3 **Identification of a new locus at 16q12 associated with time-to-asthma onset**

4 C Sarnowski *et al.*

5

6 **METHODS**

7 *Study populations*

8 The present project includes nine independent studies (Table E1) among which five
9 population-based studies: the European Community Respiratory Health Survey (ECRHS), the
10 Swiss study on Air Pollution and Lung and Heart Disease In Adults (SAPALDIA), the
11 Busselton Health Study (BUSSELTON), the GABRIEL Advanced Surveys (GABRIELA)
12 and the UFA study (UFA); three familial studies: the Epidemiological study on the Genetics
13 and Environment of Asthma (EGEA); the Saguenay-Lac-Saint-Jean Familial Collection
14 (SLSJ) and the TOMSK study (TOMSK); and one birth cohort: the Avon Longitudinal Study
15 of Parents and Children (ALSPAC). All of these studies were part of the GABRIEL European
16 consortium on asthma,¹ and had the information on age of asthma onset, age at last
17 examination and imputed genetic data available. A total of 13,886 subjects from European
18 ancestry were included in the time-to-asthma onset GWAS meta-analysis (5,462 asthmatics
19 and 8,424 non-asthmatics).

20

21 *Study populations and Phenotype definition*

22 **ALSPAC**

23 The Avon Longitudinal Study of Parents and Children (ALSPAC) is a population-based birth
24 cohort initially comprising of 14,541 mothers and their children recruited in the former
25 County of Avon, UK between 1991 and 1992.²

26 Asthmatics were defined by a positive response to the question: “Did you child had asthma in
27 past 12 months?” at 81, 91, 103, 128, 157 or 166 months. Non-asthmatics were those who
28 answered no at all surveys. In asthmatics, age of onset was defined by the first time they
29 declared wheeze or wheezing and whistling. Wheeze was defined by a positive response to
30 the question: “Has your child had wheezing, breathlessness or episodes of stopping breathing
31 in past 12 months or since he was (age at last Q)?”. Wheezing and whistling were defined by
32 a positive response to the question: “Has your child had any periods when there was wheezing
33 with whistling on his chest when he breathed in past 12 months or since he was (age at last
34 Q)?”. In non-asthmatics, we considered age at the last examination without any missing visit
35 at the preceding surveys. Thus, for non-asthmatics with negative complete reports, we
36 considered age at last examination and for non-asthmatics with negative incomplete and/or
37 discontinued reports, we considered age until the last visit before the first missing visit. We
38 did not include in the present analysis non-asthmatics who experienced wheeze or wheezing
39 and whistling before 6yrs of age.

40

41 **ECRHS**

42 The ECRHS study is a European population-based study of young adults with a 8-year
43 follow-up (ECRHS I: 1991-1993, ECRHS II: 1999-2002 and ECRHS III: 2010-ongoing).^{3,4}

44 The time-to-asthma onset GWAS is based on the two first survey data. Participants included
45 in the meta-analysis were derived from the nested asthma case/control sample subjected to
46 genome-wide genotyping in the context of the GABRIEL asthma GWAS.

47 Asthma cases were identified by participants from the random or enriched sample who said
48 yes to the question ‘Have you ever had asthma?’ at either ECRHS I Stage 2 or at ECRHS II.
49 Controls were a random sample (of the random sample) who answered ‘no’ to the same
50 question in both surveys. For individuals who developed asthma, information on asthma age

51 at onset was obtained from age at first asthma attack at ECRHS I or II. For individuals who
52 were free of disease upon examination, we considered age at last examination.

53

54 **EGEA**

55 Briefly, the EGEA study combines a case-control and a family-based study of asthma cases
56 (N=2,120 subjects) with three surveys over 20 years (EGEA1: 1991-1995, EGEA2: 2003-
57 2007 and EGEA3: 2011-2013). The whole study population included 388 asthmatic probands
58 recruited in chest clinics and their 1,317 family members (probands' parents and/or siblings)
59 plus 415 population-based controls.⁵

60 Asthma was defined in probands by a positive answer to the following four items “Have you
61 ever had attacks of breathlessness at rest with wheezing?”, “Have you ever had asthma
62 attacks?”, “Was this diagnosis confirmed by a physician?”, and “Have you had an asthma
63 attack in the last 12 months?” or on a positive self-report to two of the before mentioned items
64 plus a medical record of asthma. Individuals were considered free of disease if they answered
65 no at all items. Relatives of probands were defined as asthmatics if they answered positively
66 at either survey to “Have you ever had attacks of breathlessness at rest with wheezing?” or
67 “Have you ever had asthma attacks?” at EGEA1, EGEA2 or EGEA3.

68 For individuals who developed asthma, information on asthma age at onset was obtained from
69 adult asthmatics or parents of asthmatic children who answered to the following question:
70 “How old were you when you had your first asthma attack?” or “How old was your child
71 when he (or she) had his (her) first asthma attack?”. For individuals who were free of disease
72 upon last examination, we considered age at last examination.

73

74

75

76 **GABRIEL Advanced Surveys**

77 GABRIELA are cross-sectional population-based surveys conducted in rural areas of Austria,
78 Germany, and Switzerland during fall/winter 2006 and spring/summer 2007.⁶

79 A case was defined as a parental report of asthma diagnosed by a doctor at least once or
80 asthmatic bronchitis diagnosed at least twice during lifetime. The reference category for
81 asthma was no reported diagnosis of asthma ever and a diagnosis of asthmatic bronchitis no
82 more than once. The original question on age of onset was: “How old was your child when
83 the first symptoms of wheezing or whistling in the chest began? At the age of ... years. If
84 during the first year: At the age of ... months.” The variable is coded for years. Months were
85 transferred to years. In non-asthmatics, we considered age at examination. To define atopy,
86 we used an atopic sensitization to mite, cat, or birch upper or equal to 0.7 kU/L.

87

88 **SAPALDIA**

89 The SAPALDIA study is a cohort study with integrated biobank in the Swiss population
90 initiated in 1991 (SAPALDIA 1: n=9,651; age 18-60 at baseline) with two follow-up
91 assessments in 2001-2003 (SAPALDIA 2: n=8,047) and in 2010-2011 (SAPALDIA 3:
92 n=6,200).^{7,8} The time-to-asthma onset GWAS is based on the first two survey data.
93 Participants included in the meta-analysis were derived from the nested asthma case/control
94 sample subjected to genome-wide genotyping in the context of the GABRIEL asthma GWAS.
95 Asthma status was defined by an affirmative answer to the question “Have you ever had
96 asthma?” at baseline and/or follow-up interview. Controls were defined by a negative answer
97 to the same question. Age of onset was self-reported by study participants. For individuals
98 who were free of disease upon examination, we considered age at last examination.

99

100

101 **BUSSELTON**

102 The Busselton Health Study is a population-based, nested, case-control panel of 1,549
103 individuals of European Caucasian descent from Australia^{9,10} with seven cross-sectional
104 respiratory health surveys of adults conducted between 1966 and 2005-2007 and five cross-
105 sectional respiratory health surveys of all school children conducted between 1967 and 1983.
106 Asthma cases were defined as those who reported doctor-diagnosed asthma at any survey that
107 they attended from 1966 to 1994 (answer ‘Yes’ to ‘Has your doctor ever told you that you had
108 asthma?’). Controls are those who have consistently answered ‘No’ to ‘Has your doctor ever
109 told you that you had asthma?’ at all previous surveys that they have attended from 1966 to
110 1994. Age of onset was obtained from answer to the following question “How old were you
111 when you first developed symptoms of asthma?”. For individuals who were free of disease
112 upon examination, we considered age at last examination.

113

114 **SLSJ**

115 The Saguenay-Lac-Saint-Jean and Quebec City Familial Asthma Collection (SLSJ) consisting
116 of a French-Canadian founder population panel of 253 multigenerational families from
117 Saguenay-Lac-Saint-Jean region, ascertained through two asthmatic probands between 1997
118 and 2002.¹¹

119 Probands were included in the study if they fulfill at least two of the following criteria: 1) a
120 minimum of three clinic visits for acute asthma within one year; 2) two or more asthma-
121 related hospital admissions within one year; or 3) steroid dependency, as defined by either six
122 months of oral, or one year of inhaled corticosteroid use. Families were included in the study
123 if at least one parent was available for phenotypic assessment, at least one parent was
124 unaffected, and all four grandparents were of French-Canadian origin. For family members,
125 they were considered as asthmatic: (1) if they had a reported history of asthma (validated by a

126 physician), or (2) if they presented asthma-related symptoms and positive PC20 (less or equal
127 to 8mg/ml of methacholine) at recruitment. If individuals had at least one positive response on
128 skin prick tests (wheal diameter X 3mm at 10min), they were defined as atopic. Age of onset
129 was obtained from answers to the following questions “Have you ever had asthma attacks?
130 How old were you when you had your first asthma attack?”. When age of onset was defined
131 below 2 years (in 41 cases), a default class of 2 years was adopted to avoid uncertainty. For
132 non-asthmatics, we considered the age at examination.

133

134 **UFA**

135 UFA is a population-based case-control study of asthma cases and controls matched on age
136 and sex and recruited between 1999 and the year 2007.¹² Subjects are of different ethnic
137 origins (Russians, Tatars and Bashkirs) from Volga-Ural region of Russian Federation.

138 Cases are unrelated patients with physician-diagnosed asthma and controls are free of disease.
139 Asthma patients were diagnosed by pulmonologists on the basis of clinical examination,
140 family and medication history, objective tests of lung function. The controls were healthy
141 subjects who met all the following criteria: (1) no symptoms or history of asthma or other
142 pulmonary diseases; (2) no symptoms or history of atopy; and (3) absence of first-degree
143 relatives with a history of asthma or atopy. The age of asthma onset was obtained from
144 answer to the following question “How old were you when you had your first attack of
145 asthma?”. For non-asthmatics, we considered the age at examination.

146

147 **TOMSK**

148 TOMSK is a population-based family study conducted by the Research Institute of Medical
149 Genetics and Siberian State Medical University (TOMSK, Russia) from 1998 onwards.^{13,14}

150 Both nuclear families and extended pedigrees were recruited through atopic bronchial
151 asthmatic probands. Both probands and their relatives were clinically examined to establish
152 diagnosis of asthma and atopy using the GINA criteria (Global Initiative for Asthma: Global
153 Strategy for Asthma Management and Prevention. <http://www.ginasthma.org>). The age of
154 onset was set as the age when asthma was first diagnosed by a doctor. For newly identified
155 cases, it was established through their physical examination, while for other cases, it was
156 established through the reply to a question: “What age were you when doctor first time told
157 you that you have asthma?”. For non-asthmatics, we considered the age at examination.

158

159 *eQTL analysis and functional annotations*

160 We assessed whether significant SNPs associated with time-to-asthma onset (or their proxies)
161 were expression quantitative trait loci (eQTLs) by using publically available databases: eQTL
162 Browser (lymphoblastoid cell lines (LCLs) from British asthma (MRCA) and eczema
163 (MRCE) family subjects),¹⁵ Blood eQTL Browser (non-transformed peripheral blood
164 samples),¹⁶ Lung eQTLs (lung tissue),¹⁷ GTEx eQTL Browser release v4 (uploaded in July
165 2015 for multiple tissues including blood and lung)¹⁸ and eQTL Chicago Browser that
166 includes eQTL results from many sources among which Montgomery *et al*,¹⁹ Stranger *et al*²⁰
167 and Veyrieras *et al*²¹ that were performed in human LCLs.

168

169 *Replication of prior asthma GWAS results*

170 Finally, we evaluated whether previously reported susceptibility loci for asthma and asthma-
171 related phenotypes (asthma exacerbation, asthma-plus-rhinitis comorbidity, age of asthma
172 onset and bronchial-hyper-responsiveness) at genome-wide significance level were associated
173 with time-to-asthma onset in our meta-analysis using data from the NHGRI Catalog of
174 Published GWASs (last update June 2015).²² A total of 15 GWASs mainly conducted on

175 European populations have reported 57 SNPs belonging to 28 independent loci (including
176 seven loci specific to Japanese subjects or African-Americans and Latinos) associated with
177 asthma and/or selected asthma-related phenotypes at a genome-wide significant level.

178

179 **RESULTS**

180 *Functional annotations and effect on gene expression of main time-to-asthma onset* 181 *associated SNPs*

182 To provide some insights into the potential molecular mechanisms underlying the TAO
183 associated variants, we queried whether the seven top SNPs (or their proxies) were 1) tagging
184 potentially deleterious SNPs, 2) located in regulatory elements, and 3) reported to influence
185 the expression of one or more of nearby genes (eQTLs at $P < 5 \times 10^{-5}$; see Table III and Table
186 E3 for summary and complete results respectively).

187 The 2q12 region top SNP (rs10208293) is located within *interleukin 1 receptor-like 1* gene
188 (*ILIRL1*) in a binding site of the nuclear factor- κ B (NF κ B1) and is in strong LD ($D' = 1$ and
189 $r^2 = 0.57$) with three *ILIRL1* missense SNPs (rs4988956, rs10192157 and rs10206753). This
190 SNP and one of its proxy correlate with the expression of *interleukin 18 receptor 1* (*IL18R1*)
191 and *IL18 receptor accessory protein* (*IL18RAP*) genes in blood.¹⁶

192 In 6p21 region, the strongest association was with rs9272346 located near *HLA-DQA1*. This
193 SNP lies within an enhancer histone mark in B cells and is in strong LD ($r^2 > 0.8$) with SNPs in
194 a predicted promoter in B cells. This SNP (or its proxies) correlates with the expression of 17
195 HLA class II genes in blood tissue and lymphoblastoid cell lines (LCL).^{15,16,18-20} However,
196 due to the extensive LD within HLA region, some of these associations might reflect signal
197 inter-correlations rather than true pleiotropic effects on gene expression.

198 The two distinct SNPs (rs928413 and rs413382) associated with TAO at 9p24 are located in
199 intergenic region upstream of *IL33*. We did not find any evidence for eQTL for these SNPs or
200 their proxies.

201 The span of the SNPs associated with TAO at genome-wide significance level in 17q12-q21
202 region was approximately 389 kb. The strongest association was with a SNP (rs9901146)
203 nearby *zona pellucida binding protein 2* gene (*ZPBP2*) that is in strong LD with several SNPs
204 tagging and/or belonging to other genes in the region: *IKAROS family zinc finger 3* (*IKZF3*),
205 *ZPBP2* (including rs11557467 missense SNP), *gasdermin B* (*GSDMB*; among which two
206 missense SNPs rs2305480 and rs2305479) and *ORMDL sphingolipid biosynthesis regulator 3*
207 (*ORMDL3*). The rs9901146-G risk allele was positively correlated with the expression of
208 *GSDMB* and *ORMDL3*, and negatively with *IKZF3* expression in LCL and blood
209 tissue.^{15,16,18,19,21} The second distinct signal at 17q12-q21 (rs3859192) is located within the
210 *gasdermin A* gene (*GSDMA*), in a GABPA (GA binding protein transcription factor, alpha
211 subunit) binding site. Moreover, this SNP is in strong LD with rs56030650 missense SNP
212 (*GSDMA*) and SNPs lying in a predicted promoter in B cells. The rs3859192-T risk allele was
213 correlated with decreased expression of *GSDMA* in the lung¹⁷ and increased expression of
214 both *GSDMB* and *ORMDL3* in LCLs.¹⁵

332

333 *Position in base pairs (bp) – build 37.3 NCBI.

334 †For the calculation of the hazard ratios, effect alleles (Effect) were designated as risk alleles. Effect Freq
 335 denotes effect allele frequency, CI confidence interval, and Ref reference allele.

336 ‡P-values are obtained from meta-analysis of single-SNP Cox model of time-to-asthma onset adjusted for sex
 337 and principal components.

338 **P-Het value reflect test of heterogeneity across studies using Cochran's Q test.

339

340 Table E3. Cis-eQTLs results for the top SNPs (and their proxies) in genome-wide associated regions from the meta-analysis of time-to-asthma
 341 onset. We focused our search on eQTLs measured in blood, LCLs and lung tissue.

346 LD between TAO main SNPs and GABRIEL main SNPs in genome-wide associated regions:

347 **2q12**: rs10208293 & rs3771166 ($r^2=0.53$, $D'=0.95$); **6p21**: rs9272346 & rs9273349 ($r^2=D'=1.0$); **9p24**: rs928413 & rs1342326 ($r^2=0.51$, $D'=1.0$), rs413382 - rs1342326 ($r^2=0.0$,

348 $D'=0.23$); **17q12-21**: rs9901146 & rs2305480 ($r^2=0.82$, $D'=1.0$), rs3859192 & rs3894194 ($r^2=0.43$, $D'=0.71$)

349 *Position in megabases (Mb) – build 37.3 NCBI

350 †For the calculation of the hazard ratios, effect alleles were designated as risk alleles. Effect Freq denotes frequency of the effect allele, CI confidence interval, and Ref

351 reference allele.

352 ‡P-value obtained from single-SNP Cox model for time-to-asthma onset adjusted for sex and principal components (fixed-effect model when there was no significant evidence
353 of heterogeneity or random-effect model otherwise)

354 **P-Het reflects P-value of Cochran's Q statistic across studies

355 †† main GABRIEL SNP in 6p21 (rs9273349) was not imputable

356 ‡‡ Additional distinct SNPs detected with conditional analyses

357 Table E5. Published genome-wide associations with asthma compared with time-to-asthma onset GWAS meta-analysis results

358 * The SNP with the strongest LD with the reported SNP in the literature was used if the SNP reported in the literature was not available in the imputed data

359 [†]For the calculation of the hazard and odds ratios, Effect alleles (Effect) were designated as risk alleles. Effect Freq denotes frequency of the effect allele, CI confidence

360 interval, and Ref reference allele

361 ‡P-values are shown for tests of association under a fixed-effect model when there was no significant evidence of heterogeneity or under a random-effect model otherwise.

362 Associations with P-values ≤ 0.001 in the time-to-asthma onset meta-analysis are indicated in bold

363 NA: Not available

364 **FIGURE LEGENDS**

365 **Figure E1.** Distribution of age-of-asthma onset

366 **Figure E2.** Quantile-quantile (QQ) plots of 2,387,926 SNPs of nine GWAS (N = 13,886)
367 after quality control ($R_{sq} \geq 0.50$, $MAF \geq 0.01$, ≥ 6 contributing studies) under a fixed-effect
368 model (inflation factor, $\lambda_{GC} = 1.04$). The dots represent the distribution of observed Chi-Square
369 values against the theoretical model distribution of expected Chi-Square values. The red line
370 represents the theoretical model distribution of expected Chi-Square values under the null
371 distribution.

372 **Figure E3.** Regional association plots of the genome-wide associated regions using
373 Locuszoom³⁹ software: 2q12, 6p21, 9p24, 17q12-q21. SNPs are plotted with their P-values (-
374 \log_{10} values, left y-axis) as a function of genomic position (x-axis). Estimated recombination
375 rates (right y-axis) taken from 1000 Genomes (March 2012 EUR) are plotted in cyan to reflect
376 the local LD structure. SNPs surrounding the most significant SNP (purple circle) are color-
377 coded according to LD with lead SNP (pairwise r^2 , according to a blue to red scale from $r^2 = 0$
378 to 1). In 9p24 and 17q12-q21 regions, additional SNP detected by conditional analyses is
379 indicated by an arrow (Part A). Two additional plots show SNPs color-coded according to LD
380 with additional SNP detected in conditional analysis (Part B).

381 **Figure E4.** Forest plots of hazard ratios for SNPs associated with time-to-asthma onset at
382 genome-wide significant level ($P \leq 5 \times 10^{-8}$) and two additional SNPs detected by conditional
383 analyses in 9p24 and 17q12-q21 regions. The hazard ratios and 95% confidence intervals for
384 seven loci show distinct effect on time-to-asthma onset. In each plot, the diamond indicates
385 the effect size and the 95% CI derived from the meta-analysis of nine studies.

386 **Figure E5.** Regional plots of 9p24 (Part-a) and 17q12-q21 (Part-b) regions for distinct
387 association signals using sequential conditional analysis and time-to-asthma onset as an
388 outcome variable: original meta-analysis (A), adjusted for lead SNP (B) and additionally

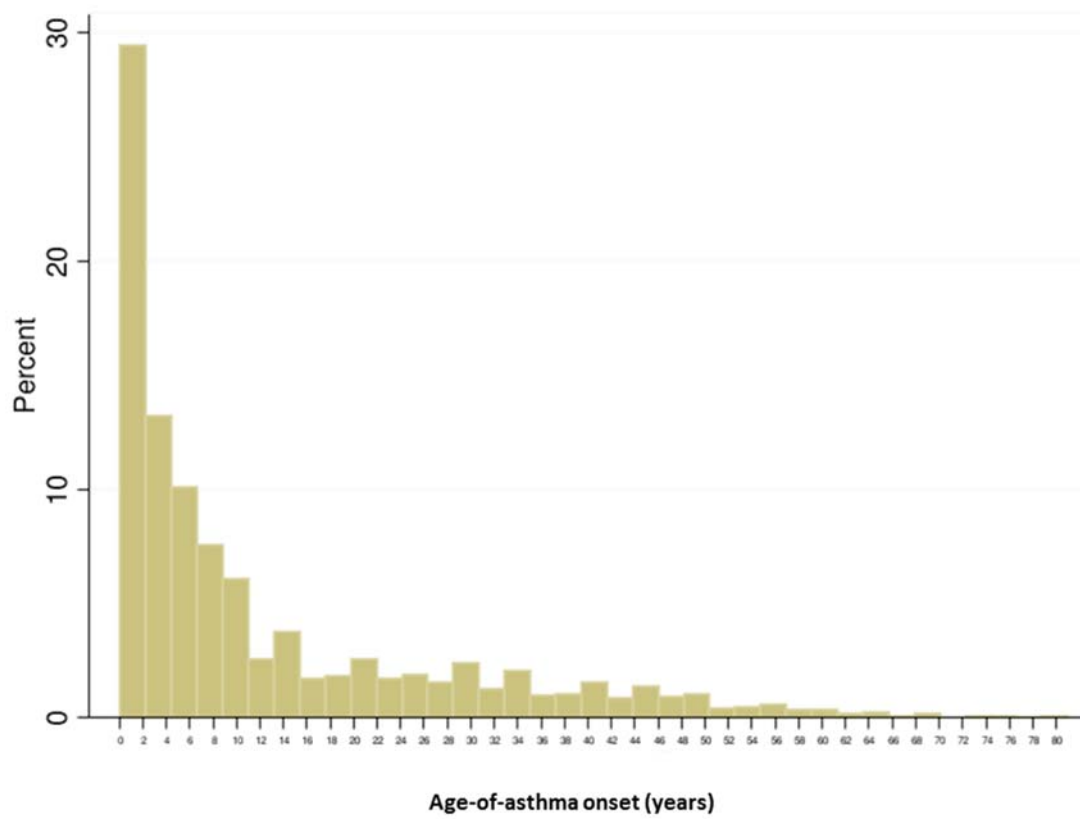

389 adjusted for the secondary signal (C). Signals above the red line ($P < 10^{-5}$) were considered to
390 exhibit evidence of association in the regions. SNPs are colored according to their pairwise
391 LD r^2 with the lead SNP. r^2 was estimated from 1000 Genomes (March 2012 EUR).

392 **Figure E6.** Association plots of the fine-mapping conducted in 16q12 region using 1000G
393 CEU reference sample. SNPs are plotted with their P-values ($-\log_{10}$ values, left y-axis) as a
394 function of genomic position (x-axis). Estimated recombination rates (right y-axis) taken from
395 1000G are plotted to reflect the local LD structure around the top associated SNP (purple
396 circle) and correlated proxies (according to a blue to red scale from $r^2 = 0$ to 1).
