# Invariants of the vacuum module associated with the Lie superalgebra $\mathfrak{g l}(1 \mid 1)$ 

A. I. Molev and E. E. Mukhin

#### Abstract

We describe the algebra of invariants of the vacuum module associated with an affinization of the Lie superalgebra $\mathfrak{g l}(1 \mid 1)$. We give a formula for its Hilbert-Poincaré series in a fermionic (cancellation-free) form which turns out to coincide with the generating function of the plane partitions over the (1,1)-hook. Our arguments are based on a super version of the Beilinson-Drinfeld-Raïs-Tauvel theorem which we prove by producing an explicit basis of invariants of the symmetric algebra of polynomial currents associated with $\mathfrak{g l}(1 \mid 1)$. We identify the invariants with affine supersymmetric polynomials via a version of the Chevalley theorem.

## 1 Introduction

Suppose that $\mathfrak{g}$ is a simple Lie algebra over $\mathbb{C}$ and $\kappa \in \mathbb{C}$. The vacuum module $V_{\kappa}(\mathfrak{g})$ at the level $\kappa$ over the affine Kac-Moody algebra $\widehat{\mathfrak{g}}$ has a vertex algebra structure. The center of this vertex algebra is trivial unless the level is critical; this is a unique value of $\kappa$ depending on the normalization of the invariant symmetric bilinear form on $\mathfrak{g}$. In this case the center $\mathfrak{z}(\widehat{\mathfrak{g}})$ is an algebra of polynomials in infinitely many variables as described by a theorem of Feigin and Frenkel [5]; see also [10]. One may regard the Feigin-Frenkel center $\mathfrak{z}(\widehat{\mathfrak{g}})$ as a commutative subalgebra of the universal enveloping algebra $\mathrm{U}\left(t^{-1} \mathfrak{g}\left[t^{-1}\right]\right)$. This leads to connections with the Gaudin model and to constructions of commutative subalgebras of $\mathrm{U}(\mathfrak{g})$ and its tensor powers; see [6], [7], 8] and [19]. Explicit constructions of generators of the Feigin-Frenkel center for the classical Lie algebras $\mathfrak{g}$ were given in [2], [3] and [13]. The Harish-Chandra images of the generators as elements of the corresponding classical $\mathcal{W}$-algebras were calculated in [14] with the use of the Yangian characters.

As explained in Kac [11, Sec. 4.7], the construction of the vertex algebra $V_{\kappa}(\mathfrak{g})$ can be extended to any Lie superalgebra $\mathfrak{g}$ equipped with an invariant supersymmetric bilinear form. In the case of general linear Lie superalgebras $\mathfrak{g}=\mathfrak{g l}(m \mid n)$, constructions of several families of elements of the center $\mathfrak{z}(\widehat{\mathfrak{g l}}(m \mid n))$ at the critical level were given in [15]. It was conjectured there that each of the families generates the center. The main result of the present paper is a proof of the conjecture in the case $m=n=1$. We believe this result will be a key ingredient for the proof of the conjecture for arbitrary $m$ and $n$. To give its precise formulation, we will recall the construction of [15] in more detail.

### 1.1 Segal-Sugawara vectors for $\mathfrak{g l}(m \mid n)$

For $\mathfrak{g}=\mathfrak{g l}(m \mid n)$ consider the Lie superalgebra $\widehat{\mathfrak{g}}=\mathfrak{g}\left[t, t^{-1}\right] \oplus \mathbb{C} K$ with the commutation relations ${ }^{1}$

$$
\begin{align*}
{\left[E_{i j}[r], E_{k l}[s]\right]=\delta_{k j} E_{i l}[r+s] } & -\delta_{i l} E_{k j}[r+s](-1)^{(\bar{\imath}+\bar{\jmath})(\bar{k}+\bar{l})} \\
& +K\left((n-m) \delta_{k j} \delta_{i l}(-1)^{\bar{\imath}}+\delta_{i j} \delta_{k l}(-1)^{\bar{\imath}+\bar{k}}\right) r \delta_{r,-s} \tag{1.1}
\end{align*}
$$

the element $K$ is even and central, and we set $E_{i j}[r]=E_{i j} t^{r}$. The $\mathbb{Z}_{2}$-degree (or parity) of the element $E_{i j}[r]$ is $\bar{\imath}+\bar{\jmath}$, where $\bar{\imath}=0$ for $1 \leqslant i \leqslant m$ and $\bar{\imath}=1$ for $m+1 \leqslant i \leqslant m+n$.

The vacuum module $V_{\text {cri }}(\mathfrak{g})$ at the critical level over $\widehat{\mathfrak{g}}$ is defined as the quotient of the universal enveloping algebra $\mathrm{U}(\widehat{\mathfrak{g}})$ by the left ideal generated by $\mathfrak{g}[t]$ and $K-1$. It possesses

[^0]a vertex algebra structure; see e.g. [11. The center of the vertex algebra $V_{\text {cri }}(\mathfrak{g})$ is defined by
$$
\mathfrak{z}(\widehat{\mathfrak{g}})=\left\{S \in V_{\text {cri }}(\mathfrak{g}) \mid \mathfrak{g}[t] S=0\right\} .
$$

Elements of $\mathfrak{z}(\widehat{\mathfrak{g}})$ are called Segal-Sugawara vectors. The axioms of the vertex algebra imply that the center is a commutative associative superalgebra and it can be identified with a commutative subalgebra of $\mathrm{U}\left(t^{-1} \mathfrak{g}\left[t^{-1}\right]\right)$. The application of the state-field correspondence map to a Segal-Sugawara vector yields a field whose Fourier coefficients are Sugawara operators commuting with the action of $\widehat{\mathfrak{g}}$. In particular, they form a commuting family of $\widehat{\mathfrak{g}}$-endomorphisms of Verma modules over $\widehat{\mathfrak{g}}$ at the critical level.

The main results of [15] include an explicit construction of several families of SegalSugawara vectors. To reproduce them, we will use the extended Lie superalgebra $\widehat{\mathfrak{g}} \oplus \mathbb{C} \tau$, where the element $\tau$ is even and

$$
\left[\tau, E_{i j}[r]\right]=-r E_{i j}[r-1], \quad[\tau, K]=0
$$

Consider the square matrix $Z=\left[Z_{i j}\right]$ with

$$
Z_{i j}=\delta_{i j} \tau+E_{i j}[-1](-1)^{\bar{\imath}}
$$

with the entries in the universal enveloping algebra $U$ for $\widehat{\mathfrak{g}} \oplus \mathbb{C} \tau$. We will identify the matrix $Z$ with an element of the tensor product superalgebra End $\mathbb{C}^{m \mid n} \otimes \mathrm{U}$ by

$$
Z=\sum_{i, j=1}^{m+n} e_{i j} \otimes Z_{i j}(-1)^{\bar{\imath} \bar{\jmath}+\bar{\jmath}}
$$

where the $e_{i j}$ denote the standard matrix units. Taking multiple tensor products

$$
\begin{equation*}
\text { End } \mathbb{C}^{m \mid n} \otimes \ldots \otimes \operatorname{End} \mathbb{C}^{m \mid n} \otimes \mathrm{U} \tag{1.2}
\end{equation*}
$$

with $k$ copies of End $\mathbb{C}^{m \mid n}$, for any $a=1, \ldots, k$ we will write $Z_{a}$ for the matrix $Z$ corresponding to the $a$-th copy of the endomorphism superalgebra so that the components in all remaining copies are the identity matrices. The symmetric group $\mathfrak{S}_{k}$ acts naturally on the tensor product space $\left(\mathbb{C}^{m \mid n}\right)^{\otimes k}$. We let $H_{k}$ and $A_{k}$ denote the respective images of the normalized symmetrizer and antisymmetrizer

$$
\frac{1}{k!} \sum_{\sigma \in \mathfrak{S}_{k}} \sigma \in \mathbb{C}\left[\mathfrak{S}_{k}\right], \quad \frac{1}{k!} \sum_{\sigma \in \mathfrak{S}_{k}} \operatorname{sgn} \sigma \cdot \sigma \in \mathbb{C}\left[\mathfrak{S}_{k}\right]
$$

in (1.2). Recall that the supertrace of an even matrix $X=\left[X_{i j}\right]$ with entries in a superalgebra is defined by

$$
\operatorname{str} X=\sum_{i=1}^{m+n} X_{i i}(-1)^{\bar{\imath}}
$$

Furthermore, if $X$ is invertible, denote by $X_{i j}^{\prime}$ the matrix elements of its inverse so that $X^{-1}=\left[X_{i j}^{\prime}\right]$. The (noncommutative) Berezinian of $X$ is defined as the product of two determinants

$$
\text { Ber } X=\sum_{\sigma \in \mathfrak{S}_{m}} \operatorname{sgn} \sigma \cdot X_{\sigma(1) 1} \ldots X_{\sigma(m) m} \sum_{\tau \in \mathfrak{S}_{n}} \operatorname{sgn} \tau \cdot X_{m+1, m+\tau(1)}^{\prime} \ldots X_{m+n, m+\tau(n)}^{\prime} .
$$

By the results of [15, Sec. 3.1], all the coefficients $s_{k l}, b_{k l}, h_{k l} \in \mathrm{U}\left(t^{-1} \mathfrak{g}\left[t^{-1}\right]\right)$ in the expansions

$$
\begin{align*}
\operatorname{str} Z^{k} & =s_{k 0} \tau^{k}+s_{k 1} \tau^{k-1}+\cdots+s_{k k}, \\
\operatorname{str}_{1, \ldots, k} A_{k} Z_{1} \ldots Z_{k} & =b_{k 0} \tau^{k}+b_{k 1} \tau^{k-1}+\cdots+b_{k k} \\
\operatorname{str}_{1, \ldots, k} H_{k} Z_{1} \ldots Z_{k} & =h_{k 0} \tau^{k}+h_{k 1} \tau^{k-1}+\cdots+h_{k k} \tag{1.3}
\end{align*}
$$

are Segal-Sugawara vectors. Moreover, these coefficients can be expressed in terms of the Berezinian through the identities

$$
\begin{aligned}
\operatorname{Ber}(1+u Z) & =\sum_{k=0}^{\infty} u^{k} \operatorname{str}_{1, \ldots, k} A_{k} Z_{1} \ldots Z_{k}, \\
{[\operatorname{Ber}(1-u Z)]^{-1} } & =\sum_{k=0}^{\infty} u^{k} \operatorname{str}_{1, \ldots, k} H_{k} Z_{1} \ldots Z_{k}, \\
{[\operatorname{Ber}(1+u Z)]^{-1} \partial_{u} \operatorname{Ber}(1+u Z) } & =\sum_{k=0}^{\infty}(-u)^{k} \operatorname{str} Z^{k+1}
\end{aligned}
$$

relying on the super-analogues of the MacMahon Master Theorem and Newton identity proved in [15].

The center $\mathfrak{z}(\widehat{\mathfrak{g}})$ of the vertex algebra $V_{\text {cri }}(\mathfrak{g})$ is invariant under the translation operator $T: V_{\text {cri }}(\mathfrak{g}) \rightarrow V_{\text {cri }}(\mathfrak{g})$ which is the derivation $T=-d / d t$ of the algebra $\mathrm{U}\left(t^{-1} \mathfrak{g}\left[t^{-1}\right]\right)$ determined by the properties

$$
\begin{equation*}
\left[T, E_{i j}[r]\right]=-r E_{i j}[r-1] \tag{1.4}
\end{equation*}
$$

where $E_{i j}[r]$ is understood as the operator of left multiplication by $E_{i j}[r]$.
The following property of the Segal-Sugawara vectors was conjectured in [15, Remark 3.4(ii)]. It can be regarded as a super-analogue of the Feigin-Frenkel theorem.

Conjecture 1.1. Each of the families $\left\{T^{r} s_{k k}\right\},\left\{T^{r} b_{k k}\right\}$ and $\left\{T^{r} h_{k k}\right\}$ with $r \geqslant 0$ and $k \geqslant 1$ generates the algebra $\mathfrak{z}(\widehat{\mathfrak{g}})$.

### 1.2 Main results

We will prove Conjecture 1.1 in the case $m=n=1$; that is, for $\mathfrak{g}=\mathfrak{g l}(1 \mid 1)$. This is the four-dimensional Lie superalgebra with the even basis elements $E_{11}, E_{22}$ and odd elements $E_{21}, E_{12}$. Define the invariant supersymmetric bilinear form (.|.) on $\mathfrak{g}$ by

$$
\left(E_{i j} \mid E_{k l}\right)=\delta_{i j} \delta_{k l}(-1)^{\bar{\imath}+\bar{k}}
$$

By [11, Sec. 2.5], the corresponding affinization $\widehat{\mathfrak{g}}$ is the centrally extended Lie superalgebra of Laurent polynomials with the commutation relations (1.1). The following is our first main result.

Theorem A. Conjecture 1.1 holds for $\mathfrak{g}=\mathfrak{g l}(1 \mid 1)$.
As explained in [10, Chap. 3] by the example $\mathfrak{g}=\mathfrak{s l}(2)$, the proof can be reduced to verifying the corresponding property of the classical limit of the vacuum module $V_{\text {cri }}(\mathfrak{g})$; that is, to describing the invariants of the $\mathfrak{g}[t]$-module $\mathrm{S}\left(\mathfrak{g}\left[t, t^{-1}\right] / \mathfrak{g}[t]\right)$. We regard $\mathfrak{g}\left[t, t^{-1}\right] / \mathfrak{g}[t]$ as a $\mathfrak{g}[t]$-module with the adjoint action and extend it to the symmetric algebra. We will identify the quotient $\mathfrak{g}\left[t, t^{-1}\right] / \mathfrak{g}[t]$ with $\widehat{\mathfrak{g}}_{-}=t^{-1} \mathfrak{g}\left[t^{-1}\right]$ via the natural vector space isomorphism. The classical limit of $\mathfrak{z}(\widehat{\mathfrak{g}})$ is the algebra of invariants

$$
\begin{equation*}
\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}=\left\{P \in \mathrm{~S}\left(\widehat{\mathfrak{g}}_{-}\right) \mid \mathfrak{g}[t] P=0\right\} . \tag{1.5}
\end{equation*}
$$

In the case where $\mathfrak{g}$ is a simple Lie algebra, the algebra (1.5) is described by the BeilinsonDrinfeld theorem (see [10, Theorem 3.4.2]), and this description is also implied by an earlier work of Raïs and Tauvel [18]. Namely, recall that the algebra $S(\mathfrak{g})^{\mathfrak{g}}$ of $\mathfrak{g}$-invariants in the symmetric algebra $S(\mathfrak{g})$ admits an algebraically independent family of generators,

$$
\mathrm{S}(\mathfrak{g})^{\mathfrak{g}}=\mathbb{C}\left[P_{1}, \ldots, P_{n}\right], \quad n=\operatorname{rank} \mathfrak{g} ;
$$

see e.g. [4, Sec. 7.3]. Identify the generators $P_{i}$ with their images under the embedding $\mathrm{S}(\mathfrak{g}) \hookrightarrow \mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$taking $X \in \mathfrak{g}$ to $X[-1]$. Then the family $\left\{T^{r} P_{k}\right\}$ is algebraically independent and

$$
\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}=\mathbb{C}\left[T^{r} P_{1}, \ldots, T^{r} P_{n} \mid r \geqslant 0\right],
$$

where $T=-d / d t$ now denotes the derivation of the algebra $\mathrm{S}\left(\hat{\mathfrak{g}}_{-}\right)$determined by the same properties (1.4) applied to the symmetric algebra.

If $\mathfrak{g}$ is a simple Lie superalgebra, then the structure of the algebra of invariants $\mathrm{S}(\mathfrak{g})^{\mathfrak{g}}$ is more complicated; see e.g. [20], [21]. In particular, it does not admit an algebraically independent family of generators. One could still expect that a natural super-analogue of the Beilinson-Drinfeld-Raïs-Tauvel theorem holds: if $\left\{P_{k} \mid k \geqslant 1\right\}$ is a family of generators of $\mathrm{S}(\mathfrak{g})^{\mathfrak{g}}$, then the derivatives $\left\{T^{r} P_{k} \mid k \geqslant 1, r \geqslant 0\right\}$ generate the algebra $\left.\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)\right)^{\mathfrak{g}[t]}$. We prove this analogue for $\mathfrak{g}=\mathfrak{g l}(1 \mid 1)$ by producing a basis of the algebra of invariants and showing
that each basis element is expressed in terms of the generators. The Chevalley images of the basis elements turn out to form a basis of the algebra $\Lambda^{\text {aff }}(1 \mid 1)$ of affine supersymmetric polynomials. We establish this property by employing a lemma of Sergeev [20, 21] which allows us to prove the second main theorem.
Theorem B. The algebra of $\mathfrak{g}[t]$-invariants of $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$is isomorphic to the algebra $\Lambda^{\text {aff }}(1 \mid 1)$ of affine supersymmetric polynomials.

In proving Theorem B, we compare the Hilbert-Poincaré series of these algebras. Both series turn out to coincide with the generating function of the plane partitions over the $(1,1)$-hook. In more detail, such a plane partition can be regarded as a finite sequence of Young diagrams $\lambda^{(1)} \supset \cdots \supset \lambda^{(r)}$, where each term of the sequence is a hook diagram $\left(a, 1^{b}\right)$. Equivalently, a plane partition can be viewed as a corner "brick wall" formed by unit cubes or "bricks", the $i$-th level of the wall has the shape of the hook $\lambda^{(i)}$, as illustrated:

The corresponding sequence of hooks in this example is $\left(5,1^{4}\right) \supset\left(3,1^{3}\right) \supset(2,1) \supset\left(1^{2}\right)$. The generating function of such plane partitions is known [9] and given by the expression

$$
\begin{equation*}
\frac{1}{(q)_{\infty}^{2}} \sum_{k=0}^{\infty}(-1)^{k} q^{\frac{k^{2}+k}{2}}=1+q+3 q^{2}+6 q^{3}+12 q^{4}+21 q^{5}+38 q^{6}+63 q^{7}+\ldots \tag{1.6}
\end{equation*}
$$

where

$$
(q)_{\infty}=\prod_{i=1}^{\infty}\left(1-q^{i}\right)
$$

and the coefficient of $q^{N}$ is the number of plane partitions with $N$ cubes. We will prove a new fermionic formula for this generating function.

Theorem C. The Hilbert-Poincaré series of the algebra $\Lambda^{\text {aff }}(1 \mid 1)$ is given by

$$
\frac{1}{(q)_{\infty}} \sum_{k=0}^{\infty} \frac{q^{k^{2}+k}}{(q)_{k}^{2}}, \quad \text { with } \quad(q)_{k}=\prod_{i=1}^{k}\left(1-q^{i}\right)
$$

Moreover, this series coincides with the generating function of the plane partitions over the $(1,1)$-hook and so equals (1.6).

We also give a conjectural characterization property of the affine supersymmetric polynomials analogous to that of the supersymmetric polynomials; see Section 3.1. It is implied by the invariance property of elements of the symmetric algebra in the same way as in the finite-dimensional case; cf. [20].

In the Appendix we prove a simple formula for the Hilbert-Poincaré series of the algebra $\Lambda(m \mid n)$ of supersymmetric polynomials. In different forms this series was previously calculated in [17] and [22].

We are grateful to Jonathan Brundan, Vera Serganova and Alexander Sergeev for useful discussions. The second author is grateful to the University of Sydney for the hospitality and support during his visit when most of this work was completed.

## 2 Invariants of the symmetric algebra

In the specialization $m=n=1$ the matrix $Z=\left[Z_{i j}\right]$ takes the form

$$
Z=\left[\begin{array}{cc}
\tau+E_{11}[-1] & E_{12}[-1] \\
-E_{21}[-1] & \tau-E_{22}[-1]
\end{array}\right] .
$$

Due to the relationship between the elements of the three families $\left\{s_{k l}\right\},\left\{b_{k l}\right\}$ and $\left\{h_{k l}\right\}$ recalled in the Introduction, it will be sufficient to prove Theorem A for one of them. We will work with the elements $h_{k l} \in \mathrm{U}\left(\widehat{\mathfrak{g}}_{-}\right)$most of the time, whose explicit form implied by (1.3) is provided by [15, Proposition 2.3]. Denote by $\bar{h}_{k l}$ their symbols in the associated graded algebra gr $\mathrm{U}\left(\widehat{\mathfrak{g}}_{-}\right) \cong \mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$. They are easily calculated and we have, in particular,

$$
\bar{h}_{k k}=E_{11}[-1]^{k-1}\left(E_{11}[-1]+E_{22}[-1]\right)+(k-1) E_{11}[-1]^{k-2} E_{21}[-1] E_{12}[-1],
$$

where we keep the same notation $E_{i j}[r]$ for the generators of the symmetric algebra. Observe that these elements are recovered from the invariants

$$
E_{11}^{k-1}\left(E_{11}+E_{22}\right)+(k-1) E_{11}^{k-2} E_{21} E_{12} \in \mathrm{~S}(\mathfrak{g})^{\mathfrak{g}}
$$

through the embedding $\mathrm{S}(\mathfrak{g}) \hookrightarrow \mathrm{S}\left(\hat{\mathfrak{g}}_{-}\right)$sending $X \in \mathfrak{g}$ to $X[-1]$. In the same way, the symbols $\bar{b}_{k k}$ and $\bar{s}_{k k}$ are obtained as the images in $\mathrm{S}\left(\hat{\mathfrak{g}}_{-}\right)$of the respective $\mathfrak{g}$-invariants

$$
E_{22}^{k-1}\left(E_{11}+E_{22}\right)-(k-1) E_{22}^{k-2} E_{21} E_{12} \quad \text { and } \quad \operatorname{str}\left[\begin{array}{rr}
E_{11} & E_{12}  \tag{2.1}\\
-E_{21} & -E_{22}
\end{array}\right]^{k}
$$

in $S(\mathfrak{g})$. As before, we regard the translation operator $T$ as a derivation on $S\left(\widehat{\mathfrak{g}}_{-}\right)$determined by (1.4). We have an easily verified generating function identity

$$
\begin{equation*}
\sum_{r=0}^{\infty} \frac{T^{r} \bar{h}_{k k}}{r!} z^{r}=E_{11}(z)^{k-1}\left(E_{11}(z)+E_{22}(z)\right)+(k-1) E_{11}(z)^{k-2} E_{21}(z) E_{12}(z) \tag{2.2}
\end{equation*}
$$

where

$$
E_{i j}(z)=\sum_{r=0}^{\infty} E_{i j}[-r-1] z^{r} .
$$

It is a consequence of the commutative vertex algebra structure on $S\left(\widehat{\mathfrak{g}}_{-}\right)$; first we note that

$$
\sum_{r=0}^{\infty} \frac{T^{r} E_{i j}[-1]}{r!} z^{r}=E_{i j}(z)
$$

and then apply the property

$$
\sum_{r=0}^{\infty} \frac{T^{r}\left(E_{i j}[-1] E_{k l}[-1]\right)}{r!} z^{r}=E_{i j}(z) E_{k l}(z)
$$

Similarly, the invariants (2.1) give rise to the power series

$$
\begin{equation*}
E_{22}(z)^{k-1}\left(E_{11}(z)+E_{22}(z)\right)-(k-1) E_{22}(z)^{k-2} E_{21}(z) E_{12}(z) \tag{2.3}
\end{equation*}
$$

and

$$
\operatorname{str}\left[\begin{array}{rr}
E_{11}(z) & E_{12}(z)  \tag{2.4}\\
-E_{21}(z) & -E_{22}(z)
\end{array}\right]^{k}
$$

respectively.
The next theorem is an analogue of the Beilinson-Drinfeld-Raïs-Tauvel theorem; see [18] (and [1] for a similar argument) and [10, Theorem 3.4.2].

Theorem 2.1. The coefficients of each of the series (2.2), (2.3) and (2.4) generate the algebra $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$.

Proof. The rest of Section 2 is devoted to the proof of Theorem 2.1. Our strategy will be to construct a basis of the algebra of $\mathfrak{g}[t]$-invariants of $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$and then to show that every basis element can be expressed as a polynomial in the coefficients of the series (2.2); i.e., in the elements $T^{r} \bar{h}_{k k}$. It will be convenient to use the following basis elements of the Lie superalgebra $\widehat{\mathfrak{g}}_{-}$: for $i \geqslant 0$ set

$$
\begin{equation*}
a_{i}=E_{11}[-i-1], \quad c_{i}=E_{11}[-i-1]+E_{22}[-i-1], \tag{2.5}
\end{equation*}
$$

and

$$
\varphi_{i}=E_{21}[-i-1], \quad \psi_{i}=E_{12}[-i-1]
$$

so that the $c_{i}$ are central in $\widehat{\mathfrak{g}}_{-}$. Moreover, for $i \geqslant 0$ introduce elements of the symmetric algebra $S\left(\widehat{\mathfrak{g}}_{-}\right)$by

$$
y_{i}=\sum_{a+b=i} \varphi_{a} \psi_{b} .
$$

Lemma 2.2. Every element of the algebra of $\mathfrak{g}[t]$-invariants of $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$can be written as a polynomial in the elements $a_{i}, c_{i}$ and $y_{i}$ with $i \geqslant 0$.

Proof. Any element $P \in \mathrm{~S}\left(\hat{\mathfrak{g}}_{-}\right)$can be written in the form

$$
\begin{equation*}
P=\sum_{I, J} P_{I J} \varphi_{i_{1}} \ldots \varphi_{i_{n}} \psi_{j_{1}} \ldots \psi_{j_{m}} \tag{2.6}
\end{equation*}
$$

with the conditions $0 \leqslant i_{1}<\cdots<i_{n}$ and $j_{1}>\cdots>j_{m} \geqslant 0$ for uniquely determined polynomials $P_{I J}$ in the $a_{i}$ and $c_{i}$, where $I=\left\{i_{1}, \ldots, i_{n}\right\}$ and $J=\left\{j_{1}, \ldots, j_{m}\right\}$. Suppose now that $P$ is invariant. It will be sufficient to use only the conditions that $E_{22}[r] P=0$ for $r=0,1$. They are clearly satisfied by any polynomial in $a_{i}, c_{i}$ and $y_{i}$. For the action of $E_{22}[r]$ we have

$$
E_{22}[r] \varphi_{i}=\left\{\begin{array}{ll}
\varphi_{i-r} & \text { if } i \geqslant r, \\
0 & \text { if } i<r,
\end{array} \quad E_{22}[r] \psi_{i}=\left\{\begin{array}{cl}
-\psi_{i-r} & \text { if } i \geqslant r, \\
0 & \text { if } i<r .
\end{array}\right.\right.
$$

Hence, $P_{I J}=0$ unless $I$ and $J$ have the same cardinality, as implied by the relation $E_{22}[0] P=0$. Given such an invariant $P$, we can find an element

$$
Q=\sum_{K} Q_{K} y_{k_{1}} \ldots y_{k_{l}} \quad \text { with } \quad k_{1} \geqslant \cdots \geqslant k_{l} \geqslant 0
$$

where $K=\left\{k_{1}, \ldots, k_{l}\right\}$ and each $Q_{K}$ is a polynomial in the $a_{i}$ and $c_{i}$, such that the expansion (2.6) for $P+Q$ does not contain monomials of the form $\varphi_{0} \ldots \varphi_{n-1} \psi_{j_{1}} \ldots \psi_{j_{n}}$ for any $n \geqslant 0$. This follows easily by induction on the $n$-tuples $\left(j_{1}, \ldots, j_{n}\right)$ with the lexicographic order; we assume that if $m<n$ then any $m$-tuple ( $h_{1}, \ldots, h_{m}$ ) precedes $\left(j_{1}, \ldots, j_{n}\right)$. Indeed, the largest monomial is eliminated by taking the sum

$$
\varphi_{0} \ldots \varphi_{n-1} \psi_{j_{1}} \ldots \psi_{j_{n}}+\text { const } y_{j_{1}} y_{j_{2}+1} \ldots y_{j_{n}+n-1}
$$

for an appropriate value of the constant.
Furthermore, assuming that none of the monomials $\varphi_{0} \ldots \varphi_{n-1} \psi_{j_{1}} \ldots \psi_{j_{n}}$ occurs in $P$, we will show that $P=0$. Suppose for the contrary that $P \neq 0$ and take the minimum $n$-tuple $\left(i_{1}, \ldots, i_{n}\right)$ in the lexicographic order such that $\varphi_{i_{1}} \ldots \varphi_{i_{n}}$ occurs in the expansion of $P$; its coefficient is a nonzero linear combination of the products $\psi_{j_{1}} \ldots \psi_{j_{n}}$. By our assumption, $\left(i_{1}, \ldots, i_{n}\right)=\left(0,1, \ldots, s-1, i_{s+1}, \ldots, i_{n}\right)$ for some $0 \leqslant s \leqslant n-1$ and $i_{s+1}>s$. The condition $E_{22}[1] P=0$ then brings a contradiction since the coefficient of the monomial $\varphi_{0} \varphi_{1} \ldots \varphi_{s-1} \varphi_{i_{s+1}-1} \ldots \varphi_{i_{n}}$ in the expansion of $E_{22}[1] P$ will be nonzero.

Introduce formal power series

$$
\begin{equation*}
c(z)=\sum_{i=0}^{\infty} c_{i} z^{i}, \quad \varphi(z)=\sum_{i=0}^{\infty} \varphi_{i} z^{i}, \quad \psi(z)=\sum_{i=0}^{\infty} \psi_{i} z^{i}, \quad y(z)=\sum_{i=0}^{\infty} y_{i} z^{i} . \tag{2.7}
\end{equation*}
$$

Note that $y(z)=\varphi(z) \psi(z)$ and we have the relations

$$
\begin{equation*}
\psi(z)^{2}=0, \quad y(z) \psi(z)=0, \quad y(z)^{2}=0 \tag{2.8}
\end{equation*}
$$

Suppose that $z=\left(z_{1}, \ldots, z_{n}\right)$ is a family of independent variables and $\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ is a partition. Its parts are nonnegative integers satisfying the condition $\lambda_{1} \geqslant \cdots \geqslant \lambda_{n} \geqslant 0$. The length $\ell(\lambda)$ is the number of nonzero parts. The corresponding Schur polynomial $s_{\lambda}(z)$ is defined as the ratio of two alternants,

$$
s_{\lambda}(z)=\frac{\left|\begin{array}{ccc}
z_{1}^{\lambda_{1}+n-1} & \ldots & z_{n}^{\lambda_{1}+n-1} \\
\vdots & \vdots & \vdots \\
z_{1}^{\lambda_{n}} & \ldots & z_{n}^{\lambda_{n}}
\end{array}\right|}{\left|\begin{array}{ccc}
z_{1}^{n-1} & \ldots & z_{n}^{n-1} \\
\vdots & \vdots & \vdots \\
1 & \ldots & 1
\end{array}\right|},
$$

where the denominator is the Vandermonde determinant

$$
\Delta=\prod_{i<j}\left(z_{i}-z_{j}\right)
$$

see e.g. [12, Ch. 1] for other presentations and properties of the Schur polynomials.
By the last relation in (2.8), the power series $y\left(z_{1}\right) \ldots y\left(z_{n}\right)$ is divisible by $\Delta$. The ratio is skew-symmetric with respect to permutations of the $z_{i}$ which implies that $y\left(z_{1}\right) \ldots y\left(z_{n}\right)$ is divisible by the square of $\Delta$. Since the Schur polynomials form a basis of the algebra of symmetric polynomials in $z_{1}, \ldots, z_{n}$, we can define elements $Y_{\lambda}^{(n)} \in \mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$by the expansion

$$
\begin{equation*}
\frac{y\left(z_{1}\right) \ldots y\left(z_{n}\right)}{\prod_{i \neq j}\left(z_{i}-z_{j}\right)}=\sum_{\lambda, \ell(\lambda) \leqslant n} Y_{\lambda}^{(n)} s_{\lambda}(z) . \tag{2.9}
\end{equation*}
$$

By Lemma 2.2, the algebra of invariants $S\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ is contained in the subalgebra $S^{\circ}$ of $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$generated by the elements $a_{i}, c_{i}$ and $y_{i}$. The subalgebra of $\mathrm{S}^{\circ}$ generated by the $a_{i}$ and $c_{i}$ with $i \geqslant 0$ can be regarded as the algebra of polynomials in these variables, which we denote by H . We regard $\mathrm{S}^{\circ}$ as an H -module; elements of H act by multiplication.

Lemma 2.3. The family

$$
\left\{Y_{\lambda}^{(n)} \mid n=0,1, \ldots, \quad \ell(\lambda) \leqslant n\right\}
$$

forms a basis of the H -module $\mathrm{S}^{\circ}$.

Proof. The expansion (2.9) implies that the family spans the H-module $\mathrm{S}^{\circ}$. To prove the linear independence over H , express the elements $Y_{\lambda}^{(n)}$ in terms of the generators $\varphi_{i}$ and $\psi_{i}$. Since these generators are odd, we have the expansions

$$
\frac{\varphi\left(z_{1}\right) \ldots \varphi\left(z_{n}\right)}{\Delta}=\sum_{\mu, \ell(\mu) \leqslant n} \varphi_{\mu_{1}+n-1} \ldots \varphi_{\mu_{n}} s_{\mu}(z)
$$

and

$$
\frac{\psi\left(z_{1}\right) \ldots \psi\left(z_{n}\right)}{\Delta}=\sum_{\nu, \ell(\nu) \leqslant n} \psi_{\nu_{1}+n-1} \ldots \psi_{\nu_{n}} s_{\nu}(z)
$$

summed over partitions $\mu$ and $\nu$. Furthermore,

$$
\frac{y\left(z_{1}\right) \ldots y\left(z_{n}\right)}{\prod_{i \neq j}\left(z_{i}-z_{j}\right)}=\frac{\varphi\left(z_{1}\right) \ldots \varphi\left(z_{n}\right) \psi\left(z_{1}\right) \ldots \psi\left(z_{n}\right)}{\Delta^{2}}
$$

and so, taking into account (2.9), we conclude that

$$
\begin{equation*}
Y_{\lambda}^{(n)}=\sum_{\mu, \nu} c_{\mu \nu}^{\lambda} \varphi_{\mu_{1}+n-1} \ldots \varphi_{\mu_{n}} \psi_{\nu_{1}+n-1} \ldots \psi_{\nu_{n}} \tag{2.10}
\end{equation*}
$$

where the sum is taken over partitions $\mu$ and $\nu$ of lengths not exceeding $n$, and the $c_{\mu \nu}^{\lambda}$ are the Littlewood-Richardson coefficients defined by the relation

$$
s_{\mu}(z) s_{\nu}(z)=\sum_{\lambda} c_{\mu \nu}^{\lambda} s_{\lambda}(z),
$$

see e.g. [12, Ch. 1]. Note that $c_{\mu \nu}^{\lambda}=0$ unless $|\lambda|=|\mu|+|\nu|$, where $|\lambda|=\lambda_{1}+\cdots+\lambda_{n}$ denotes the weight of $\lambda$. Since $c_{\lambda \varnothing}^{\lambda}=1$, and the monomials $\varphi_{\lambda_{1}+n-1} \ldots \varphi_{\lambda_{n}} \psi_{n-1} \ldots \psi_{0}$ are linearly independent over H , then so are the elements $Y_{\lambda}^{(n)}$.

Remark 2.4. Two more bases of the H -module $\mathrm{S}^{\circ}$ (which we will not use) are formed by the monomials $y_{l_{1}} \ldots y_{l_{n}}$ with $n \geqslant 0$ and the conditions $l_{i}-l_{i+1} \geqslant 2$ for $i=1, \ldots, n-1$ and $l_{n} \geqslant 0$ (cf. [24]) and by the monomials $y_{k_{1}} \ldots y_{k_{n}}$ with $k_{1} \geqslant \cdots \geqslant k_{n} \geqslant n-1$.

Now suppose that $P \in \mathrm{~S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$. By Lemmas 2.2 and 2.3 , there is a unique presentation

$$
\begin{equation*}
P=\sum_{m \geqslant 0} \sum_{\mu, \ell(\mu) \leqslant m} P_{\mu}^{(m)} Y_{\mu}^{(m)} \tag{2.11}
\end{equation*}
$$

where the coefficients $P_{\mu}^{(m)}$ are certain polynomials in $a_{i}$ and $c_{i}$.
Lemma 2.5. Given a decomposition (2.11) for an invariant $P \in \mathrm{~S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$, let $n \geqslant 0$ have the property that $P_{\mu}^{(m)}=0$ for all $m>n$ and let a partition $\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ be such that $P_{\lambda}^{(n)} \neq 0$ but $P_{\mu}^{(n)}=0$ for all $\mu$ with $|\mu|>|\lambda|$. Then $P_{\lambda}^{(n)}$ does not depend on the variables $a_{i}$ with $i \geqslant n$.

Proof. We will use the condition $E_{12}[0] P=0$. The operator $E_{12}[0]$ can be written in the form

$$
\begin{equation*}
E_{12}[0]=-\sum_{j \geqslant 0} \psi_{j} \partial_{j}+\sum_{r \geqslant 0} c_{r} \partial_{\varphi_{r}}, \tag{2.12}
\end{equation*}
$$

where we denote $\partial_{j}=\partial / \partial a_{j}$ and $\partial_{\varphi_{r}}$ is the left derivative over $\varphi_{r}$. The condition on $n$ implies

$$
\sum_{j \geqslant 0} \psi_{j} \sum_{\mu, \ell(\mu) \leqslant n} \partial_{j}\left(P_{\mu}^{(n)}\right) Y_{\mu}^{(n)}=0
$$

Take $i \geqslant n$ and consider the coefficient of the monomial $\varphi_{\lambda_{1}+n-1} \ldots \varphi_{\lambda_{n}} \psi_{i} \psi_{n-1} \ldots \psi_{0}$ on the left hand side. By the condition on $\lambda$, this monomial can only occur for $j=i$ and $\mu=\lambda$ thus implying $\partial_{i}\left(P_{\lambda}^{(n)}\right)=0$, as required.

In what follows we will call by a leading component any product of the form $R Y_{\lambda}^{(n)}$, where $R$ is a polynomial in the $a_{i}$ and $c_{i}$ which does not depend on the variables $a_{i}$ with $i \geqslant n$. By Lemma 2.5, every invariant has a leading component. Our next goal is to show that there exists an invariant $P \in \mathrm{~S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ containing any given leading component and no other leading components in the expansion (2.11). It suffices to do this for monomials of the form

$$
\begin{equation*}
Y_{\lambda}^{(n)} \partial_{0}^{-k_{0}} \ldots \partial_{n-1}^{-k_{n-1}} 1 \tag{2.13}
\end{equation*}
$$

where we regard $\partial_{i}^{-1}$ as a partial integration operator with respect to $a_{i}$ so that

$$
\begin{equation*}
\partial_{0}^{-k_{0}} \ldots \partial_{n-1}^{-k_{n-1}} 1=\frac{a_{0}^{k_{0}} \ldots a_{n-1}^{k_{n-1}}}{k_{0}!\ldots k_{n-1}!} \tag{2.14}
\end{equation*}
$$

Given a value of $n$, introduce another family of independent variables $t_{0}, \ldots, t_{n-1}$ and consider the formal power series in the variables $z_{i}$ and $t_{i}$ whose coefficients are polynomials in the $a_{i}$,

$$
\begin{aligned}
& F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=\prod_{i=0}^{n-1}\left(1-\partial_{i}^{-1} t_{i}\right)^{-1} \\
& \times \prod_{j=0}^{\infty}\left(1-\partial_{n+j}^{-1}\left(t_{n-1} s_{(j+1)}(z)-t_{n-2} s_{(j+1,1)}(z)+\cdots+(-1)^{n-1} t_{0} s_{\left(j+1,1^{n-1}\right)}(z)\right)\right)^{-1} 1
\end{aligned}
$$

where $s_{\left(j+1,1^{k}\right)}(z)$ is the Schur polynomial in the variables $z_{1}, \ldots, z_{n}$ associated with the hook partition $\left(j+1,1^{k}\right)$. In particular, the series $F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)$ is symmetric in $z_{1}, \ldots, z_{n}$.

Lemma 2.6. We have the identity

$$
F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=\prod_{i=0}^{\infty}\left(1-\partial_{i}^{-1}\left(z_{1}^{i} T_{n}^{(1)}+\cdots+z_{n}^{i} T_{n}^{(n)}\right)\right)^{-1} 1
$$

where

$$
T_{n}^{(k)}=\frac{t_{n-1}-t_{n-2} e_{1}\left(z_{1}, \ldots, \widehat{z}_{k}, \ldots, z_{n}\right)+\cdots+(-1)^{n-1} t_{0} e_{n-1}\left(z_{1}, \ldots, \widehat{z}_{k}, \ldots, z_{n}\right)}{\left(z_{k}-z_{1}\right) \ldots \wedge \ldots\left(z_{k}-z_{n}\right)}
$$

and $e_{1}, \ldots, e_{n-1}$ denote the elementary symmetric polynomials; the hats and wedges indicate symbols or zero factors to be skipped.

Proof. The rational function $T_{n}^{(k)}$ is written as the ratio

$$
T_{n}^{(k)}=\frac{\left|\begin{array}{ccccc}
z_{1}^{n-1} & \ldots & t_{n-1} & \ldots & z_{n}^{n-1} \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
z_{1} & \ldots & t_{1} & \ldots & z_{n} \\
1 & \ldots & t_{0} & \ldots & 1
\end{array}\right|}{\Delta}
$$

where the $t_{i}$ occupy the $k$-th column in the numerator. Hence, the $T_{n}^{(k)}$ are the solutions of the system of equations

$$
z_{1}^{i} T_{n}^{(1)}+\cdots+z_{n}^{i} T_{n}^{(n)}=t_{i}, \quad i=0,1, \ldots, n-1 .
$$

Furthermore, if $i \geqslant n$ and $1 \leqslant m \leqslant n$ then the coefficient of $t_{n-m}$ in the expression $z_{1}^{i} T_{n}^{(1)}+\cdots+z_{n}^{i} T_{n}^{(n)}$ equals the ratio

$$
\frac{\left|\begin{array}{ccc}
z_{1}^{n-1} & \ldots & z_{n}^{n-1} \\
\ldots & \ldots & \ldots \\
z_{1}^{i} & \ldots & z_{n}^{i} \\
\ldots & \ldots & \ldots \\
1 & \ldots & 1
\end{array}\right|}{\Delta}
$$

where $z_{1}^{i}, \ldots, z_{n}^{i}$ replace row $m$ of the Vandermonde determinant in the numerator. This ratio coincides with $(-1)^{m-1} s_{\left(i-n+1,1^{m-1}\right)}$, as required.

We are now in a position to prove a key lemma providing explicit $\mathfrak{g}[t]$-invariants in $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$. Recall the formal power series (2.7) and set

$$
\begin{equation*}
A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=\prod_{k=1}^{n}\left(c\left(z_{k}\right)+y\left(z_{k}\right) T_{n}^{(k)}\right) F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right) \tag{2.15}
\end{equation*}
$$

This is a formal power series in the $z_{i}$ and $t_{i}$, symmetric in $z_{1}, \ldots, z_{n}$, whose coefficients are elements of the subalgebra $\mathrm{S}^{\circ}$ of $\mathrm{S}\left(\hat{\mathfrak{g}}_{-}\right)$generated by the $a_{i}, c_{i}$ and $y_{i}$.
Lemma 2.7. All coefficients of the series $A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)$ belong to $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$.

Proof. It is enough to show that $E_{12}[0] A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=0$. Recall that the action of $E_{12}[0]$ is given by the operator (2.12). Lemma 2.6 implies

$$
\partial_{i} F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=\left(z_{1}^{i} T_{n}^{(1)}+\cdots+z_{n}^{i} T_{n}^{(n)}\right) F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)
$$

for all $i \geqslant 0$. Hence,
$E_{12}[0] F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=-\left(\psi\left(z_{1}\right) T_{n}^{(1)}+\cdots+\psi\left(z_{n}\right) T_{n}^{(n)}\right) F\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)$.
On the other hand, $E_{12}[0] y\left(z_{k}\right)=c\left(z_{k}\right) \psi\left(z_{k}\right)$ and so

$$
E_{12}[0] \prod_{k=1}^{n}\left(c\left(z_{k}\right)+y\left(z_{k}\right) T_{n}^{(k)}\right)=\sum_{i=1}^{n} c\left(z_{i}\right) \psi\left(z_{i}\right) T_{n}^{(i)} \prod_{k \neq i}\left(c\left(z_{k}\right)+y\left(z_{k}\right) T_{n}^{(k)}\right) .
$$

Since $y\left(z_{k}\right) \psi\left(z_{k}\right)=0$ by (2.8), we have $E_{12}[0] A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=0$.
Now expand (2.15) along the basis formed by the products of monomials in the $t_{i}$ and Schur polynomials in $z_{1}, \ldots, z_{n}$. Take a partition $\lambda$ of length not exceeding $n$ and consider the coefficient of the basis element

$$
\begin{equation*}
t_{0}^{k_{0}} \ldots t_{n-2}^{k_{n-2}} t_{n-1}^{k_{n-1}+n} s_{\lambda}(z), \quad k_{i} \geqslant 0 \tag{2.16}
\end{equation*}
$$

in the expansion. Furthermore, use Lemma 2.3 to write this coefficient as a linear combination of the basis elements $Y_{\mu}^{(m)}$. By (2.9), this linear combination contains a leading component in the form (2.13). All other elements $Y_{\mu}^{(m)}$ occurring in the linear combination will have the property $m \leqslant n$; moreover, if $m=n$ then $|\mu|<|\lambda|$. Therefore, eliminating all other leading components with the use of an easy induction, we get an invariant containing a unique leading component. Thus, taking into account Lemma 2.5, we may conclude that the coefficients of the basis elements (2.16) in the expansion of (2.15) with $n$ running over nonnegative integers form a basis of $S\left(\hat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ as a module over the algebra of polynomials in the $c_{i}$ with $i \geqslant 0$.

Take $n=1$ in (2.15) and observe that the coefficient of $t_{0}^{k-1}$ in $A\left(z_{1} ; t_{0}\right)$ equals

$$
\begin{equation*}
\frac{1}{(k-1)!}\left(a(z)^{k-1} c(z)+(k-1) a(z)^{k-2} y(z)\right), \tag{2.17}
\end{equation*}
$$

where

$$
a(z)=\sum_{i=0}^{\infty} a_{i} z^{i}
$$

This is immediate from the identity

$$
\sum_{0 \leqslant i_{1} \leqslant \cdots \leqslant i_{p}} z^{i_{1}+\cdots+i_{p}} \partial_{i_{1}}^{-1} \ldots \partial_{i_{p}}^{-1} 1=\frac{a(z)^{p}}{p!}
$$

which holds for any $p \geqslant 0$. Since the series (2.2) equals $(k-1)$ ! times (2.17), the proof of Theorem 2.1 will be completed if we show that all coefficients of the series (2.15) for all values of $n$ are expressed as polynomials in the coefficients of $A\left(z_{1} ; t_{0}\right)$. This is the statement of the next lemma.

Lemma 2.8. We have the identity

$$
A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)=A\left(z_{1} ; T_{n}^{(1)}\right) \ldots A\left(z_{n} ; T_{n}^{(n)}\right)
$$

Proof. We have

$$
\begin{equation*}
A\left(z_{1} ; t_{0}\right) \ldots A\left(z_{n} ; t_{n-1}\right)=\prod_{k=1}^{n}\left(c\left(z_{k}\right)+y\left(z_{k}\right) t_{k-1}\right) F\left(z_{1} ; t_{0}\right) \ldots F\left(z_{n} ; t_{n-1}\right) \tag{2.18}
\end{equation*}
$$

Write

$$
F\left(z_{1} ; t_{0}\right) \ldots F\left(z_{n} ; t_{n-1}\right)=\prod_{i=0}^{\infty}\left(1-\partial_{i}^{-1} z_{1}^{i} t_{0}\right)^{-1} 1 \ldots\left(1-\partial_{i}^{-1} z_{n}^{i} t_{n-1}\right)^{-1} 1
$$

Expanding the series and using the identity

$$
\partial_{i}^{-k_{1}} 1 \ldots \partial_{i}^{-k_{n}} 1=\binom{k_{1}+\cdots+k_{n}}{k_{1}, \ldots, k_{n}} \partial_{i}^{-k_{1}-\cdots-k_{n}} 1
$$

we find that

$$
F\left(z_{1} ; t_{0}\right) \ldots F\left(z_{n} ; t_{n-1}\right)=\prod_{i=0}^{\infty}\left(1-\partial_{i}^{-1}\left(z_{1}^{i} t_{0}+\cdots+z_{n}^{i} t_{n-1}\right)\right)^{-1} 1
$$

Hence, replacing $t_{i} \mapsto T_{n}^{(i+1)}$ for $i=0, \ldots, n-1$ in (2.18) we recover the formal power series $A\left(z_{1}, \ldots, z_{n} ; t_{0}, \ldots, t_{n-1}\right)$, as required.

This completes the proof of Theorem 2.1.

## 3 Affine supersymmetric polynomials

Recall that a polynomial $P(u, v)=P\left(u_{1}, \ldots, u_{m}, v_{1}, \ldots, v_{n}\right)$ in two sets of independent variables $u=\left(u_{1}, \ldots, u_{m}\right)$ and $v=\left(v_{1}, \ldots, v_{n}\right)$ is called supersymmetric, if it is symmetric in each of the sets separately and the following cancellation property holds: the result of the substitution $u_{m}=-v_{n}=t$ into $P(u, v)$ is independent of $t$. We denote the algebra of supersymmetric polynomials by $\Lambda(m \mid n)$. The supersymmetric Schur polynomials parameterized by all Young diagrams not containing the box $(m+1, n+1)$ form a basis
of this algebra. Moreover, each of the families of elementary, complete and power sums supersymmetric functions generates $\Lambda(m \mid n)$; see e.g. [12, Ch. 1].

Given a supersymmetric polynomial $P(u, v)$, replace each variable $u_{i}$ and $v_{j}$ by the respective formal power series

$$
u_{i}(z)=\sum_{r=0}^{\infty} u_{i r} z^{r}, \quad v_{j}(z)=\sum_{r=0}^{\infty} v_{j r} z^{r}
$$

and write

$$
P\left(u_{1}(z), \ldots, u_{m}(z), v_{1}(z), \ldots, v_{n}(z)\right)=\sum_{r=0}^{\infty} P_{r} z^{r}
$$

where the coefficients $P_{r}$ are polynomials in the variables $u_{1 r}, \ldots, u_{m r}, v_{1 r}, \ldots, v_{n r}$ with $r$ running over the set of nonnegative integers. Equivalently, $P_{r}$ is found as the derivative

$$
P_{r}=\frac{T^{r} P}{r!}
$$

where $P=P(u, v)$ is regarded as a polynomial in the variables $u_{i 0}=u_{i}$ and $v_{j 0}=v_{j}$, and the derivation $T$ acts on the variables by the rule (cf. Sec. (2)):

$$
T: u_{i r} \mapsto(r+1) u_{i r+1}, \quad v_{j r} \mapsto(r+1) v_{j r+1}
$$

Definition 3.1. We denote by $\Lambda^{\text {aff }}(m \mid n)$ the subalgebra of the algebra of polynomials in the variables $u_{i r}$ and $v_{j r}$ generated by all coefficients $P_{r}$ associated with all supersymmetric polynomials $P(u, v)$. Any element of $\Lambda^{\text {aff }}(m \mid n)$ will be called an affine supersymmetric polynomial.

It is clear that the algebra $\Lambda^{\text {aff }}(m \mid n)$ is generated by the coefficients $P_{r}$ associated to any family $\{P\}$ of generators of the algebra $\Lambda(m \mid n)$. For instance, considering the supersymmetric power sums

$$
u_{1}^{k}+\cdots+u_{m}^{k}-(-1)^{k}\left(v_{1}^{k}+\cdots+v_{n}^{k}\right)
$$

we get the following explicit formulas for generators of $\Lambda^{\text {aff }}(m \mid n)$ :

$$
\begin{equation*}
\sum_{i=1}^{m} \sum_{r_{1}+\cdots+r_{k}=r} u_{i r_{1}} \ldots u_{i r_{k}}-(-1)^{k} \sum_{j=1}^{n} \sum_{r_{1}+\cdots+r_{k}=r} v_{j r_{1}} \ldots v_{j r_{k}}, \quad k \geqslant 1, \quad r \geqslant 0 \tag{3.1}
\end{equation*}
$$

where the second sums are taken over the $k$-tuples $\left(r_{1}, \ldots, r_{k}\right)$ of nonnegative integers.
Setting

$$
\operatorname{deg} u_{i r}=r+1 \quad \text { and } \quad \operatorname{deg} v_{j r}=r+1
$$

defines a grading on the algebra of polynomials in the $u_{i r}$ and $v_{j r}$. In particular, the degree of the generator in (3.1) equals $k+r$. The subalgebra $\Lambda^{\text {aff }}(m \mid n)$ inherits the grading so that we have the direct sum decomposition

$$
\Lambda^{\mathrm{aff}}(m \mid n)=\bigoplus_{N \geqslant 0} \Lambda^{\mathrm{aff}}(m \mid n)^{N}
$$

where $\Lambda^{\text {aff }}(m \mid n)^{N}$ denotes the subspace of $\Lambda^{\text {aff }}(m \mid n)$ spanned by homogeneous elements of degree $N$ and we set $\Lambda^{\text {aff }}(m \mid n)^{0}:=\mathbb{C}$. We let $H_{m, n}(q)$ denote the corresponding HilbertPoincaré series

$$
H_{m, n}(q)=\sum_{N=0}^{\infty} \operatorname{dim} \Lambda^{\mathrm{aff}}(m \mid n)^{N} q^{N}
$$

As in the Introduction, by a plane partition over the $(m, n)$-hook we mean a finite sequence of Young diagrams (or partitions) $\lambda^{(1)} \supset \cdots \supset \lambda^{(r)}$ such that $\lambda^{(1)}$ does not contain the box $(m+1, n+1)$. Such a plane partition can be viewed as an array formed by unit cubes, the $i$-th level of the array has the shape $\lambda^{(i)}$. An explicit formula for the generating function of the plane partitions was conjectured in [9] and proved in [16]. For $n \geqslant m \geqslant 1$ it has the form

$$
\begin{aligned}
f_{m, n}(q)=\frac{1}{(q)_{\infty}^{m+n}} \sum_{k_{1} \geqslant \cdots \geqslant k_{m} \geqslant 0} & \left((-1)^{k_{1}+\cdots+k_{m}} q^{\frac{1}{2} \sum_{i=1}^{m}\left(k_{i}^{2}+(2 i-1) k_{i}\right)}\right. \\
& \left.\times \prod_{1 \leqslant i<j \leqslant m}\left(1-q^{k_{i}-k_{j}+j-i}\right) \prod_{1 \leqslant i<j \leqslant n}\left(1-q^{k_{i}-k_{j}+j-i}\right)\right),
\end{aligned}
$$

where $k_{j}:=0$ for $j>m$ and the coefficient of $q^{N}$ in the series is the number of plane partitions over the ( $m, n$ )-hook containing exactly $N$ unit cubes.

Conjecture 3.2. The dimension $\operatorname{dim} \Lambda^{\text {aff }}(m \mid n)^{N}$ equals the number of plane partitions over the ( $m, n$ )-hook containing exactly $N$ unit cubes. Equivalently, if $n \geqslant m \geqslant 1$ then the Hilbert-Poincaré series $H_{m, n}(q)$ coincides with $f_{m, n}(q)$.

The conjecture holds for $n=0$ (or $m=0$ ); that is, for the algebra of affine symmetric polynomials $\Lambda^{\text {aff }}(m)$. This algebra admits a family of algebraically independent generators which can be obtained, for instance, by taking $n=0$ in (3.1):

$$
\sum_{i=1}^{m} \sum_{r_{1}+\cdots+r_{k}=r} u_{i r_{1}} \ldots u_{i r_{k}}, \quad k=1, \ldots, m, \quad r \geqslant 0
$$

The Hilbert-Poincaré series is then found by

$$
\prod_{k=1}^{m} \prod_{r \geqslant k}\left(1-q^{r}\right)^{-1}=\frac{1}{(q)_{\infty}^{m}} \prod_{i=1}^{m-1}\left(1-q^{i}\right)^{m-i}
$$

which coincides with $f_{0, m}(q)$; cf. [10, Sec. 4.3].
Below we prove Conjecture 3.2 for $m=n=1$; see Sec. [4. First we give an alternative expression for the generating function $f_{m, n}(q)$ in this case.

Proposition 3.3. We have

$$
f_{1,1}(q)=\frac{1}{(q)_{\infty}} \sum_{k=0}^{\infty} \frac{q^{k^{2}+k}}{(q)_{k}^{2}}
$$

Proof. By definition,

$$
f_{1,1}(q)=\frac{1}{(q)_{\infty}^{2}} \sum_{k=0}^{\infty}(-1)^{k} q^{\frac{k^{2}+k}{2}}
$$

The desired identity follows from a more general relation which holds for $s \geqslant 0$ :

$$
\begin{equation*}
\sum_{k=0}^{\infty} \frac{q^{k^{2}+k}}{(q)_{k}^{2}}-\frac{1}{(q)_{\infty}} \sum_{k=0}^{s-1}(-1)^{k} q^{\frac{k^{2}+k}{2}}=(-1)^{s} \sum_{k=s}^{\infty} \frac{q^{k^{2}-(s-1) k+\frac{s^{2}-s}{2}}}{(q)_{k}(q)_{k-s}} \tag{3.2}
\end{equation*}
$$

We prove (3.2) by induction on $s$. It holds trivially for $s=0$ so suppose that $s \geqslant 1$. To complete the induction step we need to show that

$$
(-1)^{s} \sum_{k=s}^{\infty} \frac{q^{k^{2}-(s-1) k+\frac{s^{2}-s}{2}}}{(q)_{k}(q)_{k-s}}-(-1)^{s} \frac{q^{\frac{s^{2}+s}{2}}}{(q)_{\infty}}=(-1)^{s+1} \sum_{k=s+1}^{\infty} \frac{q^{k^{2}-s k+\frac{s^{2}+s}{2}}}{(q)_{k}(q)_{k-s-1}} .
$$

This is immediate from the identity

$$
\frac{1}{(q)_{\infty}}=\sum_{k=s}^{\infty} \frac{q^{k(k-s)}}{(q)_{k}(q)_{k-s}}
$$

which holds for $s \geqslant 0$ and is easily verified as follows. Both sides are generating functions for all partitions. This is clear for the left hand side, while the expression on the right hand side is obtained by first assigning the maximum size rectangle of the form $(k-s) \times k$ contained in a Young diagram. Then the generating function of the Young diagrams with a fixed value of $s$ is given by

$$
\frac{q^{k(k-s)}}{(q)_{k}(q)_{k-s}}
$$

as required.

### 3.1 Affine cancellation property

Using notation (2.5), we will regard $\Lambda^{\text {aff }}(1 \mid 1)$ as the subalgebra of the algebra of polynomials in the variables $a_{r}=u_{1 r}$ and $c_{r}=u_{1 r}+v_{1 r}$ with $r \geqslant 0$. Working over Laurent polynomials
in $c_{0}$ define elements $d_{r}$ by the relation

$$
d(z):=\sum_{r=0}^{\infty} d_{r} z^{r}=c(z)^{-1}, \quad c(z)=\sum_{r=0}^{\infty} c_{r} z^{r}
$$

Explicitly,

$$
d_{r}=c_{0}^{-1} \sum_{\alpha_{1}+2} \sum_{\alpha_{2}+\cdots+r \alpha_{r}=r} \frac{\left(\alpha_{1}+\cdots+\alpha_{r}\right)!}{\alpha_{1}!\alpha_{2}!\ldots \alpha_{r}!}\left(-\frac{c_{1}}{c_{0}}\right)^{\alpha_{1}} \ldots\left(-\frac{c_{r}}{c_{0}}\right)^{\alpha_{r}},
$$

summed over nonnegative integers $\alpha_{i}$. Consider the operator

$$
\mathcal{D}=\sum_{r=0}^{\infty} d_{r} \partial_{r}, \quad \partial_{r}=\partial / \partial a_{r} .
$$

Proposition 3.4. If $P \in \Lambda^{\text {aff }}(1 \mid 1)$ then $\mathcal{D} P$ does not contain negative powers of $c_{0}$.
Proof. The algebra $\Lambda^{\text {aff }}(1 \mid 1)$ is generated by the coefficients of the series $a(z)^{k} c(z)$ with $k \geqslant 0$. We have

$$
\mathcal{D} a(z)^{k} c(z)=k a(z)^{k-1} d(z) c(z)=k a(z)^{k-1} .
$$

Thus, the required property holds for generators of the algebra $\Lambda^{\text {aff }}(1 \mid 1)$. Since $\mathcal{D}$ is a derivation, it will hold for all its elements.

We conjecture that the property given by Proposition 3.4 is characteristic for the affine supersymmetric polynomials.

Conjecture 3.5. A polynomial $P$ in the variables $a_{r}$ and $c_{r}$ belongs to $\Lambda^{\text {aff }}(1 \mid 1)$ if and only if $\mathcal{D} P$ does not contain negative powers of $c_{0}$.

## 4 Chevalley-type isomorphism

In this section we prove Theorems B and C.
Let $\mathfrak{g}=\mathfrak{n}_{-} \oplus \mathfrak{h} \oplus \mathfrak{n}_{+}$be the triangular decomposition of $\mathfrak{g}=\mathfrak{g l}(m \mid n)$, where the subalgebras $\mathfrak{n}_{-}, \mathfrak{h}$ and $\mathfrak{n}_{+}$are spanned by the basis elements $E_{i j}$ with $i<j, i=j$ and $i>j$, respectively. The Chevalley homomorphism

$$
\varsigma: S(\mathfrak{g}) \rightarrow \mathrm{S}(\mathfrak{h})
$$

is the projection modulo the ideal $S(\mathfrak{g})\left(\mathfrak{n}_{-} \cup \mathfrak{n}_{+}\right)$. The restriction of $\varsigma$ to the subalgebra of invariants yields an isomorphism between $S(\mathfrak{g})^{\mathfrak{g}}$ and the algebra of supersymmetric polynomials in two sets of variables; see e.g. [20].

Consider an affine analogue of $\varsigma$ defined as the projection

$$
\begin{equation*}
\widehat{\varsigma}: S\left(\widehat{\mathfrak{g}}_{-}\right) \rightarrow \mathrm{S}\left(\widehat{\mathfrak{h}}_{-}\right) \tag{4.1}
\end{equation*}
$$

modulo the ideal $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)\left(t^{-1} \mathfrak{n}_{-}\left[t^{-1}\right] \cup t^{-1} \mathfrak{n}_{+}\left[t^{-1}\right]\right)$, where we set $\widehat{\mathfrak{h}}_{-}=t^{-1} \mathfrak{h}\left[t^{-1}\right]$. We identify $\mathrm{S}\left(\widehat{\mathfrak{h}}_{-}\right)$with the algebra of polynomials in the variables $u_{1 r}, \ldots, u_{m r}, v_{1 r}, \ldots, v_{n r}$ with $r \geqslant 0$ by setting

$$
u_{i r}=E_{i i}[-r-1] \quad \text { and } \quad v_{j r}=E_{j+m j+m}[-r-1] .
$$

Proposition 4.1. The restriction of the homomorphism (4.1) to the subalgebra $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ is injective.

Proof. Suppose that $Q \in \mathrm{~S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ and $\widehat{\varsigma}(Q)=0$. Take a positive integer $p$ such that $Q$ does not depend on the generators $E_{i j}[r]$ with $r<-p$. By the definition of the $\mathfrak{g}[t]$-action on $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)$, we have $t^{p} \mathfrak{g}[t] Q=0$. Denote by $\mathfrak{g}_{p}$ the quotient of $\mathfrak{g}[t]$ by the ideal $t^{p} \mathfrak{g}[t]$ and denote by $\mathfrak{g}_{p,-}$ the quotient of $\widehat{\mathfrak{g}}_{-}=t^{-1} \mathfrak{g}\left[t^{-1}\right]$ by the ideal $t^{-p-1} \mathfrak{g}\left[t^{-1}\right]$. The proposition will follow if we show that the restriction map

$$
\mathrm{S}\left(\mathfrak{g}_{p,-}\right)^{\mathfrak{g}_{p}} \rightarrow \mathrm{~S}\left(\mathfrak{h}_{p,-}\right)
$$

is injective for any positive integer $p$, where $\mathfrak{h}_{p,-}$ denotes the quotient of $\widehat{\mathfrak{h}}_{-}$by the ideal $t^{-p-1} \mathfrak{h}\left[t^{-1}\right]$. We will derive this claim from the following general result of Sergeev [20, Proposition 1.1]; see also [21, Lemma 4.3] for a shorter and more direct proof.

Lemma 4.2. Let $\mathfrak{g}$ be a finite-dimensional Lie superalgebra and $V$ a finite-dimensional $\mathfrak{g}$-module. Given a subspace $W$ of $V$, suppose that there exists an even element $w_{0} \in W$ such that the map

$$
\mathfrak{g} \times W \rightarrow V, \quad(x, w) \mapsto x w_{0}+w
$$

is surjective. Then the restriction map $\mathrm{S}\left(V^{*}\right)^{\mathfrak{g}} \rightarrow \mathrm{S}\left(W^{*}\right)$ is injective.
To apply the lemma we take $\mathfrak{g}=\mathfrak{g}_{p}$ and let $V=\mathfrak{g}_{p}$ be the adjoint $\mathfrak{g}_{p}$-module. The dual module $V^{*}$ is isomorphic to $\mathfrak{g}_{p,-}$; the isomorphism takes the element $E_{k l}[s]^{*}$ dual to the basis vector $E_{k l}[s]$ of $\mathfrak{g}_{p}$ to the element $E_{l k}[-s-1](-1)^{\bar{l}}$. The subspace $W$ is the quotient $\mathfrak{h}_{p}$ of $\mathfrak{h}[t]$ by the ideal $t^{p} \mathfrak{h}[t]$. The dual space $W^{*}$ is identified with $\mathfrak{h}_{p,-}$. The assumptions of Lemma 4.2 will hold for any element

$$
w_{0}=\sum_{k=1}^{m+n} \gamma_{k} E_{k k}[0]
$$

with $\gamma_{i} \neq \gamma_{j}$ for $i \neq j$. Indeed, this is clear from the relations

$$
\left[E_{i j}[r], w_{0}\right]=\left(\gamma_{j}-\gamma_{i}\right) E_{i j}[r]
$$

The proposition is proved.

Now we return to the Lie superalgebra $\mathfrak{g}=\mathfrak{g l}(1 \mid 1)$. The grading on the symmetric algebra $S\left(\hat{\mathfrak{g}}_{-}\right)$is defined by

$$
\operatorname{deg} E_{i j}[-r-1]=r+1
$$

We have $\operatorname{deg} \varphi_{i}=\operatorname{deg} \psi_{i}=i+1$, and by (2.10)

$$
\begin{equation*}
\operatorname{deg} Y_{\lambda}^{(k)}=|\lambda|+k(k+1), \quad \ell(\lambda) \leqslant k \tag{4.2}
\end{equation*}
$$

For a given $k$, let $d_{N}$ be the number of basis elements $Y_{\lambda}^{(k)}$ of degree $N$. By (4.2), the generating function is given by

$$
\sum_{N \geqslant 0} d_{N} q^{N}=\frac{q^{k^{2}+k}}{(q)_{k}}
$$

Since $\operatorname{deg} a_{i}=i+1$ the generating function of the monomials (2.14) (with $\left.n:=k\right)$ is $(q)_{k}^{-1}$. Similarly, the generating function of the algebra of polynomials in the $c_{i}$ is $(q)_{\infty}^{-1}$ and so the Hilbert-Poincaré series of $\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]}$ is given by

$$
\frac{1}{(q)_{\infty}} \sum_{k=0}^{\infty} \frac{q^{k^{2}+k}}{(q)_{k}^{2}}
$$

Furthermore, the image of the series (2.2) under the projection (4.1) equals

$$
\begin{equation*}
E_{11}(z)^{k-1}\left(E_{11}(z)+E_{22}(z)\right) \tag{4.3}
\end{equation*}
$$

Since the elements $u_{1}^{k-1}\left(u_{1}+v_{1}\right)$ with $k \geqslant 1$ generate the algebra of supersymmetric polynomials $\Lambda(1 \mid 1)$, the coefficients of the series (4.3) generate the algebra $\Lambda^{\text {aff }}(1 \mid 1)$ of affine supersymmetric polynomials. Here, as before, we identify the variables by $u_{1 r}=$ $E_{11}[-r-1]$ and $v_{1 r}=E_{22}[-r-1]$. Therefore, by Proposition 4.1, we have a Chevalleytype isomorphism of graded algebras

$$
\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]} \cong \Lambda^{\mathrm{aff}}(1 \mid 1)
$$

This completes the proof of Theorem B while Theorem C now follows from Proposition 3.3,
Conjecture 4.3. Let $\mathfrak{g}=\mathfrak{g l}(m \mid n)$. The restriction of the map (4.1) to the subalgebra of $\mathfrak{g}[t]$-invariants yields an isomorphism of graded algebras

$$
\mathrm{S}\left(\widehat{\mathfrak{g}}_{-}\right)^{\mathfrak{g}[t]} \cong \Lambda^{\mathrm{aff}}(m \mid n)
$$

In particular, their Hilbert-Poincaré series coincide.
Besides the case $m=n=1$, Conjecture 4.3 also holds for $n=0$ or $m=0$ as implied by the Beilinson-Drinfeld-Raïs-Tauvel theorem; see [10, Sec. 4.3].

## A Generating function for the supersymmetric polynomials in $m+n$ variables

Two different forms of the Hilbert-Poincaré series for the algebra $\Lambda(m \mid n)$ were given in [17] and [22]. Both proofs rely on the parametrization of basis elements of $\Lambda(m \mid n)$ by Young diagrams contained in the ( $m, n$ )-hook. We give yet another formula for the series and derive it from the characterization of the supersymmetric polynomials via the cancellation property; cf. [23].

Proposition A.1. The Hilbert-Poincaré series of the algebra $\Lambda(m \mid n)$ is found by

$$
\chi_{m, n}(q)=\sum_{k=0}^{\min \{m, n\}} \frac{q^{(m-k)(n-k)}}{(q)_{m-k}(q)_{n-k}}
$$

Proof. As before, we consider two sets of variables $u=\left(u_{1}, \ldots, u_{m}\right)$ and $v=\left(v_{1}, \ldots, v_{n}\right)$. For $m, n \geqslant 1$ we have a surjective homomorphism

$$
\Lambda(m, n) \rightarrow \Lambda(m-1, n-1), \quad u_{m} \mapsto 0, \quad v_{n} \mapsto 0
$$

Its kernel coincides with the space

$$
\prod_{i=1}^{m} \prod_{j=1}^{n}\left(u_{i}+v_{j}\right) \mathbb{C}[u, v]^{\mathfrak{S}_{m} \times \mathfrak{S}_{n}}
$$

where $\mathbb{C}[u, v]^{\mathfrak{G}_{m} \times \mathfrak{S}_{n}}$ is the algebra of bisymmetric polynomials. Hence we have a recurrence relation

$$
\chi_{m, n}(q)=\chi_{m-1, n-1}(q)+\frac{q^{m n}}{(q)_{m}(q)_{n}}
$$

which leads to the desired formula.
The recurrence relation can also be easily seen from the parametrization of basis elements by Young diagrams. The term $\chi_{m-1, n-1}(q)$ accounts for the diagrams contained in the ( $m-1, n-1$ )-hook, whereas the generating function of the diagrams in the ( $m, n$ )-hook containing the box $(m, n)$ is $q^{m n} /(q)_{m}(q)_{n}$; cf. the proof of Proposition 3.3.
