(Dated: August 14, 2009)

In this paper we present a theoretical investigation for the ground state of an impurity immersed in a Fermi sea. The molecular regime is considered where a two-body bound state between the impurity and one of the fermions is formed. Both interaction and exchange of the bound fermion take place between the dimer and the Fermi sea. We develop a formalism based on a two channel model allowing us to expand systematically the ground state energy of this immersed dimer with the scattering length a . Working up to order a^3 , associated to the creation of two particle-hole pairs, reveals the first signature of the composite nature of the bosonic dimer. Finally, a complementary variational study provides an accurate estimate of the dimer energy even at large scattering length.

I. INTRODUCTION

As demonstrated by Bardeen-Cooper and Schrieffer, superconductivity arises from the pairing of electrons with opposite spins into Cooper pairs [1]. A natural extension of their work to the case where the two spin populations are imbalanced was proposed by Clogston and Chandrasekhar [2, 3]: they suggested that when a magnetic field is applied, the existence of a pairing gap in the electron energy spectrum could prevent spin polarization as long as the Zeeman shift was smaller than the gap, a threshold known as the Clogston-Chandrasekhar (CC) limit. It was later suggested that the superfluid state could survive beyond the CC limit, into the form of a non-homogeneous superconducting state known as the FFLO (Fulde Ferrell Larkin Ovchinnikov) state [4, 5]. However, most superconductors behave like nearly ideal diamagnetic compounds (Meissner Effect), which forbids magnetically induced spin polarization in the bulk, see Ref. [6] for a short review. As a consequence, these theories were investigated experimentally only very recently in a series of works performed at Rice [7] and MIT [8] with ultra-cold Fermi gases trapped in optical potentials. Although some debate on the structure of the normal component persists between the two groups, both observe a shell structure in the density profile, with at center a fully paired region consistent with the CC scenario of robust fermionic superfluidity.

The main discrepancy between the two experiments lies in the polarization of the normal component: Indeed, while Rice's group observed that the outer rim was composed exclusively of majority atoms, the normal component obtained at MIT was only partially polarized and contained also particles of the minority spin species. Recent theoretical work demonstrated that this latter observation was compatible with the homogeneous phase diagram of a strongly interacting Fermi gas if one assumes the validity of the Local Density Approximation [9]. In particular, it was shown that some of the most salient features could be understood fairly accurately from the

study of the simpler problem of an impurity immersed in a Fermi sea [10, 11]. At unitarity (scattering length $a = \infty$), it was demonstrated that the impurity could be described as a quasi-particle dressed by particle hole excitations of the background Fermi sea [11, 12, 13, 14]. Comparison between simplified variational models and Monte-Carlo simulations have in addition shown that even in this regime of strong correlation, a single particle-hole excitation was sufficient to capture quantitatively the properties of this so-called Fermi polaron [14, 15]. However, the Fermi-polaron picture is valid only for a negative, and close to unitarity $1/k_F|a| \gg 1$. In the $1/k_F a \lesssim 1$ regime, Monte-Carlo simulations have revealed that the Fermi-polaron was not the ground state of the system anymore [15]. Indeed, for $k_F a < 1.11$, the ground-state is now described by a bosonic dimer interacting with the background Fermi sea where the atom-dimer scattering length [16] $a_{dm} \simeq 1.1786 a$ was first calculated by Skorniakov and Ter Martirosian [17].

In this paper, we use a combination of perturbative expansion and variational calculation to draw a simple and intuitive picture of the molecular sector of the impurity problem and extend diagrammatic calculations presented in [18, 19]: we show that for $a > 0$, the molecular impurity shares several features with the Fermi-polaron describing the impurity for $a < 0$. In particular, we show that the creation of a single particle-hole pair in the Fermi sea provides an accurate quantitative description of the system. The paper is organized as follows: Sec. II presents the main results of the paper. More technical aspects of this work are then relegated to following sections, Sec. III for the perturbative calculation and Sec. IV for the variational approach. Sec. V concludes.

II. MAIN RESULTS

Let us consider an ensemble of spin $F = 1/2$ fermions (for instance ${}^6\text{Li}$ in its hyperfine ground state), where all particles but one are polarized in $m_F = -1/2$. At

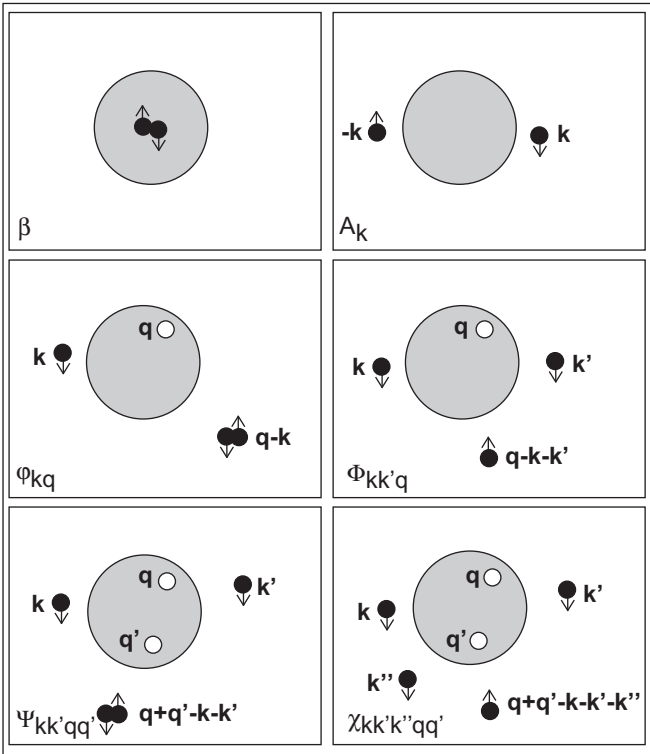

FIG. 1: Our variational scheme takes into account only a restricted number of particle-hole excitations. First row: no particle hole excitation. Second row: one particle-hole excitation of momenta $q < k_F$ and $k > k_F$. Third row: two particle-hole excitations of momenta $q, q' < k_F$ and $k, k' > k_F$.

low temperature, short range interatomic interactions between identical fermions are suppressed by Pauli exclusion principle, and the system can therefore be described as a single impurity interacting with a Fermi sea of non-interacting fermions. We note a the scattering length between particles of opposite spins. The case $a < 0$ and the vicinity of the Feshbach resonance ($a \rightarrow \infty$) have been described in previous works on the Fermi-polaron [11, 12, 13, 14], and here we concentrate on the molecular sector corresponding to a small and positive. In this particular regime the picture is relatively simple, since in the absence of a surrounding Fermi sea, the two body potential possesses a deeply bound state of size $\sim a$ and energy $E = -\hbar^2/ma^2$. When one adds a spin $m_F = +1/2$ atom to the Fermi sea, it will pair up with a majority atom to form a deeply bound dimer. In the regime $k_F a \ll 1$, the size of this molecule is much smaller than the interparticle distance, and we can describe the dimer as a point like boson of mass $2m$. In this picture, the energy shift associated with the addition of the impurity is then at leading order in $k_F a$

$$\Delta E = -\frac{\hbar^2}{ma^2} - E_F + \dots,$$

where the second term corresponds to the removal of

one majority fermion from the Fermi sea to form the bosonic dimer. The next order in the $k_F a$ expansion comes from the interactions between the bosonic dimer and the surrounding Fermi sea. Indeed, if the point-like boson picture is correct, then one should expect a mean-field energy shift $\Delta E = g_{ad}n$, where n is the density of majority atoms and g_{ad} is the atom-dimer coupling constant given by $g_{ad} = 3\pi\hbar^2 a_{ad}/m$ associated with the atom-dimer scattering length $a_{ad} \sim 1.1786a$ [16, 17]. Although this scenario has been confirmed by Monte-Carlo simulations [15], the analytic calculation of the mean field shift is not trivial for two main reasons. First, the atom-dimer scattering length is obtained by solving the three body-problem, but here antisymmetrization of the global wave-function correlates automatically the majority atom bound in the dimer with the surrounding Fermi-sea, and turns the calculation from three to many-body. Second, mean field contributions are usually obtained using a perturbation expansion based on the existence of a small parameter (here $k_F a$), and in our situation, this scheme is due to fail. Indeed, in absence of interactions ($a = 0$), the system is just an ensemble of non interacting fermions, that cannot form any dimer, which is contradictory with the intuitive picture we drew above. To circumvent this latter point, we decided to work in the two-channel picture [20, 21], where the short-range two-body bound state responsible for the Feshbach resonance is explicitly included in the model as a bosonic degree of freedom, of mass $2m$ and bare binding energy E_0 . In second quantized form, the Hamiltonian reads

$$H = \sum_{\mathbf{k}, \sigma=\uparrow, \downarrow} \epsilon_{\mathbf{k}} a_{\mathbf{k}, \sigma}^\dagger a_{\mathbf{k}, \sigma} + \sum_{\mathbf{K}} (E_0 + \epsilon_{\mathbf{K}}/2) b_{\mathbf{K}}^\dagger b_{\mathbf{K}} + \sum_{\mathbf{k}, \mathbf{K}} \frac{\Lambda_{\mathbf{k}}}{\sqrt{V}} \left(b_{\mathbf{K}}^\dagger a_{\mathbf{k}+\mathbf{K}/2, \uparrow} a_{-\mathbf{k}+\mathbf{K}/2, \downarrow} + \text{h.c.} \right), \quad (1)$$

where V is a quantization volume and $\Lambda_{\mathbf{k}}$ is the matrix element coupling fermionic and bosonic degrees of freedom. If r_b is the typical size of the bare molecule, then the width of $\Lambda_{\mathbf{k}}$ is $\sim 1/r_b$. The fermionic operator $a_{\mathbf{k}, \sigma}$ describes a momentum- \mathbf{k} atom with spin (hyperfine state) σ . Atoms in the two different spin states, $\sigma = \uparrow, \downarrow$, are coupled *via* a molecular closed channel state described by the boson operator $b_{\mathbf{K}}$ with bare energy at rest E_0 and momentum \mathbf{K} . With an even (and very weak, see below) k -dependence for the coupling strength $\Lambda_{\mathbf{k}}$, the resulting atomic interaction has an s-wave character. In the universal regime where the properties of the system depend only on the scattering length, no other ingredient is necessary, as long as E_0 and $\Lambda_{\mathbf{k}}$ are chosen to reproduce the actual interatomic scattering length. The Pauli principle imposes vanishing s-wave interaction for fermions in the same spin channel and do not require coupling between same spin particles.

Even in the case where a single spin down particle is immersed in a Fermi sea of spin up particles, this Hamiltonian does not have a complete analytical solution. One needs to rely on approximations to get some insights on

the behavior of the system. It can be assumed, in analogy with the Fermi-polaron problem, that the most salient features are obtained by taking into account the excitations of a small number of particle-hole pairs of the background Fermi sea. In the work presented here, we take into account up to two particle-hole pairs, which reveals effects due to the composite nature of the bosonic dimer. The variational state that we have studied thus takes the form (see also Fig. 1)

$$\begin{aligned}
|\psi\rangle = & \left(\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger a_{-\mathbf{k},\uparrow}^\dagger \right. \\
& - \sum_{\mathbf{k},\mathbf{q}}' \varphi_{\mathbf{k},\mathbf{q}} a_{\mathbf{k},\downarrow}^\dagger b_{-\mathbf{k}+\mathbf{q}}^\dagger a_{\mathbf{q},\downarrow} \\
& - \sum_{\mathbf{k},\mathbf{k}',\mathbf{q}}' \Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}+\mathbf{q},\uparrow}^\dagger a_{\mathbf{q},\downarrow} \\
& - \sum_{\mathbf{k},\mathbf{k}',\mathbf{q},\mathbf{q}'}' \Psi_{\mathbf{k},\mathbf{k}',\mathbf{q},\mathbf{q}'} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger b_{-\mathbf{k}'-\mathbf{k}+\mathbf{q}+\mathbf{q}'}^\dagger a_{\mathbf{q},\downarrow} a_{\mathbf{q}',\downarrow} \\
& \left. - \sum_{\mathbf{k},\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'}' \chi_{\mathbf{k},\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger a_{\mathbf{k}'',\downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}-\mathbf{k}''+\mathbf{q}+\mathbf{q}'}^\dagger a_{\mathbf{q},\downarrow} a_{\mathbf{q}',\downarrow} \right) |FS\rangle,
\end{aligned} \tag{2}$$

where \sum' means that the sum over the majority particle (resp. hole) wavevectors k (resp. q) is restricted to $k > k_F$ (resp. $q < k_F$), and $|FS\rangle$ is the noninteracting Fermi sea of majority atoms, in the absence of minority particle or short range molecule. Solving exactly the equations in this restricted subspace is a numerical difficult task outside the scope of this work. We therefore simplify the problem in two directions: one leads us to a systematic *perturbative* expansion in $k_F a$, the other one to a *variational* prediction for the molecule energy.

We first expand the variational equations in power of $k_F a$. In fact, as it was stressed in [13], an expansion in $k_F a$ is equivalent to an expansion in the number of excited particle-hole pairs. In particular, the variational space (2) is sufficient to derive the exact and systematic expansion of the immersed molecule energy up to order $(k_F a)^3$. To be more precise, extending the variational space by allowing additional electron-hole pairs would lead to corrections that are higher orders in $k_F a$.

Interestingly, the mathematical structure of the perturbative equations exhibits a separation of length scales, $k_F a \ll 1$, which can be given a simple physical interpretation. $\varphi_{\mathbf{k},\mathbf{q}}$ is seen as the atom-dimer wavefunction when the Fermi sea is composed of a single majority fermion. It presents a singularity $\sim 1/k^2$ at small k corresponding to the general large distance decay $\sim 1/r$ for the scattered wave of a short-range potential. The prefactor gives the renormalized atom-dimer scattering length. Due to this singular behaviour, the wavefunction $\varphi_{\mathbf{k},\mathbf{q}}$ is modified separately at the two length scales a and $\lambda_F = 1/k_F$

in the presence of the Fermi sea. It is first modified at small wavevectors $\sim k_F$, *i.e.* close to the singularity, the stronger effect being Pauli blocking which restricts allowed wavevectors \mathbf{k} to lie outside the Fermi sea. The corresponding contributions to the molecule energy are the same as in the point-like boson case, like the first two corrections in Eq. (3) for example. They involve large distances $\sim \lambda_F \gg a$ over which the composite nature of the molecule is not visible. In contrast to that, corrections to $\varphi_{\mathbf{k},\mathbf{q}}$ for larger wavevectors $\simeq 1/a$ reveal the composite structure of the molecule and change the value of α_3 in Eq. (3).

Using the simplifications permitted by the length-scale separation mentioned above and working out the expansion in $x_F = k_F a$ to third order yields the following expression for the molecule energy [26] (see Eq. (55))

$$\begin{aligned}
E = & -\frac{\hbar^2}{m a^2} \left(1 - \frac{x_F^3 \tilde{a}_{\text{ad}}}{2\pi} - \frac{2x_F^4 \tilde{a}_{\text{ad}}^2}{\pi^2} (\ln 2 - 3/8) \right. \\
& \left. + 2x_F^5 \alpha_3 + \dots \right),
\end{aligned} \tag{3}$$

where $\tilde{a}_{\text{ad}} = a_{\text{ad}}/a \sim 1.1786$ is the ratio between the atom-dimer and atom-atom scattering lengths, and $\alpha_3 \simeq 0.0637$ is a numerical coefficient obtained from the formalism described in Sec. III. As mentioned above, the first term of the expansion corresponds to the binding energy of a single molecule. The next two terms are obtained by taking into account single particle-hole excitations and depend only on the atom-dimer scattering length. They are identical to the energy shift obtained for a point-like boson immersed in a Fermi sea [22] and the composite nature of the dimers is only revealed by the last term of the expansion, which is calculated by taking into account two particle-hole excitations. We stress again that, although the starting point is a variational form (2), Eq. (3) is the exact low density expansion of the molecule energy. For comparison, let us mention that the energy obtained for a point-like boson immersed in a Fermi sea with boson-fermion scattering length a_{ad} also expands as Eq. (3) - from which the molecule energy in vacuum has been subtracted - but with $\alpha_3 \simeq 0.00025 \tilde{a}_{\text{ad}}^3$ instead of $\alpha_3 \simeq 0.0637$ in the composite boson case.

It has been pointed out in [15] that the exact energy of the molecular impurity was actually very close from the mean-field correction, up to $k_F a \sim 1$. Due to its perturbative nature valid only for $k_F a \ll 1$, the analysis presented above cannot explain this intriguing feature. To address this particular issue and acquire some insight on the strongly interacting regime where the perturbative expansion diverges, we develop a variational treatment of the impurity problem. In order to get a simple and tractable calculation, the general variational form (2) is simplified by allowing only one particle-hole pair excitation and by suppressing the \mathbf{q} dependence in the wavefunctions. Namely, the variational state takes

FIG. 2: Perturbative expansion of the energy of a molecular impurity immersed in a Fermi sea. Square: Monte-Carlo result of [15]. Black solid line: Free molecule $E = -\hbar^2/ma^2$. Red dashed line: single particle hole excitations corresponding to the expansion up to a^2 . Dotted blue line: expansion up to a^3 taking into account a second particle-hole excitation.

the form

$$\begin{aligned}
 |\psi\rangle = & \left(\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger a_{-\mathbf{k},\uparrow}^\dagger \right. \\
 & - \sum_{\mathbf{k},\mathbf{q}}' \varphi_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger b_{-\mathbf{k}+\mathbf{q}}^\dagger a_{\mathbf{q},\downarrow} \\
 & \left. - \sum_{\mathbf{k},\mathbf{k}',\mathbf{q}}' \Phi_{\mathbf{k},\mathbf{k}'} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}+\mathbf{q},\uparrow}^\dagger a_{\mathbf{q},\downarrow} \right) |FS\rangle.
 \end{aligned} \quad (4)$$

As shown later, this particular *ansatz* gives the correct expansion up to mean-field term. In addition, it can be extended to strong interactions, and the energy remains finite even at unitarity. Working out the variational equations, we reduce the problem to a set of two integral equations that are solved numerically, see Sec. IV. The result is displayed in Fig. 3. We observe a remarkable agreement between our simplified integral equations and the Monte-Carlo simulations. It demonstrates that, just like the Fermi-polaron problem, single particle-hole excitations provide an accurate description of the physical properties of the system.

III. PERTURBATIVE EXPANSION

We shall detail in this Section our perturbative calculation for the immersed molecule energy. A consistent expansion at a given order in $k_F a$ requires a corresponding minimal number of particle-hole excitations in the variational space. We will therefore do the calculation step

FIG. 3: Variational calculation of the energy of a molecule immersed in a Fermi sea. Solid line: Variational calculation including formation of a single particle hole pair. Points: Monte-Carlo calculation of [15].

by step by increasing the variational space size up to two particle-hole excitations. The two-body problem is considered in III A, which helps us to connect the parameters of our starting Hamiltonian (1) to the scattering length a in the single-channel limit. A trivial *ansatz* extending the two-body wavefunction is proposed, which exhibits the Pauli blocking effect. Elaborating on this *ansatz*, single particle-hole excitations are added in III B yielding the first (mean-field type) and second order corrections to the molecule energy. The third order correction requires two particle-hole excitations that are considered in III C and allows us to recover Eq. (3).

A. Two-body properties

Insight on the model (1) can be gained by solving the two-body problem. We look for a bound state of energy $E = -\frac{\hbar^2 \lambda^2}{m}$ with the *ansatz* $|\psi\rangle = (\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}} A_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger a_{-\mathbf{k},\uparrow}^\dagger) |0\rangle$. The Schrödinger equation $(H - E)|\psi\rangle = 0$ gives simple coupled equations

$$(q_0^2 + \lambda^2)\beta + \sum_{\mathbf{k}} \bar{\Lambda}_{\mathbf{k}} A_{\mathbf{k}} = 0, \quad \bar{\Lambda}_{\mathbf{k}} \beta + (k^2 + \lambda^2) A_{\mathbf{k}} = 0, \quad (5)$$

with $\bar{\Lambda}_{\mathbf{k}} = \left(\frac{m}{\hbar^2 \sqrt{V}} \right) \Lambda_{\mathbf{k}}$ and $E_0 = \frac{\hbar^2 q_0^2}{m}$. The second equation allows to express $A_{\mathbf{k}}$ as a function of β . Replacing $A_{\mathbf{k}}$ in the first equation yields an equation for the bound state

$$q_0^2 + \lambda^2 - \sum_{\mathbf{k}} \frac{\bar{\Lambda}_{\mathbf{k}}^2}{k^2 + \lambda^2} = 0. \quad (6)$$

Although $\bar{\Lambda}_{\mathbf{k}}$ has a very weak k dependence, the integral in Eq. (6) has an ultraviolet divergence if this dependence

is crudely neglected. We therefore define $\sum_{\mathbf{k}} \frac{\bar{\Lambda}_k^2}{k^2} = \frac{V\bar{\Lambda}_0^2}{4\pi\ell}$, then add and subtract this integral to Eq. (6). $\bar{\Lambda}_k$ is replaced by $\bar{\Lambda}_0$ for the resulting convergent integral. λ is finally solution of a second order equation

$$R^*\lambda^2 + \lambda - \frac{1}{a} = 0, \quad (7)$$

where we define

$$\frac{1}{a} = \frac{1}{\ell} - \frac{4\pi\hbar^2 E_0}{m\Lambda_0^2}, \quad R^* = \frac{4\pi\hbar^4}{m^2\Lambda_0^2}. \quad (8)$$

ℓ acts here as a short-distance cutoff length, it is on the order of the van der Waals potential size. The two-channel model Eq. (1) is therefore only valid if $R^* \gg \ell$ and $a \gg \ell$ for describing the two-body bound state. The two-body scattering problem can also be solved using the same *ansatz*. One concludes from its solution that a is the two-body scattering length and $R^* = -r_e/2$ where r_e is the *effective range*. The universal regime, or one-channel zero range model, is recovered with $R^* \rightarrow 0$ that is $\Lambda_k \rightarrow \infty$ at fixed value of a . In particular, Eq. (7) gives then $\lambda = 1/a$ as expected.

It is instructive to first study a simple *ansatz* where the dimer state and the spin \downarrow Fermi sea are not coupled, namely

$$|\psi\rangle = (\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k},\uparrow}^\dagger a_{-\mathbf{k},\downarrow}^\dagger) |FS\rangle. \quad (9)$$

$|FS\rangle$ denotes the \downarrow Fermi sea with Fermi wavevector k_F and density $n = k_F^3/6\pi^2$ [27]. The Pauli principle imposes that wavevectors below k_F are blocked in the FS and do not participate to the molecular state. This *ansatz* is certainly not an eigenstate of the Hamiltonian Eq. (1). The calculation that follows is therefore variational in essence. Projecting the Schrödinger equation $(H-E)|\psi\rangle = 0$ onto the two relevant sectors, two coupled equations are derived

$$(q_0^2 + \lambda^2)\beta + \sum_{|\mathbf{k}| > k_F} \bar{\Lambda}_k A_{\mathbf{k}} = 0, \quad \bar{\Lambda}_k \beta + (k^2 + \lambda^2)A_{\mathbf{k}} = 0. \quad (10)$$

Apart from the wavevector summation restriction, they are identical to Eqs. (5). The spin \downarrow Fermi sea enters only through Pauli blocking at this stage. The energy E is measured from the Fermi sea energy. Solving the system in the universal limit $R^* \rightarrow 0$, we find

$$\lambda = \frac{1}{a} - \frac{2k_F}{\pi} \left[1 - \frac{\lambda}{k_F} \text{atg} \left(\frac{k_F}{\lambda} \right) \right]. \quad (11)$$

First, we can consider the dilute limit $k_F a \ll 1$, which yields

$$E = -\frac{\hbar^2}{ma^2} + 2gn + \mathcal{O}(gn(k_F a)^2), \quad (12)$$

where $g = \frac{4\pi\hbar^2 a}{m}$. The first term in Eq. (12), *i.e.* the molecule energy in vacuum, is the correct leading result in a small $k_F a$ expansion. The second term, associated with Pauli blocking, corresponds to a mean field term treated within the Born approximation and may naively be interpreted as a first sign of the composite nature of the dimer. However, as we will see, this result is not exact, and the correct value of the mean field term requires the resolution of the three body problem. This can be improved by including particle-hole excitations in the variational wavefunction as we will show next.

B. First order

Applying two times the Hamiltonian (1) on the simple previous *ansatz* Eq. (9), one sees that the space spanned by the variational wavefunction can be extended to include states with a molecule and a single particle-hole excitation from the Fermi sea. States with a closed channel boson and a single particle-hole excitation should also be included as an intermediate step. The improved *ansatz* for the wavefunction reads

$$|\psi\rangle = \left(\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger a_{-\mathbf{k},\uparrow}^\dagger - \sum_{\mathbf{k},\mathbf{q}}' \varphi_{\mathbf{k},\mathbf{q}} a_{\mathbf{k},\downarrow}^\dagger b_{-\mathbf{k}+\mathbf{q}}^\dagger a_{\mathbf{q},\downarrow} - \sum_{\mathbf{k},\mathbf{k}',\mathbf{q}}' \Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}+\mathbf{q},\uparrow}^\dagger a_{\mathbf{q},\downarrow} \right) |FS\rangle, \quad (13)$$

where, thanks to the linearity of Schrödinger's equation, we can take $\beta = 1$. Apart from the additional \mathbf{q} dependence, Eq. (13) resembles the variational state (4). The variational space has four different sectors. Projecting the Schrödinger equation on the first two sectors, we get

$$(q_0^2 + \lambda^2) + \sum_{|\mathbf{k}| > k_F} \bar{\Lambda}_k A_{\mathbf{k}} = 0, \quad (14a)$$

$$\bar{\Lambda}_k + (k^2 + \lambda^2)A_{\mathbf{k}} + \sum_{|\mathbf{q}| < k_F} \bar{\Lambda}_k \varphi_{\mathbf{k},\mathbf{q}} = 0. \quad (14b)$$

The aim of this calculation is to determine how the $2gn$ term (mean field) in Eq. (12) is modified by the improved *ansatz* Eq. (13). Hence the \mathbf{q} -dependence of $\varphi_{\mathbf{k},\mathbf{q}}$ is not relevant because it leads to corrections of higher order in $k_F a$. For $R^* \rightarrow 0$ and $k_F a \ll 1$ the modified bound state equation is found to be

$$\lambda = \frac{1}{a} - \frac{2k_F^3 a^2}{3\pi} + \frac{2k_F^3}{3\pi} \sum_{\mathbf{k}} \frac{\varphi_{\mathbf{k}}}{k^2 + 1/a^2}, \quad (15)$$

where $\varphi_{\mathbf{k}}$ still has to be determined.

Again we neglect the \mathbf{q} -dependence when projecting on the last two sectors. Two coupled equations are derived where the anticommuting properties of fermionic operators are essential

$$2 \sum_{\mathbf{k}'} \bar{\Lambda}_{\mathbf{k}'+\mathbf{k}/2} \Phi_{\mathbf{k},\mathbf{k}'} + \left(q_0^2 + \lambda^2 + \frac{3}{4} k^2 \right) \varphi_{\mathbf{k}} = -\bar{\Lambda}_0 A_{\mathbf{k}} = \frac{\bar{\Lambda}_0^2}{k^2 + \lambda^2} \quad (16a)$$

$$\bar{\Lambda}_{\mathbf{k}'+\mathbf{k}/2} (\varphi_{\mathbf{k}} - \varphi_{\mathbf{k}'}) + 2 (\lambda^2 + k^2 + k'^2 + \mathbf{k} \cdot \mathbf{k}') \Phi_{\mathbf{k},\mathbf{k}'} = 0. \quad (16b)$$

With an additional source term on the right side of Eq. (16a), this system of equations is the same as the one derived in the three-body problem [21]. The second equation is solved readily in $\Phi_{\mathbf{k},\mathbf{k}'}$ and inserting this result in the first equation, we obtain for $R^* \rightarrow 0$

$$\left(\hat{L}_\lambda - \frac{1}{a} \right) \varphi_{\mathbf{k}} = \frac{4\pi}{k^2 + \lambda^2}, \quad (17)$$

with the usual three-body kernel [16, 17]

$$\hat{L}_\lambda \varphi_{\mathbf{k}} \equiv \sqrt{\lambda^2 + 3k^2/4} \varphi_{\mathbf{k}} + \frac{1}{2\pi^2} \int d^3 k' \frac{\varphi_{\mathbf{k}'}}{k'^2 + k^2 + \mathbf{k}' \cdot \mathbf{k} + \lambda^2}. \quad (18)$$

At this order, it is consistent to take $\lambda = 1/a$. We proceed further and make contact to the atom-dimer scattering problem. Writing $\varphi_{\mathbf{k}} = \frac{4\pi a}{k^2} a_0(ka)$ yields the integral equation

$$\frac{1}{\pi} \int_0^{+\infty} du' \frac{a_0(u')}{uu'} \ln \left(\frac{1 + u^2 + u'^2 + uu'}{1 + u^2 + u'^2 - uu'} \right) + \frac{3}{4} \frac{a_0(u)}{1 + \sqrt{1 + 3u^2/4}} = \frac{1}{1 + u^2}, \quad (19)$$

identical to the one that determines the atom-dimer scattering length [16, 17]. In particular $a_0(0) = \frac{a_{\text{ad}}}{a} \simeq 1.1786 \dots$

The last term in Eq. (15) is finally obtained by taking the $\mathbf{k} \rightarrow \mathbf{0}$ limit in Eq. (17),

$$\sum_{\mathbf{k}} \frac{\varphi_{\mathbf{k}}}{k^2 + 1/a^2} = a^2 \left(1 - \frac{3}{8} a_0(0) \right). \quad (20)$$

This contribution is positive so that the molecule energy is lowered by improving on the simple *ansatz*. This is in fact a consequence of a general variational principle which states that the ground state energy can only decrease when the parameter space is extended. Inserting Eq. (20) into Eq. (15) leads to a final expression for the low density molecule energy

$$E = -\frac{\hbar^2}{ma^2} + g_{\text{ad}} n, \quad (21)$$

where the atom-dimer coupling constant has been defined as

$$g_{\text{ad}} = \frac{2\pi\hbar^2 a_{\text{ad}}}{(2m/3)}. \quad (22)$$

Interestingly, the expansion can be pushed to the next order within the same variational space. Hence, the \mathbf{q} dependence of $\varphi_{\mathbf{k},\mathbf{q}}$ becomes relevant. Skipping details, the result for λ reads

$$\lambda = \frac{1}{a} \left(1 - \frac{2x_F^3}{3\pi} + 16\pi^2 \sum_{|\mathbf{v}| < x_F} \sum_{|\mathbf{u}| > x_F} \frac{\tilde{\varphi}_{\mathbf{u},\mathbf{v}}}{1 + u^2} \right), \quad (23)$$

where $x_F \equiv k_F a$ and $\sum_{\mathbf{v}}$ stands for $\int \frac{d^3 v}{(2\pi)^3}$. $\tilde{\varphi}_{\mathbf{u},\mathbf{v}}$ denotes a rescaled atom-dimer wavefunction

$$\varphi_{\mathbf{k},\mathbf{q}} = 4\pi a^3 \tilde{\varphi}_{\mathbf{k}a, \mathbf{q}a}, \quad (24)$$

solution of the integral equation

$$\frac{1}{2\pi^2} \int_{|\mathbf{u}'| > x_F} d^3 u' \frac{\tilde{\varphi}_{\mathbf{u}',\mathbf{v}}}{1 + u'^2 + u^2 + \mathbf{u}' \cdot \mathbf{u} - \mathbf{v}(\mathbf{u}' + \mathbf{u})} + \left(\sqrt{1 + \frac{3u^2}{4} - \frac{v^2}{4} - \frac{\mathbf{u} \cdot \mathbf{v}}{2}} - 1 \right) \tilde{\varphi}_{\mathbf{u},\mathbf{v}} = \frac{1}{1 + u^2} \quad (25)$$

For $\mathbf{v} = 0$, we recover Eq. (19) with $\tilde{\varphi}_{\mathbf{u},\mathbf{v}} = a_0(u)/u^2$ and therefore Eq. (21) for the energy. A first idea to treat Eq. (25) is to expand directly in powers of \mathbf{v} and solve it order by order. Note that Eq. (23) involves an average over the direction of \mathbf{v} . This would imply that the first non-vanishing correction goes as v^2 and therefore x_F^5 for the energy. However, this approach fails because the solution of Eq. (25) is singular as $\mathbf{u} \rightarrow 0$, $\tilde{\varphi}_{\mathbf{u},\mathbf{v}} \simeq a_0(0)/u^2$ for $\mathbf{v} = 0$.

A correct treatment requires a proper description of $\tilde{\varphi}_{\mathbf{u},\mathbf{v}}$ as a function of \mathbf{v} for $\mathbf{u} \rightarrow 0$. We therefore write

$$\tilde{\varphi}_{\mathbf{u},\mathbf{v}} = \frac{a_{s1}(u, \mathbf{v})}{u^2 - v^2/3 - 2\mathbf{u} \cdot \mathbf{v}/3}, \quad (26)$$

which translates Eq. (25) to an integral equation for $a_{s1}(u, \mathbf{v})$. The second term in the l.h.s. of Eq. (25) can then be expanded in \mathbf{v} . For the first term in the l.h.s. of Eq. (25), we add and subtract the kernel for $\mathbf{v} = 0$ and $x_F = 0$. The resulting integral corrections are simplified by changing variables, $u = vx$ and $u = x_F x$, followed by an expansion in v and x_F . Keeping only first order corrections, the integral equation reads

$$\int_0^{+\infty} du' K_0(u, u') a_{s1}(u', \mathbf{v}) = \frac{1 + a_{s1}(0, \mathbf{v}) \left[\frac{2x_F}{\pi} - \frac{v}{\pi} J_1(v/x_F) \right]}{1 + u^2}, \quad (27)$$

with the same kernel $K_0(u, u')$ as Eq. (19). We have defined

$$J_1(s) = \frac{1}{3} \int_0^s dy \int_{-1}^1 dx \frac{1 + 2x/y}{1 - y^2/3 - 2xy/3}. \quad (28)$$

The solution of Eq. (27) is then simply

$$a_{s1}(u, v) = \frac{a_0(u)}{1 - a_0(0) \left(\frac{2x_F}{\pi} - \frac{v}{\pi} J_1(v/x_F) \right)}, \quad (29)$$

and can be expanded to first order in x_F and v . The first outcome of this calculation is that the singular behavior of $\tilde{\varphi}_{\mathbf{u}, \mathbf{v}}$ at small \mathbf{u} indeed modifies the x_F (and v) expansion.

The solution (29) can be included in Eq. (23). Again we add and subtract the solution at vanishing x_F and v and rescale integral corrections with v and x_F . The final result for the energy is

$$E = -\frac{\hbar^2}{ma^2} \left(1 - \frac{x_F^3 a_0(0)}{2\pi} - \frac{2x_F^4 a_0^2(0)}{\pi^2} (\ln 2 - 3/8) \right), \quad (30)$$

which gives the next order $x_F = k_F a$ correction to Eq. (21). We have used the following result

$$\int_0^1 ds s^3 J_1(s) = \frac{7}{6} - \frac{4}{3} \ln 2. \quad (31)$$

A few conclusion can be drawn from this result (30). As we have mentioned already, the first correction to the mean field result (21) is linear in x_F and not quadratic. In fact, subtracting the dimer internal energy $-\frac{\hbar^2}{ma^2}$, the molecule energy (30) can be retrieved from a simpler model. A point-like boson of mass $2m$ interacting with a Fermi sea with a boson-fermion scattering length $a_{\text{ad}} = a_0(0)a$ leads also to Eq. (30). This means that the composite structure of the boson is not apparent at this order of the calculation. Actually this first-order correction stems from small values of $k \simeq k_F$. This originates from the low k singular behavior in the integral equation and is outlined by the rescaling of variables performed during the calculation, see above. Hence, low k corresponds to large distances over which the composite structure of the boson is smeared out.

C. Two particle-hole excitations

The treatment becomes much more involved when pushed to next order in k_F . First of all, Pauli blocking in the two-body problem adds a new contribution to λ . It corresponds to the $\sim k_F^5$ term in the expansion of Eq. (11). λ is therefore given by

$$\lambda = \frac{1}{a} \left(1 - \frac{2x_F^3}{3\pi} + \frac{2x_F^5}{5\pi} + 16\pi^2 \sum_{|\mathbf{v}| < x_F} \sum_{|\mathbf{u}| > x_F} \frac{\tilde{\varphi}_{\mathbf{u}, \mathbf{v}}}{1 + u^2} \right), \quad (32)$$

where $\tilde{\varphi}_{\mathbf{u}, \mathbf{v}}$ has to be determined. There are basically two kinds of contribution for the solution of the integral equation and consequently for the energy. The first terms come from low k , *i.e.* values of k on the order of k_F as in the last subsection. The divergence of $\varphi_{\mathbf{k}, \mathbf{q}}$ in

this regime implies that one has to go to higher orders in the calculation by including two particle-hole excitations. Nevertheless, only the $k \rightarrow 0$ part is kept which simplifies calculations a lot. The second kind of terms comes from a direct expansion of the integral equation in \mathbf{v} once singular terms have been carefully treated. They involve larger values of k , on the order of $1/a$.

We first need to derive a complete integral equation that includes all terms relevant at this order of the calculation. The wavefunction *ansatz* is extended to describe two particle-hole excitations. It is given by Eq. (2) that we recall here,

$$\begin{aligned} |\psi\rangle = & \left(\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k}, \downarrow}^\dagger a_{-\mathbf{k}, \uparrow}^\dagger \right. \\ & - \sum_{\mathbf{k}, \mathbf{q}}' \varphi_{\mathbf{k}, \mathbf{q}} a_{\mathbf{k}, \downarrow}^\dagger b_{-\mathbf{k}+\mathbf{q}}^\dagger a_{\mathbf{q}, \downarrow} \\ & - \sum_{\mathbf{k}, \mathbf{k}', \mathbf{q}}' \Phi_{\mathbf{k}, \mathbf{k}', \mathbf{q}} a_{\mathbf{k}, \downarrow}^\dagger a_{\mathbf{k}', \downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}+\mathbf{q}, \uparrow}^\dagger a_{\mathbf{q}, \downarrow} \\ & - \sum_{\mathbf{k}, \mathbf{k}', \mathbf{q}, \mathbf{q}'}' \Psi_{\mathbf{k}, \mathbf{k}', \mathbf{q}, \mathbf{q}'} a_{\mathbf{k}, \downarrow}^\dagger a_{\mathbf{k}', \downarrow}^\dagger b_{-\mathbf{k}'-\mathbf{k}+\mathbf{q}+\mathbf{q}'}^\dagger a_{\mathbf{q}, \downarrow} a_{\mathbf{q}', \downarrow} \\ & - \sum_{\mathbf{k}, \mathbf{k}', \mathbf{k}'', \mathbf{q}, \mathbf{q}'}' \chi_{\mathbf{k}, \mathbf{k}', \mathbf{k}'', \mathbf{q}, \mathbf{q}'} a_{\mathbf{k}, \downarrow}^\dagger a_{\mathbf{k}', \downarrow}^\dagger a_{\mathbf{k}'', \downarrow}^\dagger \\ & \left. a_{-\mathbf{k}'-\mathbf{k}-\mathbf{k}''+\mathbf{q}+\mathbf{q}'}^\dagger a_{\mathbf{q}, \downarrow} a_{\mathbf{q}', \downarrow} \right) |FS\rangle, \quad (33) \end{aligned}$$

where all \mathbf{q} are restricted to the Fermi surface and all \mathbf{k} outside the Fermi surface. With no loss of generality, functions are antisymmetrized with respect to the \mathbf{k} variables as well as with respect to the \mathbf{q} . This is of course consistent with the anticommuting properties of the fermionic operators.

The Schrödinger equation is projected on the various subspaces of the *ansatz*. Eqs. (14) are recovered while Eqs. (16) are changed to

$$\left(q_0^2 + \lambda^2 + \tilde{\epsilon}_{\mathbf{k}} + \frac{\tilde{\epsilon}_{-\mathbf{k}+\mathbf{q}}}{2} - \tilde{\epsilon}_{\mathbf{q}} \right) \varphi_{\mathbf{k}, \mathbf{q}} \quad (34a)$$

$$+ 2 \sum_{|\mathbf{k}'| > k_F} \bar{\Lambda}_{\mathbf{k}'+\mathbf{k}/2} \Phi_{\mathbf{k}, \mathbf{k}', \mathbf{q}} = -\bar{\Lambda}_0 A_{\mathbf{k}},$$

$$2 (\tilde{\epsilon}_{\mathbf{k}} + \tilde{\epsilon}_{\mathbf{k}'} + \tilde{\epsilon}_{-\mathbf{k}-\mathbf{k}'+\mathbf{q}} - \tilde{\epsilon}_{\mathbf{q}} + \lambda^2) \Phi_{\mathbf{k}, \mathbf{k}', \mathbf{q}}$$

$$+ \bar{\Lambda}_{\mathbf{k}'+\mathbf{k}/2} (\varphi_{\mathbf{k}, \mathbf{q}} - \varphi_{\mathbf{k}', \mathbf{q}}) + 4\bar{\Lambda}_0 \sum_{|\mathbf{q}'| < k_F} \Psi_{\mathbf{k}, \mathbf{k}', \mathbf{q}, \mathbf{q}'} = 0, \quad (34b)$$

with the notation $\tilde{\epsilon}_{\mathbf{k}} = k^2/2$. The k dependence of $\bar{\Lambda}_{\mathbf{k}}$ is kept only when necessary to regularize the two-body problem. To get an integral equation, we proceed as before. We obtain three new terms compared to Eq. (25). The first one is a source term proportional to $\Psi_{\mathbf{k}, \mathbf{k}', \mathbf{q}, \mathbf{q}'}$.

The second comes from the $|\mathbf{k}'| > k_F$ restriction in Eq. (34a). Taken for $\mathbf{k} \rightarrow 0$, it gives a term proportional to $n_F \varphi_{\mathbf{k},\mathbf{q}}$. The last term stems from the replacement of $A_{\mathbf{k}}$ using Eqs. (14). Taken for $\mathbf{k} \rightarrow 0$, it gives a term proportional to $\sum_{|\mathbf{q}'| < k_F} \varphi_{\mathbf{k},\mathbf{q}'}$.

Performing the change of variable $k = \lambda u$ followed by the rescaling (24) we obtain the integral equation

$$\begin{aligned} & \frac{1}{2\pi^2} \int_{|\mathbf{u}'| > x_F} d^3 u' \frac{\tilde{\varphi}_{\mathbf{u}',\mathbf{v}}}{1 + u'^2 + u^2 + \mathbf{u}' \cdot \mathbf{u} - \mathbf{v}(\mathbf{u}' + \mathbf{u})} \\ & + \left(\sqrt{1 + \frac{3u^2}{4} - \frac{v^2}{4} - \frac{\mathbf{u} \cdot \mathbf{v}}{2}} - \frac{1}{a\lambda} + 4\pi \left(\frac{x_F^3}{6\pi^2} \right) \right) \tilde{\varphi}_{\mathbf{u},\mathbf{v}} \\ & - \frac{1}{2\pi^2} \int_{|\mathbf{v}'| < x_F} d^3 v' \tilde{\varphi}_{\mathbf{u},\mathbf{v}'} + 4 \sum_{\mathbf{u}',\mathbf{v}'} \frac{\Psi_{\mathbf{u},\mathbf{u}',\mathbf{v},\mathbf{v}'}}{1 + u^2} = \frac{1}{1 + u^2}, \end{aligned} \quad (35)$$

and the energy is given by Eq. (32).

The new corrections that we have included are all proportional to x_F^3 and our calculations goes up to x_F^2 . Therefore these corrections are negligible except for $k \simeq k_F$ (low k) where they are partially compensated by $\varphi_{\mathbf{k},\mathbf{q}} \simeq 1/k_F^2$. This justifies the $\mathbf{k} \rightarrow 0$ limit that is taken below.

We now project the Schrödinger equation on the two remaining subspaces.

$$\begin{aligned} & \left(q_0^2 + \lambda^2 + \tilde{\epsilon}_{\mathbf{k}} + \tilde{\epsilon}_{\mathbf{k}'} + \frac{\tilde{\epsilon}_{-\mathbf{k}-\mathbf{k}'+\mathbf{q}+\mathbf{q}'}}{2} - \tilde{\epsilon}_{\mathbf{q}} - \tilde{\epsilon}_{\mathbf{q}'} \right) \Psi_{\mathbf{k},\mathbf{k}',\mathbf{q},\mathbf{q}'} \\ & + 3 \sum_{\mathbf{k}'} \bar{\Lambda}_{\mathbf{k}''+\mathbf{k}'/2} \chi_{\mathbf{k},\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'} = \frac{\bar{\Lambda}_0}{2} (\Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}'} - \Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}}), \end{aligned} \quad (36a)$$

$$\begin{aligned} & 3(\lambda^2 + \tilde{\epsilon}_{\mathbf{k}} + \tilde{\epsilon}_{\mathbf{k}'} + \tilde{\epsilon}_{\mathbf{k}''} + \tilde{\epsilon}_{-\mathbf{k}-\mathbf{k}'-\mathbf{k}''+\mathbf{q}+\mathbf{q}'} \\ & - \tilde{\epsilon}_{\mathbf{q}} - \tilde{\epsilon}_{\mathbf{q}'}) \chi_{\mathbf{k},\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'} \\ & + \bar{\Lambda}_{\mathbf{k}''+\mathbf{k}'/2} (\Psi_{\mathbf{k},\mathbf{k}',\mathbf{q},\mathbf{q}'} + \Psi_{\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'} + \Psi_{\mathbf{k}'',\mathbf{k},\mathbf{q},\mathbf{q}'}) = 0. \end{aligned} \quad (36b)$$

These coupled equations are quite complicated. Nevertheless many simplifications can be done that remain consistent with the order of our calculation. The \mathbf{q} (and \mathbf{q}') dependence can safely be neglected as well as the restriction outside the Fermi sea for the \mathbf{k} wavevectors. The limit $\mathbf{k} \rightarrow 0$ is also taken. In the source term (r.h.s.) of Eq. (36a), we can replace $\Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}}$ by using its lowest order expression from Eq. (34b),

$$\Phi_{\mathbf{k},\mathbf{k}',\mathbf{q}} = \frac{\bar{\Lambda}_0}{2} \frac{\varphi_{\mathbf{k}',\mathbf{q}} - \varphi_{\mathbf{k},\mathbf{q}}}{\lambda^2 + k'^2}. \quad (37)$$

Finally, Eq. (36b) allows to express $\chi_{\mathbf{k},\mathbf{k}',\mathbf{k}'',\mathbf{q},\mathbf{q}'}$. Once incorporated into Eq. (36a), it leads in the universal limit

$R^* \rightarrow 0$ to

$$\begin{aligned} & \left(\sqrt{\lambda^2 + 3k'^2/4} - \frac{1}{a} \right) \Psi_{\mathbf{k},\mathbf{k}',\mathbf{q},\mathbf{q}'} \\ & + 4\pi \sum_{\mathbf{k}''} \frac{\Psi_{\mathbf{k},\mathbf{k}'',\mathbf{q},\mathbf{q}'} + \Psi_{\mathbf{k}'',\mathbf{k}',\mathbf{q},\mathbf{q}'}}{\lambda^2 + k'^2 + k''^2 + \mathbf{k}' \cdot \mathbf{k}''} \\ & = \pi \frac{\varphi_{\mathbf{k}',\mathbf{q}'} - \varphi_{\mathbf{k},\mathbf{q}'} + \varphi_{\mathbf{k},\mathbf{q}} - \varphi_{\mathbf{k}',\mathbf{q}}}{\lambda^2 + k'^2}. \end{aligned} \quad (38)$$

The last step is to realize that the singular behavior at low k , $\varphi_{\mathbf{k},\mathbf{q}} \simeq 1/k^2$, implies that k -independent terms become negligible for $\mathbf{k} \rightarrow 0$. Rescaling variables, *e.g.* $\mathbf{k} = \lambda u$ with $\lambda = 1/a$ and Eq. (24), the following integral equation is obtained

$$\begin{aligned} & 4\pi \sum_{\mathbf{u}'} \frac{\Psi_{\mathbf{u},\mathbf{u}',\mathbf{v},\mathbf{v}'}}{1 + u'^2 + u'^2 + \mathbf{u}' \cdot \mathbf{u}''} \\ & + \left(\sqrt{1 + 3u'^2/4} - 1 \right) \Psi_{\mathbf{u},\mathbf{u}',\mathbf{v},\mathbf{v}'} = \frac{4\pi^2 (\tilde{\varphi}_{\mathbf{u},\mathbf{v}} - \tilde{\varphi}_{\mathbf{u},\mathbf{v}'})}{1 + u'^2}. \end{aligned} \quad (39)$$

It acts only on \mathbf{u}' and describes a three-body problem where u, v, v' are dummy variables. Its solution follows trivially from the solution of Eq. (19),

$$\Psi_{\mathbf{u},\mathbf{u}',\mathbf{v},\mathbf{v}'} = 4\pi^2 (\tilde{\varphi}_{\mathbf{u},\mathbf{v}} - \tilde{\varphi}_{\mathbf{u},\mathbf{v}'}) \frac{a_0(u')}{u'^2}. \quad (40)$$

Inserting this solution into Eq. (35) finally leads to the complete integral equation

$$\begin{aligned} & \frac{1}{2\pi^2} \int_{|\mathbf{u}'| > x_F} d^3 u' \frac{\tilde{\varphi}_{\mathbf{u}',\mathbf{v}}}{1 + u'^2 + u^2 + \mathbf{u}' \cdot \mathbf{u} - \mathbf{v}(\mathbf{u}' + \mathbf{u})} \\ & + \left(\sqrt{1 + \frac{3u^2}{4} - \frac{v^2}{4} - \frac{\mathbf{u} \cdot \mathbf{v}}{2}} - 1 \right) \tilde{\varphi}_{\mathbf{u},\mathbf{v}} \\ & - \frac{3a_0(0)}{16\pi^2} \int_{|\mathbf{v}'| < x_F} d^3 v' \tilde{\varphi}_{\mathbf{u},\mathbf{v}'} = \frac{1}{1 + u^2}. \end{aligned} \quad (41)$$

Note that the $1/(a\lambda)$ term in Eq. (35) has been compensated inside the parenthesis by using Eq. (21).

We now describe how Eq. (41) is solved perturbatively. Its solution is written in the form

$$\begin{aligned} \tilde{\varphi}_{\mathbf{u},\mathbf{v}} & = \frac{a(\mathbf{u},\mathbf{v})}{u^2 - v^2/3 - 2\mathbf{u} \cdot \mathbf{v}/3} \\ & \left(1 - \frac{a_0(0)}{2\pi^2} \int_{|\mathbf{v}'| < x_F} d^3 v' \frac{1}{u^2 - v'^2/3 - 2\mathbf{u} \cdot \mathbf{v}'/3} \right)^{-1} \end{aligned} \quad (42)$$

leading to a regularized integral equation for $a(\mathbf{u},\mathbf{v})$ that can be expanded in \mathbf{v} . The integral term inside the parenthesis of Eq. (42) is a correction $\sim x_F$. It is important only for small u to compensate the last term in the l.h.s. of Eq. (41).

Ordering the different source terms, $a(\mathbf{u}, \mathbf{v})$ can be decomposed as

$$a(\mathbf{u}, \mathbf{v}) = a_{s1}(u, v) + a_{s2}(u, v) + a_1(u)(\mathbf{u} \cdot \mathbf{v}) + v^2 a_2(u), \quad (43)$$

where the different terms are to be detailed below. $a_{s1}(u, v)$ is the same as in the last subsection and is given by Eq. (29). Its lowest order in x_F is $a_0(u)$, solution of Eq. (19). The first correction in x_F has been calculated last subsection. The expansion of Eq. (29) also yields a x_F^2 correction. Once plugged into Eq. (32), $a\lambda$ receives the correction $-a_0^3(0)x_F^5 I_3$ with

$$I_3 = \frac{3}{4\pi^3} \int_0^1 ds s^2 [2 - sJ_1(s)]^2 \simeq 0.01419, \quad (44)$$

where $J_1(s)$ is given Eq. (28). The second term, $a_{s2}(u)$, corresponds to the last term in the l.h.s. of Eq. (41). Similarly to $a_{s1}(u)$, it stems from low $k \simeq k_F$, and reduces, up to an important prefactor in the source term, to the three-body problem integral equation (19). The solution can be written as

$$a_{s2}(u, v) = - \left(\frac{a_0(0)x_F}{2\pi^2} \right)^2 a_0(u) J_2 \left(\frac{v}{x_F} \right), \quad (45)$$

where

$$J_2(y) = \int_{x>1} d^3x \frac{1}{x^2 - \frac{y^2}{3} - \frac{2\mathbf{x}\cdot\mathbf{y}}{3}} \int_{y'<1} d^3y' \frac{1}{x^2 - \frac{y'^2}{3} - \frac{2\mathbf{x}\cdot\mathbf{y}'}{3}}. \quad (46)$$

The contribution to $a\lambda$ is given by $a_0^3(0)x_F^5 I_2$ with the integral

$$I_2 = \frac{3}{16\pi^5} \int_0^1 dy y^2 J_2(y) \simeq 0.014440. \quad (47)$$

In a way similar to the first order correction, the two contributions stemming from a_{s1} and a_{s2} are produced by small wavevectors $k \simeq k_F$ and match exactly the total x_F^2 correction of the point-like boson model. They correspond to the large distance part of the scattering of the boson by the Fermi sea. On this scale $k \simeq k_F$, the composite structure of the boson is not apparent.

This is in contrast with the situation for the last two terms in Eq. (43). They result from the direct expansion in v of the integral equation. In that case, typical wavevectors k are of order $1/a \gg k_F$. These terms involve the whole spatial structure of the composite molecule. They have no equivalent in the point-like boson model and hence reveal the composite nature of the molecule. The integral equations that determine $a_1(u)$ and $a_2(u)$ follow from a tedious but systematic expansion in v .

$$\int_0^{+\infty} du' K_1(u, u') a_1(u') = S_1(u) \quad (48)$$

determines $a_1(u)$ with the Kernel

$$K_1(u, u') = \frac{3}{4} \frac{\delta(u - u')}{1 + E} + \frac{1}{\pi} \frac{u'^2}{B^2} \left[2 - \frac{A}{B} \ln \left(\frac{A + B}{A - B} \right) \right], \quad (49)$$

with $A = 1 + u^2 + u'^2$, $B = uu'$ and $E = \sqrt{1 + 3u^2/4}$. Using the same definitions, the source term can be written

$$\begin{aligned} S_1(u) = & -\frac{3}{16} \frac{a_0(u)}{E(1 + E)^2} \\ & - \frac{2}{\pi} \int_0^{+\infty} du' \frac{a_0(u')}{u^2} \left[\frac{u'^2 - A}{A^2 - B^2} + \frac{1}{2B} \ln \left(\frac{A + B}{A - B} \right) \right] \\ & - \frac{2}{3\pi} \int_0^{+\infty} du' \frac{a_0(u')}{B^2} \left[2 - \frac{A}{B} \ln \left(\frac{A + B}{A - B} \right) \right]. \end{aligned} \quad (50)$$

The integral equation for $a_2(u)$,

$$\int_0^{+\infty} du' K_0(u, u') a_2(u') = S_2^{(1)}(u) + S_2^{(2)}(u), \quad (51)$$

has the same Kernel as Eq. (19) with two sources terms. Note that this result has already been averaged over the directions of \mathbf{v} and \mathbf{u} since only that component matters for λ , see Eq. (32).

The first source term, $S_2^{(1)}(u)$, depends on $a_1(u)$

$$\begin{aligned} S_2^{(1)}(u) = & -\frac{1}{16} \frac{u^2 a_1(u)}{E(1 + E)^2} \\ & - \frac{2}{3\pi} \int_0^{+\infty} du' a_1(u') \left[\frac{u'^2 - A}{A^2 - B^2} + \frac{1}{2B} \ln \left(\frac{A + B}{A - B} \right) \right] \\ & - \frac{2}{9\pi} \int_0^{+\infty} du' a_1(u') \frac{1}{B} \ln \left(\frac{A + B}{A - B} \right). \end{aligned} \quad (52)$$

The second source term depends on $a_0(u)$,

$$\begin{aligned} S_2^{(2)}(u) = & -\frac{3a_0(u)}{32E(1 + E)^2} - \frac{u^2(1 + 3E)a_0(u)}{128E^3(1 + E)^3} \\ & - \frac{26}{27\pi} \int_0^{+\infty} \frac{du'}{u'^2} \left[\frac{a_0(u')}{2B} \ln \left(\frac{A + B}{A - B} \right) - \frac{a_0(0)}{1 + u^2} \right] \\ & - \frac{4}{9\pi} \int_0^{+\infty} du' \frac{a_0(u')}{u'^2} \left[\frac{u'^2 - A}{A^2 - B^2} + \frac{1}{2B} \ln \left(\frac{A + B}{A - B} \right) \right] \\ & - \frac{2}{3\pi} \int_0^{+\infty} du' a_0(u') \frac{(u^2 + u'^2)A - B^2}{(A^2 - B^2)^2}. \end{aligned} \quad (53)$$

The resulting contribution to $a\lambda$, Eq. (32), is added to the Pauli blocking term (third term inside the parenthesis of Eq. (32)) to give $x_F^5 I_1$ with

$$\begin{aligned} I_1 = & \frac{2}{5\pi} - \frac{3a_2(0)}{20\pi} - \frac{3a_0(0)}{320\pi} - \frac{4}{15\pi^2} \int_0^{+\infty} du \frac{u^2 a_1(u)}{(1 + u^2)^2} \\ & - \frac{8}{45\pi^2} \int_0^{+\infty} du \frac{a_0(u)(1 + 5u^2/2)}{(1 + u^2)^2} \simeq 0.063324. \end{aligned} \quad (54)$$

Gathering all x_F^2 corrections to the mean field result, we finally obtain that Eq. (30) is extended to

$$E = -\frac{\hbar^2}{ma^2} \left(1 - \frac{x_F^3 a_0(0)}{2\pi} - \frac{2x_F^4 a_0^2(0)}{\pi^2} (\ln 2 - 3/8) + 2x_F^5 [a_0^3(0)(I_2 - I_3) + I_1] \right), \quad (55)$$

with Eqs. (54),(47),(44) for I_1, I_2 and I_3 . Note that $a_0^3(0)(I_2 - I_3) + I_1 \simeq 0.0637$. It indicates that the contribution I_1 , specific to the composite boson, dominates quantitatively the last term in the energy. The point-like boson model also leads to Eq. (55) but with $I_1 = 0$. The final result (55) was announced in Sec. II as Eq. (3).

IV. VARIATIONAL TREATMENT

As mentioned in Sec. II where the main results of this article are summarized, an alternative way of treating the problem is to use a variational approach in the restricted subspace given by Eq. (4). We recall here the variational form

$$|\psi\rangle = \left(\beta b_{\mathbf{K}=0}^\dagger + \sum_{\mathbf{k}}' A_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger a_{-\mathbf{k},\uparrow}^\dagger - \sum_{\mathbf{k},\mathbf{q}}' \varphi_{\mathbf{k}} a_{\mathbf{k},\downarrow}^\dagger b_{-\mathbf{k}+\mathbf{q}}^\dagger a_{\mathbf{q},\downarrow} - \sum_{\mathbf{k},\mathbf{k}',\mathbf{q}}' \Phi_{\mathbf{k},\mathbf{k}'} a_{\mathbf{k},\downarrow}^\dagger a_{\mathbf{k}',\downarrow}^\dagger a_{-\mathbf{k}'-\mathbf{k}+\mathbf{q},\uparrow}^\dagger a_{\mathbf{q},\downarrow} \right) |FS\rangle, \quad (56)$$

where $\Phi_{\mathbf{k},\mathbf{k}'}$ has been antisymmetrized. As observed in the previous section III, this *ansatz* is sufficient to recover the mean-field correction (21) corresponding to the first order term in the perturbative expansion (55). Minimizing the energy with respect to the amplitudes β , $A_{\mathbf{k}}$, $\varphi_{\mathbf{k}}$ and $\Phi_{\mathbf{k},\mathbf{k}'}$, while keeping $\langle\psi|\psi\rangle$ constant leads to a set of equations very similar to the one obtained in the perturbative treatment of the problem

$$(E_0 - E)\beta + \frac{1}{\sqrt{V}} \sum_{\mathbf{k}}' \Lambda_{\mathbf{k}} A_{\mathbf{k}} = 0 \quad (57)$$

$$(2\varepsilon_{\mathbf{k}} - E)A_{\mathbf{k}} + \frac{\Lambda_{\mathbf{k}}}{\sqrt{V}}\beta + \frac{1}{\sqrt{V}} \sum_{\mathbf{q}}' \Lambda_{\mathbf{k}} \varphi_{\mathbf{q}} = 0 \quad (58)$$

$$\sum_{\mathbf{q}}' (E_0 + \varepsilon_{\mathbf{k}} + \varepsilon_{\mathbf{q}-\mathbf{k}}/2 - \varepsilon_{\mathbf{q}} - E)\varphi_{\mathbf{q}} + \sum_{\mathbf{q}}' \frac{\Lambda_{\mathbf{k}}}{\sqrt{V}} A_{\mathbf{k}} + \frac{2}{\sqrt{V}} \sum_{\mathbf{k}',\mathbf{q}}' \Lambda_{\mathbf{k}'+\mathbf{k}/2} \Phi_{\mathbf{k},\mathbf{k}'} = 0 \quad (59)$$

$$\sum_{\mathbf{q}'}' (\varepsilon_{\mathbf{k}} + \varepsilon_{\mathbf{k}'} + \varepsilon_{\mathbf{q}-\mathbf{k}-\mathbf{k}'} - \varepsilon_{\mathbf{q}} - E)\Phi_{\mathbf{k},\mathbf{k}'} + \frac{1}{2\sqrt{V}} \sum_{\mathbf{q}}' (\Lambda_{\mathbf{k}'+\mathbf{k}/2} \varphi_{\mathbf{q}} - \Lambda_{\mathbf{k}+\mathbf{k}'/2} \varphi_{\mathbf{k}'}) = 0 \quad (60)$$

Note that here the energy E appears as the Lagrange multiplier associated with the constraint on $\langle\psi|\psi\rangle$. Moreover, since the equations are linear, we can set $\beta = 1$.

The first two equations are identical to those we used in the perturbative calculation. Introducing λ defined by $E = -\hbar^2 \lambda^2/m$, it yields the first variational equation:

$$\lambda = \frac{1}{a} - \frac{2k_F}{\pi} \left[1 - \frac{\lambda}{k_F} \arctan(k_F/\lambda) \right] + \frac{2k_F^3}{3\pi} \sum_{\mathbf{k}}' \frac{\varphi_{\mathbf{k}}}{k^2 + \lambda^2}. \quad (61)$$

In Eq. (60), the explicit q dependence vanishes with the radial sum, and we finally recover the equation

$$\Phi_{\mathbf{k},\mathbf{k}'} = \frac{1}{2\sqrt{V}} \left(\frac{\Lambda_{\mathbf{k}+\mathbf{k}'/2} \varphi_{\mathbf{k}'} - \Lambda_{\mathbf{k}'+\mathbf{k}/2} \varphi_{\mathbf{k}}}{\varepsilon_{\mathbf{k}} + \varepsilon_{\mathbf{k}'} + \varepsilon_{\mathbf{k}+\mathbf{k}'} - E} \right). \quad (62)$$

Inserting Eq. (58) and (62) in (59) finally yields in the short range limit a closed equation for the field φ :

$$\left(-\frac{1}{4\pi a} + F_{\mathbf{k}} + \widehat{L}'_{\mathbf{k}} \right) \varphi_{\mathbf{k}} = \frac{1}{V} \frac{1}{2\varepsilon_{\mathbf{k}} - E}, \quad (63)$$

where the function F and the integral kernel \widehat{L}' are defined by

$$\widehat{L}' \varphi_{\mathbf{k}} = \frac{1}{V} \sum_{\mathbf{k}'}' \frac{\varphi_{\mathbf{k}'}}{\varepsilon_{\mathbf{k}} + \varepsilon_{\mathbf{k}'} + \varepsilon_{\mathbf{k}+\mathbf{k}'} - E} \quad (64)$$

$$F_{\mathbf{k}} = \frac{1}{V} \sum_{\mathbf{q}}' \frac{1}{E - 2\varepsilon_{\mathbf{q}}} + \frac{1}{4\pi} \sqrt{\lambda^2 + \frac{3}{4}k^2} + \frac{1}{V} \sum_{|\mathbf{k}'| < k_F} \left(\frac{1}{\varepsilon_{\mathbf{k}} + \varepsilon_{\mathbf{k}'} + \varepsilon_{\mathbf{k}+\mathbf{k}'} - E} \right) \quad (65)$$

Eq. (61) and (63) are then solved numerically, yielding the result presented in Fig. (3). A good agreement between our variational *ansatz* and the exact Monte-Carlo simulations is obtained. As already noted, it is very close to the mean-field prediction up to $k_F a \sim 1$. However, it stays finite at unitarity, since we have $E \simeq 1.1506 E_F$ for $k_F a = \infty$.

V. CONCLUSION

In analogy with the Fermi-polaron system, the work presented here shows that the molecular sector of the impurity problem can be described quantitatively as a molecule dressed by a single particle-hole excitation. However, two important points are still to be clarified and will be addressed in future work. First, what is the effective mass of the quasi-particle? This property is in particular important to capture the dynamical behavior of the system, as suggested [14] and observed recently in

experiments [23]. Moreover, the bosonic/fermionic nature of the quasi-particle should be clarified by the study of an ensemble of impurities immersed in a Fermi sea, that may help clarifying the molecule-polaron transition scenario. This formalism can also be used to interpret spectroscopic data obtained for instance in Ref. [24] and refine the Nozières Schmitt-Rink analysis of Ref. [25]. Another extension of this work deals with mixtures of

particles with unequal masses, for instance the Li-K mixture.

We thank N. Navon, S. Nascimbène, C. Lobo and P. Massignan for fruitful discussions. F.C. acknowledges support from ESF (SCALA and EuroQUAM), ANR FABIOLA and GasCor, Région Ile de France (IFRAF), ERC Ferlodim and Institut Universitaire de France.
