HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SYNCHRONISING AND NON-SYNCHRONISING DYNAMICS FOR A TWO-SPECIES AGGREGATION MODEL

CASIMIR EMAKO-KAZIANOU, JIE LIAO, AND NICOLAS VAUCHELET

ABSTRACT. This paper deals with analysis and numerical simulations of a one-dimensional two-species hyperbolic aggregation model. This model is formed by a system of transport equations with nonlocal velocities, which describes the aggregate dynamics of a two-species population in interaction appearing for instance in bacterial chemotaxis. Blow-up of classical solutions occurs in finite time. This raises the question to define measure-valued solutions for this system. To this aim, we use the duality method developed for transport equations with discontinuous velocity to prove the existence and uniqueness of measure-valued solutions. The proof relies on a stability result. In addition, this approach allows to study the hyperbolic limit of a kinetic chemotaxis model. Moreover, we propose a finite volume numerical scheme whose convergence towards measure-valued solutions is proved. It allows for numerical simulations capturing the behaviour after blow up. Finally, numerical simulations illustrate the complex dynamics of aggregates until the formation of a single aggregate: after blow-up of classical solutions, aggregates of different species are synchronising or nonsynchronising when collide, that is move together or separately, depending on the parameters of the model and masses of species involved.

1. INTRODUCTION

Aggregation phenomena for a population of individuals interacting through an interaction potential are usually modelled by the so-called aggregation equation which is a nonlocal nonlinear conservation equation. This equation governs the dynamics of the density of individuals subject to an interaction potential K . In this work, we are interested in the case where the population consists of two species which respond to the interaction potential in different ways. In the one-dimensional case, the system of equations writes:

$$(1.1) \quad \partial_t \rho_\alpha + \chi_\alpha \partial_x (a(\rho) \rho_\alpha) = 0, \quad \text{for } \alpha = 1, 2,$$

with

$$a(\rho) := \int_{\mathbb{R}} \partial_x K(x-y) \rho(t, dy), \quad \rho := \theta_1 \rho_1 + \theta_2 \rho_2,$$

where $\theta_\alpha, \chi_\alpha$ for $\alpha = 1, 2$ are positive constants.

In this work, we are interested in the case where the interaction potential K in (1.1) is *pointy* i.e. satisfies the following assumptions:

- (H1) $K \in C^1(\mathbb{R} \setminus \{0\})$.
- (H2) $\forall x \in \mathbb{R}, \quad K(x) = K(-x)$.
- (H3) $\partial_x K \in L^\infty(\mathbb{R})$.
- (H4) K is λ -concave with $\lambda > 0$ i.e.,

$$\forall x, y \in \mathbb{R}^*, \quad (\partial_x K(x) - \partial_x K(y))(x - y) \leq \lambda(x - y)^2.$$

The aggregation equation arises in several applications in biology and physics. In fact, it is encountered in the modelling of cells which move in response to chemical cues. The velocity of cells $a(\rho)$ depending on the distribution of nearby cells represents the gradient of the chemical

Key words and phrases. hydrodynamic limit, duality solution, two-species chemotaxis, aggregate dynamics.

substance which triggers the motion. Cells gather and form accumulations near regions more exposed to oxygen as observed in [20, 24]. We can also describe the movement of pedestrians using the aggregation equation as in [16] where the velocity of pedestrians is influenced by the distribution of neighbours. This equation can also be applied to model opinion formation (see [25]) where interactions between different opinions can be expressed by a convolution with the kernel K .

From the mathematical point of view, it is known that solutions to the aggregation equation with a pointy potential blow up in finite time (see e.g [11, 5, 2]). Then global-in-time existence for weak measure solutions has been investigated. In [5], existence of weak solutions for single species model has been obtained as a gradient flow. This technique has been extended to the two-species model at hand in [11]. Another approach of defining weak solution for such kind of model has been proposed in [18, 17] for the single species case. In this approach, the aggregation equation is seen as a transport equation with a discontinuous velocity $a(\rho)$. Then solutions in the sense of duality have been defined for the aggregation equation.

Duality solutions has been introduced for linear transport equations with discontinuous velocity in the one-dimensional space in [3]. Then it has been adapted to the study of nonlinear transport equations in [4, 18, 17]. In [18, 17], the authors use this notion of duality solutions for the one-species aggregation equation. Such solutions are constructed by approximating the problem with particles, i.e. looking for a solution given by a finite sum of Dirac delta functions. Particles attract themselves through the interacting potential K , when two particles collide, they stick to form a bigger particle.

In this work, we extend this approach to the two species case. To do so, we need to modify the strategy to the problem at hand. Indeed, collisions between particles of different species are more complex: particles can move together or separately after collision. This synchronising or non-synchronising dynamics implies several difficulties for the treatment of the dynamics of particles. In fact, particles of different species can not stick when they collide. Then an approximate problem is constructed by considering the transport equation with the a regularized velocity. Then measure valued solutions are constructed by using a stability result.

An important advantage of this approach is that it allows to prove convergence of finite volume schemes. Numerical simulations of the aggregation equation for the one-species case, which corresponds to the particular case of (1.1) when setting $\rho_2 = 0$, have been investigated by several authors. In [8] the authors propose a finite volume method consistent with the gradient flow structure of the equation, but no convergence result has been obtained. In [9], a Lagrangian method is proposed (see also the recent work [7]). For the dynamics after blow up, a finite volume scheme which converges to the theoretical solution is proposed in [19, 6]. In the two-species case, the behaviour is more complex since the interaction between the two species can occur and they may synchronise or not i.e. move together or separately depending on the parameters of the models and the masses of species. A numerical scheme illustrating this interesting synchronising or non-synchronising dynamics is provided in Section 6. In addition, a theoretical result on the convergence of the numerical approximation obtained with our numerical scheme towards the duality solution is given. Such complex interactions phenomena have been observed experimentally in [13].

System (1.1) can be derived from a hyperbolic limit of a kinetic chemotaxis model. In the case of two-velocities and in one space dimension, the kinetic chemotaxis model is given by

$$(1.2) \quad \begin{cases} \partial_t f_\alpha^\varepsilon + v \partial_x f_\alpha^\varepsilon = \frac{1}{\varepsilon} \int_V (T_\alpha[S](v', v) f_\alpha^\varepsilon(v') - T_\alpha[S](v, v') f_\alpha^\varepsilon(v)) dv', & \alpha = 1, 2, v \in V = \{\pm 1\}, \\ -\partial_{xx} S^\varepsilon + S^\varepsilon = \theta_1 (f_1^\varepsilon(1) + f_1^\varepsilon(-1)) + \theta_2 (f_2^\varepsilon(1) + f_2^\varepsilon(-1)), \end{cases}$$

where $f_\alpha^\varepsilon(x, v, t)$ stands for the distribution function of α -th species at time t , position x and velocity v , $S^\varepsilon(t, x)$ is the concentration of the chemical substance, $T_\alpha[S](v, v')$ is the tumbling kernel from direction $v \in V$ to direction $v' \in V$ and $\varepsilon > 0$ is a small parameter. This tumbling kernel being affected by the gradient of the chemoattractant, is chosen as in [12]

$$(1.3) \quad T_\alpha[S](v, v') = \psi_\alpha (1 + \chi_\alpha v \partial_x S),$$

where ψ_α is a positive constant called the natural tumbling kernel and χ_α is the chemosensitivity to the chemical S . This kinetic model for chemotaxis has been introduced in [21] to model the run-and-tumble process. Existence of solutions to this two species kinetic system has been studied in [14].

Summing and subtracting equations (1.2) with respect to $v = \pm 1$ for f_α^ε yields

$$(1.4) \quad \partial_t \rho_\alpha^\varepsilon + \partial_x J_\alpha^\varepsilon = 0,$$

$$(1.5) \quad \partial_t J_\alpha^\varepsilon + \partial_x \rho_\alpha^\varepsilon = \frac{2\psi_\alpha}{\varepsilon} (\chi_\alpha \partial_x S^\varepsilon \rho_\alpha^\varepsilon - J_\alpha^\varepsilon), \quad \alpha = 1, 2,$$

where $\rho_\alpha^\varepsilon := f_\alpha^\varepsilon(1) + f_\alpha^\varepsilon(-1)$ and $J_\alpha^\varepsilon := (f_\alpha^\varepsilon(1) - f_\alpha^\varepsilon(-1))$. Taking formally the limit $\varepsilon \rightarrow 0$ in (1.5), we deduce that $J_\alpha^\varepsilon \rightarrow \chi_\alpha \partial_x S^0 \rho_\alpha^0$ in the sense of distributions. Injecting in (1.4), we deduce formally that ρ_α^0 satisfies the limiting equation:

$$(1.6) \quad \partial_t \rho_\alpha^0 + \chi_\alpha \partial_x ((\partial_x S^0) \rho_\alpha^0) = 0,$$

where S^0 satisfies the elliptic equation:

$$-\partial_{xx} S^0 + S^0 = \theta_1 \rho_1^0 + \theta_2 \rho_2^0.$$

This latter equation can be solved explicitly on \mathbb{R} and S^0 is given by

$$(1.7) \quad S^0 = K * (\theta_1 \rho_1^0 + \theta_2 \rho_2^0), \quad K = \frac{1}{2} e^{-|x|}.$$

Then we recover system (1.1). This formal computation can be made rigorous. The rigorous derivation of (1.6) from system (1.2) will be proved in this work.

The paper is organized as follows. We first recall some basic notations and notions about the duality solutions and state our main results. Section 3 is devoted to the derivation of the macroscopic velocity used to define properly the product $a(\rho)\rho_\alpha$ and duality solutions. Existence and uniqueness of duality solutions are proved in Section 4, as well as its equivalence to gradient flow solutions. The convergence of the kinetic model (1.2) as $\varepsilon \rightarrow 0$ towards the aggregation model (1.6)-(1.7) is shown in Section 5. Finally, a numerical scheme that captures the synchronising and non-synchronising behaviour of the aggregate equation is studied in Section 6, as well as several numerical examples showing the synchronising and non-synchronising dynamics.

2. NOTATIONS AND MAIN RESULTS

2.1. Notations. We will make use of the following notations. Let $T > 0$, we denote

- $L_+^1(\mathbb{R})$ is the space of nonnegative functions of $L^1(\mathbb{R})$.
- $C_0(\mathbb{R})$ is the space of continuous functions that vanish at infinity.
- $\mathcal{M}_{\text{loc}}(\mathbb{R})$ is the set of local Borel measures, $\mathcal{M}_b(\mathbb{R})$ those whose total variation is finite:

$$\mathcal{M}_b(\mathbb{R}) = \{\mu \in \mathcal{M}_{\text{loc}}(\mathbb{R}), |\mu|(\mathbb{R}) < +\infty\}.$$

- $\mathcal{S}_{\mathcal{M}} = C([0, T], \mathcal{M}_b(\mathbb{R}) - \sigma(\mathcal{M}_b(\mathbb{R}), C_0(\mathbb{R})))$ is the space of time-continuous bounded Borel measures endowed with the weak topology.

- $\mathcal{P}_2(\mathbb{R})$ is the Wasserstein space of order 2:

$$\mathcal{P}_2(\mathbb{R}) = \left\{ \mu \text{ nonnegative borel measures in } \mathbb{R} \text{ s.t. } |\mu|(\mathbb{R}) = 1, \int_{\mathbb{R}} |x|^2 \mu(dx) < \infty \right\}.$$

- For $H \in C(\mathbb{R} \setminus \{0\})$, we define \widehat{H} :

$$\widehat{H} = \begin{cases} H(x), & \text{for } x \neq 0, \\ 0, & \text{else.} \end{cases}$$

We notice that if K satisfies (H2) and (H4), we have by taking $y = -x$ in (H4) and using (H2) that, $\forall x \in \mathbb{R}$, $\partial_x K(x)x \leq \lambda x^2$. We deduce that (H4) holds for $\widehat{\partial_x K}$ i.e.:

$$(2.1) \quad \forall x, y \in \mathbb{R}, \quad (\widehat{\partial_x K}(x) - \widehat{\partial_x K}(y))(x - y) \leq \lambda(x - y)^2.$$

We recall a compactness result on $\mathcal{M}_b(\mathbb{R}) - \sigma(\mathcal{M}_b(\mathbb{R}), C_0(\mathbb{R}))$. If there exists a sequence of bounded measures $\mu^n \in \mathcal{M}_b(\mathbb{R})$ such that their total variations $|\mu^n|(\mathbb{R})$ are uniformly bounded, then there exists a subsequence of μ^n that converges weakly to μ in $\mathcal{M}_b(\mathbb{R})$.

2.2. Duality solutions. For the sake of completeness, we recall the notion of duality solutions which has been introduced in [3] for one dimensional linear scalar conservation law with discontinuous coefficients. Let us then consider the linear conservation equation:

$$(2.2) \quad \partial_t \rho + \partial_x(b(t, x)\rho) = 0, \quad \text{in }]0, T[\times \mathbb{R},$$

with $T > 0$. We assume weak regularity of the velocity field $b \in L^\infty(]0, T[\times \mathbb{R})$ and b satisfies the so-called one-sided Lipschitz (OSL) condition:

$$(2.3) \quad \partial_x b \leq \gamma(t), \gamma \in L^1(]0, T[), \quad \text{in the sense of distributions.}$$

In order to define duality solutions, we introduce the related backward problem

$$(2.4) \quad \begin{cases} \partial_t p + b \partial_x p = 0, \\ p(T, \cdot) = p^T \in Lip_{loc}(\mathbb{R}). \end{cases}$$

We define the set of exceptional solutions \mathcal{E} as follows

$$\mathcal{E} := \{p \in Lip_{loc}(]0, T[\times \mathbb{R}) \text{ solution to (2.4) with } p^T = 0\}.$$

Definition 2.1 (*Reversible solutions* to (2.4)). We say that p is a *reversible* solution to (2.4) if and only if $p \in Lip_{loc}(]0, T[\times \mathbb{R})$ satisfies (2.4) and is locally constant on \mathcal{V}_e , where \mathcal{V}_e is defined by

$$\mathcal{V}_e := \{(t, x) \in]0, T[\times \mathbb{R}; \exists p_e \in \mathcal{E} p_e(t, x) \neq 0\}.$$

Definition 2.2 (*Duality solutions* to (2.2), see [3]). We say $\rho \in \mathcal{S}_M$ is a *duality solution* to (2.2) in $]0, T[$ if for any $0 < \tau \leq T$, and any p reversible solution to (2.4) compactly supported in x , the function $t \rightarrow \int_{\mathbb{R}} p(t, x)\rho(t, dx)$ is constant on $[0, \tau]$.

The following result shows existence and weak stability for duality solutions provided that the velocity field satisfied the one-sided-Lipschitz condition.

Theorem 2.3 (Theorem 2.1 in [3]).

- (1) Given $\rho^{ini} \in \mathcal{M}_b(\mathbb{R})$. Under the assumption (2.3), there exists a unique $\rho \in \mathcal{S}_M$, duality solution to (2.2), such that $\rho(0, \cdot) = \rho^{ini}$.
- (2) There exists a bounded Borel function \hat{b} , called *universal representative* of b such that $\hat{b} = b$ a. e., and for any duality solution ρ ,

$$\partial_t \rho + \partial_x(\hat{b}\rho) = 0, \quad \text{in the distributional sense.}$$

(3) Let $(b_n)_{n \in \mathbb{N}}$ be a bounded sequence in $L^\infty(]0, T[\times \mathbb{R})$, with $b_n \rightharpoonup b$ in $L^\infty(]0, T[\times \mathbb{R}) - w*$. Assume that $\partial_x b_n \leq \gamma^n(t)$, where $(\gamma^n)_{n \in \mathbb{N}}$ is bounded in $L^1(]0, T[)$. Consider a sequence $\rho_n \in \mathcal{S}_M$ of duality solutions to

$$\partial_t \rho_n + \partial_x (b_n \rho_n) = 0, \quad \text{in }]0, T[\times \mathbb{R},$$

such that $\rho_n(0, \cdot)$ is bounded in $\mathcal{M}_b(\mathbb{R})$, and $\rho_n(0, \cdot) \rightharpoonup \rho^{ini} \in \mathcal{M}_b(\mathbb{R})$. Then $\rho_n \rightharpoonup \rho$ in \mathcal{S}_M , where $\rho \in \mathcal{S}_M$ is the duality solution to

$$\partial_t \rho + \partial_x (b \rho) = 0, \quad \text{in }]0, T[\times \mathbb{R}, \quad \rho(0, \cdot) = \rho^{ini}.$$

Moreover, $\hat{b}_n \rho_n \rightharpoonup \hat{b} \rho$ weakly in $\mathcal{M}_b(]0, T[\times \mathbb{R})$.

2.3. Main results. Up to a rescaling, we can assume without loss of generality that the total mass of each species is normalized to 1. Then we will work in the space of probabilities for densities.

The first theorem states the existence and uniqueness of duality solutions for system (1.1) and its equivalence with the gradient flow solution considered in [11].

Definition 2.4. (Duality solutions for system (1.1)) We say that $(\rho_1, \rho_2) \in C([0, T], \mathcal{M}_b(\mathbb{R})^2)$ is a duality solution to (1.1) if there exists $\hat{a}(\rho) \in L^\infty((0, T) \times \mathbb{R})$ and $\gamma \in L^1_{loc}([0, T])$ satisfying $\partial_x \hat{a} \leq \gamma$ in the sense of distributions, such that for all $0 < t_1 < t_2 < T$,

$$(2.5) \quad \partial_t \rho_\alpha + \chi_\alpha \partial_x (\hat{a}(\rho) \rho_\alpha) = 0, \quad \text{for } \alpha = 1, 2, \quad \rho = \theta_1 \rho_1 + \theta_2 \rho_2,$$

in the sense of duality on (t_1, t_2) and $\hat{a}(\rho) = \partial_x K * \rho$ a.e. We emphasize that the final datum for (2.5) should be t_2 instead of T .

Then, we have the following existence and uniqueness result:

Theorem 2.5 (Existence, uniqueness of duality solution and equivalence to gradient flow solution). *Let $T > 0$ and $(\rho_1^{ini}, \rho_2^{ini}) \in \mathcal{P}_2(\mathbb{R})^2$. Under assumptions (H1)–(H4), there exists a unique duality solution $(\rho_1, \rho_2) \in C([0, T], \mathcal{P}_2(\mathbb{R})^2)$ to (1.1) in the sense of Definition 2.4 with $(\rho_1, \rho_2)(t = 0) = (\rho_1^{ini}, \rho_2^{ini})$ such that*

$$(2.6) \quad \hat{a}(\rho) := \int_{\mathbb{R}} \widehat{\partial_x K}(x - y) \rho(t, dy), \quad \rho = \theta_1 \rho_1 + \theta_2 \rho_2.$$

This duality solution is equivalent to the gradient flow solution defined in [11].

In our second main result, we prove the convergence of the kinetic model (1.2) towards the aggregation model.

Theorem 2.6 (Hydrodynamical limit of the kinetic model). *Assume that $\chi_\alpha(\theta_1 + \theta_2) < 1$ for $\alpha = 1, 2$. Let $T > 0$ and $(f_\alpha^\varepsilon, S^\varepsilon)$ be a solution to the kinetic-elliptic equation (1.2) such that $f_\alpha^\varepsilon(t = 0) = f_\alpha^{ini}$ and $f_\alpha^{ini} \in L^\infty \cap L^1_+(\mathbb{R})$ and $\int_{\mathbb{R}} x^2 f_\alpha^{ini} dx < \infty$.*

Then, as $\varepsilon \rightarrow 0$, $(f_\alpha^\varepsilon, S^\varepsilon)$ converges in the following sense:

$$\begin{aligned} \rho_\alpha^\varepsilon := f_\alpha^\varepsilon(1) + f_\alpha^\varepsilon(-1) &\rightharpoonup \rho_\alpha \quad \text{weakly in } \mathcal{S}_M, \quad \text{for } \alpha = 1, 2, \\ S^\varepsilon &\rightharpoonup S \quad \text{in } C([0, T], W^{1, \infty}(\mathbb{R})) - \text{weak}, \end{aligned}$$

*where ρ_α is the unique duality solution of (1.6) and $S = K * (\theta_1 \rho_1 + \theta_2 \rho_2)$ given in Theorem 2.5.*

The condition $\chi_\alpha(\theta_1 + \theta_2) < 1$ in the previous theorem is needed to guarantee that the tumbling kernel $T_\alpha[S]$ defined in (1.3) is positive.

To conclude this Section on the main results, we emphasize that, a finite volume scheme to simulate (2.5) is proposed in Section 6 and its convergence towards duality solutions is stated in Theorem 6.3.

3. MACROSCOPIC VELOCITY

In this section, we find the representative \hat{a} of a for which existence and uniqueness of duality solutions hold. To this end, we consider the similar system of transport equations to (1.1) associated to the velocity a^n which converges to a . Next, the limit of the product $a^n(\rho_\alpha^n)\rho_\beta^n$ for $\alpha, \beta = 1, 2$ is computed.

3.1. Regularisation. We build a sequence $(a^n)_{n \in \mathbb{N}}$ which converges to a by considering the sequence of regularised kernels $\partial_x K^n$ approaching $\partial_x K$.

Lemma 3.1. *Let $(\partial_x K^n)_{n \in \mathbb{N}}$ be the sequence of regular kernels defined by*

$$\partial_x K^n(x) = \begin{cases} \partial_x K(x), & \text{for } |x| > \frac{1}{n}, \\ n\partial_x K\left(\frac{1}{n}\right)x, & \text{else.} \end{cases}$$

Then

$$\partial_x K^n \in C^0(\mathbb{R}), \quad \forall x \in \mathbb{R}, \quad \partial_x K^n(-x) = -\partial_x K^n(x),$$

and

$$\|\partial_x K^n\|_\infty \leq \|\partial_x K\|_\infty, \quad \partial_{xx} K^n \leq \lambda \quad \text{in the distributional sense.}$$

Proof. From (H1), $\partial_x K \in C^0(\mathbb{R} \setminus \{0\})$ and since $\partial_x K^n$ is continuous at $\pm \frac{1}{n}$, we conclude that $\partial_x K^n \in C^0(\mathbb{R})$. From (H2), we deduce that $\partial_x K$ is an odd function. Using the definition of $\partial_x K^n$ and (H3), we get that $\|\partial_x K^n\|_\infty \leq \|\partial_x K\|_\infty$. From the construction of $\partial_x K^n$, we have that $\partial_x K^n = \partial_x K$ outside the interval $[-\frac{1}{n}, \frac{1}{n}]$ and from (H4) one sees $\partial_{xx} K^n \leq \lambda$ in $\mathbb{R} \setminus (-\frac{1}{n}, \frac{1}{n})$ in the sense of distributions. In addition, if we take $x = -\frac{1}{n}$ and $y = \frac{1}{n}$ in (H4), we have that

$$n\partial_x K\left(\frac{1}{n}\right) \leq \lambda.$$

Since $\partial_{xx} K^n = n\partial_x K\left(\frac{1}{n}\right)$ in $[-\frac{1}{n}, \frac{1}{n}]$, we conclude that $\partial_{xx} K^n \leq \lambda$ in $[-\frac{1}{n}, \frac{1}{n}]$ in the sense of distributions. Finally, we obtain that $\partial_{xx} K^n \leq \lambda$ in the sense of distributions. \square

In the rest of the paper, the notation $\partial_x K^n$ will refer to the regularised kernels of Lemma 3.1. Given $\partial_x K^n$, the velocity a^n is defined similarly to (2.6) as

$$(3.1) \quad \forall \rho \in \mathcal{S}_M, \quad a^n(\rho) := \int_{\mathbb{R}} \partial_x K^n(x-y)\rho(t, dy).$$

In the following lemma, we show that if ρ_α^n and ρ_β^n admit weak limits ρ_α and ρ_β respectively in \mathcal{S}_M , then the limit of the product $a^n(\rho_\alpha^n)\rho_\beta^n$ is $\hat{a}(\rho_\alpha)\rho_\beta$. Contrary to [22] where the two-dimensional case is considered, this limiting measure does not charge the diagonal.

Lemma 3.2. *For $\alpha = 1, 2$, let $\{\rho_\alpha^n\} \in \mathcal{S}_M$ be a sequence such that $\forall n \in \mathbb{N}, \forall t \in [0, T], |\rho_\alpha^n|(t, \mathbb{R}) = M_\alpha$. Suppose that there exists ρ_α in \mathcal{S}_M such that*

$$\rho_\alpha^n \rightharpoonup \rho_\alpha \quad \text{weakly in } \mathcal{S}_M,$$

Then, we have

$$a^n(\rho_\alpha^n)\rho_\beta^n \rightharpoonup \hat{a}(\rho_\alpha)\rho_\beta \quad \text{weakly in } \mathcal{M}_b([0, T] \times \mathbb{R}), \quad \alpha, \beta = 1, 2,$$

where $a^n(\cdot)$ and $\hat{a}(\cdot)$ are defined in (2.6), (3.1) respectively. That is for $\phi \in C_0([0, T] \times \mathbb{R})$,

$$\int_0^T \int_{\mathbb{R}^2} \partial_x K^n(x-y)\rho_\alpha^n(t, dx)\rho_\beta^n(t, dy)\phi(t, x)dt \rightarrow \int_0^T \int_{\mathbb{R}^2} \widehat{\partial_x K}(x-y)\rho_\alpha(t, dx)\rho_\beta(t, dy)\phi(t, x)dt.$$

Proof. Before starting the proof of the lemma, we first introduce some notations which simplify the computations

$$(3.2) \quad \begin{aligned} \mu^n(t, dx, dy) &:= \rho_\alpha^n(t, dx) \otimes \rho_\beta^n(t, dy), \quad E_n := \left\{ (x, y) \in \mathbb{R}^2, x \neq y, |x - y| \leq \frac{1}{n} \right\}, \\ \mu(t, dx, dy) &:= \rho_\alpha(t, dx) \otimes \rho_\beta(t, dy). \end{aligned}$$

For $\phi \in C_0([0, T] \times \mathbb{R})$, we denote

$$A_n(t) := \int_{\mathbb{R}^2} \partial_x K^n(x - y) \mu^n(t, dx, dy) \phi(t, x) - \int_{\mathbb{R}^2} \widehat{\partial_x K}(x - y) \mu(t, dx, dy) \phi(t, x),$$

Step 1: Convergence almost everywhere in time of $A_n(t)$.

Since $\partial_x K^n(0) = 0$, we have

$$\begin{aligned} A_n(t) &= \int_{\mathbb{R}^2} \widehat{\partial_x K^n}(x - y) \mu^n(t, dx, dy) \phi(t, x) - \int_{\mathbb{R}^2} \widehat{\partial_x K}(x - y) \mu(t, dx, dy) \phi(t, x), \\ &= \text{I}_n(t) + \text{II}_n(t), \end{aligned}$$

where $\text{I}_n(t)$ and $\text{II}_n(t)$ are defined by

$$\begin{aligned} \text{I}_n(t) &:= \int_{\mathbb{R}^2} \left(\widehat{\partial_x K^n}(x - y) - \widehat{\partial_x K}(x - y) \right) \mu^n(t, dx, dy) \phi(t, x), \\ \text{II}_n(t) &:= \int_{\mathbb{R}^2} \widehat{\partial_x K}(x - y) (\mu^n(t, dx, dy) - \mu(t, dx, dy)) \phi(t, x). \end{aligned}$$

From the definition of $\partial_x K^n$ in Lemma 3.1, it follows that

$$\text{I}_n(t) = \int_{E_n} (\partial_x K^n(x - y) - \partial_x K(x - y)) \mu^n(t, dx, dy) \phi(t, x).$$

The estimate on $\|\partial_x K^n\|_{L^\infty}$ in Lemma 3.1 and (H3) imply that

$$|\text{I}_n(t)| \leq 2\|\phi\|_{L^\infty} \|\partial_x K\|_{L^\infty} \mu^n(t, E_n),$$

with μ^n and E_n defined in (3.2).

Let $\varepsilon > 0$. Since the set E_n converges to the empty set, there exists $N \in \mathbb{N}$ such that $\forall n \geq N$,

$$(3.3) \quad \mu(t, E_n) \leq \varepsilon.$$

For all $n \geq N$, we observe that $E_n \subset E_N$, we have

$$(3.4) \quad \mu^n(t, E_n) \leq \mu^n(t, E_N) \leq (\mu^n - \mu)(t, E_N) + \mu(t, E_N).$$

From the weak convergence of ρ_α^n , $\alpha = 1, 2$, we note that the sequence $\mu^n(t, \cdot)$ converges weakly to $\mu(t, \cdot)$. Since the total variation of $\mu^n(t, \cdot)$ is constant in n , the tight convergence is achieved. Then, there exists N' such that $\forall n \geq N' \geq N$

$$|\mu^n - \mu|(t, E_N) \leq \varepsilon.$$

From (3.4) and (3.3), we conclude that $\forall n \geq N' \geq N$,

$$\mu^n(t, E_n) \leq 2\varepsilon.$$

Hence, for all $n \geq N'$, we get

$$(3.5) \quad |\text{I}_n(t)| \leq 2\|\phi\|_{L^\infty} \|\partial_x K\|_{L^\infty} \mu^n(t, E_n) \leq 4\|\phi\|_{L^\infty} \|\partial_x K\|_{L^\infty} \varepsilon.$$

We deduce that $\text{I}_n(t) \rightarrow 0$.

Next, we show that $\Pi_n(t)$ tends to zero.

$$\begin{aligned}\Pi_n(t) &= \int_{\mathbb{R}^2} (\widehat{\partial_x K}(x-y) - \widehat{\partial_x K^R}(x-y))\phi(t,x)(\mu^n(t,dx,dy) - \mu^n(t,dx,dy)) \\ &\quad + \int_{\mathbb{R}^2} \widehat{\partial_x K^R}(x-y)\phi(t,x)(\mu^n(t,dx,dy) - \mu(t,dx,dy)), \\ &:= \Pi_n^1(t) + \Pi_n^2(t),\end{aligned}$$

where R is an integer which will be fixed later. From the construction of $\partial_x K^R$ in Lemma 3.1, we get

$$\Pi_n^1 = \int_{E_R} (\partial_x K(x-y) - \partial_x K^R(x-y))\phi(t,x)(\mu^n(t,dx,dy) - \mu(t,dx,dy)).$$

Therefore, one has

$$|\Pi_n^1(t)| \leq 2\|\partial_x K\|_{L^\infty}\|\phi\|_{L^\infty}(\mu^n(t,E_R) + \mu(t,E_R)).$$

Let $\varepsilon > 0$. Using (3.4), by the same token as previously, there exists N such that for all $n \geq N$,

$$\mu^n(t,E_N) \leq 2\varepsilon, \quad \mu(t,E_N) \leq \varepsilon,$$

Setting $R = N$, we conclude that for all $n \geq N$,

$$|\Pi_n^1(t)| \leq 6\varepsilon\|\partial_x K\|_{L^\infty}\|\phi\|_{L^\infty}.$$

For $\Pi_n^2(t)$, we notice that $\partial_x K^N(x-y)\phi(t,x)$ is a continuous function that vanishes on the diagonal (x,x) and we have

$$\int_{\mathbb{R}^2} \widehat{\partial_x K^N}(x-y)\phi(t,x)(\mu^n - \mu)(t,dx,dy) = \int_{\mathbb{R}^2} \partial_x K^N(x-y)\phi(t,x)(\mu^n - \mu)(t,dx,dy).$$

The tight convergence of μ^n to μ implies that there exists $N'' > 0$ such that for all $n \geq N''$

$$\left| \int_{\mathbb{R}^2} \widehat{\partial_x K^M}(x-y)\phi(t,x)(\mu^n - \mu)(t,dx,dy) \right| \leq \varepsilon.$$

Therefore for all $n \geq \max\{N', N''\}$, one has

$$(3.6) \quad |\Pi_n(t)| \leq \varepsilon(1 + 6\|\partial_x K\|_{L^\infty}\|\phi\|_{L^\infty}).$$

This implies that $\Pi_n(t)$ converges to 0.

Combining (3.5) and (3.6), we deduce that for almost every $t \in [0, T]$, A_n converges to 0.

Step 2: Lebesgue's dominated convergence theorem

For all $t \in [0, T]$, we have that

$$|A_n(t)| \leq 2\|\phi\|_{L^\infty}\|\partial_x K\|_{L^\infty}M_\alpha M_\beta.$$

Since A_n converges almost everywhere to 0, $\int_0^T A_n(t)dt$ converges to zero from Lebesgue's dominated convergence theorem. \square

3.2. OSL condition on the macrosocopic velocity.

Proposition 3.3. *Let T, M be positive constants and $\rho \in \mathcal{S}_M$ be a positive measure such that $\forall t \in [0, T], |\rho|(t, \mathbb{R}) = M$. Let K be such that assumption (H_4) hold. Let $\hat{a}(\rho)$ and $a^n(\rho)$ be defined in (2.6) and (3.1) respectively. Then, there exists $\kappa \in L^1([0, T])$ such that*

$$\partial_x \hat{a}(t, x) \leq \kappa(t), \quad \partial_x a^n(t, x) \leq \kappa(t), \quad \text{in the sense of distributions.}$$

Proof. For $x, y \in \mathbb{R}$, we compute:

$$(\hat{a}(\rho)(t, x) - \hat{a}(\rho)(t, y))(x - y) = \int_{\mathbb{R}} (\widehat{\partial_x K}(x - z) - \widehat{\partial_x K}(y - z))(x - y)\rho(t, dz).$$

Using the λ -concavity of K , we deduce from (2.1)

$$(\hat{a}(\rho)(t, x) - \hat{a}(\rho)(t, y))(x - y) \leq \lambda(x - y)^2 \int_{\mathbb{R}} \rho(t, dz) \leq \lambda M(x - y)^2.$$

Since K^n is also λ concave from the proof of Lemma 3.1, we get the one-sided Lipschitz estimate on a^n by the same token as for a . \square

4. EXISTENCE AND UNIQUENESS OF DUALITY SOLUTIONS

4.1. Proof of the existence of duality solutions in Theorem 2.5. The proof is divided into several steps. First, we construct an approximate problem for which the existence of duality solutions holds. Then, we pass to the limit in the approximate problem to get the existence of duality solutions thanks to the weak stability of duality solutions stated in Theorem 2.3 and recover Equation (2.5) from Lemma 3.2. Finally, we recover the bound on the second order moment.

Step 1: Existence of duality solutions for the approximate problem

The macroscopic velocity a is replaced by an approximation a^n defined in (3.1) and the following system is considered:

$$(4.1) \quad \partial_t \rho_\alpha^n + \chi_\alpha \partial_x (a^n (\theta_1 \rho_1^n + \theta_2 \rho_2^n) \rho_\alpha^n) = 0, \quad \text{for } \alpha = 1, 2.$$

Since $\partial_x K^n$ is not Lipschitz continuous, we first consider $\partial_x K^{n,m}$ an approximation of $\partial_x K^n$ obtained by a convolution with a molifier. The solution $\rho_\alpha^{n,m}$ to the following equation is investigated.

$$(4.2) \quad \partial_t \rho_\alpha^{n,m} + \chi_\alpha \partial_x (a^{n,m} (\theta_1 \rho_1^{n,m} + \theta_2 \rho_2^{n,m}) \rho_\alpha^{n,m}) = 0, \quad \text{for } \alpha = 1, 2,$$

where $a^{n,m}$ is given by

$$a^{n,m}(\rho) := \int_{\mathbb{R}} \partial_x K^{n,m}(x - y)\rho(t, dy).$$

Applying Theorem 1.1 in [10] gives the existence of solutions $\rho_\alpha^{n,m}$ in $L^\infty([0, T], \mathcal{M}_b(\mathbb{R}))$ and $|\rho_\alpha^{n,m}|(t, \mathbb{R}) = |\rho_\alpha^{ini}|(\mathbb{R}) = 1$. Since the velocity field $a^{n,m}$ is Lipschitz, $\rho_\alpha^{n,m}$ is a duality solution. In addition, for $\phi \in C_c^\infty(\mathbb{R})$ we have for $\alpha = 1, 2$ the following estimate:

$$\frac{d}{dt} \left(\int_{\mathbb{R}} \rho_\alpha^{n,m}(t, dx) \phi(x) \right) = \int_{\mathbb{R}^2} \partial_x K^{n,m}(x - y) (\theta_1 \rho_1^{n,m}(t, dy) + \theta_2 \rho_2^{n,m}(t, dy)) \rho_\alpha^{n,m}(t, dx) \partial_x \phi(x).$$

Then,

$$(4.3) \quad \left| \frac{d}{dt} \left(\int_{\mathbb{R}} \rho_\alpha^{n,m}(t, dx) \phi(x) \right) \right| \leq \|\partial_x \phi\|_{L^\infty} \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2).$$

Using (4.3) and the density of $C_c^\infty(\mathbb{R})$ in $C_0(\mathbb{R})$, we deduce that $\rho_\alpha^{n,m} \in \mathcal{S}_M$. Moreover, the equicontinuity of $\rho_\alpha^{n,m}$ in \mathcal{S}_M follows from (4.3) and the density of $C_c^\infty(\mathbb{R})$ in $C_0(\mathbb{R})$. Since $|\rho_\alpha^{n,m}|(t, \mathbb{R}) = |\rho_\alpha^{ini}|(\mathbb{R}) = 1$, Ascoli Theorem gives the existence of a subsequence in m of $\rho_\alpha^{n,m}$ which converges to a limit named ρ_α^n in \mathcal{S}_M . We pass to the limit when m tends to infinity in Equation (4.2) and obtain that ρ_α^n satisfies (4.1).

Step 2 : Extraction of a convergent subsequence of ρ_α^n and existence of duality solutions.

As above, there exists a subsequence of ρ_α^n in \mathcal{S}_M such that

$$\rho_\alpha^n \rightharpoonup \rho_\alpha \quad \text{weakly in } \mathcal{S}_M, \quad \text{for } \alpha = 1, 2.$$

Let us find the equation satisfied by ρ_α in the distributional sense. Let ϕ be in $C_c^\infty([0, T] \times \mathbb{R})$. Since ρ_α^n satisfies (4.1) in the distributional sense, we have

$$\int_0^T \int_{\mathbb{R}} \partial_t \phi(t, x) \rho_\alpha^n(t, dx) dt + \chi_\alpha \int_0^T \int_{\mathbb{R}} a^n(\theta_1 \rho_1^n + \theta_2 \rho_2^n) \rho_\alpha^n(t, dx) \phi(t, x) dt = 0.$$

Using Lemma 3.2, we can pass to the limit in the latter equation and obtain,

$$\int_0^T \int_{\mathbb{R}} \partial_t \phi(t, x) \rho_\alpha(t, dx) dt + \chi_\alpha \int_0^T \int_{\mathbb{R}} \hat{a}(\theta_1 \rho_1 + \theta_2 \rho_2) \rho_\alpha(t, dx) \phi(t, x) dt = 0.$$

Thus ρ_α satisfies (2.5) in the sense of distributions. From Proposition 3.3, the macroscopic velocity $a^n(\rho^n)$ satisfies an uniform OSL condition. Then, by weak stability of duality solutions in (see Theorem 2.3 (3)), we deduce that

$$\partial_t \rho_\alpha + \chi_\alpha \partial_x (\hat{a}(\rho) \rho_\alpha) = 0, \quad \text{for } \alpha = 1, 2, \quad \text{in the sense of duality in }]0, T[\times \mathbb{R}.$$

Step 3 : Finite second order moment.

From Equation (2.5), we deduce that the first and second moments satisfy in the sense of distributions

$$\begin{aligned} \frac{d}{dt} \left(\int |x| \rho_\alpha(t, dx) \right) &= - \int \text{sgn}(x) \hat{a}(\rho) \rho_\alpha(t, dx), \\ \frac{d}{dt} \left(\int |x|^2 \rho_\alpha(t, dx) \right) &= -2 \int \hat{a}(\rho) \rho_\alpha(t, dx), \quad \text{for } \alpha = 1, 2. \end{aligned}$$

Since $\rho_\alpha^{ini} \in \mathcal{P}_2(\mathbb{R})$ and $\hat{a}(\rho)$ is bounded from ((H2)), we deduce that the first two moments of ρ_α are finite, then $\rho_\alpha(t) \in \mathcal{P}_2(\mathbb{R})$ for $t > 0$. \square

Remark 4.1. If we define the weighted center of mass of the system x_c as follows:

$$x_c(t) := \frac{\theta_1}{\chi_1} \int_{\mathbb{R}} x \rho_1(t, dx) + \frac{\theta_2}{\chi_2} \int_{\mathbb{R}} x \rho_2(t, dx).$$

We remark from straightforward computation that $\frac{d}{dt} x_c = 0$. Then the weighted center of mass is conserved for this system.

4.2. Proof of the uniqueness of duality solutions in Theorem 2.5. Uniqueness relies on a stability estimate in Wasserstein distance, which is the metric endowed in $\mathcal{P}_2(\mathbb{R})$. This Wasserstein distance d_W is defined by (see e.g. [26, 27])

$$d_W(\nu, \mu) = \inf_{\gamma \in \Gamma(\nu, \mu)} \left\{ \int_{\mathbb{R}^2} |y - x|^2 \gamma(dx, dy) \right\}^{1/2},$$

where $\Gamma(\mu, \nu)$ is the set of measures on $\mathbb{R}^2 \times \mathbb{R}^2$ with marginals μ and ν , i.e.,

$$\Gamma(\nu, \mu) = \left\{ \gamma \in \mathcal{P}_2(\mathbb{R} \times \mathbb{R}), \forall \xi \in C_0(\mathbb{R} \times \mathbb{R}), \int_{\mathbb{R}^2} \xi(y_0) \gamma(dy_0, dy_1) = \int_{\mathbb{R}} \xi(y_0) \mu(dy_0), \right. \\ \left. \int_{\mathbb{R}^2} \xi(y_1) \gamma(dy_0, dy_1) = \int_{\mathbb{R}} \xi(y_1) \nu(dy_1) \right\}.$$

The Wasserstein distance d_W takes a more practical form in the one-dimensional setting. Indeed, in one space dimension, we have (see e.g [23, 26])

$$d_W(\nu, \mu)^2 = \int_0^1 |F_\nu^{-1}(z) - F_\mu^{-1}(z)|^2 dz,$$

where F_ν^{-1} and F_μ^{-1} are the generalised inverse of cumulative distributions of ν and μ , defined by

$$F_\nu^{-1}(z) = \inf\left\{x \in \mathbb{R}, \nu((-\infty, x)) > z\right\}, \quad F_\mu^{-1}(z) = \inf\left\{x \in \mathbb{R}, \mu((-\infty, x)) > z\right\}.$$

This Wasserstein distance can be extended to the product space $\mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R})$. In the case at hand, we define $W_2(\nu, \mu)$ by

$$(4.4) \quad W_2(\nu, \mu)^2 = \int_0^1 |F_{\nu_1}^{-1}(z) - F_{\mu_1}^{-1}(z)|^2 dz + \frac{\chi_1 \theta_2}{\chi_2 \theta_1} \int_0^1 |F_{\nu_2}^{-1}(z) - F_{\mu_2}^{-1}(z)|^2 dz,$$

where $\nu = \begin{pmatrix} \nu_1 \\ \nu_2 \end{pmatrix}, \mu = \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} \in \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R})$ and $F_{\nu_\alpha}^{-1}, F_{\mu_\alpha}^{-1}$ are the generalised inverse of cumulative distributions of ν_α and μ_α for $\alpha = 1, 2$, respectively. Using W_2 we prove a contraction inequality between duality solutions of (1.1).

Proposition 4.2. *Let $\mu^{ini} = \begin{pmatrix} \mu_1^{ini} \\ \mu_2^{ini} \end{pmatrix}$ and $\nu^{ini} = \begin{pmatrix} \nu_1^{ini} \\ \nu_2^{ini} \end{pmatrix}$ be in $\mathcal{P}_2(\mathbb{R})^2$. We define $\mu = \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix}$*

and $\nu = \begin{pmatrix} \nu_1 \\ \nu_2 \end{pmatrix}$ duality solutions of (1.1) with respectively the initial data μ^{ini}, ν^{ini} .

Then $W_2(\mu, \nu)$ defined in (4.4) is bounded and satisfies the estimate:

$$W_2(\mu, \nu) \leq W_2(\mu^{ini}, \nu^{ini}) \exp(2\lambda(\chi_1 + \chi_2)(\theta_1 + \theta_2)t).$$

Proof. Since $(\mu, \nu) \in \mathcal{P}_2(\mathbb{R})^2 \times \mathcal{P}_2(\mathbb{R})^2$, $W_2(\mu, \nu)$ is bounded. For the sake of clarity in the proof, we denote

$$F_\alpha^{-1} := F_{\nu_\alpha}^{-1}, \quad G_\alpha^{-1} := F_{\mu_\alpha}^{-1}, \quad \text{for } \alpha = 1, 2.$$

We also omit the argument t in notations $F_\alpha^{-1}(t, x)$ and $G_\alpha^{-1}(t, x)$. Computing the derivative of $W_2(\mu, \nu)^2$ with respect to time,

$$\begin{aligned} \partial_t W_2(\mu, \nu)^2 &= 2 \int_0^1 (F_1^{-1}(x) - G_1^{-1}(x)) (\partial_t F_1^{-1}(x) - \partial_t G_1^{-1}(x)) dx \\ &\quad + 2 \frac{\chi_1 \theta_2}{\chi_2 \theta_1} \int_0^1 (F_2^{-1}(x) - G_2^{-1}(x)) (\partial_t F_2^{-1}(x) - \partial_t G_2^{-1}(x)) dx. \end{aligned}$$

Straightforward and standard computations give that

$$\partial_t F_\alpha^{-1}(x) = \chi_\alpha \hat{a}(t, F_\alpha^{-1}(x)), \quad \partial_t G_\alpha^{-1}(x) = \chi_\alpha \hat{a}(t, G_\alpha^{-1}(x)), \quad \text{for } \alpha = 1, 2.$$

From the definition of \hat{a} in (2.6), we get

$$\partial_t F_1^{-1}(x) = \chi_1 \theta_1 \int_0^1 \widehat{\partial_x K}(F_1^{-1}(x) - z) \mu_1(t, dz) + \chi_1 \theta_2 \int_0^1 \widehat{\partial_x K}(F_1^{-1}(x) - z) \mu_2(t, dz).$$

Setting $z = F_1^{-1}(y)$ in the first integral and $z = F_2^{-1}(y)$ in the second one yields

$$\partial_t F_1^{-1}(x) = \chi_1 \theta_1 \int_0^1 \widehat{\partial_x K}(F_1^{-1}(x) - F_1^{-1}(y)) dy + \chi_1 \theta_2 \int_0^1 \widehat{\partial_x K}(F_1^{-1}(x) - F_2^{-1}(y)) dy.$$

Similarly, we get

$$\partial_t G_1^{-1}(x) = \chi_1 \theta_1 \int_0^1 \widehat{\partial_x K}(G_1^{-1}(x) - G_1^{-1}(y)) dy + \chi_1 \theta_2 \int_0^1 \widehat{\partial_x K}(G_1^{-1}(x) - G_2^{-1}(y)) dy.$$

Using the oddness of $\partial_x K$, we can symmetrise the terms in the right-hand side of $\partial_t F_1^{-1}$, $\partial_t G_1^{-1}$. One gets

$$\begin{aligned} & \int_0^1 (F_1^{-1}(x) - G_1^{-1}(x)) (\partial_t F_1^{-1}(x) - \partial_t G_1^{-1}(x)) dx = \\ & \quad \frac{1}{2} \chi_1 \theta_1 \int_0^1 \int_0^1 \left(\widehat{\partial_x K}(F_1^{-1}(x) - F_1^{-1}(y)) - \widehat{\partial_x K}(G_1^{-1}(x) - G_1^{-1}(y)) \right) \times \\ & \quad \quad \quad (F_1^{-1}(x) - G_1^{-1}(x) - (F_1^{-1}(y) - G_1^{-1}(y))) dx dy \\ & + \chi_1 \theta_2 \int_0^1 \int_0^1 \left(\widehat{\partial_x K}(F_1^{-1}(x) - F_2^{-1}(y)) - \widehat{\partial_x K}(G_1^{-1}(x) - G_2^{-1}(y)) \right) (F_1^{-1}(x) - G_1^{-1}(x)) dy dx. \end{aligned}$$

Similar computations can be carried out for $\int_0^1 (F_2^{-1}(t, x) - G_2^{-1}(t, x)) (\partial_t F_2^{-1}(t, x) - \partial_t G_2^{-1}(t, x))$. Finally, $\partial_t W_2(\nu, \mu)^2$ reads

$$\begin{aligned} (4.5) \quad \partial_t W_2(\nu, \mu)^2 &= \chi_1 \theta_1 \int_0^1 \int_0^1 \left(\widehat{\partial_x K}(F_1^{-1}(x) - F_1^{-1}(y)) - \widehat{\partial_x K}(G_1^{-1}(x) - G_1^{-1}(y)) \right) \times \\ & \quad (F_1^{-1}(x) - G_1^{-1}(x) - (F_1^{-1}(y) - G_1^{-1}(y))) dx dy \\ & + \frac{\chi_1 \theta_2^2}{\theta_1} \int_0^1 \int_0^1 \left(\widehat{\partial_x K}(F_2^{-1}(x) - F_2^{-1}(y)) - \widehat{\partial_x K}(G_2^{-1}(x) - G_2^{-1}(y)) \right) \times \\ & \quad (F_2^{-1}(x) - G_2^{-1}(x) - (F_2^{-1}(y) - G_2^{-1}(y))) dx dy \\ & + 2\chi_1 \theta_2 \int_0^1 \int_0^1 \left(\widehat{\partial_x K}(F_1^{-1}(x) - F_2^{-1}(y)) - \widehat{\partial_x K}(G_1^{-1}(x) - G_2^{-1}(y)) \right) \times \\ & \quad (F_1^{-1}(x) - F_2^{-1}(y) - (G_1^{-1}(x) - G_2^{-1}(y))) dx dy. \end{aligned}$$

Applying inequality (2.1) to (4.5) and using Young's inequality yields

$$\partial_t W_2(\nu, \mu)^2 \leq 4\chi_1 \lambda \times \left((\theta_1 + \theta_2) \int_0^1 (F_1^{-1}(x) - G_1^{-1}(x))^2 dx + (\theta_2 + \frac{\theta_2^2}{\theta_1}) \int_0^1 (F_2^{-1}(x) - G_2^{-1}(x))^2 dx \right).$$

By definition of W_2 (4.4), we conclude

$$\partial_t W_2(\nu, \mu)^2 \leq 4\lambda(\chi_1 + \chi_2)(\theta_1 + \theta_2)W_2(\nu, \mu)^2.$$

Then the result follows from Gronwall's Lemma. \square

Proof of uniqueness. From Proposition 4.2, it is clear that if $\mu^{ini} = \nu^{ini}$, then $\mu = \nu$. We deduce uniqueness of duality solution in Theorem 2.5.

4.3. Equivalence with gradient flow. We recall that $\mu \in AC^2([0, T], \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R}))$ if μ is locally Hölder continuous of exponent 1/2 with respect to the Wasserstein distance W_2 in $\mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R})$.

Proposition 4.3. *Let assumptions of Theorem 2.5 hold. Given $\rho^{ini} = \begin{pmatrix} \rho_1^{ini} \\ \rho_2^{ini} \end{pmatrix} \in \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R})$.*

Let $\rho = \begin{pmatrix} \rho_1 \\ \rho_2 \end{pmatrix}$ and $\tilde{\rho} = \begin{pmatrix} \tilde{\rho}_1 \\ \tilde{\rho}_2 \end{pmatrix}$ be respectively the duality and gradient flow solution. Then, we have $\rho \in AC^2([0, T], \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R}))$ and $\rho = \tilde{\rho}$.

Proof. We have that $\begin{pmatrix} \hat{a}(\rho) \\ \hat{a}(\rho) \end{pmatrix} \in L^1([0, T], L^2(\rho_1 \otimes \rho_2, \mathbb{R}^2))$. This comes from the fact that $\partial_x K$ is bounded and

$$\left| \int_{\mathbb{R}} \widehat{\partial_x K}(x-y)(\theta_1 \rho_1(t, dy) + \theta_2 \rho_2(t, dy)) \right| \leq \|\partial_x K\|_{L^\infty}(\theta_1 + \theta_2).$$

From Theorem 8.3.1 in [1], we deduce that $\rho \in AC^2([0, T], \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R}))$. Since ρ satisfies (2.5) in the distributional sense, we deduce by uniqueness of such solution that $\tilde{\rho}$ is a gradient flow solution.

Conversely, we suppose that $\tilde{\rho}$ is a gradient flow solution, we have that $\rho \in C([0, T], \mathcal{P}_2(\mathbb{R}) \times \mathcal{P}_2(\mathbb{R}))$ and ρ verifies (2.5)–(2.6). By uniqueness of the solution in Theorem 2.5, we deduce that $\rho = \tilde{\rho}$. \square

5. CONVERGENCE FOR THE KINETIC MODEL

The convergence of the kinetic model (1.2) towards the aggregation model is analysed in this section.

Proof of Theorem 2.6. From the assumption $\chi^\alpha(\theta_1 + \theta_2) < 1$ for $\alpha = 1, 2$, we obtain that $T_\alpha[S]$ defined in (1.3) is positive. Since $T_\alpha[S]$ is a bounded and Lipschitz continuous function, we get the global in time existence of solutions to (1.2) and we have that $f_\alpha^\varepsilon \in C([0, T], L^\infty \cap L_1^+(\mathbb{R}))$ and $\int x^2 f_\alpha^\varepsilon dx < \infty$.

To prove the convergence result stated in Theorem 2.6, we consider the zeroth and first order moments of the distribution $f_\alpha^\varepsilon(x, v, t)$ introduced previously.

$$\rho_\alpha^\varepsilon := f_\alpha^\varepsilon(1) + f_\alpha^\varepsilon(-1), \quad J_\alpha^\varepsilon := (f_\alpha^\varepsilon(1) - f_\alpha^\varepsilon(-1)), \quad \text{for } \alpha = 1, 2.$$

From (1.2), these moments satisfy the following equations

$$(5.1) \quad \begin{aligned} \partial_t \rho_\alpha^\varepsilon + \partial_x J_\alpha^\varepsilon &= 0, \\ \partial_t J_\alpha^\varepsilon + \partial_x \rho_\alpha^\varepsilon &= \frac{2}{\varepsilon} (\chi_\alpha \partial_x S^\varepsilon \rho_\alpha^\varepsilon - J_\alpha^\varepsilon), \quad \text{for } \alpha = 1, 2. \end{aligned}$$

From the first equation of (5.1), we deduce that $\forall t \in [0, T]$, $|\rho_\alpha^\varepsilon|(t, \mathbb{R}) = |\rho_\alpha^{ini}|(\mathbb{R})$. Therefore, for all $t \in [0, T]$ the sequence $(\rho_\alpha^\varepsilon(t, \cdot))_\varepsilon$ is relatively compact in $\mathcal{M}_b(\mathbb{R}) - \sigma(\mathcal{M}_b(\mathbb{R}), C_0^0(\mathbb{R}))$. Since J_α^ε is uniformly bounded in $C^0([0, T], L^1(\mathbb{R}))$, using the same token as in the proof of the existence, there exists $\rho_\alpha \in \mathcal{S}_M$ such that

$$\rho_\alpha^\varepsilon \rightharpoonup \rho_\alpha \quad \text{weakly in } \mathcal{S}_M, \quad \text{for } \alpha = 1, 2.$$

From the second equation of (5.1), we have

$$\begin{aligned} J_\alpha^\varepsilon &= \chi_\alpha \partial_x S^\varepsilon \rho_\alpha^\varepsilon - \frac{\varepsilon}{2} (\partial_t J_\alpha^\varepsilon + \partial_x \rho_\alpha^\varepsilon), \quad \text{in the distributional sense} \\ &:= A^\varepsilon + R^\varepsilon. \end{aligned}$$

We have that R^ε converges weakly to zero in the sense of distributions. From Lemma 3.2, one obtains

$$\int_0^T \int_{\mathbb{R}} \hat{a}(\theta_1 \rho_1^\varepsilon + \theta_2 \rho_2^\varepsilon) \phi(t, x) \rho_\alpha^\varepsilon(t, dx) dt \rightarrow \int_0^T \int_{\mathbb{R}} \hat{a}(\theta_1 \rho_1 + \theta_2 \rho_2) \phi(t, x) \rho_\alpha(t, dx) dt.$$

We conclude that

$$J_\alpha^\varepsilon \rightharpoonup \chi_\alpha \hat{a}(\theta_1 \rho_1 + \theta_2 \rho_2) \rho_\alpha \quad \text{in the sense of distributions.}$$

Passing to the limit in the first equation of (5.1), we deduce that ρ_α satisfies (2.5) in the sense of distributions. We use uniqueness of duality solutions to conclude the proof. \square

6. NUMERICAL SIMULATIONS

This section is devoted to the numerical simulation of system (2.5). We provide a numerical scheme which preserves basic properties of the system such as positivity, conservation of mass for each species and conservation of the weighted center of mass. Moreover, we prove the convergence of the numerical approximation towards the duality solution defined in Theorem 2.5.

6.1. Numerical scheme and properties. Let us consider a cartesian grid of time step Δt and space step Δx . We denote $x_j = j\Delta x, j \in \mathbb{Z}, t^n = n\Delta t, n \in \mathbb{N}$. An approximation of $\rho_\alpha(t^n, x_j)$ denoted $\rho_{\alpha,j}^n$ is computed by using a finite volume approach where the flux $F_{\alpha,j-1/2}^n$ is given by the flux vector splitting method (see [15]). Assuming that $(\rho_{\alpha,j}^n)$ are known at time t^n , we compute $\rho_{\alpha,j}^{n+1}$ by the scheme:

$$(6.1) \quad \begin{cases} \frac{\rho_{\alpha,j}^{n+1} - \rho_{\alpha,j}^n}{\Delta t} + \frac{F_{\alpha,j+1/2}^n - F_{\alpha,j-1/2}^n}{\Delta x} = 0 & \text{for } \alpha = 1, 2 \text{ and } j \in \mathbb{Z}, \\ F_{\alpha,j-1/2}^n = (\hat{a}_{j-1}^n)^+ \rho_{\alpha,j-1}^n + (\hat{a}_j^n)^- \rho_{\alpha,j}^n, \\ \hat{a}_j^n = \sum_{i \neq j} \partial_x K(x_j - x_i) (\theta_1 \rho_{1,i}^n + \theta_2 \rho_{2,i}^n), \end{cases}$$

where $(\cdot)^+ := \max\{\cdot, 0\}$, $(\cdot)^- := \min\{\cdot, 0\}$ are respectively the positive and negative part of (\cdot) . Then we reconstruct

$$\rho_{\alpha,\Delta x}(t, x) = \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^n \mathbb{1}_{[t^n, t^{n+1}[}(t) \delta_{x_j}(x),$$

where δ_{x_j} is the Dirac delta function at $x_j = j\Delta x$. We first verify that this scheme allows the conservation of the mass and of the weighted center of mass.

Proposition 6.1. *Let us consider $(\rho_1^{ini}, \rho_2^{ini}) \in \mathcal{P}_2(\mathbb{R})^2$ such that for $\alpha = 1, 2$, $\rho_\alpha^{ini} = \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^0 \delta_{x_j}$. We assume that for $n \in \mathbb{N}^*$, $(\rho_{\alpha,j}^n)_{j,n}$ are given by the numerical scheme (6.1). Then the conservation of the mass of each species and of the weighted center of mass hold:*

$$(6.2) \quad \forall n \in \mathbb{N}, \quad \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^{n+1} = \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^n \quad \text{for } \alpha = 1, 2,$$

$$(6.3) \quad \forall n \in \mathbb{N}, \quad \frac{\theta_1}{\chi_1} \sum_{j \in \mathbb{Z}} x_j \rho_{1,j}^{n+1} + \frac{\theta_2}{\chi_2} \sum_{j \in \mathbb{Z}} x_j \rho_{2,j}^{n+1} = \frac{\theta_1}{\chi_1} \sum_{j \in \mathbb{Z}} x_j \rho_{1,j}^n + \frac{\theta_2}{\chi_2} \sum_{j \in \mathbb{Z}} x_j \rho_{2,j}^n.$$

Proof. Identity (6.2) can be obtained directly by summing over $j \in \mathbb{Z}$ the first equation in (6.1).

We now show (6.3). Multiplying by x_j the first equation in (6.1) and summing over $j \in \mathbb{Z}$, one gets

$$\begin{aligned} \frac{1}{\chi_\alpha} \sum_{j \in \mathbb{Z}} x_j \rho_{\alpha,j}^{n+1} &= \frac{1}{\chi_\alpha} \sum_{j \in \mathbb{Z}} x_j \rho_{\alpha,j}^n - \frac{\Delta t}{\Delta x} \sum_{j \in \mathbb{Z}} x_j (\hat{a}_j^n)^+ \rho_{\alpha,j}^n + \frac{\Delta t}{\Delta x} \sum_{j \in \mathbb{Z}} x_j (\hat{a}_{j-1}^n)^+ \rho_{\alpha,j-1}^n \\ &\quad + \frac{\Delta t}{\Delta x} \sum_{j \in \mathbb{Z}} x_j (\hat{a}_j^n)^- \rho_{\alpha,j}^n - \frac{\Delta t}{\Delta x} \sum_{j \in \mathbb{Z}} x_j (\hat{a}_{j+1}^n)^- \rho_{\alpha,j+1}^n, \quad \text{for } \alpha = 1, 2. \end{aligned}$$

Using a discrete integration by parts, one gets

$$\frac{1}{\chi_\alpha} \sum_{j \in \mathbb{Z}} x_j \rho_{\alpha,j}^{n+1} = \frac{1}{\chi_\alpha} \sum_{j \in \mathbb{Z}} x_j \rho_{\alpha,j}^n + \Delta t \sum_{j \in \mathbb{Z}} ((\hat{a}_j^n)^+ + (\hat{a}_j^n)^-) \rho_{\alpha,j}^n = \frac{1}{\chi_\alpha} \sum_{j \in \mathbb{Z}} x_j \rho_{\alpha,j}^n + \Delta t \sum_{j \in \mathbb{Z}} \hat{a}_j^n \rho_{\alpha,j}^n.$$

Finally, we get

$$\frac{\theta_1}{\chi_1} \sum_{j \in \mathbb{Z}} x_j \rho_{1,j}^{n+1} + \frac{\theta_2}{\chi_2} \sum_{j \in \mathbb{Z}} x_j \rho_{2,j}^{n+1} = \frac{\theta_1}{\chi_1} \sum_{j \in \mathbb{Z}} x_j \rho_{1,j}^n + \frac{\theta_2}{\chi_2} \sum_{j \in \mathbb{Z}} x_j \rho_{2,j}^n + \Delta t \sum_{j \in \mathbb{Z}} \hat{a}_j^n (\theta_1 \rho_{1,j}^n + \theta_2 \rho_{2,j}^n).$$

From (6.1), we have that

$$\sum_{j \in \mathbb{Z}} \hat{a}_j^n (\theta_1 \rho_{1,j}^n + \theta_2 \rho_{2,j}^n) = \sum_{i \neq j} \partial_x K(x_j - x_i) (\theta_1 \rho_{1,j}^n + \theta_2 \rho_{2,j}^n) (\theta_1 \rho_{1,i}^n + \theta_2 \rho_{2,i}^n).$$

Swapping indices i and j and using the oddness of $\partial_x K$ yields

$$\sum_{j \in \mathbb{Z}} \hat{a}_j^n (\theta_1 \rho_{1,j}^n + \theta_2 \rho_{2,j}^n) = 0.$$

Then (6.3) follows. \square

Lemma 6.2. *Let $(\rho_1^{ini}, \rho_2^{ini})$ be in $\mathcal{P}_2(\mathbb{R})^2$ such that $\rho_\alpha^{ini} = \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^0 \delta_{x_j}$ with $\sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^0 = 1$ and $\rho_{\alpha,j} \geq 0$ for $\alpha = 1, 2$. Assuming that for $n \in \mathbb{N}^*$, $(\rho_{\alpha,j}^n)_{j,n}$ are given by the numerical scheme (6.1). If the following CFL condition holds*

$$(6.4) \quad \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2) \frac{\Delta t}{\Delta x} < 1,$$

Then for all $n \in \mathbb{N}$, $\rho_{\alpha,j}^n \geq 0$ and we have $\sup_{j,n} |\hat{a}_j^n| \leq \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2)$.

Proof. This result is proved by induction. Let us assume that at time n , for all $j \in \mathbb{Z}$, $\rho_{\alpha,j}^n$ is positive and $\sup_j |\hat{a}_j^n| \leq \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2)$. From (6.1), it follows that

$$(6.5) \quad \rho_{\alpha,j}^{n+1} = \left(1 - \frac{\Delta t}{\Delta x} |\hat{a}_j^n|\right) \rho_{\alpha,j}^n + \frac{\Delta t}{\Delta x} (\hat{a}_{j-1}^n)^+ \rho_{\alpha,j-1}^n - \frac{\Delta t}{\Delta x} (\hat{a}_{j+1}^n)^- \rho_{\alpha,j+1}^n.$$

Using the condition (6.4) and the fact that $\sup_j |\hat{a}_j^n| \leq \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2)$, we get that $\frac{\Delta t}{\Delta x} |\hat{a}_j^n| < 1$. Therefore $\rho_{\alpha,j}^{n+1}$ is positive as a linear combination of positive numbers.

Then, recalling the expression of \hat{a}_j^n given in (6.1), using the fact that $\rho_{\alpha,j}^{n+1}$, $j \in \mathbb{Z}$, are positive and the conservation of the mass, (6.2) yields

$$|\hat{a}_j^{n+1}| \leq \|\partial_x K\|_{L^\infty} (\theta_1 + \theta_2).$$

\square

6.2. Convergence of the numerical solution to the theoretical solution. In this part, we prove that the numerical scheme given in (6.1) converges to the duality solution obtained in Theorem 2.5.

Theorem 6.3 (Convergence of the numerical scheme). *Let $T > 0$, $\Delta x > 0$ and $\Delta t > 0$ such that (6.4) is satisfied and denote $N_t = \frac{T}{\Delta t}$. Let $\rho_\alpha^{ini} \in \mathcal{P}_2(\mathbb{R})$, we define*

$$\rho_{\alpha,j}^0 = \int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} \rho_\alpha^{ini}(x) dx, \quad j \in \mathbb{Z}.$$

Let us define $\rho_{\alpha,\Delta x} \in \mathcal{M}_b([0, T] \times \mathbb{R})$ by

$$(6.6) \quad \rho_{\alpha,\Delta x}(t, x) = \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^n \mathbb{1}_{[t^n, t^{n+1}[}(t) \delta_{x_j}(x),$$

where $(\rho_{\alpha,j}^n)_{j,n}$ computed by (6.1).

Then, we have

$$\rho_{\alpha,\Delta x} \rightharpoonup \rho_\alpha \text{ weakly in } \mathcal{M}_b([0,T] \times \mathbb{R}) \text{ as } \Delta x \rightarrow 0,$$

where ρ_α is the duality unique solution of Theorem 2.5 with initial data ρ_α^{ini} .

Proof of Theorem 6.3. For the initial data, it is clear that when $\Delta x \rightarrow 0$, we have $\rho_{\alpha,\Delta x}(t=0) \rightharpoonup \rho_\alpha^{ini}$ weakly. From Lemma 6.2, we get that for all $j \in \mathbb{Z}, n \in \mathbb{N}$, values of $\rho_{\alpha,j}^n$ are positive.

Step 1: Extraction of a convergent subsequence

Equation (6.2) implies that the total variation of $\rho_{\alpha,\Delta x}$ is fixed and independant of Δx .

$$|\rho_{\alpha,\Delta x}|([0,T] \times \mathbb{R}) = T \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^{ini}.$$

Therefore, there exists a subsequence of $\rho_{\alpha,\Delta x}$ that converges weakly to $\rho_\alpha \in \mathcal{M}_b([0,T] \times \mathbb{R})$.

Step 2: Modified equation satisfied by $\rho_{\alpha,\Delta x}$

Let be $\phi \in C_c^\infty((0,T) \times \mathbb{R})$. From the definition of $\rho_{\alpha,\Delta x}$ in (6.6), we have

$$\langle \partial_t \rho_{\alpha,\Delta x}, \phi \rangle = - \int_{[0,T] \times \mathbb{R}} \rho_{\alpha,\Delta x} \partial_t \phi = - \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^n \int_{t^n}^{t^{n+1}} \partial_t \phi(x_j, t) dt,$$

Here and below we use $\langle \cdot, \cdot \rangle$ to denote the dual product in the sense of distributions. Discrete integration by parts yields

$$\langle \partial_t \rho_{\alpha,\Delta x}, \phi \rangle = - \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \rho_{\alpha,j}^n (\phi_j^{n+1} - \phi_j^n) = \sum_{n=1}^{N_t} \sum_{j \in \mathbb{Z}} (\rho_{\alpha,j}^n - \rho_{\alpha,j}^{n-1}) \phi_j^n,$$

where we use the notation $\phi_j^n := \phi(x_j, t^n)$. Using (6.5) and applying transformations to indices yields

$$\langle \partial_t \rho_{\alpha,\Delta x}, \phi \rangle = \frac{\Delta t}{\Delta x} \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} (\hat{a}_j^n)^+ \rho_{\alpha,j}^n (\phi_{j+1}^{n+1} - \phi_j^{n+1}) + \frac{\Delta t}{\Delta x} \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} (\hat{a}_j^n)^- \rho_{\alpha,j}^n (\phi_j^{n+1} - \phi_{j-1}^{n+1}).$$

Taylor expansions gives the existence of ζ^j in (x_j, x_{j+1}) and $\hat{\zeta}^j$ in (x_{j-1}, x_j) such that

$$\begin{aligned} \phi_{j+1}^{n+1} &= \phi_j^{n+1} + \Delta x \partial_x \phi_j^{n+1} + \frac{(\Delta x)^2}{2} \partial_{xx} \phi(\zeta^j, t^{n+1}), \\ \phi_{j-1}^{n+1} &= \phi_j^{n+1} - \Delta x \partial_x \phi_j^{n+1} + \frac{(\Delta x)^2}{2} \partial_{xx} \phi(\hat{\zeta}^j, t^{n+1}). \end{aligned}$$

Putting together, one obtains

$$\langle \partial_t \rho_{\alpha,\Delta x}, \phi \rangle = \Delta t \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \hat{a}_j^n \rho_{\alpha,j}^n \partial_x \phi_j^{n+1} + R_\alpha^1(\Delta x, \Delta t),$$

where $R_\alpha^1(\Delta x, \Delta t)$ is given by

$$\begin{aligned} R_\alpha^1(\Delta x, \Delta t) &:= \frac{\Delta t}{\Delta x} \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} (\hat{a}_j^n)^+ \rho_{\alpha,j}^n \left(\frac{(\Delta x)^2}{2} \partial_{xx} \phi(\zeta^j, t^{n+1}) \right) \\ &\quad - \frac{\Delta t}{\Delta x} \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} (\hat{a}_j^n)^- \rho_{\alpha,j}^n \left(\frac{(\Delta x)^2}{2} \partial_{xx} \phi(\hat{\zeta}^j, t^{n+1}) \right). \end{aligned}$$

From (6.6) and the definition of \hat{a} in (2.6), we have

$$\hat{a}(\theta_1\rho_{1,\Delta x} + \theta_2\rho_{2,\Delta x}) = \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \hat{a}_j^n \mathbb{1}_{[t^n, t^{n+1}[}(t) \delta_{x_j}(x).$$

where \hat{a}_j^n are defined in (6.1). We get that

$$\langle \hat{a}(\theta_1\rho_{1,\Delta x} + \theta_2\rho_{2,\Delta x})\rho_{\alpha,\Delta x}, \partial_x \phi \rangle = - \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \hat{a}_j^n \rho_{\alpha,j}^n \int_{t^n}^{t^{n+1}} \partial_x \phi(x_j, t) dt.$$

From the Taylor expansion of $\partial_x \phi(x_j, t)$:

$$\partial_x \phi(x_j, t) = \partial_x \phi(x_j, t^{n+1}) + (t - t^{n+1}) \partial_{xt} \phi(x_j, \tau_t^n),$$

with $\tau_t^n \in (t, t^{n+1})$, one sees that

$$\langle \hat{a}(\theta_1\rho_{1,\Delta x} + \theta_2\rho_{2,\Delta x})\rho_{\alpha,\Delta x}, \partial_x \phi \rangle = -\Delta t \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \hat{a}_j^n \rho_{\alpha,j}^n \partial_x \phi_j^{n+1} + R_\alpha^2(\Delta x, \Delta t),$$

where $R_\alpha^2(\Delta x, \Delta t)$ is defined as follows:

$$R_\alpha^2(\Delta x, \Delta t) := - \sum_{n=0}^{N_t-1} \sum_{j \in \mathbb{Z}} \hat{a}_j^n \rho_{\alpha,j}^n \int_{t^n}^{t^{n+1}} (t - t^{n+1}) \partial_{xt} \phi(x_j, \tau_t^n) dt.$$

The modified equation satisfied by $\rho_{\alpha,\Delta x}$ in the distributional sense writes:

$$\int_0^T \int_{\mathbb{R}} \rho_{\alpha,\Delta x} \partial_t \phi(t, x) + \int_0^T \int_{\mathbb{R}} \hat{a}(\theta_1\rho_{1,\Delta x} + \theta_2\rho_{2,\Delta x})\rho_{\alpha,\Delta x} \partial_x \phi = R_\alpha^1(\Delta x, \Delta t) + R_\alpha^2(\Delta x, \Delta t).$$

From Lemma 6.2, we deduce that the terms R_α^1 and R_α^2 satisfy the estimates:

$$|R_\alpha^1| \leq CT\Delta x \|\partial_{xx} \phi\|_{L^\infty}, \quad |R_\alpha^2| \leq CT\Delta x \|\partial_{tx} \phi\|_{L^\infty},$$

where C stands for a nonnegative constant. Passing to the limit and using the technical Lemma 3.2, we conclude that the limit ρ_α satisfies (2.5) in the distributional sense with the expression (2.6) for the velocity. By uniqueness result in Theorem 2.5, we deduce that ρ_α is the unique duality solution of (1.1). \square

6.3. Dynamics of aggregates and numerical simulations. In this part, we carry out simulations of Equation (2.5) obtained thanks to scheme (6.1). Before numerically simulating the hydrodynamic behavior of the chemotaxis model, we first clarify the aggregate dynamics of this model, especially on the synchronising dynamics between aggregates of different species.

For the sake of simplicity, we choose $\theta_1 = \theta_2 = 1$ and $K = \frac{1}{2}e^{-|x|}$ in (2.5), which corresponds to the particular case of bacterial chemotaxis (see (1.7)). To illustrate the synchronising dynamics of the aggregates for (2.5), we consider the initial data given by sums of aggregates

$$\rho_1^0 = \sum_k \mu_k \delta_{x_k^0}, \quad \rho_2^0 = \sum_k \nu_k \delta_{y_k^0},$$

and look for a solution in the form

$$\rho_1(t, x) = \sum_k \mu_k \delta_{x_k(t)}, \quad \rho_2(t, x) = \sum_k \nu_k \delta_{y_k(t)}.$$

We denote by u_1 and u_2 antiderivatives of ρ_1 and ρ_2 , respectively. Then the equation (2.5) reads

$$(6.7) \quad \partial_t u_\alpha + \chi_\alpha \hat{a} \rho_\alpha = 0, \quad \alpha = 1, 2,$$

in the sense of distributions. Direct computation shows that

$$\begin{aligned}\hat{a}\rho_1 &= \sum_{k,\ell} \mu_k (\mu_\ell \widehat{\partial_x K}(x_k - x_\ell) + \nu_\ell \widehat{\partial_x K}(x_k - y_\ell)) \delta_{x_k}, \\ \hat{a}\rho_2 &= \sum_{k,\ell} \nu_k (\mu_\ell \widehat{\partial_x K}(y_k - x_\ell) + \nu_\ell \widehat{\partial_x K}(y_k - y_\ell)) \delta_{y_k}.\end{aligned}$$

Injecting these expressions into equation (6.7), the positions x_k and y_k satisfy the system of ODEs

$$\begin{aligned}x'_k(t) &= \chi_1 \sum_{\ell} (\mu_\ell \widehat{\partial_x K}(x_k - x_\ell) + \nu_\ell \widehat{\partial_x K}(x_k - y_\ell)), \\ y'_k(t) &= \chi_2 \sum_{\ell} (\mu_\ell \widehat{\partial_x K}(y_k - x_\ell) + \nu_\ell \widehat{\partial_x K}(y_k - y_\ell)).\end{aligned}$$

We recover the same system for particle solutions as in DiFrancesco and Fagioli [11] for two species. See also similar aggregate dynamics for single species in [5, 18]. In the case of one single species, the system of ODEs is determinant before any collision of aggregates, and after each collision, one can always ‘restart’ the particle system till final collapse of all aggregates. However, the case of collisions between particles of different species is more complex, since it does not necessarily imply whether the particles of different species will synchronise or not after colliding. In fact, as observed in the following simulations, both ‘synchronising’ (colliding particles of different species staying together) and ‘non-synchronising’ cases can occur, and the transitions between the synchronising types may happen, depending on the weighted attraction of other aggregates acting on them.

For illustration, we assume that two points of different species collide at a time t_0 . For instance, take $x_k(t_0) = y_k(t_0)$ for some k , then at this time t_0 we have

$$(6.8) \quad x'_k(t_0) = \chi_1 \gamma_k(t_0), \quad y'_k(t_0) = \chi_2 \gamma_k(t_0), \quad \gamma_k = \sum_{\ell,k} (\mu_\ell \widehat{\partial_x K}(x_k - x_\ell) + \nu_\ell \widehat{\partial_x K}(x_k - y_\ell)).$$

Note that γ_k characterises external weighted attraction on ν_k and μ_k , depending on chemosensitivities, distances to other aggregates and the masses of all other aggregates.

Thus if $\chi_1 \neq \chi_2$ the velocity of species 1 and 2 is not the same at this time t_0 . However, with the special case at hand, $K(x) = \frac{1}{2}e^{-|x|}$, we have $\partial_x K(x_k - y_k) \rightarrow \frac{1}{2}$ when $x_k \xrightarrow{<} y_k$; and $\partial_x K(x_k - y_k) \rightarrow -\frac{1}{2}$ when $x_k \xrightarrow{>} y_k$. We deduce that when $x_k < y_k$ and $x_k \rightarrow y_k$ we have

$$(y_k - x_k)'(t) = -\frac{1}{2}(\chi_1 \nu_k + \chi_2 \mu_k) + (\chi_2 - \chi_1) \gamma_k(t).$$

Obviously, in this case, particles μ_k and ν_k stay together if $(y_k - x_k)'(t) \leq 0$. On the other hand, when $y_k < x_k$ and $y_k \rightarrow x_k$ we have

$$(x_k - y_k)'(t) = -\frac{1}{2}(\chi_1 \nu_k + \chi_2 \mu_k) + (\chi_1 - \chi_2) \gamma_k(t).$$

In this case, particles μ_k and ν_k stay together when $(x_k - y_k)'(t) \leq 0$. Finally, to keep $x_k(t) = y_k(t)$ for $t \geq t_0$, we need the condition

$$(6.9) \quad |(\chi_1 - \chi_2) \gamma_k(t)| \leq \frac{1}{2}(\chi_1 \nu_k + \chi_2 \mu_k),$$

where $\gamma_k(t)$ is defined in (6.8). This relation characterises the weighted attraction of other aggregates acting on them. If the external weighted attraction on ν_k and μ_k (the left hand side of (6.9)) is small, they will stay together. When the external weighted attraction is big, the attraction between ν_k and μ_k is relatively weak and they will move separately, the one with bigger motility will move faster than the other.

We call (6.9) the synchronising condition for μ_k and ν_k . Similarly, we can get the synchronising condition for any μ_i and ν_j , $\forall i, j$. If more than two aggregates collide simultaneously, we can simply replace them by two aggregates of each species, each aggregate accumulating the total mass of each species.

In conclusion, according to the dynamics defined above, we can see that the initial aggregates will collapse such that they eventually form a single aggregate of the two species. The final aggregate can not separate, which is similar but illustrate more complex behaviour as one species case discussed in [18]. Now we give some numerical examples showing “synchronising”, “non-synchronising”, transitions between “synchronising” and “non-synchronising” dynamical behaviours for the hydrodynamic model (2.5).

Example 1: Synchronising dynamics. Take the chemosensitivity constants $\chi_1 = 10$, $\chi_2 = 1$ in (2.5), and consider initial data

$$\rho_1^0 = 4e^{-5000(x+0.5)^2} + 2e^{-5000(x-0.5)^2}, \quad \rho_2^0 = 2e^{-5000(x+0.15)^2}.$$

It corresponds to small bumps located at position $x_1(0) = -0.5$, $y_1(0) = -0.15$, $x_2(0) = 0.5$, with mass $\mu_1 = 4m_0$, $\mu_2 = 2m_0$, $\nu_1 = 2m_0$, where $m_0 = \int_{\mathbb{R}} e^{-5000x^2} dx$. Figure 6.1 displays

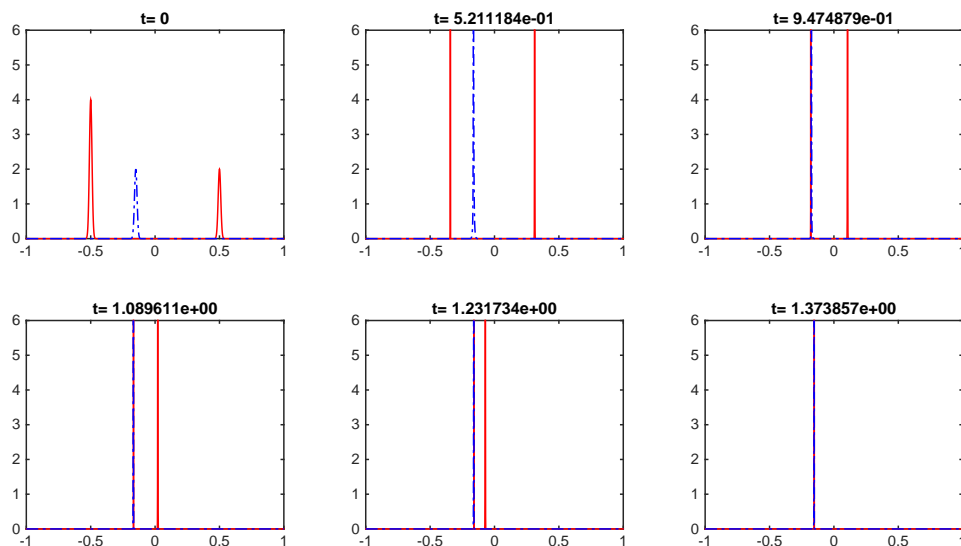

FIGURE 6.1. Example 1. Snapshots of ρ_1 (red solid line) and ρ_2 (blue dashdot). The evolution shows the synchronising dynamics after first collision.

numerical results obtained thanks to the scheme (6.1) defined above. We first observe the fast blow-up with the formation of Dirac deltas. Then, the numerical simulation shows that μ_1 and ν_1 collapse for the first time at $t_1 \approx 0.947$, with $x_1(t_1) = y_1(t_1) \approx -0.18$, and $x_2(t_1) \approx 0.12$. We check the “synchronising condition” (6.9):

$$\begin{aligned} LHS &= |(\chi_1 - \chi_2)\gamma_1(t_1)| = (10 - 1) \times 2 \times \frac{1}{2} e^{-(x_2 - x_1)} = 9e^{-(x_2 - x_1)} < 9, \quad \forall x_1, x_2, \\ RHS &= \frac{1}{2}(\chi_1\nu_1 + \chi_2\mu_1) = \frac{1}{2}(10 \times 2 + 1 \times 4) = 12. \end{aligned}$$

Thus the “synchronising condition” (6.9) is always satisfied, then they will move together afterwards till final collapse with μ_2 . This evolutionary dynamics is shown in Figure 6.1. The numerical result confirms the synchronising dynamics of the aggregates.

Example 2: Non-synchronising dynamics. Take the chemosensitivity constants $\chi_1 = 10$, $\chi_2 = 1$ in (2.5), and consider initial data

$$\rho_1^0 = 2e^{-5000(x+0.5)^2} + 4e^{-5000(x-0.5)^2}, \quad \rho_2^0 = 2e^{-5000(x+0.15)^2}.$$

It corresponds to small bumps located at position $x_1(0) = -0.5$, $y_1(0) = -0.15$, $x_2(0) = 0.5$, with mass $\mu_1 = 2m_0$, $\mu_2 = 4m_0$, $\nu_1 = 2m_0$, where $m_0 = \int_{\mathbb{R}} e^{-5000x^2} dx$. The numerical simulation in Figure 6.2 shows that μ_1 and ν_1 collapse for the first time at $t_1 \approx 0.9$, $x_1(t_1) = y_1(t_1) \approx -0.15$, and $x_2(t_1) \approx 0.25$. Direct computation shows that

$$\begin{aligned} LHS &= |(\chi_1 - \chi_2)\gamma_1(t_1)| = (10 - 1) \times 4 \times \frac{1}{2}e^{-(x_2-x_1)} \approx 18e^{-0.4} \approx 12.066, \\ RHS &= \frac{1}{2}(\chi_1\nu_1 + \chi_2\mu_1) = \frac{1}{2}(10 \times 2 + 1 \times 2) = 11, \end{aligned}$$

thus the ‘‘synchronising condition’’ (6.9) is not satisfied, then they will change their order after intersection and travel separately. The simulation shows μ_1 will collapse with μ_2 at time $t_2 \approx 1.61$, and finally collapse with ν_1 at time $t_3 \approx 1.85$. This dynamics is shown in Figure 6.2. The numerical result confirms the non-synchronising dynamics of the aggregates.

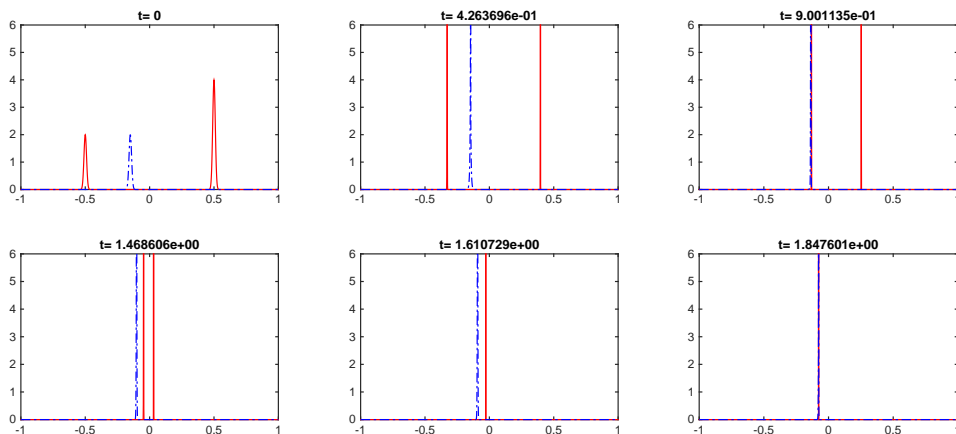

FIGURE 6.2. Example 2. Snapshots of ρ_1 (red solid line) and ρ_2 (blue dashdot). The evolution shows the non-synchronising dynamics after first collision.

Example 3: Transition from synchronising to non-synchronising dynamics. Take the chemosensitivity constants $\chi_1 = 10$, $\chi_2 = 1$ in (2.5), and slightly modify the initial data of Example 2 to

$$\rho_1^0 = 2e^{-5000(x+0.5)^2} + 4e^{-5000(x-0.5)^2}, \quad \rho_2^0 = 2e^{-5000(x+0.3)^2}.$$

It corresponds to small bumps located at position $x_1(0) = -0.5$, $y_1(0) = -0.3$, $x_2(0) = 0.5$, with mass $\mu_1 = 2m_0$, $\mu_2 = 4m_0$, $\nu_1 = 2m_0$. The numerical simulation displayed in Figure 6.3 shows that μ_1 and ν_1 collapse for the first time at $t_1 \approx 0.47$ with $x_1(t_1) = y_1(t_1) \approx -0.29$, and $x_2(t_1) \approx 0.39$. Direct computation shows that

$$\begin{aligned} LHS &= |(\chi_1 - \chi_2)\gamma_1(t_1)| = (10 - 1) \times 4 \times \frac{1}{2}e^{-(x_2-x_1)} \approx 18e^{-0.68} \approx 9.1191, \\ RHS &= \frac{1}{2}(\chi_1\nu_1 + \chi_2\mu_1) = \frac{1}{2}(10 \times 2 + 1 \times 2) = 11, \end{aligned}$$

thus the ‘‘synchronising condition’’ (6.9) is satisfied, then they will move together toward μ_2 . The interesting phenomenon is that, as their distance to μ_2 is decreasing, the LHS of the

“synchronising condition” (6.9) is increasing and finally greater than the RHS. The simulation shows that, at $t_2 \approx 1.04$, $x_1(t_2) = y_1(t_2) \approx -0.26$, and $x_2(t_2) \approx 0.23$, then

$$LHS = |(\chi_1 - \chi_2)\gamma_1(t_1)| = (10 - 1) \times 4 \times \frac{1}{2}e^{-(x_2-x_1)} \approx 18e^{-0.49} \approx 11 = RHS,$$

then after this time t_2 , the interaction type has been changed: the “synchronising condition” (6.9) is no longer satisfied, then they will travel separately. Further simulation shows that μ_1 collapses with μ_2 at time $t_3 \approx 2.037$, and finally collapse with ν_1 at time $t_4 \approx 2.32$. The full dynamics is shown in Figure 6.3. The numerical result shows the transition from synchronising to non-synchronising dynamics of the aggregates.

FIGURE 6.3. Example 3. Snapshots of ρ_1 (red solid line) and ρ_2 (blue dashdot). From time $t_0 = 0$ to $t_1 \approx 0.47$, μ_1 moves toward ν_1 . From time $t_1 \approx 0.47$ to $t_2 \approx 1.04$, μ_1 and ν_1 travel together. The synchronising type changed at t_2 . After time t_2 , μ_1 overtakes ν_1 and collapse with μ_2 at $t_3 \approx 2.037$, and finally all the aggregates collapse at $t_4 \approx 2.32$. The evolution shows the transition from synchronising to non-synchronising dynamics.

Example 4: More complex transition. Take the chemosensitivity constants $\chi_1 = 10$, $\chi_2 = 1$ in (2.5), and consider initial data

$$\rho_1^0 = 3e^{-5000(x+0.8)^2} + 1.5e^{-5000(x+0.02)^2}, \quad \rho_2^0 = 3.5e^{-5000(x-0.02)^2} + 8.5e^{-5000(x-0.5)^2}.$$

It corresponds to small bumps located at position $x_1(0) = -0.8$, $x_2(0) = -0.02$, $y_1(0) = 0.02$, $y_2(0) = 0.5$, with mass $\mu_1 = 3m_0$, $\mu_2 = 1.5m_0$, $\nu_1 = 3.5m_0$, $\nu_2 = 8.5m_0$. The snapshots

of ρ_1 and ρ_2 are shown in Figure 6.4. We observe that μ_2 and ν_1 meet for the first time at

FIGURE 6.4. Example 4. Snapshots of ρ_1 (red solid line) and ρ_2 (blue dashdot).

$t_1 \approx 0.0459$ and satisfy non-synchronising condition so they separate after t_1 . See the snapshot at $t_2 \approx 0.4288$ for evidence. They meet for the second time at $t_3 \approx 0.9494$ but the synchronising type has been changed: now they satisfy synchronising condition thus they travel together afterwards. At time $t_4 \approx 1.04$, μ_1 catches μ_2 and ν_1 . Now we treat them as $(\mu_1 + \mu_2)$ and ν_1 : they satisfy non-synchronising condition and separate, see snapshot at $t_5 \approx 1.256$ for evidence. At time $t_6 \approx 1.684$, $(\mu_1 + \mu_2)$ collapse with ν_2 , satisfying synchronising condition and staying together till final collapse with ν_1 at $t_7 \approx 2.756$. The illustration shows the complex changing of interaction types for the aggregate dynamics of two species chemotaxis model.
