The Goh necessary optimality conditions for the Mayer problem with control constraints

Hélène Frankowska and Daniela Tonon[‡]

Abstract

The well known Goh second order necessary optimality conditions in optimal control theory concern singular optimal controls taking values in the interior of a set of controls U . In this paper we investigate these conditions for the Mayer problem when U is a convex polytope or a closed subset of class C^2 for an integrable optimal control $\bar{u}(\cdot)$ that may take values in the boundary of U . This is indeed a frequent situation in optimal control and for this reason the understanding of this issue is crucial for the theory of second order optimality conditions. Applying the Goh transformation we derive necessary conditions on tangent subspace to U at $\bar{u}(t)$ for almost all t 's.

In the presence of an endpoint constraint, if the Mayer problem is calm, then similar second order necessary optimality conditions are satisfied whenever the maximum principle is abnormal. If it is normal, then analogous results hold true on some smaller subspaces.

1. Introduction

Let $U \subset \mathbb{R}^m$, $K \subset \mathbb{R}^n$ be closed, $x_0 \in \mathbb{R}^n$, $f : [0, 1] \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ and $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}$ be sufficiently regular. Consider the Mayer optimal control problem

$$\min \{ \varphi(x(1)) : x(\cdot) \in S_{[0,1]}(x_0), x(1) \in K \}, \quad (1)$$

where $S_{[0,1]}(x_0)$ is the set of all absolutely continuous solutions of the control system

$$x'(t) = f(t, x(t), u(t)), u(t) \in U, x(0) = x_0. \quad (2)$$

[‡]Daniela Tonon is with Department of Electrical and Electronic Engineering, Imperial College London, Exhibition Road, London, SW7 2BT, UK, dtonon@imperial.ac.uk

Define the Hamiltonian $\mathcal{H} : [0, 1] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$:

$$\mathcal{H}(t, x, p, u) = \langle p, f(t, x, u) \rangle.$$

We first consider the Mayer problem without endpoint constraints:

$$\min \{ \varphi(x(1)) : x(\cdot) \in S_{[0,1]}(x_0) \}. \quad (3)$$

Let $(\bar{x}(\cdot), \bar{u}(\cdot))$ be a strong local minimizer of (3). By the maximum principle, for an absolutely continuous $p : [0, 1] \rightarrow \mathbb{R}^n$ satisfying

$$-p'(t) = \mathcal{H}_x(t, \bar{x}(t), p(t), \bar{u}(t)) \text{ for a.e. } t \in [0, 1] \quad (4)$$

and

$$-p(1) = \nabla \varphi(\bar{x}(1)) \quad (5)$$

the following maximum principle holds true for a.e. t :

$$\langle p(t), f(t, \bar{x}(t), \bar{u}(t)) \rangle = \max_{u \in U} \langle p(t), f(t, \bar{x}(t), u) \rangle. \quad (6)$$

Thus for a.e. $t \in [0, 1]$ such that the optimal control $\bar{u}(t)$ lies in the interior of U , $\mathcal{H}_u[t] = 0$ and the Legendre-Clebsch condition $\mathcal{H}_{uu}[t] \leq 0$ is satisfied, where $[t] := (t, \bar{x}(t), p(t), \bar{u}(t))$. If $\bar{u}(\cdot)$ is singular, in the sense that $\mathcal{H}_{uu}[\cdot] = 0$, the Legendre-Clebsch condition doesn't bring any additional information about optimal controls. Different, but related, definitions of singular controls and discussions on their importance can be found for instance in [1, 2, 3], and the references therein.

Assume that $\mathcal{H}_{uu}[t] = 0$ a.e. in $[t_1, t_2]$. According to [4], if U is an open convex polytope, then the matrix $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric and

$$R(t) := \frac{1}{2} f_u[t]^* \mathcal{H}_{xx}[t] f_u[t] - \frac{1}{2} \frac{d}{dt} \mathcal{H}_{xu}[t] f_u[t] - \mathcal{H}_{xu}[t] f_x[t] f_u[t] + \frac{1}{2} \mathcal{H}_{xu}[t] \frac{d}{dt} f_u[t]$$

is negative definite for a.e. $t \in [t_1, t_2]$. The first property, known in the literature as the Goh condition, in the case of affine control systems reduces to a condition on the Lie brackets of the flux functions, as we recall

in Remark 3.2. The second property can be seen as a generalized Legendre-Clebsch condition.

To deal with closed control constraints Goh also suggested to use variations of the optimal control which are equal to zero when $\bar{u}(t) \in \partial U$. However, this can't be applied to recover second-order optimality conditions when $\bar{u}(t) \in \partial U$ almost everywhere.

We present here a different approach, based on non-zero variations of the optimal control even when $\bar{u}(\cdot)$ is a boundary control.

For every $u \in U$ let us consider the maximal subspace P_u contained in the tangent cone to U at u .

Below, Theorems 4.1 and 5.2 provide pointwise second order necessary optimality conditions respectively in the case when U is a convex polytope or a subset of class C^2 for a singular optimal control $\bar{u}(\cdot)$ being merely integrable. Considering $\mathcal{H}_{xu}[t]f_u[t]$ and $R(t)$ as bilinear operators on the subspace $P_{\bar{u}(t)}$, in both cases, we still have symmetry of $\mathcal{H}_{xu}[t]f_u[t]$. In the former case we also get the negative definiteness of $R(t)$ on $P_{\bar{u}(t)}$.

In Corollary 4.2 we prove that if U is a closed convex polytope in \mathbb{R}^m and f is affine with respect to u :

$$f(x, u) = f_0(x) + g(x)u, \quad (7)$$

with $g(\cdot) \in C^2(\mathbb{R}^n; M(n \times m))$ and if $g_k(x)$ denotes the k -th column of the matrix $g(x)$, then the matrix valued mapping $\Theta : [0, 1] \rightarrow M(m \times m)$, given by

$$\theta_{k,l}(t) := \langle p(t), [g_k, g_l](\bar{x}(t)) \rangle \quad \forall k, l \in \{1, \dots, m\},$$

enjoys the following property: for a.e. $t \in [0, 1]$, the subspace $\Theta(t)$ ($P_{\bar{u}(t)}$) (the image of $P_{\bar{u}(t)}$ by the linear operator $\Theta(t)$) is orthogonal to the subspace $P_{\bar{u}(t)}$. In particular we recover the well known Goh condition in the geometric optimal control: $\Theta(t) = 0$ for a.e. t such that $\bar{u}(t) \in \text{Int } U$.

For the Mayer problem with the endpoint constraint K , we assume calmness at $\bar{x}(\cdot)$. This allows to reduce the problem to the one without endpoint constraints but involving a *nondifferentiable* cost function and so the classical first and second order necessary conditions are not satisfied. Still we are able to derive second order conditions through a variational approach similar to the one without end point constraints.

Since the very first work by Goh, [4], the Goh condition was investigated by many researchers in the geometric optimal control theory following fundamental works by Krener, cf. [5] and [6], on the Goh condition (and its higher order extensions) when the optimal control is piecewise C^∞ . His approach was taken over by several authors and the Goh condition became mostly known in the form involving Lie brackets, as a

second-order necessary optimality condition for the abnormal maximum principle. See for instance [7, 8] and [3, pp.314-319].

Several authors made an extensive use of the Goh transformation to recover necessary and sufficient second order optimality conditions in an integral and a pointwise form, see for instance [9], [10] and the bibliographies contained therein. However, in these latter works many additional structural restrictions on the control system, control sets and also on the optimal control are imposed, as for instance in Assumptions 1, 2 from [9] concerning the structure optimal controls.

The outline of this paper is as follows. In Section 2 we introduce some notations and provide some preliminary results. Section 3 is devoted to the second order necessary optimality conditions for an arbitrary set U and any integrable optimal control at times when it belongs to the interior of U . Section 4 deals with the case when U is a convex polytope and Section 5 with the case when U is of class C^2 . The last section addresses the second order necessary optimality conditions for the Mayer problem involving endpoint constraints.

Most of results presented here are given without proofs, because they are quite long and technical and will be published elsewhere.

2. Preliminaries and notations

The norm in \mathbb{R}^n is denoted by $\|\cdot\|$ and the inner product by $\langle \cdot, \cdot \rangle$. Let $\mathring{B} := \{x \in \mathbb{R}^n : \|x\| < 1\}$ be the open unit ball in \mathbb{R}^n . For a nonempty subset K of \mathbb{R}^n , ∂K denotes its boundary, $\text{Int } K$ its interior and K^c its complement. The distance function $d_K : \mathbb{R}^n \rightarrow \mathbb{R}_+$ is defined by $d_K(x) := \inf_{y \in K} \|x - y\|$ for all $x \in \mathbb{R}^n$ and the *oriented distance* $b_K : \mathbb{R}^n \rightarrow \mathbb{R}$ from $K \neq \mathbb{R}^n$ by $b_K(x) := d_K(x) - d_{K^c}(x)$ for all $x \in \mathbb{R}^n$. We set $b_K(\cdot) = 0$ if $K = \mathbb{R}^n$. Finally, by $M(k \times r)$ we denote the space of matrices having k lines and r columns.

Definition 2.1 Let $C : \mathbb{R}^m \rightarrow \mathbb{R}^m$ be a linear mapping and F be a subspace of \mathbb{R}^m . We say that C is symmetric on F if $\langle Cu, v \rangle = \langle u, Cv \rangle$ for all $u, v \in F$ and that C is negative definite on F if $\langle Cu, u \rangle \leq 0$ for all $u \in F$.

Let U be a nonempty closed subset of \mathbb{R}^m . For $u_0 \in U$ the adjacent tangent cone to U at u_0 is defined by

$$T_U^b(u_0) := \left\{ u \in \mathbb{R}^m : \lim_{h \rightarrow 0^+} \frac{d_U(u_0 + hu)}{h} = 0 \right\}.$$

The *second-order adjacent subset* to U at $(u_0, u) \in \mathbb{R}^m \times \mathbb{R}^m$ is the set defined by

$$T_U^{b(2)}(u_0, u) := \left\{ v \in \mathbb{R}^m : \lim_{h \rightarrow 0^+} \frac{d_U(u_0 + hu + h^2v)}{h^2} = 0 \right\}.$$

For any $u \in U$ we denote by

P_u the largest subspace contained in $T_U^b(u)$.

Let $f : [0, 1] \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$, $f'(t, x, u)$ be the derivative of $f(t, \cdot, \cdot)$ at (x, u) , $f_x(t, x, u)$ and $f_u(t, x, u)$ be the partial derivatives of f with respect to x and u ; $f''(t, x, u)$ denotes the Hessian of $f(t, \cdot, \cdot)$ at (x, u) , while f_{xx} , f_{xu} and f_{uu} denote the second-order partial derivative of f with respect to x and u .

Fix a trajectory-control pair $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (2) and set $f[t] = f(t, \bar{x}(t), \bar{u}(t))$. Let $f_u[t]$, $f_x[t]$ and $f''[t]$ be defined in a similar way. Throughout the whole paper we impose the following assumptions : For some $\delta > 0$

- (a) $f(t, \cdot, \cdot) \in C^2$ on $(\bar{x}(t) + \delta \hat{B}) \times (\bar{u}(t) + \delta \hat{B})$, $\forall t$;
- (b) $\|f_u[\cdot]\|$, $\|f'[\cdot]\|$, $\|f''[\cdot]\| \in L^1([0, 1]; \mathbb{R}_+)$ and $\exists a(\cdot) \in L^1([0, 1]; \mathbb{R}_+)$ such that the mappings $f'(t, \cdot, \cdot)$ and $f''(t, \cdot, \cdot)$ are $a(t)$ -Lipschitz on $(\bar{x}(t) + \delta \hat{B}) \times (\bar{u}(t) + \delta \hat{B})$ for a.e. $t \in [0, 1]$;
- (c) $f(t, x, U)$ is closed for all $t \in [0, 1]$, $x \in \bar{x}(t) + \delta \hat{B}$;
- (d) $\varphi(\cdot) \in C^2$ on $\bar{x}(1) + \delta \hat{B}$.

Recall that $(\bar{x}(\cdot), \bar{u}(\cdot))$ is a *strong local minimizer* for (3) (resp. (1)) if there exists $\eta > 0$ such that $\bar{x}(\cdot)$ minimizes φ over all $x(\cdot) \in S_{[0,1]}(x_0)$ (resp. over all $x(\cdot) \in S_{[0,1]}(x_0)$ with $x(1) \in K$) satisfying $\|\bar{x}(\cdot) - x(\cdot)\|_\infty \leq \eta$.

Remark 2.2 *Results contained in Sections 3-5 below are stated only for strong local minimizers. However they are also valid for the so called weak local minimizers. In contrast, Section 6 concerns only strong local minimizers. Not to switch between these different notions, in this paper we investigate only strong local minimizers.*

Theorem 2.3 (Maximum Principle, [11]) *Let $(\bar{x}(\cdot), \bar{u}(\cdot))$ be a strong local minimizer of the Mayer problem (3). Then there exists an absolutely continuous $p : [0, 1] \rightarrow \mathbb{R}^n$ satisfying (4), (5) and (6). Furthermore, for a.e. $t \in [0, 1]$ and for any $u \in P_{\bar{u}(t)}$ we have $\mathcal{H}_u[t]u = 0$.*

Define $A := \{t \in [0, 1] : \bar{u}(t) \in \partial U, \mathcal{H}_u[t] \neq 0\}$ and

$$\begin{aligned} \mathcal{U}_A &= \{u(\cdot) \in L^\infty([0, 1]; \mathbb{R}^m) : \exists c > 0, h_0 > 0 \text{ s.t.} \\ &\quad \forall h \in [0, h_0], \forall t \in A, d_U(\bar{u}(t) + hu(t)) \leq ch^2\}. \end{aligned}$$

Note that for any $u(\cdot) \in \mathcal{U}_A$, $u(t) \in T_U^b(\bar{u}(t))$ a.e. in A .

Theorem 2.4 (Integral second order conditions)

Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of the Mayer problem (3). Then for all

$u(\cdot), v(\cdot) \in L^\infty([0, 1]; \mathbb{R}^m)$ such that $u(\cdot) \in \mathcal{U}_A$ and $v(t) \in T_U^{b(2)}(\bar{u}(t), u(t))$ for a.e. $t \in A$, and for $p(\cdot)$ as in the maximum principle either $\int_0^1 \mathcal{H}_u[t]u(t)dt < 0$ or $\mathcal{H}_u[t]u(t) = 0$ a.e. in $[0, 1]$ and

$$\begin{aligned} 0 &\geq \int_0^1 (\mathcal{H}_u[t]v(t) + \frac{1}{2}y(t)^* \mathcal{H}_{xx}[t]y(t) \\ &\quad + u(t)^* \mathcal{H}_{xu}[t]y(t) + \frac{1}{2}u(t)^* \mathcal{H}_{uu}[t]u(t))dt \quad (8) \\ &\quad - \frac{1}{2}y(1)^* \varphi''(\bar{x}(1))y(1), \end{aligned}$$

where $y(\cdot)$ solves the linear system

$$\begin{cases} y'(t) = f_x[t]y(t) + f_u[t]u(t) \\ y(0) = 0. \end{cases} \quad (9)$$

The proof follows the same lines as the one in [12].

3. Second order conditions in the interior of control constraints

Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of the Mayer problem (3) and $p(\cdot)$ as in the maximum principle of Theorem 2.3. Let the matrix valued mapping $R(t)$ be defined as in the introduction.

Theorem 3.1 *Assume that for some $0 \leq t_1 < t_2 \leq 1$, $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$ and*

$$\begin{aligned} \mathcal{H}_{uu}[t] &= 0 \text{ a.e. in } [t_1, t_2]; \\ \mathcal{H}_{xu}[\cdot], f_u[\cdot] &\text{ are Lipschitz on } [t_1, t_2]; \quad (10) \\ \mathcal{H}_{xx}[\cdot], f_x[\cdot] &\text{ are essentially bounded on } [t_1, t_2]. \end{aligned}$$

Then, for a.e. $t \in [t_1, t_2]$ such that $\bar{u}(t) \in \text{Int } U$, the matrix $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric and $R(t) \leq 0$.

The statement of the above theorem is proved for the Lebesgue points t of $(\bar{u}(\cdot), R(\cdot))$ such that $\bar{u}(t) \in \text{Int } U$. The proof is long and technical and will be published elsewhere. It involves the Goh transformation and some advanced properties of Lebesgue points.

Remark 3.2 *If f is affine with respect to controls, the symmetry of the matrix $\mathcal{H}_{xu}[t]f_u[t]$ implies that the adjoint state is orthogonal to the Lie brackets of the flux. Indeed let f be as in (7), where $g(\cdot) \in C^2(\mathbb{R}^n; M(n \times m))$ and U is a closed nonempty subset of \mathbb{R}^m and let $g_k(x)$ denote the k -th column of $g(x)$. Then for all t such that $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric and for any $k, l \in \{1, \dots, m\}$,*

$$\begin{aligned} 0 &= (\mathcal{H}_{xu}[t]f_u[t] - f_u[t]^* \mathcal{H}_{xu}[t]^*)_{k,l} \\ &= \sum_{j=1}^n p_j(t) \sum_{s=1}^n \left(\frac{\partial g_{j,k}}{\partial x_s}[t]g_{s,l}[t] - \frac{\partial g_{j,l}}{\partial x_s}[t]g_{s,k}[t] \right), \end{aligned}$$

where $g_{j,k}$ is the j -th element of g_k . Hence for any $k, l \in \{1, \dots, m\}$,

$$\left\langle p(t), \frac{\partial g_k}{\partial x}[t]g_l[t] - \frac{\partial g_l}{\partial x}[t]g_k[t] \right\rangle = \langle p(t), [g_k, g_l][t] \rangle = 0.$$

4. Second order conditions on convex polytopes

A nonempty subset $U \subset \mathbb{R}^m$ is called a convex polytope in \mathbb{R}^m if U is an intersection of a finite family of affine half-spaces of \mathbb{R}^m . Then the adjacent tangent cone $T_U^b(u_0)$ is equal to the tangent cone of convex analysis to U for any $u_0 \in U$.

Theorem 4.1 *Let $U \subset \mathbb{R}^m$ be a convex polytope in \mathbb{R}^m . Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of the Mayer problem (3) and $p(\cdot)$ as in the maximum principle of Theorem 2.3. Assume that $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$ for some $0 \leq t_1 < t_2 \leq 1$ and (10) holds true. Then $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric on the subspace $P_{\bar{u}(t)}$ and $R(t)$ is negative definite on $P_{\bar{u}(t)}$ for a.e. $t \in [t_1, t_2]$.*

The proof follows the same lines as the proof of Theorem 3.1, but a change of base is involved and the control variations take values in the tangent to U at $\bar{u}(t)$.

The following corollary generalizes the classical Goh condition to boundary controls.

Corollary 4.2 *Under all the assumptions of Theorem 4.1 suppose that f is as in (7), where $g(\cdot) \in C^2(\mathbb{R}^n; M(n \times m))$ and U is a closed convex polytope in \mathbb{R}^m and let $g_k(x)$ denote the k -th column of $g(x)$. Consider the matrix valued mapping $\Theta: [0, 1] \rightarrow M(m \times m)$, whose elements are*

$$\theta_{k,l}(t) := \langle p(t), [g_k, g_l](\bar{x}(t)) \rangle \quad \forall k, l \in \{1, \dots, m\}.$$

Then for a.e. $t \in [t_1, t_2]$, the subspace $\Theta(t)(P_{\bar{u}(t)})$ is orthogonal to $P_{\bar{u}(t)}$. In particular, $\Theta(t)$ is equal to zero for a.e. $t \in [t_1, t_2]$ such that $\bar{u}(t) \in \text{Int } U$.

Proof. By Theorem 4.1 for a.e. $t \in [t_1, t_2]$, $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric on $P_{\bar{u}(t)}$. Fix such t . Since for all $a, b \in P_{\bar{u}(t)}$, $a^*(\mathcal{H}_{xu}[t]f_u[t] - (\mathcal{H}_{xu}[t]f_u[t])^*)b = 0$, we get

$$0 = \sum_{k=1}^m \sum_{l=1}^m a_k (\mathcal{H}_{xu}[t]f_u[t] - f_u[t]^* \mathcal{H}_{xu}[t]^*)_{k,l} b_l.$$

Consequently $\langle p(t), \sum_{k=1}^m \sum_{l=1}^m a_k [g_k, g_l](\bar{x}(t)) b_l \rangle = 0$ and therefore $0 = \sum_{k=1}^m \sum_{l=1}^m a_k \langle p(t), [g_k, g_l](\bar{x}(t)) \rangle b_l = \langle a, \Theta(t)b \rangle$, as claimed.

5. Second order conditions for smooth control constraints

In this section we consider a proper closed set $U \subset \mathbb{R}^m$ of class C^2 , see for instance [13]. For a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of the Mayer problem (3) define the following matrix valued mapping $C(\cdot)$ on $[0, 1]$

$$C(t) = \begin{cases} b_U''(\bar{u}(t)) & \text{if } \bar{u}(t) \in \partial U \\ 0 & \text{otherwise} \end{cases}$$

Remark 5.1 *If U is of class C^2 , then*

a) $\forall u_0 \in \partial U$ there exists a neighborhood $W(u_0)$ of u_0 such that the oriented distance $b_U(\cdot) \in C^2(W(u_0))$, see for instance Theorem 4.3 in [13];

b) $\forall u_0 \in \partial U$, $T_U^b(u_0) = \{v \in \mathbb{R}^m : \langle \nabla b_U(u_0), v \rangle \leq 0\}$ and the subspace

$$P_{u_0} := \{v \in \mathbb{R}^m : \langle \nabla b_U(u_0), v \rangle = 0\} = \partial T_U^b(u_0)$$

has the dimension equal to $m - 1$.

c) $\forall u_0 \in \partial U$, $\nabla b_U(u_0)$ is the unit outward normal to U at u_0 and, applying the inverse mapping theorem to b_U , it is not difficult to show that for any $u \in \partial T_U^b(u_0)$ we have $-\frac{1}{2} \langle b_U''(u_0)u, u \rangle \nabla b_U(u_0) \in T_U^{b(2)}(u_0, u)$.

For a trajectory-control pair $(\bar{x}(\cdot), \bar{u}(\cdot))$ and for every $t \in [0, 1]$ such that $\nabla b_U(\bar{u}(t))$ does exist, define the $m - 1$ dimensional subspace

$$S(t) := \{u \in \mathbb{R}^m : \langle \nabla b_u(\bar{u}(t)), u \rangle = 0\}.$$

Theorem 5.2 *Let U be of class C^2 . Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of the Mayer problem (3) and $p(\cdot)$ as in the maximum principle of Theorem 2.3. Assume that for some $0 \leq t_1 < t_2 \leq 1$, $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$.*

Then for a.e. $t \in [t_1, t_2]$ such that $\bar{u}(t) \in \partial U$ and for some $\delta_t > 0$

$$u^* (\mathcal{H}_{uu}[s] - \|\mathcal{H}_u[t]\| b_U''(\bar{u}(s))) u = 0$$

for all $u \in S(s)$ and for a.e. $s \in [t - \delta_t, t + \delta_t]$

satisfying $\|\bar{u}(t) - \bar{u}(s)\| \leq \delta_t$;

$\mathcal{H}_{xu}[\cdot], f_u[\cdot]$ are Lipschitz on $[t - \delta_t, t + \delta_t]$;

$\mathcal{H}_{xx}[\cdot], f_x[\cdot]$ are essentially bounded on $[t - \delta_t, t + \delta_t]$,

we have $\mathcal{H}_{xu}[t]f_u[t]$ is symmetric on the subspace $P_{\bar{u}(t)}$.

6. Mayer's problem with the endpoint constraints

Let K be a proper closed nonempty subset of \mathbb{R}^n of class C^2 . Then $b_K(\cdot) \in C^2$ on a neighborhood of ∂K , cf. [13]. We study here the Mayer optimal control problem (1) involving the end point constraints.

Let $(\bar{x}(\cdot), \bar{u}(\cdot))$ be a strong local minimizer of the above problem and $P_{\bar{u}(t)}$ be defined as in Section 2. If $\bar{x}(1)$ belongs to $\text{Int } K$, then the previously developed second order variational analysis does apply as though there were no endpoint constraints. This is due to the fact that small perturbations of $\bar{u}(\cdot)$ lead to feasible trajectories. For this reason we have to investigate only the case $\bar{x}(1) \in \partial K$. We deduce, for instance from [14], the following maximum principle.

Theorem 6.1 Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (1) with $\bar{x}(1) \in \partial K$. Then there exists an absolutely continuous function $p : [0, 1] \rightarrow \mathbb{R}^n$ and $\lambda \in \{0, 1\}$, $\mu \geq 0$, satisfying $\lambda + \mu > 0$, (4), (6) and the transversality condition

$$-p(1) = \lambda \nabla \varphi(\bar{x}(1)) + \mu \nabla b_K(\bar{x}(1)).$$

The above maximum principle may be abnormal, that is $\lambda = 0$. In this case $p(1)$ may be taken equal to $-\nabla b_K(\bar{x}(1))$.

Lemma 6.2 Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (1) with $\bar{x}(1) \in \partial K$ for which an abnormal maximum principle of Theorem 6.1 holds true for some $\mu > 0$. Then for every measurable bounded selection $u(t) \in P_{\bar{u}(t)}$ a.e. in $[0, 1]$, the solution $y(\cdot)$ of (9) satisfies $\langle \nabla b_K(\bar{x}(1)), y(1) \rangle = 0$ and $\langle p(t), f_u[t]u(t) \rangle = 0$ a.e. in $[0, 1]$.

If the maximum principle is abnormal, then the cost is not involved into the first order optimality conditions. To apply the variational approach developed in the previous sections, we use the exact penalization which allows to deal with a normal maximum principle.

Definition 6.3 The Mayer problem (1) is called calm at $\bar{x}(\cdot)$ if there exist $\varepsilon > 0$ and $M > 0$ such that $\forall v \in (0, \varepsilon)$ and $x(\cdot) \in S_{[0,1]}(x_0)$ satisfying $d_K(x(1)) \leq v$ and $\|x(\cdot) - \bar{x}(\cdot)\|_\infty \leq \varepsilon$ we have $\varphi(x(1)) \geq \varphi(\bar{x}(1)) - Mv$.

If the Mayer problem (1) is calm at $\bar{x}(\cdot)$, then by Proposition 6.4.3 from [15], there exists $k > 0$ such that $(\bar{x}(\cdot), \bar{u}(\cdot))$ is a strong local minimizer of the following minimization problem:

$$\min \left\{ \varphi(x(1)) + kd_K(x(1)) : x(\cdot) \in S_{[0,1]}(x_0) \right\}. \quad (11)$$

Since $\varphi(\cdot) + kd_K(\cdot)$ is no longer C^2 , we need the following (non smooth) maximum principle that can be deduced, for instance, from [14].

Theorem 6.4 Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (11) with $\bar{x}(1) \in \partial K$. Then there exists an absolutely continuous function $p : [0, 1] \rightarrow \mathbb{R}^n$ satisfying (4), (6) and the transversality condition

$$-p(1) \in \nabla \varphi(\bar{x}(1)) + k[0, \nabla b_K(\bar{x}(1))], \quad (12)$$

where $[0, \nabla b_K(\bar{x}(1))] = \{\mu \nabla b_K(\bar{x}(1)) : \mu \in [0, 1]\}$.

Denote by $q^1(\cdot)$ the solution of (4) for $p(1) = -\nabla \varphi(\bar{x}(1))$ and by $q^2(\cdot)$ the solution of (4) for $p(1) = -\nabla \varphi(\bar{x}(1)) - k \nabla b_K(\bar{x}(1))$. Note that $q^i(1)$ are extremal

points in the transversality condition (12). The mappings $q^i(\cdot)$ do not satisfy, in general, the maximum principle (6) but are used below to express the second order necessary optimality conditions. Define for $i = 1, 2$

$$\begin{aligned} \varphi^1(\cdot) &:= \varphi(\cdot), \quad \varphi^2(\cdot) := \varphi(\cdot) + kb_K(\cdot), \\ \mathcal{H}_{xx}^i[\cdot] &:= \mathcal{H}_{xx}(\cdot, \bar{x}(\cdot), q^i(\cdot), \bar{u}(\cdot)). \end{aligned}$$

The mappings $\mathcal{H}_{xu}^i[\cdot]$ and $\mathcal{H}_{uu}^i[\cdot]$ are defined similarly.

Theorem 6.5 Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (11) with $\bar{x}(1) \in \partial K$ and $p(\cdot)$ as in Theorem 6.4. Then for every $u(\cdot) \in \mathcal{U}_A$ such that $\mathcal{H}_u[\cdot]u(\cdot) = 0$ and the corresponding solution $y(\cdot)$ of (9) verifies $\langle \nabla b_K(\bar{x}(1)), y(1) \rangle = 0$, and for any $v(\cdot) \in L^\infty([0, 1]; \mathbb{R}^m)$ satisfying $v(t) \in T_U^{b(2)}(\bar{u}(t), u(t))$ for a.e. $t \in A$, there exists $i \in \{1, 2\}$ such that

$$\begin{aligned} 0 &\geq \int_0^1 \left(\mathcal{H}_u^i[t]v(t) + \frac{1}{2}y(t)^* \mathcal{H}_{xx}^i[t]y(t) \right. \\ &\quad \left. + u(t)^* \mathcal{H}_{xu}^i[t]y(t) + \frac{1}{2}u(t)^* \mathcal{H}_{uu}^i[t]u(t) \right) dt \quad (13) \\ &\quad - \frac{1}{2}y(1)^* (\varphi^i)''(\bar{x}(1))y(1). \end{aligned}$$

Consider the solution $q(\cdot)$ of the linear system (4) such that $q(1) = -\nabla b_K(\bar{x}(1))$ and define the subspaces $\mathcal{T}_i \subset P_{\bar{u}(t)}$

$$\mathcal{T}_i := \{u \in P_{\bar{u}(t)} : \langle q(t), f_u[t]u \rangle = 0\}.$$

By Lemma 6.2, if the abnormal maximum principle of Theorem 6.1 holds true, then $\mathcal{T}_i = P_{\bar{u}(t)}$ a.e. in $[0, 1]$ and $q(\cdot)$ satisfies the maximum principle. Observe next that for every measurable essentially bounded selection $u(t) \in \mathcal{T}_i$ and the corresponding solution $y(\cdot)$ of (9) we have $\langle \nabla b_K(\bar{x}(1)), y(1) \rangle = 0$. Therefore, by Theorem 6.5, (13) holds true for every $u(\cdot) \in \mathcal{U}_A$ such that $u(t) \in \mathcal{T}_i$ a.e. in $[0, 1]$. This and similar, but lengthy proofs as those of results from Sections 3,4,5 allow to deduce from (13) the following three theorems.

Theorem 6.6 Consider a strong local minimizer $(\bar{x}(\cdot), \bar{u}(\cdot))$ of (1) such that $\bar{x}(1) \in \partial K$. Assume that (1) is calm at $\bar{x}(\cdot)$, that for some $0 \leq t_1 < t_2 \leq 1$, $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$ and for $j = 1, 2$

$$\begin{aligned} \mathcal{H}_{uu}^j[t] &= 0 \text{ a.e. in } [t_1, t_2]; \\ \mathcal{H}_{xu}^j[\cdot], f_u[\cdot] &\text{ are Lipschitz on } [t_1, t_2]; \\ \mathcal{H}_{xx}^j[\cdot], f_x[\cdot] &\text{ are essentially bounded on } [t_1, t_2]. \end{aligned} \quad (14)$$

Then for a.e. $t \in [t_1, t_2]$ with $\bar{u}(t) \in \text{Int}U$ there exists $i \in \{1, 2\}$ such that $\mathcal{H}_{xu}^i[t]f_u[t]$ is symmetric on \mathcal{T}_i and

$$\begin{aligned} R^i(t) &:= \frac{1}{2}f_u[t]^* \mathcal{H}_{xx}^i[t]f_u[t] - \frac{1}{2} \frac{d}{dt} \mathcal{H}_{xu}^i[t]f_u[t] \\ &\quad - \mathcal{H}_{xu}^i[t]f_x[t]f_u[t] + \frac{1}{2} \mathcal{H}_{xu}^i[t] \frac{d}{dt} f_u[t] \end{aligned}$$

is negative definite on \mathcal{T}_i .

Theorem 6.7 Let U be a convex polytope and $(\bar{x}(\cdot), \bar{u}(\cdot))$ be a strong local minimizer of (1) such that $\bar{x}(1) \in \partial K$. Assume that (1) is calm at $\bar{x}(\cdot)$ and for some $0 \leq t_1 < t_2 \leq 1$, $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$ and (14) holds true for $j = 1, 2$. Then for a.e. $t \in [t_1, t_2]$ there exists $i \in \{1, 2\}$ such that $\mathcal{H}_{xu}^i[t]f_u[t]$ is symmetric on \mathcal{I}_t and $R^i(t)$ is negative definite on \mathcal{I}_t .

Corollary 6.8 Under all the assumptions of Theorem 6.7 suppose that f is as in (7), where $g(\cdot) \in C^2(\mathbb{R}^n; M(n \times m))$ and U is a closed convex polytope in \mathbb{R}^m and let $g_k(x)$ denote the k -th column of $g(x)$. For $i = 1, 2$ define the matrix valued mappings $\Theta^i : [0, 1] \rightarrow M(m \times m)$, where

$$\theta_{k,l}^i(t) := \langle q^i(t), [g_k, g_l](\bar{x}(t)) \rangle \quad \forall k, l \in \{1, \dots, m\}.$$

Then for a.e. $t \in [t_1, t_2]$ there exists $i \in \{1, 2\}$ such that $\Theta^i(t)$ (\mathcal{I}_t) is orthogonal to \mathcal{I}_t .

Consider subspaces $S(s)$ defined as in Section 5.

Theorem 6.9 Let U be of class C^2 and $(\bar{x}(\cdot), \bar{u}(\cdot))$ be a strong local minimizer of the Mayer problem (1) such that $\bar{x}(1) \in \partial K$. Assume that (1) is calm at $\bar{x}(\cdot)$ and for some $0 \leq t_1 < t_2 \leq 1$, $\bar{u}(\cdot)$ is integrable on $[t_1, t_2]$.

Then for a.e. $t \in (t_1, t_2)$ such that $\bar{u}(t) \in \partial U$ and for some $\delta_t > 0$ and $j = 1, 2$ the following relations are satisfied:

$$u^* \left(\mathcal{H}_{uu}^j[s] - \|\mathcal{H}_u^j[s]\| b_{ij}''(\bar{u}(s)) \right) u = 0 \quad \forall u \in \mathcal{I}_s$$

and a.e. $s \in (t - \delta_t, t + \delta_t)$ with $\|\bar{u}(t) - \bar{u}(s)\| \leq \delta_t$;
 $\mathcal{H}_{xu}^j[\cdot], f_u[\cdot]$ are Lipschitz on $(t - \delta_t, t + \delta_t)$;
 $\mathcal{H}_{xx}^j[\cdot], f_x[\cdot]$ are essentially bounded on $(t - \delta_t, t + \delta_t)$

we can find $i \in \{1, 2\}$ for which $\mathcal{H}_{xu}^i[t]f_u[t]$ is symmetric on \mathcal{I}_t .

Remark 6.10 Similar results can be obtained when K is an intersection of a finite family of closed sets K_j of class C^2 . Then the assumptions and statements will involve Hamiltonians \mathcal{H}^j for each active index j .

7. Conclusions and future works

For a nonlinear Bolza optimal control problem we proposed pointwise second order necessary optimality conditions extending those of Goh to the case of a closed control constraint given by a polytope or by a C^2 subset of \mathbb{R}^m and for integrable optimal controls that may take values on the boundary of control constraints. Furthermore, we have shown that on the interior of the control constraints Goh conditions hold true for integrable optimal controls without imposing any structural properties on the control set.

This was done by investigating first the free endpoint problem and then, the calmness assumption allowed us to reduce the Mayer problem with endpoint constraints to the one without them, but involving a non-differentiable cost function. For this equivalent problem we obtained similar pointwise conditions using the developed variational approach for the free endpoint problems. Our future work will concern a larger class of end-point constraints and more general control sets.
