canine cytokine transcripts exist, *TNF α* and *IL-1 α* and *IL-1 β* cDNAs derived from various tissues of dog breeds both with and without a known predisposition for the development of MH were screened. Cytokine cDNAs were derived from healthy lung, skin, liver, spleen and testis tissues from different breeds including BMDs, West Highland Terriers and Collies.

Materials and Methods

Spleen, lung, liver, skin and testis tissue from BMDs, Collies and West Highland Terriers were provided by the Small Animal Clinic, University of Veterinary Medicine, Hannover, Germany. Canine cytokine cDNA transcripts were screened and synthesised by total RNA from 17 different individuals (15 BMDs, one Collie and one West Highland Terrier).

Total RNA was isolated using the RNeasy Mini Kit (QIAGEN, Hilden, Germany) protocol for animal tissues and proteinase K digestion. *RNase-Free DNase* Set was used for preventing genomic DNA contamination by *DNase* I digestion of the total RNA. For cDNA 3'-RACE synthesis up to 5 μ g of total RNA was set as template for reverse transcription (SuperScript II RT, Invitrogen) using AP2 poly-T adaptor primer (AAGGATCCGTCGACATCT₁₇). The adjacent RT-PCRs for cytokine cDNA screening were carried out with the following primer pairs. *TNF α* : primer pair TNFaUP / TNFaLO (5'AGCCCCTCTCAGAAGCAGAC'3 / 5'GTCATCGGG GTCTCACATCC'3). *IL-1 β* : primer pair ILbUP / ILbLO (5'TTCAGGTTTCTAAAGCAGCCAT'3 / 5'TTAGCAGTGAT TTAGGGAAGGC'3). *IL-1 α* : primer pair ILaUP / ILaLO (5'ACAAAAGGCGAAGTAGTCTG'3 / 5'TGTTAGTGTCGGT TCCATTAG'3). A 1.5 % agarose gel electrophoresis was performed to separate the PCR products, the fragments were recovered with the QIAquick Gel Extraction Kit (QIAGEN, Hilden, Germany). The PCR products were cloned in the pGEM-T Easy Vector System (Promega, Madison, WI, USA) and sequenced in forward and reverse direction for verification (MWG-Biotech AG, Ebersberg, Germany). The protein sequences were deduced by in silico analyses. Identity comparison of the proteins and respective cDNA contigs were done by Lasergene software (DNASar, Madison, USA) and

miscellaneous canine and human cytokine sequences from the NCBI database (accession numbers AY423389, AF047011, AF322077, AF322078, NM_001037971).

Results

Of the 17 individuals screened, eight cytokine transcripts showed nucleotide substitutions leading to amino acid exchanges within the deduced proteins of *TNF α* , *IL-1 α* and *IL-1 β* (Table I). SNPs causing no amino acid exchange were not taken into account for further analysis.

A BMD lung sample showed one nucleotide substitution affecting *TNF α* exon 4 codon 113 (GAT → GGT, Asp → Gly).

For *IL-1 α* , the complete canine *IL-1 α* coding sequence and the sequence for the alternative *IL-1 α Exon 5 del* splice variant were amplified (14). The complete *IL-1 α* coding sequence of one lung sample (BMD) showed substitutions in exon 2 codon 23 (TTC → TCC, Ser → Pro) and exon 4 codon 47 (TGC → CGC, Cys → Arg). One substitution was found in the *IL-1 α Exon 5 del* splice variant transcript in a skin sample (West Highland Terrier). The transcript showed one nucleotide substitution in exon 4 codon 43 (CTT → CCT, Leu → Pro).

Three *IL-1 β* transcripts derived from liver samples showed nucleotide substitution in the canine exons. Two samples (BMD) each showed one nucleotide substitution in the coding sequence of exon 5, affecting codon 113 (GAT → GGT, Asp → Gly) and codon 124 (CAG → AAG, Gln → Lys), respectively. One sample (BMD) showed two substitutions each in exon 7 codon 228 (TCT → CCT, Ser → Pro) and codon 234 (TAC → CAC, Tyr → His).

Discussion

Cytokines are considered to play a major role in the pathogenesis of malignant histiocytosis. In the present study, we focused on SNPs in the canine coding sequences of the cytokines *TNF α* , *IL-1 α* and *IL-1 β* , causing amino acid exchanges in the deduced protein sequences. With the exception of two samples (West Highland Terrier and

Collie), all samples were taken from BMDs, known to be frequently affected by malignant histiocytosis.

IL-1 α and *IL-1 β* both belong to the same gene family of *Interleukin-1* and are translated as precursor proteins with a molecular weight of 31 kD. They are expressed in various cell types e.g. activated monocytes, macrophages and lymphocytes. The processing of proIL-1 α and proIL-1 β by cellular proteases results in a mature form of the protein of approximately 17 kD. Both proteins induce cell signalling pathways upon binding with a membrane-bound receptor IL-1R1, including the NF κ B inducing kinase (NIK) and three distinct MAP kinase cascades (13, 15). These switched pathways activate different transcription factors, e.g. NF κ B, AP1 and CREB for regulation of immediate early genes vital to inflammatory and immune responses (13). Intracellular proIL- α is fully active and is cleaved by Ca²⁺-dependent membrane associated cysteine proteases called calpains. ProIL- α is cleaved to IL-1 α propiece and mature IL-1 α , which is released to the extra cellular compartment (15, 16).

The *IL-1 α* transcript (BMD sample 2 / lung tissue) in the present study revealed two amino acid exchanges at position 23 and 47 within the deduced protein sequence of the IL-1 α propiece. At position 23, the polar amino acid serine was substituted by unpolar proline. At position 47, the polar amino acid cysteine was exchanged with positively-charged arginine. Cysteines are able to form disulfide bridges, which are often modified by methylation. Both 32 kD proIL-1 α and the 16kD IL-1 α propiece are able to bind to nuclear DNA. ProIL-1 α is commonly found in the cytoplasm and after myristoylation it binds to the membrane (17).

An SNP in the *IL-1 α Exon 5 del* splice variant from skin (Western Highland Terrier sample 9) showed one amino acid exchange at position 43 within the deduced protein isoform IL-1 α . Unpolar leucine is substituted to unpolar proline. Due to deletion of exon 5, the calpain cleavage site is lacking and calpain is unable to cleave the mature protein. These splice variant transcripts were mainly detected in macrophages and synovial membrane tissue of dogs, cats and pigs at various expression levels (14).

Pro IL- β remains in the cytoplasm until it is cleaved by the cysteine proteinase interleukin 1 β converting enzyme (ICE) to the 16kD IL-1 β propiece and the biologically active 17 kD mature IL-1 β protein. Either proteins can be myristoylated and are able to be bound to the cell membrane or to be transported out of the cell (14, 15). In the *IL-1 β* transcript (BSH sample 1), one SNP showed an amino acid substitution in the deduced canine mature IL-1 β sequence. At position, 124 glutamine was substituted by lysine within a β -strand motif of the protein (18-20). At position 228 and 234, two SNPs (BSH sample 4) caused two amino acid exchanges in the deduced canine mature IL-1 β

also within a β strand motif. At position 228, serine was exchanged with proline and at position 234 tyrosine was exchanged with histidine. Regarding the tyrosine exchange at position 234 the motif asparagine-tryptophan-tyrosine is highly conserved in different species, e.g. human, mouse, rat, cattle and rabbit. However side-directed mutagenesis in this peptide motif of human IL-1 β changing the tyrosine residue (Tyr 237) to phenylalanine did not affect the protein binding affinity to its receptor (19).

At position 113, one SNP (BSH sample 5) led to an amino acid exchange in the deduced propiece IL-1 β protein. Position 113 covers the last amino acid in the sequence. Hydrophilic aspartic acid is exchanged with unpolar glycine. The aspartic acid – alanine side (canine amino acid position 113 - 114) was determined to be cleaved by cysteine proteinase interleukin β converting enzyme (ICE). Interestingly, all SNPs in the IL-1 β transcripts were exclusively detected in liver samples.

The pleiotropic cytokine TNF α is primarily secreted by stimulated macrophages. It additionally acts as a potent pyrogen when stimulated by IL-1. Further on, it plays an important role in abundant cellular signal transduction processes during immune response and inflammation. It can induce cell death in certain tumour cells. TNF α exists in two forms: a soluble form of 157 amino acids (17 kD), cleaved at amino acid position 76 and 77 by ADAM17 and as a type II membrane protein of 233 amino acids (26 kD) (21). One SNP in the canine TNF α transcript (BSH sample 2 / lung tissue) led to an amino acid exchange in the deduced membrane binding region of TNF α . At position 206, the amino acid aspartic acid was exchanged with glycine.

SNPs within the promoter and or enhancer region of the cytokine genes IL-1 α/β and TNF α , which play an important role in the development of diseases e.g. cancer, Alzheimer disease, sepsis and rheumatoid arthritis, were described (22-24). For malignant histiocytosis, the data regarding SNP screening in canine cytokine transcripts is currently scarce. Our results showed several SNPs within the cytokine coding sequence of mRNA isolated from BMD tissue samples. These SNPs led to missense mutations causing changes of amino acid sequences within the deduced protein. Due to the fact that the BMDs show a genetic predisposition for malignant histiocytosis, these dogs could be used to elucidate the genetic mechanisms of malignant histiocytosis and to elucidate in further studies if the found SNPs play a role in the pathogenesis of this disease.

Abstract

The cytokines interleukin-1 (*IL-1 α* and *IL-1 β*) and the tumor necrosis factor- α (*TNF- α*) both play a major role in the initiation and regulation of inflammation and immunity responses. Polymorphisms within the gene sequences of these cytokines *IL-1* and *TNF- α* have been proposed to play an important role in the pathogenesis of certain diseases. Affecting nearly every organ, various diseases, including some cancers, are described to be associated with an increased level of *IL-1* and *TNF- α* proteins, for example, solid tumors, hematologic malignancies, malignant histiocytosis, autoimmune disorders, Alzheimer's disease, Parkinson's disease, sepsis, and rheumatoid arthritis. Regarding genetic backgrounds and pathways, numerous canine diseases show close similarities to their human counterparts. As a genetic model, the dog could be used to unravel the genetic mechanisms, for example, in particular the predispositions, the development, and progression of cancer and metabolic diseases. The identity comparison of gene and protein sequences of different species could be used to elucidate the structure and function of the genes and proteins by identifying the evolutionary conserved regions and domains. Herein we analyzed in detail the mRNA and protein structures and identities of the present known mammalian (human, canine, murine, rat, ovine, equine, feline, porcine, and bovine) *TNF- α* , *IL-1 α* , and *IL-1 β* mRNAs and proteins. Additionally, based on the canine genome sequence, we derived in silico the complete mRNA structures of the *IL-1 α* and *IL-1 β* mRNAs.

The cytokines interleukin-1 (*IL-1 α* and *IL-1 β*) and tumor necrosis factor- α (*TNF- α*) are primarily secreted by monocytes and macrophages and act as potent multifunctional cytokines in abundant signal transduction processes during immune response and inflammation, acting as proinflammatory proteins. These cytokines bind to cell-surface receptors inducing the activation of different transcription factors, for example, AP1, CREB, and NF- κ B for regulation of immediate early genes. In detail, *IL-1 α* and *IL-1 β* will bind to membrane-bound receptor *IL-1RI*, whereas 2 distinct receptors *TNFR55* and *TNFR60* exist for *TNF- α* . Although both receptors for *IL-1 α* and *TNF- α* are structurally unrelated, they operate both in a similar biological manner (Brockhaus et al. 1990; Eisenberg et al. 1991; Dinarello 1996).

In particular, NF κ B-dependent signaling pathways play a key role for inflammatory responses caused by injury and infection stimuli. In mammals, 5 NF- κ B proteins, RelA, RelB, c-Rel, NF- κ B1, and NF- κ B2 were described, which form homo- and heterodimer complexes in the cytoplasm. NF- κ B

proteins are inactivated by binding the inhibitory protein I κ B. *IL-1* and *TNF- α* are able to trigger phosphorylation and ubiquitinylation pathways to degrade the I κ B protein having a releasing effect for NF- κ B and thus inducing the transcription of several genes in the nucleus (for review see Beutler and Cerami 1989; Stylianou and Saklatvala 1998; Alberts et al. 2002).

IL-1 α and *IL-1 β* both belong to the same gene family of *Interleukin-1* and are translated as precursor proteins with a molecular weight of 31 kDa. The processing of the isoforms of pro*IL-1 α* and pro*IL-1 β* by cellular proteases results in a mature form of the protein of approximately 17 kDa (Dinarello 1996).

Intracellular pro*IL-1 α* is fully active and cleaved by Ca²⁺-dependent membrane-associated cysteine proteases called calpains to *IL-1 α* propiece (16 kDa), which then is able to bind to nuclear DNA, and to mature *IL-1 α* , which is released to the extracellular compartment (Kobayashi et al. 1990; Dinarello 1996). *IL-1 α* shows significant antitumor activity

on solid tumor cells in vitro and in vivo (Braunschweiger et al. 1988). It also has an effect on bone marrow cells to produce colony-stimulating factors (Bagby et al. 1986).

ProIL- β remains in the cytoplasm until it is cleaved by the cysteine proteinase IL-1 β -converting enzyme to the IL-1 β propeptide (16 kDa) and the biologically active 17-kDa mature IL-1 β protein. Either protein is able to bind the cell membrane or to be transported out of the cell (Dinarelo 1996).

The TNF- α protein exists in 2 forms: a soluble form of 157 amino acids (aa) (17 kDa) cleaved at aa position 76 and 77 by ADAM17 and as a membrane-bound form of 233 aa (26 kDa). Additionally, it acts as a potent pyrogen when stimulated by IL-1. Also TNF- α can induce cell death of certain tumor cells (Beutler and Cerami 1989).

The human nucleotide sequences of the *IL-1 α* and *IL-1 β* genes contain 6 introns and 7 exons. The genes are located on HSA 2q14 (Furutani et al. 1986; Webb et al. 1986; Modi et al. 1988; Lafage et al. 1989). In humans, the *TNF- α* gene consists of 3 introns and 4 exons and spans approximately 3 kb and was mapped on HSA 6p21 (Nedwin et al. 1985; Spies et al. 1986).

Cytokines are considered to play a major role in the pathogenesis of several diseases.

Polymorphisms within the promoter and/or enhancer regions within the gene sequences of *IL-1 α / β* and *TNF- α* are proposed to play a role in the development and pathogenesis of Alzheimer's disease and Parkinson's disease (Nicoll et al. 2000; McGeer PL and McGeer EG 2001; Mattila et al. 2002), as well as nonsmall cell lung cancer (Zienolddiny et al. 2004), tuberculosis (Correa et al. 2005), sepsis, and rheumatoid arthritis (Cox et al. 1999; Ruuls and Sedgwick 1999). Also the production of large quantities of IL-1 and TNF- α cytokines in T-cells are expected to be responsible for the development and progression of certain autoimmune and tumor diseases like in human the Langerhans' cell histiocytosis and the canine malignant histiocytosis (Ramsey et al. 1996; Egeler et al. 1999; Tazi et al. 2000; Affolter and Moore 2002; Arico 2006).

Some human and canine diseases show similarities, concerning the dysfunction of regulation of the immune system and inflammatory processes and the genetic pathways for the development of neoplastic diseases, for example, malignant histiocytosis (Ramsey et al. 1996; Affolter and Moore 2002). Comparative analyses of canine cytokine genes to the known gene information of other mammals could be used to clarify the mechanisms of etiology and pathogenesis. The knowledge gained by the species comparison could help to evaluate the different species as appropriate models for research studies opening new aspects for experimental and therapeutic approaches.

In Figure 1A and B, the *IL-1 α* , *IL-1 β* , and *TNF- α* mRNA sequences of 7 mammals currently present at the National Center for Biological Information (NCBI) database (October 2006) are shown in detail (including the present information on the coding sequences (CDS), 5' untranslated regions [UTRs] and 3'UTRs). Additionally, we derived in silico the complete structures of the *IL-1 α* and *IL-1 β* mRNAs using the released canine genome sequence (Lindblad-Toh et al. 2005).

For CDS and protein identity analyses, we used the described sequences from human, dog, mouse, cat, pig, cattle, rat, horse, and sheep and deduced, if necessary, the corresponding parts for analysis. The in silico analysis were done using LASERGENE software programs (DNASTAR, Madison, WI).

The first publications of human and murine *IL-1 α* gene sequences (NM_000575, NM_010554) were done at the middle of the 1980s. The human CDS is composed of 816 bp and 813 bp for the murine sequence (Furutani et al. 1985; Lomedico et al. 1984; March et al. 1985). Straubinger et al. characterized the canine (798 bp) and feline (813 bp) CDS and parts of 3'UTR for the *IL-1 α* mRNAs (NM_001003157, AF047012) spanning exon 2–7, respectively. Two different splice variant transcripts of canine, feline, and porcine *IL-1 α* were described to be found in total RNA from lipopolysaccharide-stimulated lung macrophages. One transcript was identified as a new mRNA splice variant of canine *IL-1 α* missing the 175 bp of exon 5 (Straubinger et al. 1999). Due to the deletion of exon 5, the calpain cleavage site is lacking, and calpain is unable to cleave the precursor protein to the mature protein. In previous studies aimed at a single-nucleotide polymorphism screening analysis in canine cytokine mRNA transcripts of *IL-1(α / β)* and *TNF- α* , we cloned the *IL-1 α* mRNAs adding new information on the 5'UTR (complete exon 1 and parts of exon 2) and additional parts for the 3'UTR (Soller et al. 2006). We also found both splice variants *IL-1 α* (DQ923806) and the splice variant bearing the exon 5 deletion (EF068230): We analyzed them in detail and submitted them to the NCBI database completing the known information due to the fact that the sequences describing the splice variant were not submitted to the databases by the respective author. The genetic structure and organization of all compared *IL-1 α* cytokines are highly conserved among the different mammals. The detailed sequence comparisons (Figure 1A) showed that all cytokine transcripts of the different species with exception of the feline and ovine sequences are composed of equal number of 7 exons. The ovine and feline exceptions are the missing of the sequence information coding for exon 1, probably due to the transcripts have not been completely characterized up to date.

The identities of the canine *IL-1 α* CDS (NM_001003157) to the CDS sequences of other species vary between mouse CDS (NM_008361) 43.9%, rat CDS (D00403) 69.3%, human CDS (NM_000575) 79.6%, horse CDS (U92480) 84.8%, and cat CDS (AF047012) 88.8% (Table 1). Respectively, the identities of the canine *IL-1 α* protein sequence (ABJ51907) to the protein sequences of the other species vary between mouse protein (NP_034684) 57.1%, rat protein (BAA00306) 59.6%, human protein (NP_000566) 68.5%, horse protein (AAC39255) 79.3%, and cat protein (AAC03067) 82.7% (Table 1).

The *IL-1 α* proteins of all mammals show strong conservation of the predicted calpain cleavage site (-KPRSV-), located between the arginine residue at position 108 and the serine residue at position 109 of the canine protein. The average *IL-1 α* protein size of the described mammals is about 270 aa. The protein size range about 266 aa (dog,

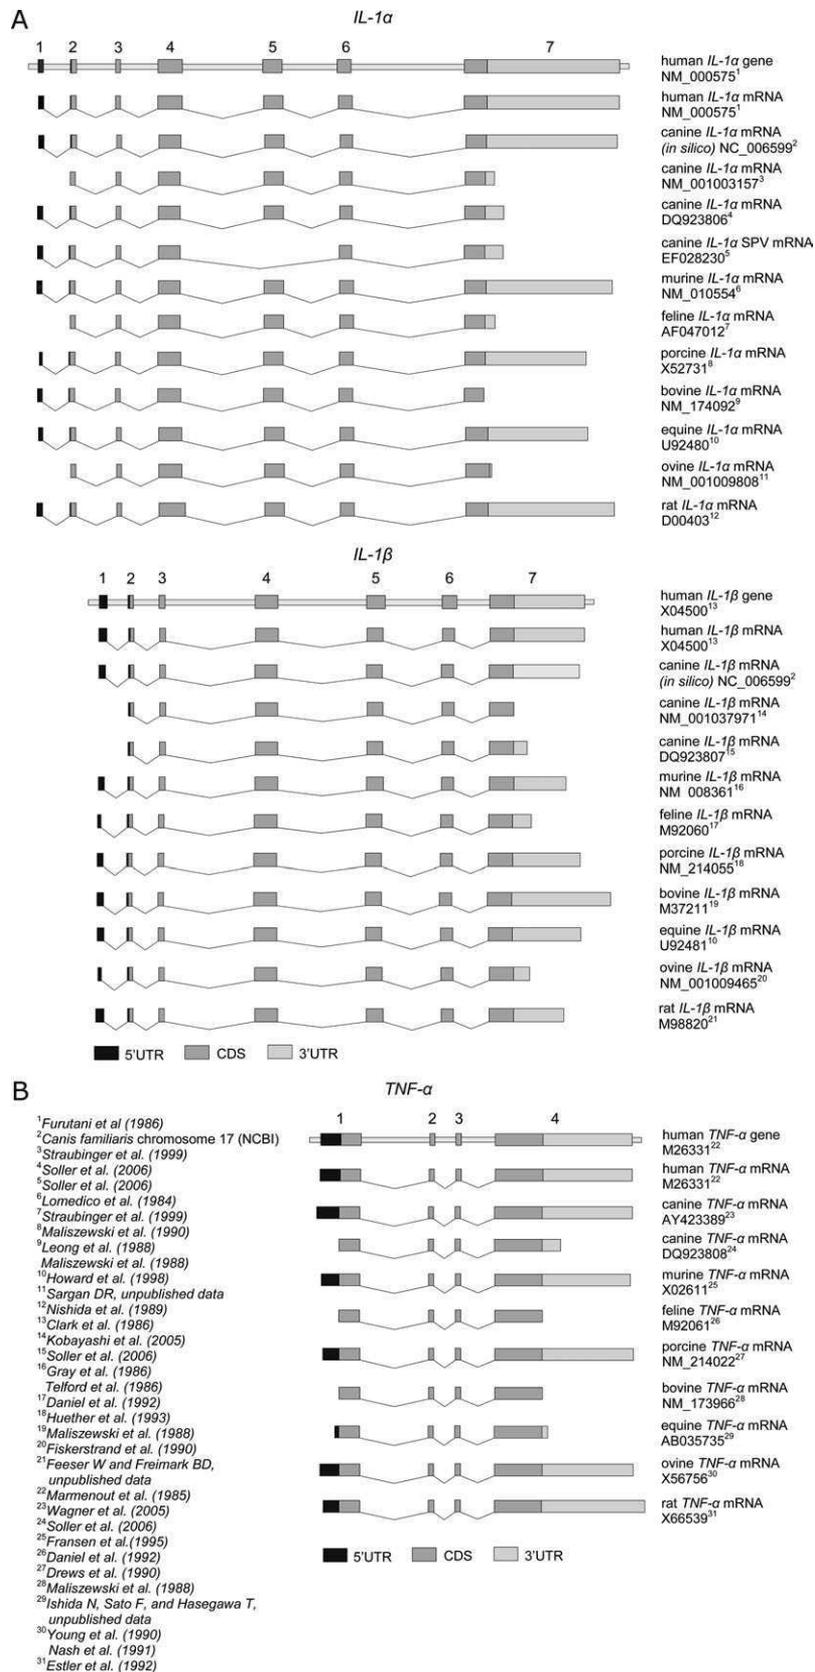

Figure 1. (A) Species comparison of *IL-1*(α/β) transcripts. The introns are scaled down by factor 0.4. (B) Species comparison of *TNF- α* transcripts.

Table 1. Cytokines IL-1 and TNF- α identity comparison (CDS and protein) of various species to canine transcripts and proteins; size in base pairs (bp) and amino acids (aa), and listed accession numbers

IL-1 α	Identity (%) to <i>Canis. familiaris</i>	
	CDS 798 bp (DQ923806)	Protein 266 aa (ABJ51907)
Human (<i>Homo sapiens</i>) (NM_000575/NP_000566)	79.6 (816 bp)	68.5 (272 aa)
Mouse (<i>Mus musculus</i>) (NM_000575/NP_000566)	43.9 (813 bp)	57.1 (271 aa)
Cat (<i>Felis catus</i>) (AF047012/AAC03067)	88.8 (813 bp)	82.7 (271 aa)
Pig (<i>Sus scrofa</i>) (X52731/CAA36945)	81.8 (813 bp)	73.2 (271 aa)
Cattle (<i>Bos Taurus</i>) (NM_174092/NP_776517)	81.2 (807 bp)	75.1 (269 aa)
Horse (<i>Equus caballus</i>) (U92480/AAC39255)	84.8 (813 bp)	79.3 (268 aa)
Sheep (<i>Ovis aries</i>) (NM_001009808/NP_001009808)	81.0 (807 bp)	75.1 (266 aa)
Rat (<i>Rattus norvegicus</i>) (D00403/BAA00306)	69.3 (813 bp)	59.1 (268 aa)
IL-1β	CDS 801 bp (DQ923807)	Protein 267 aa (ABJ51908)
Human (<i>Homo sapiens</i>) (X04500/CAA28185)	76.4 (810 bp)	62.8 (270 aa)
Mouse (<i>Mus musculus</i>) (NM_008361/NP_032387)	71.7 (810 bp)	58.3 (270 aa)
Cat (<i>Felis catus</i>) (M92060/AAA30814)	83.8 (804 bp)	74.0 (268 aa)
Pig (<i>Sus scrofa</i>) (NM_214055/NP_999220)	76.3 (804 bp)	64.7 (268 aa)
Cattle (<i>Bos Taurus</i>) (M37211/AAA30584)	76.5 (801 bp)	62.5 (267 aa)
Horse (<i>Equus caballus</i>) (U92481/AAC39256)	79.5 (806 bp)	67.3 (266 aa)
Sheep (<i>Ovis aries</i>) (NM_001009465/NP_001009465)	75.5 (800 bp)	61.4 (261 aa)
Rat (<i>Rattus norvegicus</i>) (M98820/AAA41426)	70.3 (806 bp)	58.0 (263 aa)
TNF-α	CDS 702 bp (AY423389)	Protein 234 aa (AAR27885)
Human (<i>Homo sapiens</i>) (M26331/AAA36758)	90.8 (702 bp)	91.0 (234 aa)
Mouse (<i>Mus musculus</i>) (X02611/CAA26457)	80.4 (708 bp)	78.2 (236 aa)
Cat (<i>Felis catus</i>) (M92061/AAA30818)	93.3 (702 bp)	94.4 (234 aa)
Pig (<i>Sus scrofa</i>) (NM_214022/NP_999187)	85.5 (699 bp)	85.5 (233 aa)
Cattle (<i>Bos Taurus</i>) (NM_173966/NP_776391)	83.4 (705 bp)	78.7 (235 aa)
Horse (<i>Equus caballus</i>) (AB035735/BAA349)	89.3 (705 bp)	87.7 (233 aa)
Sheep (<i>Ovis aries</i>) (NM_001024860/NP_001020031)	83.9 (705 bp)	79.1 (233 aa)
Rat (<i>Rattus norvegicus</i>) (X66539/CAA47146)	79.7 (708 bp)	77.0 (234 aa)

sheep), 268 aa (horse, rat), 269 aa (cattle) to 271 aa (mouse, cat, pig), and 272 aa (human).

Correspondingly, the human (BC_008678) and the murine *IL-1 β* (NM_008361) CDS and protein sequences (Auron et al. 1984; Gray et al. 1986; Telford et al. 1986) were analyzed by identity comparison and evaluated with the canine, feline, porcine, bovine, equine, ant rat sequences.

As described for *IL-1 α* , we cloned the canine *IL-1 β* mRNA, analyzed it in detail, and submitted it to the NCBI database adding new information on the 3'UTR to the present data. As shown in Figure 1A, again the genetic structure and organization of all compared *IL-1 β* cytokine transcripts are highly conserved among the different analyzed mammals. The detailed sequence data comparison (Figure 1A) showed that all analyzed mammalian cytokine transcripts, with the exception of the cloned canine sequences (NM_001037971 and DQ923807), are composed of equal number of 7 exons. The canine sequences (NM_001037971 and DQ923807) are missing the sequence information for the 5'UTR (exon 1) that have not been completely cloned until now. Taking into account the in silico-derived structure of the canine *IL-1 β* (Figure 1A), the dog shows also 7 exons with a highly conserved structure to the compared species.

The CDS identities of the canine *IL-1 β* (NM_001037971, DQ923807) to the sequences of the other mammals vary between mouse CDS (NM_008361) 71.7%, human CDS

(BC_008678) 76.4%, horse CDS (U92481) 79.3%, and cat CDS (M92060) 83.8% (Table 1). The identities of the canine *IL-1 β* protein to the protein sequences of the other mammals vary between mouse (NP_032387) 58.3%, human protein (CAA28185) 62.8%, horse protein (AAC39256) 67.3%, and cat protein (AAA30814) 74.0% (Table 1).

In the canine *IL-1 β* protein, a β -strand motif at aa residue position 232–240 (-PNWYISTSQ-) is highly conserved in the other described mammals human, mouse, rat, cat, pig, sheep, horse, and cattle. The *IL-1 β* protein sizes of the different species vary between 267 aa (cattle, dog) and 270 aa (human).

The genetic structure and organization of all compared *TNF- α* cytokine transcripts are also highly conserved among the different species. The detailed sequence comparisons (Figure 1B) showed that all *TNF- α* transcripts of the different species are composed of 4 exons. All described sequences, with the exception of feline (M92061), bovine (NM_173966), and equine cDNAs (BAA88349), show the full mRNA sequences including the CDS, 5'UTR, and 3'UTRs. The feline, bovine, and equine sequences exceptions are the missing of the sequence information coding for the 5'UTRs and 3'UTRs, surely due to the missing complete characterization of the respective mRNA transcripts.

The highest identity values among the analyzed cytokines show the CDS and proteins of *TNF- α* . The canine CDS for

TNF- α (AY423389) shows identities from mouse CDS (X02611) 80.4%, sheep CDS (NM_001024860) 83.9%, pig CDS 85.5% (NM_214022), to human CDS 90.8% (M26331), and cat CDS 93.3% (M92061) (Table 1). Respectively, the identities of the canine TNF- α protein sequence (AAR27885) to the protein sequences of the other species vary between mouse protein (CAA26457) 78.2%, sheep protein (NP_001020031) 79.1%, pig protein (NP_999187) 85.5%, human protein (AAA36758) 91.0%, and cat protein (AAA30818) 94.4%. The TNF- α protein sizes vary between 233 aa (pig and sheep), 234 aa (human, dog, cat and rat) to 235 aa (cattle), and 236 aa (mouse).

The overall described cytokine identity values (Table 1) of the analyzed CDS and the derived proteins show a wide variance from 43.9% to 93.43% among the CDS and from 57.1% to 94.4% for the analyzed proteins.

The described mammalian cytokine transcript and protein comparison data emphasizes the relevance of structural comparative analysis of genes and proteins for the development of therapeutic strategies aimed at the development of therapeutic approaches targeting canine disorders. The observed overall cytokine identities are variable among the different species analyzed. In particular, the performed protein alignments of the cytokines IL-1 and TNF- α showed highly conserved protein regions and domains of the compared elements among the mammalian species. In spite of the observed high variability in terms of nucleotide sequence identity, the structure of the analyzed genes is highly conservative.

The described properties of the cytokine genes IL-1 and TNF- α and their described role in the development of tumor and metabolic diseases offer various possibilities for new approaches and applications and also for existing therapy concepts. The highly conserved structure of the cytokine proteins seen in mammals allows knowledge transfer of already established experimental data and approaches from one mammalian species to another due to the fact that essential protein properties are comparable. It is to expect that future therapeutic approaches targeting cytokine-mediated diseases in humans and dogs will benefit from each other.

Abstract

THADA, mapping to chromosomal band 2p21 is target gene of specific chromosomal rearrangements observed in thyroid benign tumors. Thus, it is one of the most common gene targets in chromosomal rearrangements in benign epithelial tumors. Nevertheless, nothing is known about the function of its protein. Therefore, we have analyzed the genetic structure of *THADA* homologous genes in selected vertebrates (*Canis familiaris*, *Chlorocebus aethiops*, *Gallus gallus*, and *Mus musculus*), which are not characterized up to now. The coding sequences of the mRNA of these species have been sequenced and analyzed revealing similarities to ARM repeat structures which indicates an involvement in protein–protein interactions. Using multiple alignments we identified the most conserved part of the protein (aa 1033–1415 *Homo sapiens*) with an identity of 70.5% between the most different organisms implying a putative important functional domain. The truncations observed in human thyroid adenomas disrupt this conserved domain of the protein indicating a loss of function of *THADA* contributing to the development of the follicular neoplasias of the thyroid.

1. Introduction

The thyroid adenoma associated gene (*THADA*) first has been described as the target gene of chromosomal 2p21 rearrangements in benign thyroid lesions (Rippe et al., 2003). For benign thyroid lesions including hyperplasias and follicular thyroid adenomas 2p21 rearrangements are beneath rearrangements of chromosomal region 19q13.4 and trisomy 7 the third frequent cytogenetic subgroup (Bondeson et al., 1989; Teyssier et al., 1990; Dal Cin et al., 1992; Belge et al., 1994, 1998; Bol et al., 1999). 3'-RACE analysis on two cell lines derived from benign thyroid lesions with 2p21-translocations revealed fusion genes involving *THADA* (*THADA-FUS3p* and *THADA-FUS7p*). The breakpoints of chromosomal band 2p21 in these cell lines are located within intron 28 of *THADA*. In both fusion genes *THADA* ends after exon 28 followed by ectopic non-coding sequences derived from the translocation partners (Rippe et al.,

2003). In *THADA-FUS3p* the ectopic sequences are derived from an intronic region of the *peroxisome proliferator-activated gene gamma* (*PPAR γ*). A functional *THADA/PPAR γ* fusion was excluded because the fused sequences were in reverse orientation to the genomic *PPAR γ* orientation (Drieschner et al., 2006). It was thus concluded that the truncation of the gene rather than its fusion to coding sequences is the critical event in benign thyroid tumors with *THADA* rearrangements (Rippe et al., 2003; Drieschner et al., 2006).

As for the possible function of *THADA* there is only one databank entry indicating that *THADA* is involved in the death receptor pathway (Puduvalli VK and Ridgeway L, Gene Bank reference note). Accordingly, the truncation of *THADA* and its loss of the C-terminus may lead to an altered apoptosis induction facilitating the development and/or the proliferation of benign thyroid lesions (Rippe et al., 2003).

THADA has a genomic size of about 365 kb. So far, two transcript variants (GeneBank accession nos. NM_022065 and NM_198554) have been described. The cDNA of transcript variant 1 (NM_022065) contains 38 exons with a size of 6090 bp. Transcript variant 2 comprises 36 exons with a size of 5900 bp (GeneBank accession no. NM_198554). To date for other species (e.g. *Pan troglodytes*, *Mus musculus*, and *Rattus norvegicus*) only predicted cDNA and/or mRNA sequences are accessible from databases.

The ORF of transcript variant 1 of human *THADA* has a length of 5862 bp hypothetically coding for 1953 amino acids. There is so far no homology to other human proteins or domains described and only one uncharacterized conserved domain COG5543 (Cluster of Orthologous Groups NCBI (Tatusov et al., 2003)) has been found in databases.

In this work, the *THADA* cDNA sequences of four different species (*Canis familiaris*, *Chlorocebus aethiops*, *Gallus gallus*, and *M. musculus*) have been analyzed and the genomic structures of *THADA* have been described. Based on these results the mRNA sequences as well as the protein sequences of the different species were compared in order to identify similar regions and possible conserved domains.

2. Materials and methods

2.1. Tissue samples and cell lines

For RNA isolation fresh-frozen tissue samples of liver and myocardium (*G. gallus*) and of the testis (*C. familiaris*) were used. The tissue samples were obtained commercially (*G. gallus*) and from the Small Animal Clinic (University of Veterinary Medicine, Hanover, Germany) (*C. familiaris*), respectively. For *C. aethiops* a cell line (CV1) derived from fibroblasts of the kidney and for *M. musculus* a cell line (NIH3T3) derived from embryonic fibroblasts were used for RNA isolation.

2.2. Fluorescence in situ hybridization (FISH)

For analysis of chromosomal localisation of *THADA* in *C. aethiops* fluorescence in situ hybridization on the cell line CV1

was performed. Cell culture of the cell line and karyotyping of Giemsa-banded metaphases were performed as previously described for pleomorphic adenomas of the parotid gland (Bullerdiek et al., 1987). For FISH analyses human BAC clones (RP11-1069E24 (GeneBank accession nos. AQ694385 and AQ703756) and RP11-183F15 (GeneBank accession no. AC092838)) (RZPD, Heidelberg, Germany) located within human *THADA* were used. FISH analyses were performed after GTG banding of the same metaphase spreads. Treatment of metaphases and subsequent FISH experiments were performed as described previously (Kievits et al., 1990). For FISH studies, BAC DNA was labeled with dig-11-dUTP by nick translation (Roche Diagnostics, Mannheim, Germany). For FISH experiments the labeled BAC DNA was pooled (concentration: 3 ng/ μ l). Post-hybridization was performed at 42 °C in 0.1 \times SSC for 5 min. Detection was performed with anti-dig-fluorescein fab-fragments (Roche Diagnostics, Mannheim, Germany). Chromosomes were counterstained with DAPI (0.025 mg/ml). For the cell line CV1, 10 metaphases were examined. Slides were analyzed on a Zeiss Axiophot fluorescence microscope using an FITC and DAPI filter set. Metaphases were recorded with the Power Gene Karyotyping System (Applied Imaging, Newcastle, UK).

2.3. RNA isolation and cDNA synthesis

The RNeasy Mini Kit (QIAGEN, Hilden, Germany) was used for the extraction and purification of total RNA from the fresh–frozen tissue samples (*G. gallus* and *C. familiaris*). Prior to the RNA isolation the tissue samples were homogenized with a tissue lyser (QIAGEN, Hilden, Germany). Total RNA was isolated from the cell lines (CV1 and NIH3T3) using the Trizol reagent (Invitrogen, Karlsruhe, Germany).

cDNA synthesis was performed with 5 μ g total RNA using the M-MLV reverse transcriptase (Invitrogen, Karlsruhe, Germany).

2.4. Oligonucleotides and RT-PCR

Primers were designed using Lasergene primer select (DNASar) and Vector NTI (Invitrogen). Up to nine PCR primer pairs were selected covering the whole CDS of the predicted *THADA* cDNA sequence of each organism. The fragment lengths of the primer pairs varied between 200 bp and 1800 bp. RT-PCR was performed with the Taq-DNA Polymerase (Invitrogen, Karlsruhe, Germany). Optimal annealing temperatures were detected by gradient RT-PCR (55 °C–65 °C) with a Mastercycler Gradient (Eppendorf, Hamburg, Germany) for each primer pair and organism. 1 μ l of cDNA was used as template in a total reaction volume of 50 μ l containing 0.2 mM of each primer, the reaction buffer supplied by manufacturer (Invitrogen, Karlsruhe, Germany), 0.2 mM dNTPs, 1.5 mM MgCl₂, and 2.5 U Taq DNA polymerase (Invitrogen, Karlsruhe, Germany). After 3 min initial denaturation at 95 °C 35 cycles of 60 s at 95 °C, 90 s at optimized annealing temperature (55 °C–65 °C) and 60 s at 72 °C followed by a final extension at 72 °C for 10 min. were performed in a Mastercycler Gradient (Eppendorf, Hamburg, Germany).

2.5. Purification and determination of yield of RT-PCR products

RT-PCR fragments were isolated and purified with the Gel Extraction Kit (QIAGEN, Hilden, Germany). Quantification of the purified DNA was done by dot blot. A dilution series of the purified DNA was dotted on an agarose gel (1%) and stained with ethidiumbromide. The concentration was estimated by comparing the intensities of the dots of the purified DNA and a standardized dilution series of the 1 kb Plus DNA ladder (Invitrogen, Karlsruhe, Germany).

2.6. Determination of gene sequences

The sequence analysis of the mRNA and chromosomal assignment of the human *THADA* gene have been described previously (Rippe et al., 2003). According to the human *THADA* gene sequence the genomic structures of the homolog *THADA* genes in the examined organisms have been predicted aligning the human *THADA* sequence (GeneBank accession nos. NM_022065 and NP_071348) with the available genomic sequences (*C. familiaris*, *G. gallus*, and *M. musculus*). For this purpose Spidey (Lander et al., 2001), BLAST (Altschul et al., 1997), and Perl (www.perl.org) with Bioperl Modules (Stajich et al., 2002) have been used for sequence assembly and identification of splicing sites. If no similarities were detectable or splice sites have been missed manual corrections have been done. For all species described mRNA sequences have been included in the analyses.

20 ng/100 bp of purified DNA was used for DNA sequencing (MWG Biotech, Ebersberg, Germany). Each PCR fragment was sequenced in both directions using the corresponding PCR-primers. The sequencing chromatograms were corrected manually using the ChomasLite software (http://www.technelysium.com.au/). Clustering of the sequences has been done with the help of the Vector NTI Software ContigExpress (Vector NTI, Invitrogen).

2.7. Bioinformatics

The genomic organisation of the different *THADA* genes were determined by aligning the cDNA sequences with the available genomic sequences using Spidey with the option to use large intron sizes (Lander et al., 2001). Comparative interspecies sequence alignments were performed by the

European Bioinformatics Institute (EBI) online tool, clustalw (http://www.ebi.ac.uk/clustalw/) (Higgins, 1994), PROBCONS (http://probcons.stanford.edu/), and AlignX (Vector NTI, Invitrogen). Protein pattern, profiles, and motives have been searched using the EBI tool InterProScan an integrated documentation resource for protein families, domains, and sites (http://www.ebi.ac.uk/) and HHpred using Homology detection by Hidden Markov Model — Hidden Markov Model comparison (http://toolkit.tuebingen.mpg.de/).

3. Results

3.1. Gene prediction and primer design

For primer design the *THADA* genes or *THADA* homologous sequences, respectively, of the analyzed organisms (*C. familiaris*, *C. aethiops*, *G. gallus*, and *M. musculus*) have been determined with bioinformatic tools. The human *THADA* mRNA and amino acid sequences (GeneBank accession nos. NM_022065, NP_071348) were split into sequences corresponding to single exons of the human gene. The conserved sequences AG and GT indicating the splice sites have been added to the nucleotide sequences. For alignments with the mouse, dog, and chicken genomic sequences in which the *THADA* genes have been detected (GenBank accession nos. NT_039649, NW_876251, NW_001471679) bl2seq blastn and tblastn programs have been used (Tatusova and Madden, 1999)). Perl and Bioperl Modules (Stajich et al., 2002) in combination with the program BLAST (Altschul et al., 1997) and Spidey have been used for sequence assembly and identification of splicing sites. The predicted sequences which were nearly identical to the later determined sequences (data not shown) served as template for the primer design. For the analysis of the African green monkey human *THADA* specific primers have been used. The primer pairs were constructed spanning 200 to 1800 bp and the produced PCR products were overlapping for optimal sequencing and contig building.

3.2. Genomic organisation of the *THADA* homologous genes from *C. familiaris*, *C. aethiops*, *G. gallus*, and *M. musculus*

The predicted mRNA sequences from *C. familiaris*, *G. gallus*, and *M. musculus* have been used for primer design. Therefore, the lengths of the deduced mRNA sequences and the

^a Genomic sequences of *Chlorocebus aethiops* not available.

^b The genomic contig (GeneBank accession no. NW_001471679) of *Gallus gallus* chromosome 3 contains parts in this region which are not fully determined. This result should be treated as preliminary.

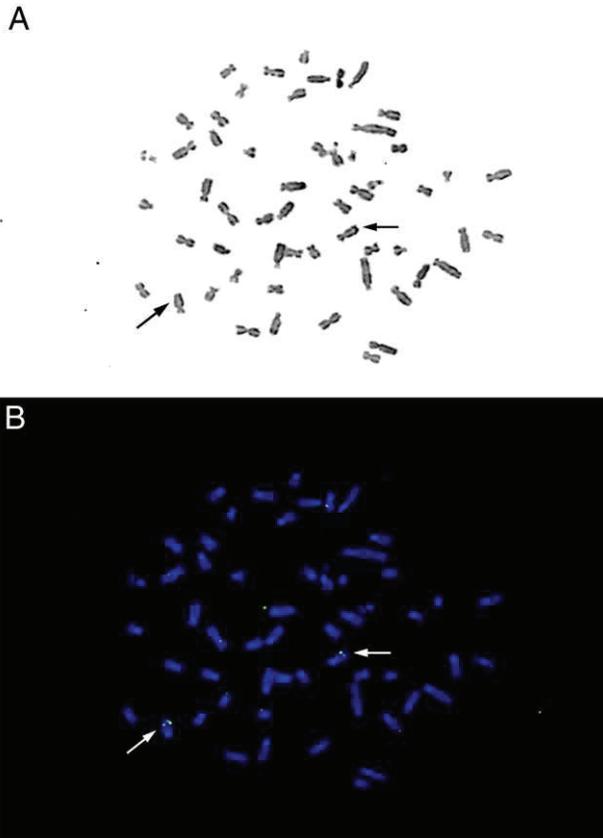

Fig. 1. Chromosomal localisation of *THADA* in *Chlorocebus aethiops*. A metaphase of the cell line CV1 after GTG banding (A) and the same metaphase after FISH with human *THADA* BAC clones (B). Arrows indicating signals on the long arms of both chromosomes 14 of *Chlorocebus aethiops*.

corresponding genomic regions depend on this design. Parts of the 5' and 3' untranslated regions have not been determined. Nevertheless, in all cases the predicted coding regions have been sequenced including ATG translational initiation codons and stop codons. The mRNA sequences of the analyzed organisms (Table 1) were submitted to GenBank (Benson et al., 2006) under accession numbers EF222204 (*C. familiaris*), EF222205 (*C. aethiops*), F222206 (*G. gallus*), and EF222207 (*M. musculus*). The genomic size of *THADA* in human is 365,186 bp. The *THADA* homologous sequences of the organisms analyzed herein are spanning shorter genomic regions compared to the human *THADA* gene (Table 1). For *C. aethiops* no genomic sequences of the corresponding region are available. Fluorescence in situ hybridization (FISH) analysis with human BAC clones containing *THADA* confirms the localisation on the long arm of *C. aethiops* chromosome 14 (Fig. 1).

3.3. Identification and characterization of the open reading frame

All deduced mRNA sequences of *THADA* from *C. familiaris*, *C. aethiops*, *G. gallus*, and *M. musculus* are containing only one reasonable open reading frame (Table 1). To determine the position of the start codon a sequence analysis of a 100 bp region

containing the putative start codon has been performed by multiple alignments of the *C. familiaris*, *G. gallus*, *Homo sapiens*, and *M. musculus* mRNAs. The overall nucleotide similarity calculated by an AlignX (Invitrogen) multiple alignment is 13.7% upstream the predicted start codon and 58.8% within the first 50 bp of the coding region indicating the translation start at this ATG. Furthermore a Kozak sequence is strongly indicating the translation start. The most important positions at position -3 (A) and position +4 (G) (Kozak, 2002) with respect to the predicted translation initiation codon ATG were found to be conserved in all analyzed organisms.

The physical properties of the deduced proteins resemble the human *THADA*. The lengths of the proteins range between 1930 aa (*G. gallus*) and 1953 aa (*C. aethiops*) which is the same as in humans (Table 1). Thus, the molecular weight is between 216,601 Da (*G. gallus*) and 219,595 Da (*Homo sapiens*), respectively.

3.4. Sequence comparison

Using PROBCONS (Do et al., 2005) for the alignment and AlignX (Vector NTI, Invitrogen) for calculation of the similarity the determined mRNA and protein sequences have been aligned and the similarity has been calculated. The similarities between the human *THADA* and the *THADA* proteins of the other organisms correspond to the evolutionary relationship between these organisms. The African green monkey as the nearest relative has the highest similarity to the human (97.1% nucleotide similarity of the coding region and 95.9% amino acid similarity). The chicken as the only non-mammalian organism has the lowest similarity, i.e. 64.7% nucleotide similarity of the coding region and 64.9% amino acid similarity (Table 2).

3.5. Identification of conserved domains

The predicted *THADA* protein sequences from *C. familiaris*, *C. aethiops*, *G. gallus*, *M. musculus*, and the human sequence have been aligned with PROBCONS (Do et al., 2005) in a multiple sequence alignment. For visualisation of the similarity and identification of conserved regions a similarity plot has been calculated (AlignX similarity plot) (Fig. 2). The region with the highest similarity is found from position 1043–1425 in the

Table 2

Similarity comparison of the open reading frame and deduced protein sequences from *Canis familiaris*, *Chlorocebus aethiops*, *Gallus gallus*, and *Mus musculus* (GeneBank accession nos. ABQ10598, ABQ10599, ABQ10600, and ABQ10601) to the human mRNA transcript of *THADA* (GeneBank accession no. NM_022065) and the human *THADA* protein (GeneBank accession no. NP_071348)

Organism	Similarity to <i>THADA Homo sapiens</i>	
	ORF/CDS (%)	Protein (%)
<i>Chlorocebus aethiops</i>	97.1	95.9
<i>Canis familiaris</i>	86.7	83.1
<i>Mus musculus</i>	81.1	78.2
<i>Gallus gallus</i>	64.7	57.2

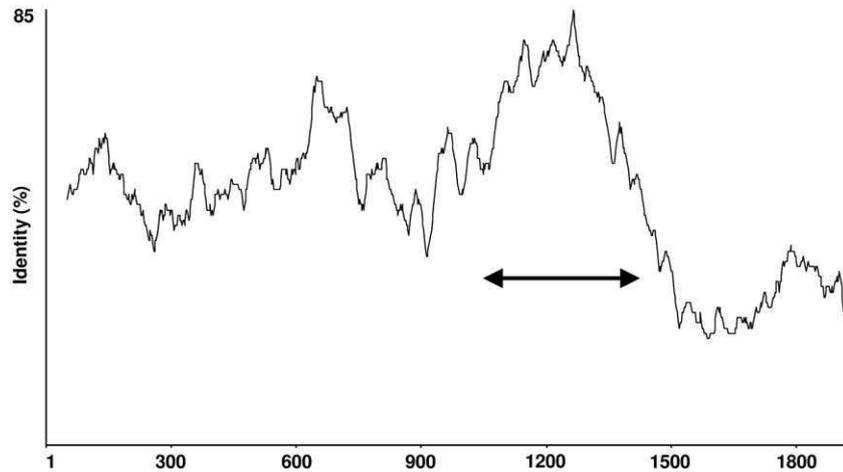

Fig. 2. Similarity plot of the THADA protein from *Canis familiaris*, *Chlorocebus aethiops*, *Gallus gallus*, *Homo sapiens*, and *Mus musculus*. For the sake of visualisation clarity only identical positions in all organisms are included. A window size of 100 aa has been used, therefore the first and last positions are not shown. The most conserved part, position 1043–1425, is marked by an arrow.

multiple alignment corresponding to region 1033–1415 in humans with an identity calculation of 70.4% and the similarity including conserved amino acid changes being 78.6%. The overall similarity of the THADA proteins is calculated to 48.6% identical amino acids and including conserved amino acid changes to 60.9%. Another shorter segment (position 586–705 in humans) is highly similar, 72.5% identity and 78.3% similarity including conserved amino acid substitutions. The lowest similarity is seen in the carboxy terminal part of the protein from position 1491 to 1953 in humans with 27.5% identical positions and 41.9% if conserved substitutions are included.

3.6. Domain and motif assignment

The deduced THADA protein sequences were compared with different domain and motif databases by the help of EBI InterProScan tool and NCBI Conserved Domain Database (CDD) to gather more information regarding the function of THADA. The conserved domain search of the NCBI CDD yields one domain with the identifier COG5543 (COG = Clusters of orthologous groups of proteins). The COG5543 is a cluster of 3 hypothetical proteins from different fungi (GeneBank accession nos. NP_588532, NP_597091, Q03496)

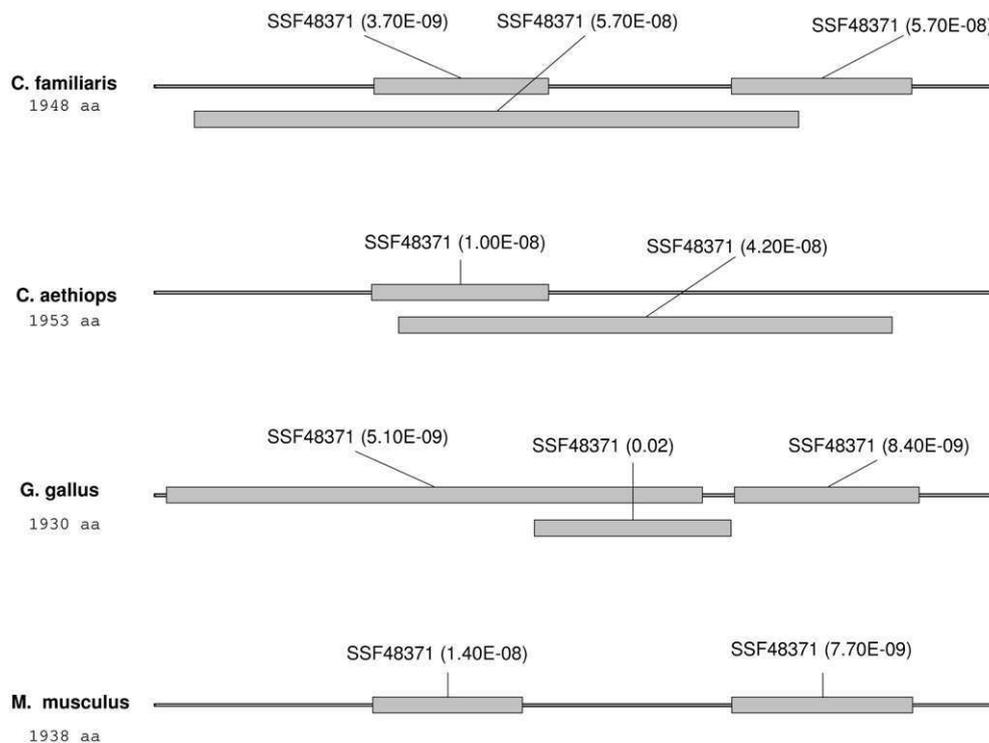

Fig. 3. Similarities to the superfamily of ARM repeat structures (SSF48371) detected in the THADA protein from *Canis familiaris*, *Chlorocebus aethiops*, *Gallus gallus* and *Mus musculus*.

without functional assignment. This conserved multi domain cluster COG5543 has a length of 1400 aa. The alignment to the conserved cluster is localised in the most conserved region of the protein (see Identification of conserved domains) from approx. aa 1025 to aa 1425 in the different THADA proteins with an expect value around $2e-40$. In mouse and chicken another part of the THADA protein shows similarities to this cluster with a lower significance (mouse THADA pos 394–902, e-value 0.00002 and chicken THADA position 396–837, e-value 0.00009).

The InterProScan reveals in the THADA proteins from all analyzed organisms significant assignments to the superfamily ARM repeat (SSF48371) of the Superfamily database of profile Hidden Markov Models (HMMs) (Gough et al., 2001) (Fig. 3). The Superfamily database is based of the SCOP (Structural Classification of Proteins) database which provides a description of structural and evolutionary relationships of proteins with known structure (Murzin et al., 1995). The ARM repeat superfamily summarizes different right-handed superhelices of helices like Armadillo repeat, HEAT repeat, and clathrin associated domains. Similarities with low significance (e-value from 17 to 0.055) to HEAT domains have been found repeatedly, from 5 in the human, dog, and green monkey to 8 in the chicken THADA using the Pfam database (Finn et al., 2006) (data not shown).

The HHpred server of the Max Planck Institute for Developmental Biology for remote protein homology detection and structure prediction has been used for aligning the previously described PROBSCON multiple alignment of THADA from *C. familiaris*, *C. aethiops*, *G. gallus*, *Homo sapiens*, and *M. musculus* with Hidden Markov Models from different databases of protein domains like InterPro, SCOP, Superfamily and COG. The HHpred software is an implementation of pair wise comparisons of profile Hidden Markov Models (HMM) (Soding et al., 2005). The HMM of the COG5543 cluster found with a PSI-BLAST in the CDD Database “aligns” using the HHpred software with an e-value of 0 to the HMM of the THADA multiple alignment (position 394–1749). If the Superfamily database was used in the HHpred scan different models of the superfamily ARM repeat SSF48371 aligning with lower significance (e-values 16–8600) to the multiple alignment of THADA (position 35–1756). Using HMMs calculated by HHpred from entries of the Protein Data Bank (PDB) (Berman et al., 2000) and the SCOP database the best matches to THADA are CAND1 (e-value 0.00025) and different importin proteins (e-value 0.11–10). CAND1 and importins are proteins containing ARM repeat related structures.

4. Discussion

The human THADA gene is the target gene of rearrangements involving chromosomal region 2p21 in thyroid neoplasias (Rippe et al., 2003). These rearrangements constitute one of the most frequent specific chromosomal rearrangements in human epithelial tumors at all and lead to fusion genes in which the 3' part of THADA is truncated. Up to now there is no further

information regarding the function of the protein and the possible molecular background of the cell transformation resulting from that chromosomal rearrangement (Rippe et al., 2003). Hypothetically the truncated form of the protein may lead to an altered apoptosis induction due to the possible involvement in the death receptor pathway (Rippe et al., 2003). In the present study the orthologous THADA mRNA sequences of the vertebrates *C. familiaris*, *C. aethiops*, *G. gallus*, and *M. musculus* have been determined and characterized to gather more information regarding the function of the THADA gene and its role in the development of human thyroid neoplasias.

The size of the mRNA, the protein size, and the genomic organisation of THADA is conserved among humans and the other species analyzed. Furthermore the genomic organisation of THADA in all analyzed organisms is very similar to the genomic organisation of the THADA gene in humans. All homologous THADA genes have the same number of 38 exons corresponding to the genomic organisation of the human THADA gene (Table 1). The start codons are localised always in the second exon and the stop codon in the last exon. With the exception of exons 1, 2, and 38 containing the 5' and 3' untranslated regions all exons have a very similar size and 23 exons are even identical in length. All exon/intron boundaries are conforming to the AG/GT rule for acceptor and donor of splicing sites (Madhani and Guthrie, 1994). Thus, the different genomic sizes of THADA in the analyzed organisms are due to distinct length of the intronic sequences. The chromosomal expansion of the genes (*Homo sapiens* 365186 bp, *C. familiaris* 326318 bp, *M. musculus* 274,170 bp, and *G. gallus* approx. 152,400 bp) corresponds roughly – with the exception of mouse and dog, which differ in length only slightly – to the total length of the genome of the analyzed organisms (3000 Mb in humans, 2400 Mb in the dog, 2500 Mb in the mouse, and 1200 Mb in the chicken; estimated genome lengths according to NCBI genome database). This observation is in accordance to the general findings by (Deutsch and Long, 1999) that the lengths of the introns correspond with the size of the whole genome.

Neither the structures nor the sequences of the deduced proteins of THADA were confirmed with biochemical techniques. This study was aimed at the characterization of the coding region and the determination of the start codon for further expression studies. The longest putative open reading frames have been predicted as coding regions. Similarity in length (>1930 aa in all analyzed organisms) and sequence make this assumption highly reasonable. The first ATG translational initiation codon of the open reading frame is seen as start codon. The analysis of the region surrounding the predicted start position revealed a high similarity of the sequence beginning with the position –3 (A) in all organisms whereas the 5' untranslated region is showing less similarity. This is in concordance with the observation that sequences of 5'-UTRs as well as 3'-UTRs are less conserved compared to coding regions (Pesole et al., 2000). Furthermore, the positions at –3 (A) and +4 (G) to the predicted ATG translation initiation codon meet the criteria for a Kozak sequence (Kozak, 2002). Thus, it is highly probable that this ATG codon is the initial start codon for protein synthesis.

The protein size of all analyzed organisms lies in between 1931 aa (*G. gallus*) and 1954 aa (*C. aethiops* and *Homo sapiens*). Interestingly only 5% (513) of 24,264 annotated human proteins (NCBI RefSeq database; (Pruitt et al., 2005)) exceed the human THADA size.

The multiple alignment of the THADA protein sequences serves to identify conserved domains in THADA. In the region from approximately 1033–1415 aa in human THADA the sequence similarity in the PROBCONS multiple alignment shows the highest regional similarity with an identity calculation of 70.5% and including conserved amino acid substitutions of 78.6%. Furthermore, there are two parts within this region with a size of 21 aa and 23 aa that are identical in all species analyzed. In the same region similarities to the uncharacterized conserved domain COG5543 of the NCBI Conserved Domain Database have been detected. This conserved part of the protein could be a functional important region of THADA as conserved domains correspond in most cases to functional regions (Bornberg-Bauer et al., 2005).

Interestingly, the truncation at the position 1352 of THADA observed in the previously described fusion genes in human benign thyroid lesions (Rippe et al., 2003) is located in the middle of the conserved part of THADA. Thus, it seems that this part harbours a domain with important function and in thyroid adenomas this function is destroyed. Also, it cannot be excluded that the c-terminal part of THADA beginning with position 1491 in humans showing the lowest similarity of 27.5% identity could have structural important functions and maybe the truncation results in an overall rearrangement of the protein.

The similarities to the superfamily domain ARM repeat (SSF48371) a domain of the Superfamily database (Gough et al., 2001) and the HHpred alignments (Soding et al., 2005), which are used for more remote homology detection, are helpful to gather more information regarding the function of THADA. The Superfamily database is based of the SCOP (Structural Classification of Proteins) database and superfamilies are families of proteins, that have low sequence identities but whose structures and, in many cases, functional features suggest that they have a common evolutionary origin (Murzin et al., 1995). The superfamily ARM repeat summarizes repeated domains like Armadillo repeats and HEAT repeats which contain tandem copies of a degenerate protein sequence motif that forms right-handed superhelices of helices. This repeated structure creates a surface for protein–protein interaction (Coates, 2003). The HEAT domains are detected repeatedly with low significance in the human THADA and as well as in the predicted THADA homologous proteins herein analyzed. The ARM repeats like the here mentioned Armadillo repeat and HEAT repeat are difficult to detect because of low constraints of sequence conservation (Andrade et al., 2001). Armadillo repeats were found among others in plakoglobin, β -catenin, the nuclear import factor α -importin, and the tumor suppressor adenomatous polyposis coli (Andrade et al., 2001). HEAT domains are present in importins β 1, β 2, and proteins related to the clathrin-associated adaptor complex. Members of these proteins are also detected in the HHpred scan. The best alignment is to CAND1/TIP120 cullin-associated neddylation-

dissociated protein 1. This protein is binding to cullin-RING-ligases, which regulate diverse cellular functions such as cell cycle progression and cytokine signalling by ubiquitinating key regulatory proteins (Min et al., 2005). With lower significance similarities to importins which are involved in the protein transport through nuclear pore complexes are found. All proteins with similarities to THADA share the ARM repeats which are involved in protein–protein interactions. The Gene Ontology (Ashburner et al., 2000) term “protein binding (GO:0005515)” commonly refer to different protein binding activities like, among others, the death receptor activities.

With these new findings, similarities to protein–protein binding proteins with receptor activities and the possible structure with ARM repeats, the conserved and expressed in *Homo sapiens*, *C. familiaris*, *C. aethiops*, *G. gallus*, and *M. musculus* THADA appears to be involved in protein binding activity as e.g. found in proteins belonging to the death receptor pathway. This, indicating a function as receptor with protein–protein interaction, corroborates our theory of THADA involvement in the death receptor pathway. In thyroid adenomas with 2p21 rearrangements (Rippe et al., 2003) the truncation results in a disruption of the most conserved part of the protein which seems to be a functional important domain.

Abstract

Background: Chromosomal translocations affecting the chromosome 2p21 cluster in a 450 kb breakpoint region are frequently observed in human benign thyroid adenomas. *THADA* (thyroid adenoma associated) was identified as the affected gene within this breakpoint region. In contrast to man tumours of the thyroid gland of dogs (*Canis lupus familiaris*) constitute mainly as follicular cell carcinomas, with malignant thyroid tumours being more frequent than benign thyroid adenomas. In order to elucidate if the *THADA* gene is also a target of chromosomal rearrangements in thyroid adenomas of the dog we have physically mapped the canine *THADA* gene to canine chromosome 10.

A PCR was established to screen a canine genome library for a BAC clone containing the gene sequence of canine *THADA*. Further PCR reactions were done using the identified BAC clone as a template in order to verify the corresponding PCR product by sequencing.

Canine whole blood was incubated with colcemid in order to arrest the cultured cells in metaphases. The verified BAC DNA was digoxigenin labeled and used as a probe in fluorescence *in situ* hybridization (FISH). Ten well spread metaphases were examined indicating a signal on canine chromosome 10 on both chromatids. A detailed fine mapping was performed indicating the canine *THADA* gene locus on the q-arm of chromosome 10.

Results: The canine *THADA* gene locus was mapped on chromosome 10q25. Our mapping results obtained in this study following the previously described nomenclature for the canine karyotype.

Conclusion: We analysed whether the *THADA* gene locus is a hotspot of canine chromosomal rearrangements in canine neoplastic lesions of the thyroid and in addition might play a role as a candidate gene for a possible malignant transformation of canine thyroid adenomas. Although the available cytogenetic data of canine thyroid adenomas are still insufficient the chromosomal region to which the canine *THADA* has been mapped seems to be no hotspot of chromosomal aberrations seen in canine thyroid adenomas.

Background

In human thyroid adenomas chromosomal translocations involving the regions 19q13 and 2p21 have frequently been described [1,2]. Chromosomal aberrations showing 2p21 rearrangements belong to the most common abnormalities in benign epithelial tumours with an observed frequency of 10% [3]. Recently, a gene named *THADA* (thyroid adenoma associated) [GenBank: [NM_022065](#)] which is directly affected by this cytogenetic rearrangement, could be identified within the 2p21 breakpoint region [3].

In terms of animal cancer models, the dog has lately been attracting significant interest due to the fact that the malignancies of humans and dogs show various similarities [4]. Among the striking arguments for the dog as an animal model for man are spontaneous appearance of the tumours, comparable histological variance, similar cancer types and similar biological behaviour of the observed neoplasias, including metastasis [5-7].

In man the majority of tumours affecting the thyroid gland are benign, whereas in dogs the situation is quite different. Thyroid carcinomas are rare in the human population, the overall incidence is <1% [8,9]. A total of 1.2% of all canine tumours affects the thyroid gland with thyroid carcinomas occurring more frequently than adenomas [9,10]. Carcinomas of follicular origin are the most common form of canine thyroid neoplasias [11].

In order to elucidate whether human genes which are involved in the pathogenesis of benign thyroid adenomas could play a role as orthologous candidate genes for a possible malignant transformation of thyroid tumours in dogs, we have mapped the canine *THADA* gene and analysed if the canine gene locus is involved in cytogenetic rearrangements.

Methods

BAC library screening

A PCR reaction for PCR-based screening of the *Canis familiaris* DogBAC library [12] (Institute of Animal Genetics, Nutrition and Housing, University of Berne, Berne, Switzerland) for a BAC clone containing *THADA* was established using canine genomic DNA derived from blood. The primers T1: 5'GCATTTTCGATTGTCATAAC'3 and T2: 5'TCAGCCAAAAGTAGATAACAC'3 were designed using the predicted canine *THADA* gene sequence of canine chromosome 10, [GeneBank: [NC_006592](#)]. PCR parameters were: 95°C for 5 min, followed by 35 cycles of 95°C 30 sec, 55°C 30 sec, 72°C 30 sec, and a final elongation of 72°C for 10 min. The corresponding 601 bp PCR product was cloned into the pGEM-T Easy vector system (Promega) and verified by sequencing. The obtained canine sequence contained the 97 bp of exon 2 with a

92% similarity to human exon 2 of *THADA* [GenBank: [NM_022065](#)]. The sequence was submitted to the NCBI database [GenBank [DQ836130](#)]. The DNA contigs and alignments were done with Lasergene software (DNASTar, Madison, USA) and various sequences from the NCBI database [GeneBank: [AC_000045](#), [NM_022065](#)].

For verification and secondary screening a semi-nested PCR reaction was established, using the T1 primer and a nested primer T1B (5'TCAGTACTATTGGCATTGGAG'3) generating a 147 bp amplicon. A positive BAC clone (DogBAC library ID S011P24K05RE) was identified and verified by PCR. The obtained PCR products were cloned into the pGEM-T Easy vector system (Promega) and verified by sequencing. The verified clone was used as probe for following FISH experiments.

Slide Preparation

1 ml of canine whole blood was incubated for 72 h in Chromosome Medium B (Biochrom). Subsequently, colcemide (0.1 µg/ml) (Biochrom) was added for 2 hours. The cells were centrifuged at 135 × g for 10 min and incubated for 20 min in 0.05 M KCl. Finally, the cells were fixed overnight with methanol/glacial acetic acid. This suspension was dropped on ice-cold slides and dried for at least 7 days at 37°C. The chromosomes were stained by GTG banding for karyotype description. Prior to use in FISH investigations, the slides were destained with 70% ethanol.

Fluorescence in situ hybridization

BAC-DNA was digoxigenin labeled (Dig-Nick-Translation-Kit, Roche). The hybridization mixture contained 200 ng probe, 40 ng ssDNA, 600 ng sonicated dog DNA, 2 × SSC, 2 × SSPE, 50% formamide and 10% dextran sulfate. 50 µl of this mixture were applied to each slide and the cover slips were sealed with rubber cement. Probe and chromosomes were denatured at 75°C on an Eppendorf thermocycler gradient, using the in situ adapter. Afterwards, the slides were incubated in a moist chamber at 37°C over night. Cover slips were carefully removed and the slides were incubated in 0.1 × SSC at 61°C and 1 × PBS at RT. Slides were then covered with 100 µl NFDm for 20 min. at 37°C in a moist chamber. For signal detection 100 µl NFDm containing 3 µg of anti-digoxigenin-rhodamine, fab fragments (Roche) were added to each slide and again incubated for 20 min at 37°C in a moist chamber, followed by washes with 1 × PBS, 3 × 3 min at RT. Slides were air dried before chromosome staining was performed with 25 µl of Vectashield mounting medium with DAPI (Vector Laboratories).

Ten well spread metaphases were examined indicating a signal on canine chromosome 10 on both chromatids of both chromosomes of canine chromosome 10 (Fig. 1).

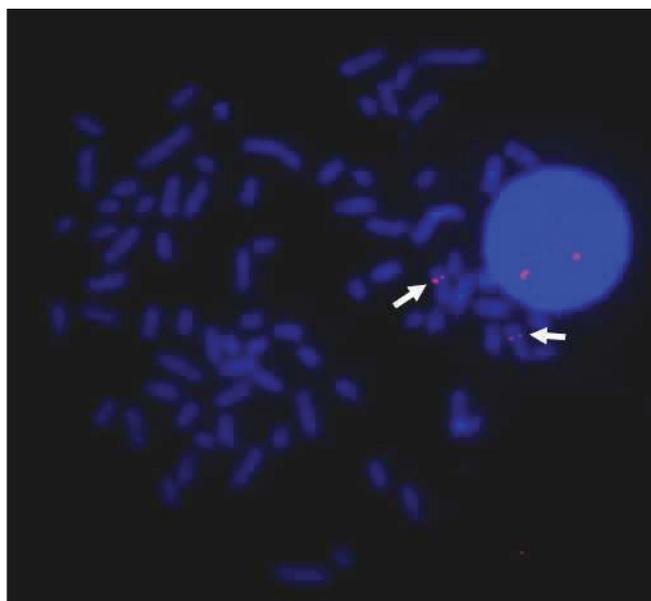

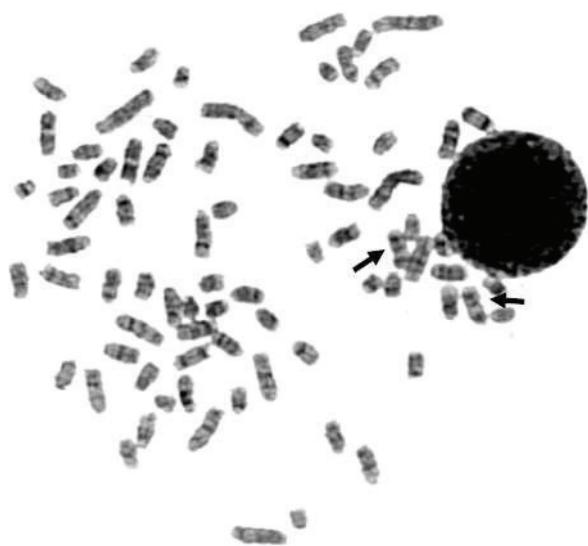

Figure 1
FISH mapping of canine THADA. Metaphase spread after fluorescence *in situ* hybridisation with signals on CFA 10q25 (right) of both chromosomes, the same metaphase after GTG-banding (left).

The determination of chromosomes followed the nomenclature of the canine karyotype as described previously [13].

Results and Discussion

In humans 10% of all chromosomal rearrangements in benign thyroid tumours involve a 450 kb breakpoint region on 2p21 [14]. These 2p21 rearrangements are the most commonly detected cytogenetic aberrations in benign thyroid adenomas. Within the mentioned breakpoint region the *THADA* gene was identified as a target gene for translocation events. *THADA* transcripts fused downstream to ectopic sequences of human chromosome 3 and 7 have been detected in thyroid adenoma cell lines S325/TSV40 and S533/TSV40 [3] (Centre for Human Genetics, University of Bremen, Bremen, Germany). The loss of parts of the *THADA* coding sequence is proposed to play a major role in the pathogenesis of these lesions affecting the thyroid gland due to the truncation of the gene and its deduced protein sequence [3,15]. Rippe et al. (2003) proposed an involvement of *THADA* in a death receptor pathway and characterized the human *THADA*. The mRNA of *THADA* contains 6090 bp (ORF 5862 bp) and 38 exons and encodes a hypothetical protein of 1954 amino acids.

The UCSC genome browser on Dog May 2005 [16] assembly showed the canine *THADA* chromosomal location on CFA 10 at region 48,883,266 to 49,209,580 and the gene encompasses a sequence of 326,315 bp. The genome

browser also described that the canine *THADA* region is highly conserved between the homologous gene locations of man, mouse and rat. Particularly the *THADA* region seems to be more evolutionarily conserved between man and dog than in rodents. In detail NCBI Blast analyses [17] were performed in order to show similarities between various mammalian and avian *THADA* nucleotide sequences from the NCBI databases. The similarities of the canine *THADA* [GenBank: [EF222204](#)] coding sequence (CDS) to the CDS of other species vary between human CDS [GenBank: [NM_022065](#)] 87%, mouse CDS 80% [GenBank: [EF222207](#)], rat predicted CDS 80% [GenBank: [XM_001060686.1](#)] and chicken 69% [GenBank: [EF222206](#)]. Respectively the similarities of the canine proposed *THADA* protein sequence to the deduced protein sequence of other species vary between human protein 83% [GenBank: [NP_071348](#)], mouse protein 75% [GenBank: [ABQ10601](#)], rat predicted protein 76% [[XP_233829](#)] and chicken protein 59% [GenBank: [NP_001103529](#)]. Also all deduced mammalian and avian *THADA* proposed protein sequence have in common one highly conserved domain termed COG5543 [CDD: 35102], the clusters of orthologous groups protein motif with yet unknown function, identified by the NCBI Conserved Domain Database (CDD) [18].

The mapping of *THADA* to canine chromosome 10 shows that the chromosomal region to which the canine *THADA* has been mapped is not a hotspot of chromosomal aberrations seen in canine thyroid adenomas. Previous case

reports of canine thyroid adenomas showed either a trisomy of chromosome 18 as a sole cytogenetic abnormality [19], or a rather complex karyotype of chromosomal fusions [20]. However, the available cytogenetic data of canine thyroid adenomas are still insufficient.

In 1999, reciprocal chromosome painting probes were established for a comparative chromosome map between human, red fox and dog showing the hybridisation pattern of canine probes onto human chromosomes [21,22]. Corresponding to the data obtained by the painting probes conserved synteny exists between canine chromosome 10 and the human chromosomes 2, 12, and 22. Our mapping result obtained in this study is in accordance with the described homology of the canine and human chromosomes allowing a fine mapping of the *THADA* gene locus on canine chromosome 10q25 (Fig 1.) which corresponds to the 2p21 region of the p-arm of human chromosome 2.

Conclusion

In dogs malignant thyroid carcinomas occur more often than adenomas but interestingly no cytogenetic reports of canine thyroid carcinomas have been published until now (NCBI, Pubmed 2008). In order to elucidate whether canine *THADA* could be a candidate gene for a possible malignant transformation of canine thyroid adenomas further cytogenetic studies of the tumours could be of significant value.

Competing interests

The authors declare that they have no competing interests.

Authors' contributions

JTS and CB carried out the molecular genetic studies, established the PCR condition, performed the *in silico* analyses and drafted the manuscript, SW and ND carried out the FISH, SW and NRB determined the gene locus and performed the fine-mapping following the nomenclature of the canine karyotype, GD and CS screened the DogBAC library for a BAC clone containing gene of interest, HME, IN and JB conceived the study, participated in the experimental design and coordination, and helped to draft the manuscript. All authors read and approved the final manuscript.
