HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

*From Black-Scholes and Dupire formulae to
last passage times of local martingales*

Part B : The finite time horizon

Amel Bentata*and Marc Yor†

July, 2nd, 2008

1. These notes are the second half of the contents of the course given by the second author at the Bachelier Seminar (8-15-22 February 2008) at IHP. They also correspond to topics studied by the first author for her Ph.D.thesis.
2. Unlike Part A of the course ([3]), this document still raises a number of questions, pertaining to various extensions of the classical Black-Scholes formula.
3. Comments are welcome and may be addressed to : bentata@clipper.ens.fr.

A rough description of Part B of the course

In Part B of the Course, we further our discussion of relations between Black-Scholes type formulae and distributions of last times, begun in Notes 1 to 5 of Part A ([3]).

In Note 6, following a suggestion by J. Akahori, we consider, instead of the last passage times \mathcal{G}_K , which “look into the filtration up to time ∞ ”, the times : $g_l^{(\nu)}(t) = \sup\{s \leq t, B_s^{(\nu)} = l\}$ ¹ which present the advantage, although they are not stopping times, to look into the filtration only up to the finite horizon t . Computing the associated Azéma’s supermartingale : $Z_{s,t} = \mathbb{P}\left(g_l^{(\nu)}(t) > s | \mathcal{F}_s\right)$, for $s < t$, leads us to study (super-)martingales with respect to the two-parameter filtration $\mathcal{F}_{s,t} = \sigma\{B_u^{(\nu)}, u \leq s, B_v^{(\nu)}, v \geq t\}$, $0 < s < t < \infty$.

In Note 7, we no longer make the assumption that (M_t) is continuous, and we discuss which of the results from the previous notes still hold, or how they may be modified. In particular, some of our discussion applies to the Esscher martingales : $\mathcal{E}_t^\psi = \exp(\lambda X_t - t\psi(\lambda))$, $t \geq 0$, associated with a Lévy process (X_t) with some exponential moments.

In Note 8, we discuss a recent result by P. Carr, C. Ewald and Y. Xiao asserting that $\mathbb{E}\left[\left(\frac{1}{T}A_T - K\right)^+\right]$ is increasing in T , when $A_t = \int_0^t ds \exp\left(B_s - \frac{s}{2}\right)$; clearly, our previous discussion does not apply there.

In Note 9, we examine how careful one should be when changing “puts” into “calls”, and examining the modifications one should make in our previous discussions.

Note 10 concludes : a number of our results may be stated in quite some generality, at the cost of introducing certain conditional expectations, which, in the Markovian context, are easily computed, but in the general martingale framework, bring some fundamental “unknowns” into the discussion. Thus, this case study may be seen as a further illustration of the passage from a Markovian discussion to a “general theory of stochastic processes” type discussion.

Finally, an appendix, presents a number of developments/ solutions for some of the exercises suggested in the different notes of both Part A and Part B.

Throughout the text, we may refer to some of the results of Part A; when we do so we write e.g : $A - (65)$ for the equation (65) in Part A.

¹In general, we use capital letters such as K for “geometric type” objects, and small letters such as l for items related to Brownian motion with drift, with the correspondence : $l = \ln K$.

6 Note 6 : Working under a finite horizon

This note aims to counterbalance the difficulty of bringing into the picture quantities such as $\mathcal{G}_K = \sup\{t, M_t = K\}$ which take into account the whole history of M (or (\mathcal{F}_t)).

Thus, we are now interested in finding formulae up to finite maturity, which may replace our previous formula :

$$\mathbb{P}(\mathcal{G}_K \leq t | \mathcal{F}_t) = \left(1 - \frac{M_t}{K}\right)^+, \quad (1)$$

when $M \in \mathcal{M}_0^+$, or even the more general² :

$$\mathbb{E}[(\mathcal{G}_K \leq t); (K - M_\infty)^+] = \mathbb{E}[(K - M_t)^+] \quad (2)$$

The following developments are most recent³, therefore we shall study only the particular case where : $M_t = \mathcal{E}_t = \exp(B_t - \frac{t}{2})$, and \mathcal{G}_K is replaced by $\mathcal{G}_K(t) = \sup\{s \leq t, \mathcal{E}_s = K\}$.

6.1 Past-future (sub)martingales

Rather than starting with some “explicit” computation about $\mathcal{G}_K(t)$, it seems of interest (see below !) to introduce the past-future filtration of Brownian motion :

$$\mathcal{F}_{s,t} = \sigma\{B_u, u \leq s, B_v, v \geq t\},$$

indexed by pairs (s, t) , with $0 \leq s \leq t < \infty$.

Note that, for $s = t$, $\mathcal{F}_{s,s} = \mathcal{F}_\infty$, and that, if $[s, t] \subset [s', t']$, then : $\mathcal{F}_{s,t} \supseteq \mathcal{F}_{s',t'}$.

In this note, we shall naturally deal with :

- i. $(\mathcal{F}_{s,t})$ positive submartingales, i.e : \mathbb{R}^+ valued, $(\mathcal{F}_{s,t})$ adapted processes $(\Sigma_{s,t})$ such that :

$$\mathbb{E}[\Sigma_{s,t} | \mathcal{F}_{s',t'}] \geq \Sigma_{s',t'}; \quad (3)$$

- ii. $(\mathcal{F}_{s,t})$ positive martingales, i.e :

$$\mathbb{E}[M_{s,t} | \mathcal{F}_{s',t'}] = M_{s',t'}. \quad (4)$$

²We often write $\mathbb{E}[\Lambda; X]$ for $\mathbb{E}[1_\Lambda X]$

³They were very much motivated by some computations of Akahori-Imamura-Yano [1], which Madan-Royennette-Yor [24] have later shown to match formula (13) below.

Here are some particular examples of such processes : let Γ be a Borel set in \mathbb{R} , and define :

$$\Sigma_{s,t}^\Gamma = \mathbb{P}(\{\forall u \in (s,t), B_u \in \Gamma\} | \mathcal{F}_{s,t}), \quad (5)$$

and the sets :

$$A_{s,t}^\Gamma = \{\forall u \in (s,t), B_u \in \Gamma\}.$$

They satisfy : $A_{s,t}^\Gamma \supset A_{s',t'}^\Gamma$, which implies that $\Sigma_{s,t}^\Gamma$ satisfies (3).

Moreover, from the Markov property of Brownian motion, there exists a function $f^\Gamma(s,t;x,y)$ such that :

$$\Sigma_{s,t}^\Gamma = f^\Gamma(s,t; B_s, B_t). \quad (6)$$

We shall call such functions f (depending on the 4 arguments) past-future subharmonic functions (*PFS*-functions). Naturally, we may also be interested in past-future harmonic functions $h(s,t;x,y)$ (*PFH*-functions) such that :

$$\Sigma_{s,t}^h = h(s,t; B_s, B_t) \quad \text{is a } (\mathcal{F}_{s,t})\text{-martingale.}$$

Thanks to basic properties of Brownian motion, i.e : stability by time inversion, that is : if $(B_t, t \geq 0)$ is a Brownian motion starting from 0, then :

$$(\hat{B}_t = tB_{1/t}, t > 0)$$

is also a Brownian motion (which extends to 0, by continuity), and so on, the following Proposition is easily obtained :

Proposition 6.1. *i. If $f(\equiv f(s,t;x,y))$ is PFH, resp PFS, then \hat{f} is also PFH, resp PFS, where :*

$$\hat{f}(s,t;x,y) = f\left(\frac{1}{t}, \frac{1}{s}, \frac{y}{t}, \frac{x}{s}\right) \quad (0 < s < t; x, y \in \mathbb{R}) \quad (7)$$

We also note that the application $f \rightarrow \hat{f}$ is involutive, i.e :

$$\hat{\hat{f}} = f.$$

ii. If f is PFH, then, for any $\nu, \lambda \in \mathbb{R}$:

$$f_{\nu,\lambda}(s,t;x,y) \equiv f(s,t;x + \nu s + \lambda, y + \nu t + \lambda) \quad (8)$$

is PFH.

iii. If f is PFH, then for any $a > 0$,

$$f_{(a)}(s,t;x,y) \equiv f(a^2s, a^2t; ax; ay) \quad (9)$$

is also PFH

Proof. We leave the proof to the reader. □

6.2 The case of Brownian motion with drift

6.2.1

Here are some particular examples of the previous discussion, which are closely connected with our random times :

$$g_l^{(\nu)}(t) = \sup\{s \leq t, B_s^{(\nu)} = l\},$$

where :

$$B_s^{(\nu)} = B_s + \nu s.$$

Indeed, for $s \leq t$:

$$\left(g_l^{(\nu)}(t) \leq s\right) = A_{s,t}^+ + A_{s,t}^-, \quad (10)$$

where :

$$\begin{cases} A_{s,t}^+ &= \{\forall u \in (s, t), B_u^{(\nu)} > l\} \\ A_{s,t}^- &= \{\forall u \in (s, t), B_u^{(\nu)} < l\}. \end{cases} \quad (11)$$

Therefore,

$$\begin{aligned} \Sigma_{s,t}^{(l,\nu)} &\stackrel{\text{def}}{=} \mathbb{P}\left(g_l^{(\nu)}(t) \leq s \mid \mathcal{F}_{s,t}\right) \\ &= \Sigma_{s,t}^+ + \Sigma_{s,t}^-, \end{aligned}$$

with

$$\begin{cases} \Sigma_{s,t}^+ &= \mathbb{P}\left(A_{s,t}^+ \mid \mathcal{F}_{s,t}\right) \\ \Sigma_{s,t}^- &= \mathbb{P}\left(A_{s,t}^- \mid \mathcal{F}_{s,t}\right). \end{cases} \quad (12)$$

Our main result here is :

Theorem 6.1.

$$\Sigma_{s,t}^{(l,\nu)} = \left(1 - \exp\left(-\frac{2}{t-s}(B_s^{(\nu)} - l)(B_t^{(\nu)} - l)\right)\right)^+ \quad (13)$$

Thus the function :

$$\begin{aligned} f^{(l,\nu)}(s, t; x, y) &= \left(1 - \exp\left(-\frac{2}{t-s}(x + \nu s - l)(y + \nu t - l)\right)\right)^+ \\ &= 1 - \exp\left(-\frac{2}{t-s}((x + \nu s - l)(y + \nu t - l))^+\right) \end{aligned} \quad (14)$$

is *PFS*.

This leads us naturally to the next theorem :

Theorem 6.2. *The function :*

$$h^{(l,\nu)}(s,t;x,y) = \exp\left(-\frac{2}{t-s}(x+\nu s-l)(y+\nu t-l)\right) \quad (15)$$

is PFH.

The sequel of this note consists in proving both theorems.

As an illustration of both theorems, and of Proposition 6.1, an elementary computation shows that :

$$\widehat{h^{(l,\nu)}} = h^{(\nu,l)}; \widehat{f^{(l,\nu)}} = f^{(\nu,l)} \quad (16)$$

6.2.2 A connection with Section 4.3 (Part A)

We now interpret our result (13) in terms of the martingale : $(\mathcal{E}_u, u \leq t)$, which terminates at $\mathcal{E}_t > 0$. Now, with the same notation as in Section 4.3 (Part A), the Azéma supermartingale : $(Z_s^K, s \leq t)$ is :

$$Z_s^K = 1 - \Sigma_{s,t}^{(l,\nu)},$$

with $l = \log(K)$ and $\nu = -\frac{1}{2}$.

Hence :

$$Z_s^K = \exp\left(-\frac{2}{(t-s)}\left((B_s^{(-1/2)} - l)(B_t^{(-1/2)} - l)\right)^+\right).$$

We consider the easiest case : $K = 1$, hence : $l = 0$, so that :

$$\mathcal{G}_1(t) = \sup\{s \leq t, B_s - \frac{s}{2} = 0\},$$

and we wish to compute :

$$\mathbb{E}\left[f\left(\exp\left(B_t - \frac{t}{2}\right)\right) \mid \mathcal{G}_1(t)\right] = \frac{\mathbb{E}\left[f\left(\exp(B_t)\right) \exp\left(-\frac{B_t}{2}\right) \mid g_t\right]}{\mathbb{E}\left[\exp\left(-\frac{B_t}{2}\right) \mid g_t\right]}, \quad (17)$$

where : $g_t = \sup\{u \leq t, B_u = 0\}$.

Now, we use the fact that : $B_t = B_{g_t+(t-g_t)} = \sqrt{t-g_t} \tilde{m}_1$ where $\tilde{m}_1 = \epsilon\sqrt{2\mathbf{e}}$, and $g_t, \epsilon, \mathbf{e}$ are independent. ϵ is symmetric Bernoulli, and \mathbf{e} is a standard exponential variable.

Since :

$$\mathbb{P}(\tilde{m}_1 \in d\mu) = \frac{1}{2}|\mu|e^{-\mu^2/2}d\mu, \quad (\mu \in \mathbb{R}),$$

we obtain with $\lambda = \sqrt{t - g_t}$:

$$\mathbb{E} [f(\mathcal{E}_t) | \mathcal{G}_1(t)] = \frac{\int_{-\infty}^{\infty} \frac{d\mu}{2} |\mu| e^{-\mu^2/2} e^{-\lambda\mu/2} f(e^{\lambda\mu})}{\int_{-\infty}^{\infty} \frac{d\mu}{2} |\mu| e^{-\mu^2/2} e^{-\lambda\mu/2}}, \quad (18)$$

which provides us with an explicit form of the law $\nu_1(dm)$ defined in *Part A* – (125). From there, all quantities found in Subsection *A* – 4.3 can be made explicit.

6.3 Proof of Theorem 6.2

It will follow from the next proposition

Proposition 6.2. *A regular function $h(s, t; x, y)$ is PFH if and only if it satisfies the following system :*

$$h'_s(s, t; x, y) + \frac{y-x}{t-s} h'_x(s, t; x, y) + \frac{1}{2} h''_{x^2}(s, t; x, y) = 0 \quad (-)$$

$$-h'_t(s, t; x, y) - \frac{y-x}{t-s} h'_y(s, t; x, y) + \frac{1}{2} h''_{y^2}(s, t; x, y) = 0 \quad (+)$$

- The proof of this proposition hinges on the following lemma :

Lemma 6.1. *Let*

$$M_{s,t}^f = f(s, t; B_s, B_t),$$

for f a regular function; it is a past-future martingale if and only if :

- a) *for fixed t , $\{(M_{s,t}^f)_s, s < t\}$ is a $(\mathcal{F}_s^{(t)}, s < t)$ -martingale, where :*

$$\mathcal{F}_s^{(t)} = \mathcal{F}_s \vee \sigma(B_t),$$

- b) *for fixed s , $\{(M_{s,t}^f)_t, t > s\}$ is a $({}^{(s)}\mathcal{F}_t^{(+)}, t > s)$ -martingale where :*

$${}^{(s)}\mathcal{F}_t^{(+)} = \sigma(B_s) \vee \mathcal{F}_t^{(+)}, \quad \text{and} \quad \mathcal{F}_t^{(+)} = \sigma(B_v, v \geq t)$$

Proof. Note that $(M_{s,t}^f)$ is an $(\mathcal{F}_{s,t})$ -martingale if and only if :

for every $\phi_{s'} \in b(\mathcal{F}_{s'})$, $\psi_{t'} \in b(\mathcal{F}_{t'}^{(+)})$, with $s' < s < t < t'$, one has :

$$\mathbb{E} [\phi_{s'} M_{s,t}^f \psi_{t'}] = \mathbb{E} [\phi_{s'} M_{s',t'}^f \psi_{t'}]. \quad (19)$$

We now prove :

1. (19) \implies a) and b) :
 Take $s' < s < t = t'$, and $\psi_t = g(B_t)$ for a generic bounded function g ; this proves (19) \implies a), and by past-future symmetry, (19) \implies b).
2. a) and b) \implies (19) :
 We wish to prove (19). From the Markov property, the *LHS* of (19), say l , is equal to :

$$l = \mathbb{E} \left[\phi_{s'} M_{s,t}^f \gamma(t, B_t) \right],$$

where

$$\gamma(t, B_t) = \mathbb{E} [\psi_{t'} | \mathcal{F}_t] = \mathbb{E} [\psi_{t'} | B_t].$$

From a), we now get :

$$l = \mathbb{E} \left[\phi_{s'} M_{s,t}^f \gamma(t, B_t) \right] = \mathbb{E} \left[\phi_{s'} M_{s',t}^f \psi_{t'} \right].$$

Again, from the Markov property, we get :

$$l = \mathbb{E} \left[\beta(s', B_{s'}) M_{s',t}^f \psi_{t'} \right],$$

where :

$$\beta(s', B_{s'}) = \mathbb{E} [\phi_{s'} | B_{s'}].$$

Now, using b), we get :

$$l = \mathbb{E} \left[\beta(s', B_{s'}) M_{s',t}^f \psi_{t'} \right] = \mathbb{E} \left[\phi_{s'} M_{s',t}^f \psi_{t'} \right].$$

The lemma is proven⁴.

□

- We now give a proof of Proposition 6.2 :

Proof. For fixed $t > 0$, $(B_s, s \leq t)$ is a $(\mathcal{F}_s^{(t)}, s \leq t)$ semimartingale, with :

$$B_s = \beta_s^{(t)} + \int_0^s du \frac{B_t - B_u}{t - u}, \quad (20)$$

and $(\beta_s^{(t)}, s \leq t)$ a $(\mathcal{F}_s^{(t)}, s \leq t)$ Brownian motion (see [18]; also [36]).

⁴We remark that these arguments only make use of the Markov property and not of the Brownian framework. A further discussion is provided in [4].

We now apply Itô's formula to $(M_{s,t}^f, s \leq t)$ in the filtration $(\mathcal{F}_s^{(t)}, s \leq t)$. We obtain for $u < s < t$:

$$\begin{aligned} M_{s,t} &= M_{u,t} + \int_u^s dh f'_s(h, t; B_h, B_t) \\ &\quad + \int_u^s (d\beta_h^{(t)} + dh \frac{B_t - B_h}{t - h}) f'_x(h, t; B_h, B_t) \\ &\quad + \frac{1}{2} \int_u^s dh f''_{x^2}(h, t; B_h, B_t). \end{aligned} \quad (21)$$

Hence, the martingale property holds if and only if :

$$f'_s(s, t; x, y) + \frac{y - x}{t - s} f'_x(s, t; x, y) + \frac{1}{2} f''_{x^2}(s, t; x, y) = 0. \quad (22)$$

Thus, we have obtained $(-)$. We might obtain $(+)$ using some similar arguments; however a time inversion argument is much quicker and reduces the obtention of $(+)$ to $(-)$. \square

- Elementary computations now show that $h^{(l, \nu)}$ is *PFH*; that is we have proven Theorem 6.2.

Exercise 6.1. Consider $h^{(l, \nu)}$ as a generating function, depending on the 2 parameters l, ν . We write :

$$\begin{aligned} h^{(l, \nu)}(s, t; x, y) &= \exp\left(-\frac{2}{t - s}(x + \nu s - l)(y + \nu t - l)\right) \\ &= \sum_{p=0}^{\infty} \sum_{q=0}^{\infty} l^p \nu^q H_{p,q}(s, t; x, y). \end{aligned}$$

Prove that for any p, q , $H_{p,q}$ is *PFH*, and give an expression for $H_{p,q}$.

Exercise 6.2. Introduce the 5 variables Hermite polynomials $\mathcal{H}_{p,q}(a, b, c, d, f)$ defined by the generating function :

$$\exp\left(al + b\nu - \frac{c\nu^2}{2} - \frac{dl^2}{2} + fl\nu\right) = \sum_{p=0, q=0}^{\infty} l^p \nu^q \mathcal{H}_{p,q}(a, b, c, d, f).$$

Write $H_{p,q}$ in terms of $\mathcal{H}_{p,q}$.

Solutions to Exercises 6.1 and 6.2 are given in the Appendix.

Exercise 6.3. (A second family of PFH functions). Check that, for any $a \in \mathbb{R}$,

$$h^{(a)}(s, t; x, y) = \exp \left(a \frac{y-x}{t-s} - \frac{a^2}{2} \frac{1}{t-s} \right) \quad (23)$$

is a PFH function.

Hint: recall that, if

$$B_{[s,t]} = \frac{B_t - B_s}{t-s},$$

then :

$$\mathbb{E} [B_{[s,t]} | \mathcal{F}_{s',t'}] = B_{[s',t']}.$$

This property of (B_t) is the Harness property, which holds more generally for any integrable Lévy process. More generally, see Mansuy-Yor ([25]) on Harnesses. We refer to [7] (exercise 6.19), [16], [33], [34].

Exercise 6.4. Give other examples of PFH functions for other Lévy processes.

An excellent candidate is the Gamma process $(\gamma_t, t \geq 0)$, since the Harness property in this case :

$$\mathbb{E} [\gamma_{[s,t]} | \mathcal{F}_{s',t'}] = \gamma_{[s',t]},$$

is reinforced as follows :

$$\frac{\gamma_t - \gamma_s}{\gamma_{t'} - \gamma_{s'}} \text{ is independent from } \mathcal{F}_{s',t'},$$

and is distributed as :

$$\beta(t-s; (t'-s') - (t-s))$$

where $\beta(a; b)$ is the beta variable with parameters a and b . Thus, we have, for any $m > 0$:

$$\mathbb{E} \left[\left(\frac{\gamma_t - \gamma_s}{\gamma_{t'} - \gamma_{s'}} \right)^m | \mathcal{F}_{s',t'} \right] = \frac{\mathbb{E} [(\gamma_t - \gamma_s)^m]}{\mathbb{E} [(\gamma_{t'} - \gamma_{s'})^m]},$$

ie : for any $m > 0$:

$$\frac{(\gamma_t - \gamma_s)^m}{\mathbb{E} [(\gamma_t - \gamma_s)^m]} = \frac{(\gamma_t - \gamma_s)^m}{\Gamma(m + (t-s))/\Gamma(t-s)} \text{ is a } (\mathcal{F}_{s,t}) \text{ martingale.}$$

For more references about the nice properties of the Gamma process, see, e.g. [39].

Exercise 6.5. Give a version of Proposition 6.2, i.e : the differential system $(-)$ and $(+)$, when Brownian motion now takes values in \mathbb{R}^n .

(Solution : $\frac{y-x}{t-s} h'_x$ is replaced by : $\frac{y-x}{t-s} \cdot \nabla_x h$, and h''_{x^2} is replaced by : $\Delta_x h$, and so on...)

6.4 Proof of Theorem 6.1

We have :

$$Z_{s,t}^{(+)} = 1_{\{B_s^{(\nu)} > l\}} \mathbb{P} \left(\inf_{\{s \leq u \leq t\}} (B_u^{(\nu)} - B_s^{(\nu)}) > l - B_s^{(\nu)} | B_t^{(\nu)} - B_s^{(\nu)} \right). \quad (24)$$

Thus, we need to compute, for l , and $\lambda = l - B_s^{(\nu)}$:

$$\begin{aligned} & \mathbb{P} \left(\inf_{\{s \leq u \leq t\}} (B_u^{(\nu)} - B_s^{(\nu)}) > l - B_s^{(\nu)} | B_t^{(\nu)} - B_s^{(\nu)} = m \right) \\ &= \mathbb{P} (T_\lambda > (t - s) | B_{(t-s)} = m), \end{aligned} \quad (25)$$

since :

- i. the quantity in (25) clearly depends only on $(t - s)$ and not on the pair (s, t) ,
- ii. the law of the Bridge from a to b , over the time interval $[0, \alpha]$ of a Brownian motion with drift ν does not depend on ν .

Thus, from (25), we need to compute :

$$\mathbb{P} (T_\lambda > (t - s) | B_{(t-s)} = m) = 1 - \mathbb{P} (T_\lambda < (t - s) | B_{(t-s)} = m). \quad (26)$$

Let us denote by $\mathbb{P}_{0 \rightarrow m}^{(u)}$ the law of the Brownian bridge of length u , starting at 0, ending at m . Then, there is the result :

$$\mathbb{P}_{0 \rightarrow m}^{(u)} (T_\lambda < u) = \exp \left(-\frac{(2\lambda(\lambda - m))^+}{u} \right) \quad (27)$$

Comment : We learnt from G.Pagès [27] that the Brownian Bridge method to estimate the error due to discretization for path dependent options relies upon formula (27), which is also proven in Section 7.7 of [27].

We give two proofs of (27) :

- **A first proof via the reflection principle :**

- (a) By scaling, we can restrict ourselves to $u = 1$;
- (b) In [38], it is remarked, following [31], that if $S_t = \sup_{u \leq t} B_u$, then $2S_1(S_1 - B_1)$ is independent from B_1 , and satisfies :

$$2S_1(S_1 - B_1) \stackrel{\text{law}}{=} \mathbf{e},$$

where \mathbf{e} is a standard exponential variable. Thus :

$$\begin{aligned}\mathbb{P}_{0 \rightarrow m}^{(1)}(T_\lambda < 1) &= \mathbb{P}_{0 \rightarrow m}^{(1)}(S_1 > \lambda) \\ &= \mathbb{P}_{0 \rightarrow m}^{(1)}(2S_1(S_1 - B_1) > 2\lambda(\lambda - m)) \\ &= \exp(-2\lambda(\lambda - m))\end{aligned}$$

(here, we have assumed a priori : $\lambda(\lambda - m) > 0$.)

- **A second proof via Doob's maximal identity :** In order to show :

$$p_{\lambda, m} \equiv \mathbb{P} \left[\sup_{u \leq 1} B_u > \lambda | B_1 = m \right] = \exp(-2\lambda(\lambda - m)), \quad (28)$$

($\lambda > m, \lambda > 0$), we use time inversion :

$$\begin{aligned}p_{\lambda, m} &= \mathbb{P} \left[\sup_{t \geq 1} B_{1/t} > \lambda | B_1 = m \right] \\ &= \mathbb{P} \left[\sup_{t \geq 1} \frac{\hat{B}_t}{t} > \lambda | \hat{B}_1 = m \right] \\ &= \mathbb{P} \left[\exists t \geq 1, (\hat{B}_t - \lambda t) > 0 | \hat{B}_1 = m \right] \\ &= \mathbb{P} \left[\exists u \geq 0, (\hat{B}_{1+u} - \lambda(1+u)) > 0 | \hat{B}_1 = m \right] \\ &= \mathbb{P} \left[\exists u \geq 0, ((\hat{B}_{1+u} - \hat{B}_1) - \lambda u) > (\lambda - m) \right] \\ &= \mathbb{P} \left[\sup_{u \geq 0} (B_u - \lambda u) > (\lambda - m) \right] \\ &= \mathbb{P} \left[\sup_{u \geq 0} \exp(2\lambda(B_u - \lambda u)) > \exp(2\lambda(\lambda - m)) \right] \\ &= \mathbb{P} \left[\frac{1}{\mathbf{U}} > \exp(2\lambda(\lambda - m)) \right] \\ &= \mathbb{P}[\mathbf{U} < \exp(-2\lambda(\lambda - m))] \\ &= \exp(-2\lambda(\lambda - m)).\end{aligned}$$

We note that since we derive formula (28) from Doob's maximal identity, we can recover the joint law of (S_1, B_1) from this identity; traditionally, this joint law is obtained from the reflection principle.

Exercise 6.6. a) Prove (27) with the help of the absolute continuity relationship between $\mathbb{P}_{0 \rightarrow m}^{(u)}$ and \mathbb{P}_0 on \mathcal{F}_t , for any $t < u$.

b) Compute the law of T_λ under $P_{0 \rightarrow m}^{(u)}$.

The answer is :

$$P_{0 \rightarrow m}^{(u)}(T_\lambda \in dt) = dt \frac{\lambda}{t} p_t(0, \lambda) \frac{p_{u-t}(\lambda, m)}{p_u(0, m)}.$$

Exercise 6.7. Compute :

$$\mathbb{P} \left(\sup_{t \leq 1} \left(\frac{B_t}{a + bt} \right) > \lambda \mid B_1 = m \right).$$

The previous method yields :

$$\mathbb{P} \left(\sup_{t \leq 1} \left(\frac{B_t}{a + bt} \right) > \lambda \mid B_1 = m \right) = \exp(-2\lambda a(\lambda(a+b) - m)),$$

for $\lambda > \frac{m}{a+b}$, $\lambda > 0$.

6.5 Towards an integral representation of the positive PFH functions

So far, we have discovered two families of *PFH* functions, i.e : $h^{(l, \nu)}$ on one hand and $h^{(a)}$ on the other hand. It would be nice to exhibit a unifying formula for all these *PFH* functions.

In fact, we are interested in the following question : is there an integral representation of all positive *PFH* functions? We were motivated to raise this question from the following classical result, due to D. Widder [32], see also J.L. Doob [13], concerning positive space-time harmonic functions (of Brownian motion) : $h \geq 0$ is space-time harmonic, if, by definition, $\{h(B_s, s), s \geq 0\}$ is a Brownian martingale. Thus, there exists a positive finite measure $\mu(d\lambda)$ such that :

$$h(x, s) = \int_{-\infty}^{\infty} d\mu(\lambda) \exp \left(\lambda x - \frac{\lambda^2 s}{2} \right). \quad (29)$$

Comment on (29):

In chapter I of [36], a probabilistic proof of Widder's result is obtained with the help of the non canonical Brownian motion :

$$B'_t = B_t - \int_0^t \frac{ds}{s} B_s, \quad t \geq 0.$$

It would be most interesting to obtain a representation of the *PFH* functions by constructing a two-parameter process, with a past-future filtration $\mathcal{F}'_{s,t}$ such that :

$$\mathcal{F}_{s,t} = \mathcal{F}'_{s,t} \vee \sigma(B_s, B_t),$$

and $\mathcal{F}'_{s,t}$ is independent from the pair (B_s, B_t) . Such a filtration is exhibited in the next exercise :

Exercise 6.8. *The past-future Bridge filtration.*

i. Let us consider the following two-parameter filtration :

$$\mathcal{F}'_{s,t} = \sigma\left\{B_u - \frac{u}{s}B_s, u \leq s; B_{t+h} - B_t, h \geq 0\right\}.$$

Note that the σ -field $\mathcal{F}_{s,t}$ satisfies :

$$\mathcal{F}_{s,t} = \mathcal{F}'_{s,t} \vee \sigma(B_s, B_t),$$

and that $\mathcal{F}'_{s,t}$ is independent from $\sigma(B_s, B_t)$, in fact from $\mathcal{F}_{[s,t]} = \sigma\{B_u, s \leq u \leq t\}$.

ii. Prove that $(\mathcal{F}'_{s,t})_{0 \leq s < t < \infty}$ is the natural two-parameter filtration associated with :

$$X_{s,t} = \left(B_s - \int_0^s \frac{du}{u} B_u\right) + \left(\frac{1}{t}B_t - \int_t^\infty \frac{dv}{v^2} B_v\right),$$

that is :

$$\mathcal{F}'_{s,t} = \Xi_{s,t} \equiv \sigma\{X_{u,v}; u \leq s, v \geq t\}.$$

Hint : simply show that :

$$\mathbb{E}[X_{s,t}B_s] = \mathbb{E}[X_{s,t}B_t] = 0,$$

and proceed from there.

iii. Note that :

$$X_{s,t} = X_s^{(-)} + X_t^{(+)},$$

where : $X_s^{(-)} = \beta(B)_s$; $X_t^{(+)} = \beta(\hat{B})_{1/t}$, and : $\beta(B)_s = B_s - \int_0^s \frac{du}{u} B_u$ is the Brownian motion introduced in Chapter I of Yor, Zürich [36].

Furthermore : $\hat{B}_u = uB_{1/u}$.

Question 6.1. It may also be of interest to consider the family of interval- σ -field : $\mathcal{F}_{[s,t]} = \sigma\{B_u, s \leq u \leq t\}$, and to look for the "generation" of $\mathcal{F}'_{[s,t]}$, a sub σ -fields of $\mathcal{F}_{[s,t]}$:

$$\mathcal{F}'_{[s,t]} = \sigma\left\{\frac{B_u - B_v}{u - v} - \frac{B_t - B_s}{t - s}; s \leq u \leq v \leq t\right\}.$$

Can one give a simpler description of $\mathcal{F}'_{[s,t]}$? Note that, if I_1, \dots, I_k are disjoint intervals then $\mathcal{F}'_{I_1}, \dots, \mathcal{F}'_{I_k}$ are independent

Independently from the previous exercise, we have obtained the following partial answers presented in the next two propositions.

Proposition 6.3. *Let $h(s, t; x, y) = \phi(\frac{1}{t-s}; \frac{y-x}{t-s})$ for a function $\phi(u, z)$. Then, h is PFH if and only if ϕ is space-time harmonic, i.e :*

$$\phi'_u + \frac{1}{2}\phi''_{z^2} = 0. \quad (30)$$

Proof. The LHS of the first equation in (-) writes, in this case : (with : $u = 1/(t-s)$; $z = (y-x)/(t-s)$)

$$\frac{1}{(t-s)^2}\phi'_u(u, z) - \frac{y-x}{(t-s)^2}\phi'_z(u, z) + \frac{y-x}{(t-s)^2}\phi'_z(u, z) + \frac{1}{2(t-s)^2}\phi''_{z^2}. \quad (31)$$

Hence, the result. \square

Proposition 6.4. *Let $h(s, t; x, y) = F(\frac{x}{\sqrt{t-s}}, \frac{y}{\sqrt{t-s}})$ for a function F . Then, h is PFH if and only if :*

$$\begin{cases} aF'_a + (2a-b)F'_b + F''_{b^2} = 0 \\ (2b-a)F'_a + bF'_b + F''_{a^2} = 0 \end{cases} \quad (32)$$

Proof.

$$\begin{aligned} h'_s &= \frac{1}{2} \frac{x}{(t-s)^{3/2}} F'_a + \frac{1}{2} \frac{y}{(t-s)^{3/2}} F'_b; \\ h'_x &= \frac{1}{\sqrt{t-s}} F'_a; \\ h''_{x^2} &= \frac{1}{t-s} F''_{a^2}. \end{aligned}$$

We must have :

$$\frac{1}{2} \frac{1}{t-s} \left[\frac{x}{\sqrt{t-s}} F'_a + \frac{y}{\sqrt{t-s}} \right] + \frac{1}{t-s} \frac{y-x}{\sqrt{t-s}} F'_a + \frac{1}{2(t-s)} F''_{a^2} = 0$$

Hence :

$$\frac{1}{2} (aF'_a + bF'_b) + (b-a)F'_a + \frac{1}{2} F''_{a^2} = 0.$$

We leave the end of the proof to the reader. \square

Note that F , solution of (32), is harmonic for the 2-dimensional Ornstein-Uhlenbeck process (X, Y) defined by :

$$X_t = \beta_t + \int_0^t Y_s ds; Y_t = \gamma_t + \int_0^t X_s ds,$$

where β and γ is a 2-dimensional Brownian motion.

A question :

We dispose of the equations $(-)$ and $(+)$. We would like to find a more general family of PFH functions, than the ones we obtained in Proposition 6.3 and Proposition 6.4. More precisely, we consider the functions defined by :

$$h(s, t; x, y) = \exp(a(s, t)xy + b(s, t)x + c(s, t)y + d(s, t)),$$

associated to the four time dependent functions a, b, c, d .

- h satisfies formula $(-)$ if and only if : (after computation of h'_s, h'_x, h'_{x^2} and identification of the terms in xy, y^2, x, y and the constant parts)

$$\left\{ \begin{array}{l} (1) \quad \frac{\partial a}{\partial s} = \frac{1}{t-s}a(s, t) \\ (2) \quad a(s, t) \left(\frac{1}{t-s} + \frac{1}{2}a(s, t) \right) = 0 \\ (3) \quad \frac{\partial b}{\partial s} = \frac{1}{t-s}b(s, t) = 0 \\ (4) \quad \frac{\partial c}{\partial s} + b(s, t) \left(\frac{1}{t-s} + a(s, t) \right) = 0 \\ (5) \quad \frac{\partial d}{\partial s} + \frac{1}{2}b(s, t)^2 = 0 \end{array} \right. \quad (33)$$

(2) gives :

$$a(s, t) = 0, \quad \text{or} \quad a(s, t) = -\frac{2}{t-s}.$$

(3) gives :

$$b(s, t) = \frac{\beta(t)}{t-s}.$$

Let us take $a(s, t) = -\frac{2}{t-s}$ (leaving the case $a(s, t) = 0$ aside for the moment). Then (4) gives :

$$c(s, t) = \frac{\beta(t)}{t-s} + \gamma(t).$$

(5) gives :

$$d(s, t) = -\frac{1}{2} \frac{\beta(t)^2}{t-s} + \delta(t).$$

- h satisfies formula (+) if and only if : (after computation of h'_t, h'_y, h'_{y^2} and identification of the terms in xy, y^2, x, y and the constant parts)

$$\begin{cases} (1') & -\frac{\partial a}{\partial t} = \frac{1}{t-s}a(s, t) \\ (2') & a(s, t) \left(\frac{1}{t-s} + \frac{1}{2}a(s, t) \right) = 0 \\ (3') & -\frac{\partial b}{\partial t} + a(s, t)c(s, t) + \frac{c(s, t)}{t-s} = 0 \\ (4') & \frac{\partial c}{\partial t} \left(\frac{1}{t-s} \right) + c(s, t) = 0 \\ (5') & \frac{\partial d}{\partial t} + c(s, t)^2 = 0 \end{cases} \quad (34)$$

Again (2') gives :

$$a(s, t) = 0, \quad \text{or} \quad a(s, t) = -\frac{2}{t-s}.$$

(4') gives :

$$c(s, t) = \hat{\gamma}(s)(t-s).$$

(3') gives :

$$b(s, t) = -\hat{\gamma}(s)t + \hat{\beta}(s).$$

(5') gives :

$$d(s, t) = \hat{\gamma}(s)^2 \frac{(t-s)^3}{3} + \hat{\delta}(s).$$

We now have to compare the different expressions we have obtained for a, b, c, d and determine 6 functions of one variable, i.e : β, γ, δ on one hand and $\hat{\beta}, \hat{\gamma}, \hat{\delta}$ on the other hand.

6.5.1 A first attempt to represent $PFH \geq 0$ functions :

Let $h(s, t; B_s, B_t)$ be an $\mathcal{F}_{s,t}$ -martingale. Then, for fixed t ,

$$s \rightarrow h(s, t; B_s, B_t) \quad (s < t) \text{ is an } \mathcal{F}_s^{(t)} \text{ martingale.}$$

Hence : for fixed (t, y) , $h(s, t; x, y)$ is space-time harmonic for $\mathbb{P}_{0 \rightarrow y}^{(t)}$, that is : $h(s, t; B_s, y)p_{t-s}(B_s, y)$ is a martingale, (but only until t) for Brownian motion, i.e (with obvious notations) :

$$H_{t,y}(s, x) = h(s, t; x, y)p_{t-s}(x, y) \text{ is space - time harmonic in } (s, x).$$

We shall note : (s, x) -space-time harmonic. Hence,

$$h(s, t; x, y) = \frac{1}{p_{t-s}(x, y)} H_{t,y}(s, x). \quad (35)$$

Moreover, thanks⁵ to Proposition 6.1, we have also :

$$h\left(\frac{1}{t}, \frac{1}{s}; \frac{y}{t}, \frac{x}{s}\right) = \frac{1}{p_{t-s}(x, y)} K_{t,y}(s, x), \quad (36)$$

where $K_{t,y}$ is a (s, x) -space-time harmonic function. Let us rewrite (36) with $u = \frac{1}{t}$, $v = \frac{1}{s}$, $x' = \frac{y}{t}$, $y' = \frac{x}{s}$:

$$\begin{aligned} h(u, v; x', y') &= \frac{1}{p_{\frac{1}{u}-\frac{1}{v}}(sy', tx')} K_{\frac{1}{u}, tx'}\left(\frac{1}{v}, sy'\right) \\ &= \frac{1}{p_{\frac{1}{u}-\frac{1}{v}}\left(\frac{y'}{v}, \frac{x'}{u}\right)} K_{\frac{1}{u}, \frac{x'}{u}}\left(\frac{1}{v}, \frac{y'}{v}\right). \end{aligned} \quad (37)$$

Thus, H and K need to satisfy :

$$h(s, t; x, y) = \frac{1}{p_{t-s}(x, y)} H_{t,y}(s, x) = \frac{1}{p_{\frac{1}{s}-\frac{1}{t}}\left(\frac{y}{t}, \frac{x}{s}\right)} K_{\frac{1}{s}, \frac{x}{s}}\left(\frac{1}{t}, \frac{y}{t}\right). \quad (38)$$

After some elementary computation, we have :

$$\frac{1}{p_{\frac{1}{s}-\frac{1}{t}}\left(\frac{y}{t}, \frac{x}{s}\right)} = \frac{\sqrt{st}}{\sqrt{2\pi(t-s)}} \exp\left(-\frac{1}{2} \frac{(sy - xt)^2}{st(t-s)}\right). \quad (39)$$

Hence, (38) becomes :

$$\begin{aligned} H_{t,y}(s, x) &= \frac{1}{\sqrt{st}} \exp\left(\frac{(sy - xt)^2}{st(t-s)} - \frac{(y-x)^2}{t-s}\right) K_{\frac{1}{s}, \frac{x}{s}}\left(\frac{1}{t}, \frac{y}{t}\right) \\ &= \frac{1}{\sqrt{st}} \exp\left(-\frac{1}{2} \left(\frac{y^2}{t} - \frac{x^2}{s}\right)\right) K_{\frac{1}{s}, \frac{x}{s}}\left(\frac{1}{t}, \frac{y}{t}\right). \end{aligned} \quad (40)$$

If we assume that :

$$K_{\frac{1}{s}, \frac{x}{s}}\left(\frac{1}{t}, \frac{y}{t}\right) = \int_{-\infty}^{\infty} d\eta \mathcal{K}_{\frac{1}{s}, \frac{x}{s}}(\eta) \exp\left(\eta \frac{y}{t} - \frac{\eta^2}{2t}\right),$$

i.e : the representing measure of $K_{a,z}(s, x)$ is absolutely continuous, it “is likely” that :

$$\frac{1}{\sqrt{s}} \exp\left(-\frac{x^2}{2s}\right) \mathcal{K}_{\frac{1}{s}, \frac{x}{s}}(\eta),$$

⁵Here, our treatment is not totally rigorous since we assume that an (s, x) -space-time harmonic function, for $s < t$, may be extended to an (s, x) -space-time harmonic, for all $s > 0$. Can one characterize such t -space-time harmonic functions? Our second attempt (see 6.5.2) does not suffer from this abuse.

is (s, x) -space-time harmonic, i.e :

$$\frac{1}{\sqrt{s}} \exp\left(-\frac{x^2}{2s}\right) \mathcal{K}_{\frac{1}{s}, \frac{x}{s}}(\eta) = \int \tau_\eta(d\lambda) \exp\left(\lambda x - \frac{\lambda^2 s}{2}\right). \quad (41)$$

Using again (38), and taking $t = \frac{1}{u}$, $\frac{y}{t} = uy = z$, we have :

$$K_{\frac{1}{s}, \frac{x}{s}}(u, z) = \sqrt{\frac{u}{s}} \exp\left(\frac{1}{2} \left(\frac{x^2}{s} + z^2 t\right)\right) H_{\frac{1}{u}, \frac{z}{u}}(s, x) \quad (42)$$

If we assume that :

$$H_{t,y}(s, x) = \int_{-\infty}^{\infty} d\lambda \mathcal{H}_{t,y}(\lambda) \exp\left(\lambda x - \frac{\lambda^2 s}{2}\right),$$

it “is likely” that :

$$\frac{1}{\sqrt{u}} \exp\left(\frac{z^2}{u}\right) \mathcal{H}_{\frac{1}{u}, \frac{z}{u}}(\lambda),$$

is (u, z) -space-time harmonic, i.e :

$$\frac{1}{\sqrt{u}} \exp\left(\frac{z^2}{u}\right) \mathcal{H}_{\frac{1}{u}, \frac{z}{u}}(\lambda) = \int \theta_\lambda(d\rho) \exp\left(\rho z - \frac{\rho^2 u}{2}\right). \quad (43)$$

It now remains to find a correspondence between τ_η and θ_λ

Exercise 6.9. *Show from the above arguments that :*

$$e_s^{(t)} \equiv \exp\left(-\frac{2B_s B_t}{t-s}\right) \text{ is a } (\mathcal{F}_{s,t}, s < t) \text{ martingale.}$$

More generally, if (B_u) is a n -dimensional Brownian motion, show that :

$$\exp\left(-\frac{2B_s \bullet B_t}{t-s}\right) \text{ is a PF martingale.}$$

Solution : We need to show in particular that :

$$\exp\left(-\frac{2B_s m}{t-s}\right) p_{t-s}(B_s, m) \text{ is a } (\mathcal{F}_s, s < t) \text{ martingale.}$$

In fact, this expression is : $p_{t-s}(B_s, -m)$, which is of course a $(\mathcal{F}_s, s < t)$ martingale!!

Exercise 6.10. (*: T. Fujita, M. Yor [15]*).

- i. Assume (X_t) is a symmetric Lévy process, with semigroup density :
 $p_t(x, y) \equiv q_t(|x - y|)$, for q_t a function on \mathbb{R}^+ . Prove that, for any
 $a \in \mathbb{R}$,

$$\frac{p_{t-s}(X_s + a, -(X_t + a))}{p_{t-s}(X_s, X_t)},$$

is a $\mathcal{F}_{s,t}$ martingale.

- ii. Application : for the Cauchy process $X_t = C_t$, one gets :

$$\frac{(t-s)^2 + (C_t - C_s)^2}{(t-s)^2 + (C_t + C_s + 2a)^2}$$

is a $(\mathcal{F}_{s,t})$ martingale.

Question : does there exist an adequate extension of this result to non-symmetric Lévy processes?

Exercise 6.11. Define $R_u = |B_u|$, the n -dimensional Bessel process associated with B a Brownian motion in \mathbb{R}^n ; compute the projection of $e_s^{(t)}$ on $\mathcal{R}_{s,t}$.

Exercise 6.12. Show that : $e_s^{(t)} \rightarrow 0$ when $s \rightarrow t$.
Identify the law of $\mathcal{G}_1^{(t)} = \sup\{s < t, e_s^{(t)} = 1\}$, and more generally the law of $\mathcal{G}_K^{(t)}$

6.5.2 A second attempt to represent $PFH \geq 0$ functions :

Recall again that : $h(s, t; x, y)$ is PFH if and only if :

- i. $\forall(t, y), (s, x) \rightarrow h(s, t; x, y)$ is harmonic under $\mathbb{P}_{0 \rightarrow y}^{(t)}$;
- ii. $h(s, t; x, y) \equiv k(\frac{1}{t}, \frac{1}{s}; \frac{y}{t}, \frac{x}{s})$, where k is PFH ; and we shall apply (i) to k , for fixed (s, x) .

Based on this, we can state the following :

Proposition 6.5. h is $PFH \geq 0$ if and only if :

- a) $\forall(t, y)$, there exists a space-time harmonic function for Brownian motion : $K_{(t,y)}^{(+)}$ such that :

$$h(s, t; x, y) = K_{(t,y)}^{(+)} \left(\frac{s}{t-s}; \frac{xt - ys}{\sqrt{t}(t-s)} \right) \quad (44)$$

b) $\forall(s, x)$, there exists a space-time harmonic function for Brownian motion : $K_{\left(\frac{1}{s}, \frac{x}{s}\right)}^{(-)}$ such that :

$$h(s, t; x, y) = K_{\left(\frac{1}{s}, \frac{x}{s}\right)}^{(-)} \left(\frac{s}{t-s}; \frac{\sqrt{s}(y-x)}{t-s} \right) \quad (45)$$

To help the reader with these slightly complicated formulae, let us compute $K^{(+)}$ and $K^{(-)}$ for :

$$h(s, t; x, y) = \exp \left(-\frac{2xy}{t-s} \right),$$

in the following exercise :

Exercise 6.13. a) Fix t and m ; find $K^{(+)}$ a space-time harmonic function such that :

$$\exp \left(-\frac{2xm}{t-s} \right) = K^{(+)} \left(\frac{s}{t-s}; \frac{xt-ms}{\sqrt{t}(t-s)} \right).$$

Answer :

$$K^{(+)}(u, \xi) = \exp (-2m'\xi - 2m'^2u),$$

where $m' = \frac{m}{\sqrt{t}}$. (Note the remarkable fact that $K^{(+)}$ depends only on m').

b) Fix s and x ; find $K^{(-)}$ a space-time harmonic function such that :

$$\exp \left(-\frac{2xy}{t-s} \right) = K^{(-)} \left(\frac{s}{t-s}; \frac{\sqrt{s}(y-x)}{t-s} \right).$$

Answer :

$$K^{(-)}(u, \xi) = \exp (-2x'(\xi + x'u)),$$

where : $x' = x/\sqrt{s}$.

(Note the remarkable fact that $K^{(-)}$ depends only on x').

Proof. (of Proposition 6.5)

As explained just before stating that Proposition, the proof consists in expressing the generic ≥ 0 , space-time harmonic function $h_m^{(t)}(s, x)$ for the Brownian bridge $BB_{0 \rightarrow m}^{(t)}$ in terms of a space-time harmonic function for Brownian motion. The result is :

$$h_m^{(t)}(s; x) = K \left(\frac{s}{t-s}; \frac{xt-ms}{\sqrt{t}(t-s)} \right). \quad (46)$$

we denote by $\mathcal{H}_m^{(t)}$ the set of the $h_m^{(t)}$ functions, space-time harmonic functions for the Brownian bridge $BB_{0 \rightarrow m}^{(t)}$, and by \mathcal{H} the set of the space-time harmonic functions for Brownian motion.

1. Clearly, by scaling,

$$h_m^{(t)}(s; x) = h_{m/\sqrt{t}}^{(1)}\left(\frac{s}{t}; \frac{x}{\sqrt{t}}\right). \quad (47)$$

2. Let $h \in \mathcal{H}_m^{(1)}$; then, we shall show that there exists $K \in \mathcal{H}$ such that :

$$h\left(\frac{1}{\tau+1}; \frac{m+y}{\tau+1}\right) = K\left(\frac{1}{\tau}; \frac{y}{\tau}\right). \quad (48)$$

Then, we obtain (46) from (47) and (48).

3. It now remains to prove (48).

In order to state properties in Brownian terms, and not in terms of Brownian bridges, we use time inversion (in a first instance) :

$$B'_v = vB_{1/v}.$$

Then, the martingale property for h writes : ($s < s' < 1$)

$$\begin{aligned} & \mathbb{E}\left[F\left(uB'_{1/u}, \frac{1}{u} \geq \frac{1}{s'}\right) h(s; sB'_{1/s}) | B'_1 = m\right] = \\ & \mathbb{E}\left[F\left(uB'_{1/u}, \frac{1}{u} \geq \frac{1}{s'}\right) h(s'; s'B'_{1/s'}) | B'_1 = m\right]. \end{aligned}$$

We use : $\sigma = 1/s$; $\sigma' = 1/s'$, then :

$$\begin{aligned} & \mathbb{E}\left[F(B'_v, v \geq \sigma') h\left(\frac{1}{\sigma}; \frac{B'_\sigma}{\sigma}\right) | B'_1 = m\right] = \\ & \mathbb{E}\left[F(B'_v, v \geq \sigma') h\left(\frac{1}{\sigma'}; \frac{B'_{\sigma'}}{\sigma'}\right) | B'_1 = m\right]. \end{aligned}$$

We now shift time by 1 : $\sigma = \tau + 1$; $\sigma' = \tau' + 1$; and we introduce : $\tilde{B}_u = B'_{(u+1)} - B'_1$, a new Brownian motion. Then :

$$\begin{aligned} & \mathbb{E}\left[F\left(\tilde{B}_u, u \geq \tau'\right) h\left(\frac{1}{\tau+1}; \frac{m + \tilde{B}_\tau}{\tau+1}\right)\right] = \\ & \mathbb{E}\left[F\left(\tilde{B}_u, u \geq \tau'\right) h\left(\frac{1}{\tau'+1}; \frac{m + \tilde{B}_{\tau'}}{\tau'+1}\right)\right]. \end{aligned}$$

It is advantageous to introduce the notation :

$$H(\tau, x) = h\left(\frac{1}{\tau+1}; \frac{m+x}{\tau+1}\right).$$

The previous equality writes :

$$\mathbb{E} \left[F \left(\tilde{B}_u, u \geq \tau' \right) H \left(\tau; \tilde{B}_\tau \right) \right] = \mathbb{E} \left[F \left(\tilde{B}_u, u \geq \tau' \right) H \left(\tau'; \tilde{B}_{\tau'} \right) \right].$$

Finally, we shall bring time “back in order” by introducing β such that : $\tilde{B}_u = u\beta_{1/u}$, (time inversion : second instance), and : $\frac{1}{\tau'} = \theta' < \frac{1}{\tau} = \theta$. Hence :

$$\begin{aligned} \mathbb{E} \left[F \left(\beta_{1/k}, \frac{1}{k} \leq \theta' \right) H \left(\frac{1}{\theta}; \frac{1}{\theta}\beta_\theta \right) \right] &= \\ &= \mathbb{E} \left[F \left(\beta_{1/k}, \frac{1}{k} \leq \theta' \right) H \left(\frac{1}{\theta'}; \frac{1}{\theta'}\beta_{\theta'} \right) \right]. \end{aligned} \quad (49)$$

Consequently, $K(\theta; x) = H \left(\frac{1}{\theta}; \frac{x}{\theta} \right)$ belongs to \mathcal{H} . We have obtained (48).

□

6.6 An explicit expression for the law of $g_x^{(\nu)}(t)$

In Note 2, we discussed the Black-Scholes formula in relation with the law of \mathcal{G}_K . Similarly, here in our finite horizon framework, we would like to give an explicit expression for the law of :

$$g_x^{(\nu)}(t) = \sup\{s \leq t, B_s^{(\nu)} = x\}.$$

Already, in the case $\nu = 0$, the following result has been obtained (see [37] and also [17] Proposition 4.3.3.3) :

$$\mathbb{P} \left(g_x^{(0)}(t) \in du \right) = \frac{du}{\pi \sqrt{u(t-u)}} \exp \left(-\frac{x^2}{2u} \right) \quad (0 < u < t). \quad (50)$$

Note that this is a sub-probability, since $\frac{du}{\pi \sqrt{u(t-u)}} \quad (0 < u < t)$ is the arcsin distribution; indeed,

$$\begin{aligned} \mathbb{P} \left(g_x^{(0)}(t) = 0 \right) &= \mathbb{P} \left(T_x \geq t \right) \\ &= \mathbb{P} \left(|\mathbf{N}| \leq \frac{|x|}{\sqrt{t}} \right). \end{aligned}$$

We are now interested in the general case : $\nu \neq 0$; we shall compute, for $0 \leq s \leq t$:

$$\gamma_{x,t}^{(\nu)}(s) \stackrel{\text{def}}{=} \mathbb{P}(0 < g_x^{(\nu)}(t) \leq s).$$

$$\gamma_{x,t}^{(\nu)}(s) = \mathbb{E} \left[\mathbf{1}_{\{0 < g_x^{(0)}(t) \leq s\}} \exp \left(\nu B_t - \frac{\nu^2 t}{2} \right) \right]. \quad (51)$$

On $\{0 < g_x^{(0)}(t) \leq s\}$, we have : $T_x \leq s$, and introducing :

$$\tilde{B}_u = B_{T_x+u} - x,$$

a new Brownian motion, independent from \mathcal{F}_{T_x} , we have :

$$g_x^{(0)}(t) = T_x + \tilde{g}(t - T_x),$$

where $\tilde{g}(h) = \sup\{s < h, \tilde{B}_s = 0\}$. We have :

$$\begin{aligned} \gamma_{x,t}^{(\nu)}(s) &= \mathbb{E} \left[\mathbf{1}_{\{T_x \leq s\}} \mathbf{1}_{\{\tilde{g}(t-T_x) \leq s-T_x\}} \exp \left(\nu(x + \tilde{B}_{t-T_x}) \frac{\nu^2 t}{2} \right) \right] \\ &= \exp \left(\nu x - \frac{\nu^2 t}{2} \right) \\ &\quad \mathbb{E} \left[\mathbf{1}_{\{T_x + \tilde{g}(t-T_x) \leq s\}} \exp \left(\nu \sqrt{(t-T_x) - \tilde{g}(t-T_x)} \tilde{m}_1 \right) \right], \end{aligned}$$

where we have used the factorisation :

$$\tilde{B}_{t-T_x} = \sqrt{(t-T_x) - \tilde{g}(t-T_x)} \tilde{m}_1,$$

with $\tilde{m}_1 = \epsilon m_1$ independent from $(T_x, \tilde{g}(t-T_x))$, ϵ is Bernoulli, $m_1 \stackrel{\text{law}}{=} \sqrt{2\mathbf{e}}$. We introduce the function :

$$\phi(\lambda) = \mathbb{E}[\exp(\lambda \tilde{m}_1)] = \mathbb{E}[\cosh(\lambda m_1)] = \int_0^\infty dt e^{-t} \cosh(\lambda \sqrt{2t}). \quad (52)$$

An integration by parts shows that :

$$\phi(\lambda) = 1 + e^{\lambda^2/2} |\lambda| \sqrt{2\pi} \mathbb{P}(|\mathbf{N}| \leq |\lambda|). \quad (53)$$

See [2] for similar computations. Consequently, we obtain :

$$\gamma_{x,t}^{(\nu)}(s) = \mathbb{P} \left(\mathbf{1}_{\{0 < g_x(t) \leq s\}} e^{\nu x - \frac{\nu^2 t}{2}} \phi(\nu \sqrt{t - g_x(t)}) \right), \quad (54)$$

which from (50), gives :

$$\mathbb{P}(g_x^{(\nu)}(t) \in du) = \frac{du}{\pi \sqrt{u(t-u)}} \exp \left(-\frac{x^2}{2u} \right) \phi(\nu \sqrt{t-u}). \quad (55)$$

Very close computations may be found in Chapter 4, subsection 4.3.9 in [17].

6.7 On the time spent below a level by Brownian motion with drift

Consider :

$$A_x^{(\nu)}(t) = \int_0^t ds 1_{\{B_s^{(\nu)} \leq x\}}, \quad x > 0.$$

Thus, it is shown in [37], that, for $\nu = 0$:

$$A_x^{(0)}(t) \stackrel{\text{law}}{=} g_x^{(0)}(t). \quad (56)$$

Question 6.2. *We may ask whether this identity in law also holds with $(B^{(\nu)})$ instead of (B) .*

Question 6.3. *Another question consists in studying :*

$$\mathbb{P} (A_x^{(\nu)}(t) \leq s | \mathcal{F}_s).$$

(Maybe already studied by Dassios [11], and Embrechts, Rogers and Yor [14])

6.8 Another class of past-future martingales

(To appear in second edition of Chaumont-Yor, [7], Chapter 7). We are interested in constructing $(\mathcal{F}_{s,t})$ martingales from the simple recipe : if $F \in L^1(\mathbb{W}, \mathcal{F}_\infty)$, then :

$$M_{s,t}(F) \stackrel{\text{def}}{=} \mathbb{E} [F | \mathcal{F}_{s,t}] \text{ is a } (\mathcal{F}_{s,t})\text{-martingale.}$$

For a number of functionals F , we are able to compute $M_{s,t}(F)$.

Example 6.1.

$$F = \exp \left(\int_0^\infty f(u) dB_u - \frac{1}{2} \int_0^\infty f^2(u) du \right), \quad (57)$$

where $f \in L^2([0, \infty), du)$. Then,

$$\begin{aligned} \mathbb{E} [F | \mathcal{F}_{s,t}] &= \exp \left(\int_0^s f(u) dB_u + \int_t^\infty f(u) dB_u - \frac{1}{2} \int_0^\infty f^2(u) du \right) \\ &\times \mathbb{E} \left[\exp \left(\int_s^t f(u) dB_u \right) | \mathcal{F}_{s,t} \right]. \end{aligned}$$

We know that :

$$\begin{aligned} \mathbb{E} \left[\int_s^t f(u) dB_u | \mathcal{F}_{s,t} \right] &= \frac{1}{t-s} \left(\int_s^t f(u) du \right) (B_t - B_s) \\ &= \left(\int_s^t f(u) du \right) B_{[s,t]}. \end{aligned}$$

Hence :

$$\mathbb{E} \left[\exp \left(\int_s^t f(u) dB_u \right) \middle| \mathcal{F}_{s,t} \right] = \exp \left(\left(\int_s^t f(u) du \right) B_{[s,t]} \right) \exp \frac{1}{2} \left(\int_s^t f^2(u) du - \frac{1}{t-s} \left(\int_s^t f(u) du \right)^2 \right).$$

Finally, we have obtained :

$$\mathbb{E} [F | \mathcal{F}_{s,t}] = F_s^{(1)} F_{s,t}^{(2)} F_t^{(3)}, \quad (58)$$

where :

$$\begin{cases} F_s^{(1)} = \exp \left(\int_0^s f(u) dB_u - \frac{1}{2} \int_0^s f^2(u) du \right) \\ F_{s,t}^{(2)} = \exp \left(\left(\int_s^t f(u) du \right) B_{[s,t]} - \frac{1}{2(t-s)} \left(\int_s^t f(u) du \right)^2 \right) \\ F_t^{(3)} = \exp \left(\int_t^\infty f(u) dB_u - \frac{1}{2} \int_t^\infty f^2(u) du \right). \end{cases} \quad (59)$$

Wishful thinking : Recall that the computation of $\mathbb{E}[F | \mathcal{F}_t]$, for F in (57), and the fact that these functionals are total in $L^1(\mathbb{W}, \mathcal{F}_\infty)$ easily leads to the representation result of Brownian martingales as stochastic integrals with respect to Brownian motion. Could there be an analogous result for the $(\mathcal{F}_{s,t})$ filtration? What might be the PF martingale of reference, perhaps : $B_{[s,t]}$?

Exercise 6.14. Compute :

$$\mathbb{E} \left[\int_0^\infty du e^{-\lambda u} f(B_u) \middle| \mathcal{F}_{s,t} \right].$$

A first attempt :

$$\begin{aligned} \mathbb{E} \left[\int_0^\infty du e^{-\lambda u} f(B_u) \middle| \mathcal{F}_{s,t} \right] &= \int_0^s du e^{-\lambda u} f(B_u) + \int_t^\infty du e^{-\lambda u} f(B_u) \\ &\quad + \int_s^t du e^{-\lambda u} \mathbb{E} [f(B_u) | \mathcal{F}_{s,t}]. \end{aligned}$$

We observe that, for $s < u < t$:

$$B_u = B_s + \left(\frac{u-s}{t-s} \right) (B_t - B_s) + R,$$

with R independent of $(B_s, B_t - B_s)$ and $\mathbb{E}[R^2] \equiv r^2 = \frac{(u-s)(t-u)}{(t-s)}$. Hence :

$$\mathbb{E}[f(B_u)|\mathcal{F}_{s,t}] = \frac{1}{\sqrt{2\pi r^2}} \int_{-\infty}^{\infty} dx e^{-\frac{x^2}{2r^2}} f(x + B_s + (u-s)B_{[s,t]}). \quad (60)$$

We also note that we have obtained :

$$\forall y \in \mathbb{R}, \quad \frac{1}{\sqrt{2\pi r^2}} e^{-\frac{(y - (B_s + (u-s)B_{[s,t]}))^2}{2r^2}}$$

is a $(\mathcal{F}_{s,t})$ martingale for $s < u < t$, but we need to compute :

$$\int_s^t du e^{-\lambda u} \mathbb{E}[f(B_u)|\mathcal{F}_{s,t}]$$

with the help of (60)

7 Note 7 : Which results still hold for discontinuous martingales?

7.1 No positive jumps

In this section, $(M_t, t \geq 0)$ denotes a càdlàg \mathbb{R}^+ -valued local martingale, such that : $M_0 = 1$, $\lim_{t \rightarrow \infty} M_t = 0$, and (M_t) has no positive jumps.

Then, our previous main results still hold; precisely :

Proposition 7.1. *Under the previous hypotheses,*

a)

$$\sup_{s \geq 0} M_s \stackrel{\text{law}}{=} \frac{1}{\mathbf{U}};$$

b) if $\mathcal{G}_K(M) = \sup\{s \geq 0, M_s \geq K\}$, with $K > 0$, then, for any stopping time T :

$$\mathbb{P}(\mathcal{G}_K(M) > T | \mathcal{F}_T) = \left(\frac{M_T}{K} \right) \wedge 1. \quad (61)$$

Remark : In the same vein, we mention that the so-called “Azéma-Yor martingales” $F(S_t, M_t)$, with $S_t = \sup_{s \leq t} M_s$ admit an extension (with no formal change in the formula) to the family of martingales with no positive jumps. See L. Nguyen- M. Yor [26].

7.2 A formula in the Lévy process framework

We would like to apply the preceding to $M_t = \exp(X_t - t\psi(1))$, $t \geq 0$, where $(X_t, t \geq 0)$ is a Lévy process with no Brownian component.

A general version of Tanaka’s formula (see [35]) is :

$$(M_t - K)^+ = (M_0 - K)^+ + \int_0^t 1_{\{M_{s-} > K\}} dM_s + \Sigma_t^{(K)}, \quad (62)$$

where :

$$\Sigma_t^{(K)} = \sum_{s \leq t} (1_{\{M_{s-} > K\}} (M_s - K)^- + 1_{\{M_{s-} \leq K\}} (M_s - K)^+). \quad (63)$$

Let $\nu(dx)$ denote the Lévy measure of X . Then, Lévy’s compensation formula

gives :

$$\begin{aligned}
\mathbb{E} \left[\Sigma_t^{(K)} \right] &= \mathbb{E} \left[\int_0^t 1_{\{M_{s-} > K\}} ds \int \nu(dx) (M_{s-} e^x - K)^- \right] \\
&+ \mathbb{E} \left[\int_0^t 1_{\{M_{s-} \leq K\}} ds \int \nu(dx) (M_{s-} e^x - K)^+ \right] \\
&= \int_0^t ds \phi(s, K),
\end{aligned} \tag{64}$$

with :

$$\begin{aligned}
\phi(s, K) &= \int_0^1 du \mu(]0, u]) \mathbb{E} \left[M_s 1_{\{K < M_s < \frac{K}{u}\}} \right] \\
&+ \int_1^\infty du \mu([u, \infty[) \mathbb{E} \left[M_s 1_{\{\frac{K}{u} < M_s < K\}} \right],
\end{aligned} \tag{65}$$

where μ is the image of ν by the exponential application : $x \rightarrow \exp(x)$.

Finally, we have obtained :

$$\mathbb{E} [(M_t - K)^+] = (M_0 - K)^+ + \int_0^t ds \phi(s, K),$$

which plays the same role as Tanaka's formula in the continuous framework.

8 Note 8 : Other option prices which increase with maturity

The contents of this note are taken entirely from a preprint by Carr-Ewald-Xiao [6], to whom we are grateful for free access.

The main result of that paper is the following :

Theorem 8.1. *Let g be a continuous convex function; then, the function :*

$$\mathcal{A}_g^{(t)} = \mathbb{E} \left[g \left(\frac{1}{t} \int_0^t ds \mathcal{E}_s \right) \right]$$

is an increasing function of t .

Exercise 8.1. *Compute, for any $n \geq 1$, the function :*

$$a_n(t) = \mathbb{E} \left[\left(\frac{1}{t} \int_0^t ds \mathcal{E}_s \right)^n \right] \equiv \frac{\tilde{a}_n(t)}{t^n}.$$

Partial solution and hints :

- $a_1(t) = 1$;
- $a_2(t) = \frac{2}{t^2}(e^t - 1 - t)$;
- *In order to compute $a_n(t)$, it may be useful to first prove the following formula : for α sufficiently large,*

$$\int_0^\infty dt e^{-\alpha t} \tilde{a}_n(t) = \frac{n!}{\alpha^2(\alpha-1)(\alpha-3)\dots(\alpha-\frac{n(n-1)}{2})},$$

where

$$\tilde{a}_n(t) = \mathbb{E} \left[\left(\int_0^t ds \mathcal{E}_s \right)^n \right] \equiv t^n a_n(t);$$

- *More directly, we obtain :*

$$\begin{aligned} a_n(t) &= \frac{n!}{t^n} \mathbb{E} \left[\int_0^t ds_1 \int_{s_1}^t ds_2 \dots \int_{s_{n-1}}^t ds_n \right. \\ &\quad \left. \exp \left((B_{s_1} + \dots + B_{s_n}) - \frac{1}{2}(s_1 + \dots + s_n) \right) \right] \\ &= \frac{n!}{t^n} \int_0^t ds_1 \int_{s_1}^t ds_2 \dots \int_{s_{n-1}}^t ds_n \exp \left(\frac{1}{2} C(s_1, \dots, s_n) \right) \end{aligned}$$

where :

$$C(s_1, \dots, s_n) = \mathbb{E} [(B_{s_1} + \dots + B_{s_n})^2] - (s_1 + \dots + s_n).$$

and we find :

$$\mathbb{E} [(B_{s_1} + \dots + B_{s_n})^2] = n^2 s_1 + (n-1)^2 (s_2 - s_1) + \dots + (s_n - s_{n-1}).$$

Hence :

$$\begin{aligned} C(s_1, \dots, s_n) &\equiv \sum_{j=0}^{n-1} ((n-j)^2 - (n-j)) (s_{j+1} - s_j) \\ &\equiv \sum_{j=0}^{n-1} ((n-j)(n-(j+1))) (s_{j+1} - s_j) \end{aligned}$$

- Finally, it may be useful in order to solve this question to use the “Asian Option identity in law” :

$$A_{T_\lambda}^{(\nu)} = \int_0^{T_\lambda} ds \exp 2(B_s + \nu s) \stackrel{\text{law}}{=} \frac{\beta_{1,a}}{2\gamma_b},$$

where T_λ is an independent exponential time with parameter λ , and $\beta_{1,a}$ and γ_b are 2 independent random variables, respectively distributed as beta(1, a) and gamma(b), with $a = \frac{\mu+\nu}{2}$, $b = \frac{\mu-\nu}{2}$, and $\mu = \sqrt{2\lambda + \nu^2}$. For a compendium of results/papers on this topic, see Yor [40].

9 Note 9 : From puts to calls : more care is needed!

9.1 Why should one be careful?

In pricing financial options , the *LHS* of Part A-(12) arises very naturally in terms of put options, i.e. when considering :

$$\mathbb{E} [(K - M_t)^+] \quad (66)$$

On the other hand, the price of a call option is :

$$\mathbb{E} [(M_t - K)^+] \quad (67)$$

A most common argument to “reduce” (67) to (66) is to invoke “call-put parity” and/or “change of numéraire”. Mathematically, this means that we consider the new probability \mathbb{Q} defined via :

$$\mathbb{Q}|_{\mathcal{F}_t} = M_t \cdot \mathbb{P}|_{\mathcal{F}_t}, \quad (68)$$

and the martingale $(\frac{1}{M_t}, t \geq 0)$ under \mathbb{Q} , since :

$$\begin{aligned} \mathbb{E}_{\mathbb{P}} [(M_t - K)^+] &= \mathbb{E}_{\mathbb{Q}} \left[\left(1 - \frac{K}{M_t} \right)^+ \right] \\ &= K \mathbb{E}_{\mathbb{Q}} \left[\left(\frac{1}{K} - \frac{1}{M_t} \right)^+ \right]. \end{aligned} \quad (69)$$

However, two difficulties arise in order to perform these operations rigorously :

- i. in order that \mathbb{Q} , as defined via (68), be a probability, we need that $(M_t, t \geq 0)$ is a true martingale under \mathbb{P} , i.e : it satisfies in particular $\mathbb{E}_{\mathbb{P}}(M_t) = 1$;
- ii. some care is needed also concerning (69); in particular M_t might take the value 0 on some \mathcal{F}_t -set of positive \mathbb{P} -probability.

To summarize, (68) and (69) are correct
if $(M_t, t \geq 0)$ is a strictly positive true martingale under \mathbb{P} .

Formally, this may be stated as :

Proposition 9.1. *If (M_t) is a strictly positive true continuous martingale under \mathbb{P} , define \mathbb{P}^M via :*

$$\mathbb{P}^M|_{\mathcal{F}_t} = M_t \cdot \mathbb{P}|_{\mathcal{F}_t}.$$

Denote :

$$g_\infty^{(1)} = \sup\{t \geq 0, M_t = 1\}.$$

Then :

- i. $\mathbb{E}_{\mathbb{P}} [F_t (M_t - 1)^+] = \mathbb{E}^M [F_t 1_{\{g_\infty^{(1)} \leq t\}}]$, for every $F_t \in \mathcal{F}_t$;
- ii. $\mathbb{E}_{\mathbb{P}} [F_t |M_t - 1|] = \mathbb{E}_{\mathbb{P}} [F_t 1_{\{g_\infty^{(1)} \leq t\}}] + \mathbb{E}^M [F_t 1_{\{g_\infty^{(1)} \leq t\}}]$;
- iii. $g_\infty^{(1)}$ has the same distribution under \mathbb{P} and under \mathbb{P}^M .

Proof. i. We write :

$$\begin{aligned} \mathbb{E}_{\mathbb{P}} [F_t (M_t - 1)^+] &= \mathbb{E}^M \left[F_t \left(1 - \frac{1}{M_t}\right)^+ \right] \\ &= \mathbb{E}^M [F_t 1_{\{g_\infty^{(1)} \leq t\}}], \end{aligned}$$

from Theorem 1.1 (Part A), since $\left(\frac{1}{M_t}, t \geq 0\right)$ is, under \mathbb{P}^M , a martingale which converges to 0 as $t \rightarrow \infty$.

ii.

$$\mathbb{E}_{\mathbb{P}} [F_t |M_t - 1|] = \mathbb{E}_{\mathbb{P}} [F_t (M_t - 1)^+] + \mathbb{E}_{\mathbb{P}} [F_t (1 - M_t)^+],$$

and we apply both the previous result and Theorem 1.1 (Part A).

iii. Taking $F_t = 1$ in i., we obtain :

$$\begin{aligned} \mathbb{P}^M (g_\infty^{(1)} \leq t) &= \mathbb{E}_{\mathbb{P}} [(M_t - 1)^+] \\ &= \mathbb{E}_{\mathbb{P}} [(M_t - 1)] + \mathbb{E}_{\mathbb{P}} [(M_t - 1)^-] \\ &= \mathbb{E}_{\mathbb{P}} [(1 - M_t)^+] \\ &= \mathbb{E}_{\mathbb{P}} [g_\infty^{(1)} \leq t], \end{aligned}$$

from Theorem 1.1 (Part A). □

We note that Proposition 9.1 extends in the case when (M_t) is a true continuous martingale, taking values in \mathbb{R}^+ , but it may vanish, i.e : $\mathbb{P}(T_0 < \infty) > 0$. Indeed, under \mathbb{P}^M , $T_0 = \infty$ a.s., and the previous arguments are still valid.

In order to obtain some analogue of Theorem 1.1 (Part A) for :

$$\mathbb{E} [F_t (M_t - K)^+]$$

in the general case when (M_t) is a local martingale belonging to $\mathcal{L}_0^{(+)}$, we shall proceed directly.

9.2 The “common” Bessel example

Before discussing in a general framework, we write some version of the identity Part A-(12) for $(M_t = \frac{1}{R_t}, t \geq 0)$, where R is a $BES(3)$, starting from 1. We denote by \mathbb{W}_a and $\mathbb{P}_a^{(3)}$ ($a > 0$) the respective laws of Brownian motion and $BES(3)$ starting at $a > 0$, on the canonical space $\mathcal{C}(\mathbb{R}^+, \mathbb{R})$, with $X_t(\omega) = \omega(t)$, and $\mathcal{F}_t = \sigma\{X_s, s \leq t\}$; then, there is the well-known Doob’s h -transform relationship :

$$\mathbb{P}_a^{(3)}|_{\mathcal{F}_t} = \frac{X_{t \wedge T_0}}{a} \cdot \mathbb{W}_a|_{\mathcal{F}_t}. \quad (70)$$

Proposition 9.2. *There is the identity :*

$$\mathbb{E}_1^{(3)} \left[F_t \left(\frac{1}{X_t} - 1 \right)^+ \right] = \mathbb{W}_1 (F_t 1_{\{\gamma \leq t \leq T_0\}}), \quad (71)$$

for every $F_t \in \mathcal{F}_t$, and $\gamma = \sup\{t < T_0, X_t = 1\}$.

Proof. Thanks to (70), the *LHS* of (71) equals :

$$\mathbb{W}_1 (F_t (1 - X_{t \wedge T_0})^+ 1_{\{t \leq T_0\}}),$$

which is equal to the *RHS* of (71) thanks to formula Part A-(12), applied with $F'_t = F_t 1_{\{t \leq T_0\}}$. \square

Remarks.

- a) We understand that the present discussion is close to recent work by S. Pal and P. Protter motivated by financial bubbles. In fact, we had acces to their preprint [28], at the beginning of April 2008 and after writing this Note 9.

b) It is worth noting that, as a consequence of (71), there is the identity

$$\mathbb{E}_1^{(3)} \left[\left(\frac{1}{\bar{X}_t} - 1 \right)^+ \right] = \mathbb{W}_1(\gamma \leq t \leq T_0),$$

which shows clearly that the *LHS* is not an increasing function of t ; indeed, the *RHS* converges to 0 as $t \rightarrow \infty$, as a consequence of Lebesgue's dominated convergence theorem.

In fact, we can compute explicitly this *RHS*, which equals :

$$\begin{aligned} r(t) &\equiv \mathbb{W}_1(T_0 \geq t) - \mathbb{W}_1(\gamma \geq t) \\ &\equiv (1 - \mathbb{W}_1(T_0 \leq t)) - (1 - \mathbb{W}_1(\gamma \leq t)) \\ &\equiv \mathbb{W}_1(\gamma \leq t) - \mathbb{W}_1(T_0 \leq t). \end{aligned}$$

Recall that, under $\mathbb{W}_1 : T_0 \stackrel{\text{law}}{=} \frac{1}{B_1^2}$ and $\gamma \stackrel{\text{law}}{=} \frac{\mathbf{U}_{[0,2]}}{B_1^2}$; thus :

$$r(t) = \mathbb{P} \left(|B_1| \leq \frac{1}{\sqrt{t}} \right) - \mathbb{P} \left(|B_1| \leq \frac{\mathbf{U}_{[0,2]}}{\sqrt{t}} \right), \quad (72)$$

that is :

$$r(t) = \sqrt{\frac{2}{\pi}} \int_0^{\frac{1}{\sqrt{t}}} dx e^{-x^2/2} - \sqrt{\frac{2}{\pi}} \int_0^{\infty} dx e^{-x^2/2} \left(1 - \frac{\sqrt{t}x}{2} \right)^+ \quad (73)$$

In particular, it easily follows from (72) that :

$$r(t) \sim_{t \rightarrow \infty} \sqrt{\frac{2}{\pi t^3}} \left(\frac{1}{6} \right). \quad (74)$$

It is also easily proven directly that :

$$r(t) \sim_{t \rightarrow 0} \sqrt{\frac{t}{2\pi}} \quad (75)$$

Formulae (74), (75) are proven in the Appendix.

Exercise 9.1. *Prove the formula :*

$$\int_0^{\infty} \lambda e^{-\lambda t} dt r(t) = \left(\frac{1 - e^{-2\sqrt{2\lambda}}}{2\sqrt{2\lambda}} \right) - e^{-\sqrt{2\lambda}}.$$

- b) There is an extension of formula (71) for pairs of Bessel processes with respective dimensions $\delta \in (0, 2)$, and $4 - \delta$; formula (70) generalizes as :

$$\mathbb{P}_1^{(4-\delta)} \left(F_t \left(\frac{1}{X_t^{2-\delta}} - 1 \right)^+ \right) = \mathbb{P}_1^{(\delta)} (F_t 1_{\{\gamma \leq t \leq T_0\}}),$$

for every $F_t \in \mathcal{F}_t$, and $\gamma = \sup\{t < T_0, X_t = 1\}$. Proposition 9.2 leads us easily to a general statement, whose proof simply mimicks that of Proposition 9.2, hence it is left to the reader.

Proposition 9.3. *Let $\mathbb{Q}|_{\mathcal{F}_t} = M_t \cdot \mathbb{P}|_{\mathcal{F}_t}$, with $M_0 = 1$, and let us assume that $T_0 = \inf\{t, M_t = 0\} < \infty$ \mathbb{P} a.s.*

Then, $M'_t = \frac{1_{\{t < T_0\}}}{M_t}$ is well defined and strictly positive under \mathbb{Q} ;

$M'_t \in \mathcal{L}_0^{(+)}$; moreover it is a strict local martingale under \mathbb{Q} .

Finally :

$$\mathbb{E}_{\mathbb{Q}} \left[F_t (M'_t - 1)^+ \right] = \mathbb{E}_{\mathbb{P}} \left[F_t 1_{\{\gamma \leq t < T_0\}} \right], \quad (76)$$

where $\gamma = \sup\{t < T_0, M_t = 1\}$.

Note that, as for Proposition 9.2, the *RHS* of (76), for $F_t \equiv 1$, is no longer an increasing function of t .

The result (76) should be compared with the general expression given in [20], Proposition 2, p.160, for $\mathbb{E}_{\mathbb{Q}} [(M'_t - K)^+]$.

The construction of (M'_t) in Proposition 9.3 is very close to the discussion by Delbaen-Schachermayer [12] of arbitrage within the Bessel processes framework.

9.3 A general discussion

This is based on [20]; extensions of that discussion to discontinuous local martingales have been done by Chybiryakov [9], Kaji [19].

Let $(M_t, t \geq 0)$ denote an \mathbb{R}^+ -valued continuous local martingale, with $M_0 = a > 0$. We denote by $(\mathcal{L}_t^K, t \geq 0)$ the local time at level K of $(M_t, t \geq 0)$.

The following theorem shows how careful one should be when “integrating Tanaka’s formula” when $(M_{t \wedge \tau}, t \geq 0)$ is not a uniformly integrable martingale, with τ a stopping time. This care should be taken in particular for fixed time τ when (M_t) is a strict local martingale.

Theorem 9.1. *[[20], Theorem 1] With the previous notation, and hypotheses, there is the formula :*

$$\mathbb{E} [(M_\tau - K)^+] = (a - K)^+ + \frac{1}{2} \mathbb{E} [\mathcal{L}_\tau^K] - c_M(\tau), \quad (77)$$

where the “correction term” $c_M(\tau)$ does not depend on K , and is equal to either of the four following quantities :

- i.* $\mathbb{E} [a - M_\tau]$;
- ii.* $\lim_{K \rightarrow \infty} \frac{1}{2} \mathbb{E} [\mathcal{L}_\tau^K]$;
- iii.* $\lim_{\sigma \rightarrow \infty} \sigma \mathbb{P} (\sup_{u \leq \tau} M_u \geq \sigma)$;
- iv.* $\lim_{q \rightarrow \infty} \sqrt{\frac{\pi}{2}} \left(q \mathbb{P} \left(\sqrt{\langle M \rangle_\tau} \geq q \right) \right)$.

See [20] for a discussion of the financial meaning of (77). Let us insist, once again, about the formula different, from (77), which one obtains when considering the put quantity : $\mathbb{E} [(K - M_\tau)^+]$, instead of the call quantity : $\mathbb{E} [(M_\tau - K)^+]$:

$$\mathbb{E} [(K - M_\tau)^+] = (K - a)^+ + \frac{1}{2} \mathbb{E} [\mathcal{L}_\tau^K]. \quad (78)$$

Clearly, there is agreement between the identities (77),(78) and the expression (i) of $c_M(\tau)$.

10 Note 10 : A temporary conclusion

10.1 What have we learnt?

- a) Clearly, the knowledge of the call/put quantities :

$$\mathbb{E} [(M_t - K)^\pm],$$

for all strikes and maturities, is equivalent to the knowledge of the 1-dimensional marginals of M . We have learnt that it is also equivalent to the knowledge of the laws of last passage times \mathcal{G}_K .

- b) In our discussion, some fundamental quantities are certain conditional expectations, namely :

$$\mathbb{E} [M_\infty | S_\infty] \text{ and } \mathbb{E} [\sigma_s^2 | M_s],$$

which would certainly deserve more study. However, once introduced, they allow to develop our discussion in a purely martingale framework instead of the more usual Markovian framework.

10.2 Where is all this going?

This course seems to open a number of fairly general questions :

- a) (Note 1). May the universal character of the law of $\sup_{u \geq t} M_u$ be extended to a study involving :

$$\int_t^\infty d\langle M \rangle_u f(M_u), \text{ for suitable } f \text{'s?}$$

- b) (Note 6). Can one develop a stochastic calculus with respect to the two-parameter filtration $(\mathcal{F}_{s,t})$? Creating a two-parameter Itô stochastic integration has already been done, in the context of the study of double points of 2- and 3-dimensional Brownian motion by J. Rosen, M. Yor [29]. We would also like to connect this study with the fairly well developed Markovian Fields theory. (see, e.g, Dang-Ngoc-Yor [10], Royer-Yor [30]).
- c) (Note 8)The Black-Scholes formula has been the first fundamental option pricing formula, and may be considered to have fathered many other such formulae, e.g : for quantile options, Asian options, and so on... Could one develop a last time or more generally a past-future viewpoint for these options?
- d) We plan to develop answers to some of these questions in [4].

10.3 Dealing with last passage times :

Throughout both Part A and Part B, last passage times (of local martingales) play a crucial role. It has been comforting that in private discussions around these lectures we did not experience. The reluctance about these “non-stopping times”, which existed during the seventies, as K. L. Chung [8] describes very well : “For some reason, the notion of a last exit time would not be dealt with openly and directly. This may be due to the fact that such a time is not an “optional”, or “stopping time”, does not belong to the standard equipment, and so must be evaded at all costs.”

The positive attitude (which we experienced in these private discussions) may be partly be due to the fact that the main results of enlargements of filtrations theory are nowadays reasonably well-known.

On the other hand, one should not deny that, when dealing with last passage times, difficulties occur, due to the fact that these times look forever into the future. Undoubtedly, J. Akahori’s suggestion (Note 6) originated from these difficulties.

11 Appendix : Developments of some particular points-solutions to the exercises for both Part A and Part B

This appendix is decomposed into sections 11-1, 11-2, ... which correspond to the Notes 1, 2, ...

11.1 Note 1

- **Solution to Exercise 1.1 :**

From the strong Markov property :

$$\begin{aligned} G_a^{(\nu)} &= \sup\{t, B_t^{(\nu)} = a\} \\ &= T_a^{(\nu)} + \sup\{u, B_{T_a^{(\nu)}+u}^{(\nu)} - a = 0\} \\ &= T_a^{(\nu)} + \tilde{G}_0^{(\nu)}, \end{aligned}$$

where : $\tilde{G}_0^{(\nu)} = \sup\{u, \tilde{B}_u + \nu u = 0\}$, and $(\tilde{B}_u, u \geq 0)$ is a Brownian motion starting from 0 and independent from (B_t) . Now, the law of $\tilde{G}_0^{(\nu)}$ has a simple expression, since :

$$\begin{aligned} \tilde{G}_0^{(\nu)} &= \sup\{u, \tilde{B}_u = -\nu u\} \\ &\stackrel{\text{law}}{=} \frac{1}{T^{(\nu)}(\tilde{B})} \quad (: \text{ time inversion}) \\ &\stackrel{\text{law}}{=} \frac{1}{\nu^2 \tilde{T}_1} \quad (: \text{ scaling}) \\ &\stackrel{\text{law}}{=} \frac{\tilde{B}_1^2}{\nu^2} \quad (: \text{ classical result}). \end{aligned}$$

Hence :

$$(T_a^{(\nu)}, G_a^{(\nu)}) \stackrel{\text{law}}{=} \left(T_a^{(\nu)}, T_a^{(\nu)} + \frac{\tilde{B}_1^2}{\nu^2} \right),$$

with \tilde{B}_1 independent from $T_a^{(\nu)}$.

- **Solution to Exercise 1.2 :**

We first have thanks to Theorem A – 1.1 :

$$\mathbb{E} [(\mathcal{E}_t - K)^+] = K \mathbb{P} \left(0 < G_{\ln K}^{(-1/2)} \leq t \right).$$

The laws of $G_a^{(\nu)}$ and $G_a^{(-\nu)}$ are related via the Cameron-Martin formula :

$$\mathbb{W}^{(-\nu)}|_{\mathcal{F}_{G_a} \cap (G_a > 0)} = \exp(-2\nu a) \mathbb{W}^{(\nu)}|_{\mathcal{F}_{G_a}}. \quad (79)$$

Hence :

$$\mathbb{P}(G_a^{(-\nu)} \in dt | G_a^{(-\nu)} > 0) = \mathbb{P}(G_a^{(\nu)} \in dt).$$

Moreover thanks to (79) :

$$\mathbb{P}(G_a^{(-\nu)} > 0) = \exp(-2\nu a).$$

So the result :

$$\mathbb{E}[(\mathcal{E}_t - K)^+] = \mathbb{P}(G_{\ln K}^{(1/2)} \leq t),$$

follows. We leave the end of the proof to the reader (take derivative in t of the *RHS* of (A – 5) and recover the density of the law of $G_{\ln K}^{(1/2)}$ given in (A – 22).

• **Solution to Exercise 1.3 :**

We recall that :

$$\mathbb{E}[(\mathcal{E}_t - K)^\pm] = (1 - K)^\pm + \frac{1}{2} \mathbb{E}[\mathcal{L}_t^K(\mathcal{E})].$$

From the time occupation formula :

$$\mathbb{E}\left[\int_0^t f(\mathcal{E}_s) d\langle \mathcal{E} \rangle_s\right] = \mathbb{E}\left[\int_0^t f(\mathcal{E}_s) \mathcal{E}_s^2 ds\right] = \mathbb{E}\left[\int_0^\infty f(K) \mathcal{L}_t^K(\mathcal{E}) dK\right],$$

and the change of variable $e^{y - \frac{s}{2}} = K$, we deduce :

$$\int_0^t \frac{ds}{\sqrt{2\pi s}} \int_0^\infty f(e^{y - \frac{s}{2}}) e^{2y - s} e^{-\frac{y^2}{2s}} dy = \int_0^t \frac{ds}{\sqrt{2\pi s}} \int_0^\infty f(K) K e^{-\frac{1}{2s}(\log K + \frac{s}{2})^2} dK,$$

so that :

$$\begin{aligned} \mathbb{E}[\mathcal{L}_t^K(\mathcal{E})] &= \int_0^t \frac{ds}{\sqrt{2\pi s}} K e^{-\frac{1}{2s}(\log K + \frac{s}{2})^2} \\ &= \sqrt{K} \int_0^t \frac{ds}{\sqrt{2\pi s}} e^{-\frac{(\log K)^2}{2s} - \frac{s}{8}} \\ &= 2\sqrt{K} \mathbb{E}\left[1_{\{4B_1^2 \leq t\}} \exp\left(-\frac{(\log K)^2}{8B_1^2}\right)\right] \end{aligned}$$

since the density of the r.v B_1^2 is : $\frac{ds}{\sqrt{2\pi s}} e^{-\frac{s}{2}} 1_{[0, \infty[}(s)$.

11.2 Note 2

- **Discussion of Example 2.1 :**

Thanks to time reversal, one has :

$$(B_{T_0-u}, u \leq T_0) \stackrel{\text{law}}{=} (R_u, u \leq G_1(R)),$$

where $(R_u, u \geq 0)$ is a $BES_0(3)$ and $G_1(R) = \inf\{u \geq 0, R_u = 1\}$.

Hence :

$$T_0 - G_1(M) \stackrel{\text{law}}{=} T_K(R),$$

where on the *LHS*, T_0 and $G_1(M)$ are independent and on the *RHS*, $T_K(R) = \inf\{u \geq 0, R_u = K\}$. Taking the Laplace transform in $(\frac{\lambda^2}{2})$ of both sides, one obtains :

$$e^{-\lambda} = \frac{\lambda K}{\sinh \lambda K} \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(M)} \right], \quad (80)$$

since :

$$\mathbb{E} \left[e^{-\frac{\lambda^2}{2} T_0} \right] = e^{-\lambda}; \quad \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(R)} \right] = \frac{\lambda K}{\sinh \lambda K}.$$

Formula (80) becomes :

$$\begin{aligned} \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(M)} \right] &= \frac{e^{-\lambda(1-K)} - e^{-\lambda(1+K)}}{2\lambda K} \\ &= \frac{1}{2K} \int_{1-K}^{1+K} \exp(-\lambda x) dx \\ &= \frac{1}{2K} \int_{1-K}^{1+K} \mathbb{E} \left[\exp -\frac{\lambda^2}{2} T_x \right], \end{aligned}$$

where T_x is the first hitting time at level x of a Brownian motion $(\beta_t, t \geq 0)$ starting from 0; thus :

$$\begin{aligned} \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(M)} \right] &= \frac{1}{2K} \int_{1-K}^{1+K} \mathbb{E} \left[\exp -\frac{\lambda^2 x^2}{2\beta_1^2} \right] \\ &= \mathbb{E} \left[\exp -\frac{\lambda^2 \mathbf{U}_K^2}{2\beta_1^2} \right], \end{aligned}$$

since :

$$T_x \stackrel{\text{law}}{=} \frac{x^2}{\beta_1^2}.$$

- **Discussion of Example 2.1 :**

We observe that :

$$\sup\{t \geq 0, \frac{1}{R_t} = K\} = \sup\{t \geq 0, R_t = \frac{1}{K}\}.$$

We consider the process R as obtained by time reversal from a Brownian motion $(B_t, t \geq 0)$ starting from $\frac{1}{K}$ and killed when it first hits 0. Hence, with the same notation as before, we have :

$$T_0 \stackrel{\text{law}}{=} G_K(M) + T_1(R), \quad (\text{with independence}).$$

Thus, taking once again the Laplace transform in $(\frac{\lambda^2}{2})$ of both sides, one obtains :

$$\begin{aligned} e^{-\lambda \frac{1}{K}} &= \frac{\lambda}{\sinh \lambda} \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(M)} \right], \\ \mathbb{E} \left[e^{-\frac{\lambda^2}{2} G_K(M)} \right] &= \frac{1}{2\lambda} \left(\exp \left(-\lambda \left(\frac{1}{K} - 1 \right) \right) - \exp \left(-\lambda \left(\frac{1}{K} + 1 \right) \right) \right) \\ &= \frac{1}{2} \int_{\frac{1}{K}-1}^{\frac{1}{K}+1} e^{-\lambda x} dx. \end{aligned}$$

We leave the end of the proof to the reader (conclude as above).

- **Solution to Exercise 2.4 :**

From Itô's formula, one obtains :

$$\sigma_t = \sinh(B_t) e^{-\frac{t}{2}}.$$

Hence : $\sigma_t^2 = M_t^2 - e^{-t}$; therefore, using Theorem A – 2.1 :

$$\mathbb{P}(\mathcal{G}_K \in dt) = \left(1 - \frac{1}{K}\right)^+ \epsilon_0(dt) + \frac{1_{\{t>0\}}}{2K} \theta_t(K) m_t(K) dt.$$

We leave the computation of $m_t(K)$ to the reader.

11.6 Note 6

- **Solution to Exercise 6.2 :**

We recall the generating function expansion of the Hermite polynomials :

$$\exp \left(\lambda x - \frac{\lambda^2 u}{2} \right) = \sum_{n=0}^{\infty} \frac{\lambda^n}{n!} H_n(x, u).$$

Now we write :

$$\begin{aligned}
& \exp\left(al - \frac{dl^2}{2}\right) \exp\left(b\nu - \frac{c\nu^2}{2}\right) \exp(fl\nu) \\
&= \left(\sum_{k=0}^{\infty} \frac{l^k}{k!} H_k(a, d)\right) + \left(\sum_{j=0}^{\infty} \frac{\nu^j}{j!} H_j(b, c)\right) \left(\sum_{m=0}^{\infty} \frac{(l\nu)^m}{m!} f^m\right) \\
&= \sum_{k,j,m=0}^{\infty} \frac{l^{k+m} \nu^{j+m}}{k!j!m!} H_k(a, d) H_j(b, c) f^m.
\end{aligned}$$

Now, we may write :

$$\begin{aligned}
& \sum_{p,q=0}^{\infty} l^p \nu^q \mathcal{H}_{p,q}(a, b, c, d, f) \\
&= \sum_{k,j,n=0}^{\infty} \frac{l^{k+m} \nu^{j+m}}{k!j!m!} H_k(a, d) H_j(b, c) f^m \\
&= \sum_{m=0}^{\infty} \frac{f^m}{m!} \left(\sum_{p=m}^{\infty} \frac{l^p}{(p-m)!} H_{p-m}(a, d)\right) \left(\sum_{q=m}^{\infty} \frac{\nu^q}{(q-m)!} H_{q-m}(b, c)\right) \\
&= \sum_{p,q=0}^{\infty} l^p \nu^q \left(\sum_{m \leq p,q} \frac{f^m}{m!} H_{p-m}(a, d) H_{q-m}(b, c) \frac{1}{(p-m)!(q-m)!}\right)
\end{aligned}$$

Consequently, we have :

$$\mathcal{H}_{p,q}(a, b, c, d, f) = \sum_{m \leq p,q} H_{p-m}(a, d) H_{q-m}(b, c) \frac{1}{(p-m)!(q-m)!}.$$

• **Solution to Exercise 6.1 :**

First, we need to write :

$$\begin{aligned}
& -\frac{2}{(t-s)}(x + \nu s - l)(y + \nu t - l) \\
&= -\frac{2}{t-s} [(x + \nu s)(y + \nu t) - l(x + y + \nu(s + t)) + l^2] \\
&= -\frac{2}{t-s} [xy + \nu(sy + tx) + \nu^2(st) - l(x + y) - l\nu(s + t) + l^2] \\
&\equiv al - \frac{dl^2}{2} + b\nu - \frac{c\nu^2}{2} + fl\nu.
\end{aligned}$$

Comparing the two developments as polynomials in (l, ν) , we obtain :

$$\begin{aligned} a &= \frac{2(x+y)}{t-s}; & b &= -\frac{2}{t-s}(sy+tx) \\ c &= \frac{4(st)}{t-s}; & d &= \frac{4}{t-s}; & f &= \frac{2(s+t)}{t-s}. \end{aligned}$$

Consequently, we obtain :

$$H_{p,q}(s, t; x, y) = \mathcal{H}_{p,q} \left(\frac{2(x+y)}{t-s}, \frac{-2(sy+tx)}{t-s}, \frac{4st}{t-s}, \frac{4}{t-s}, \frac{2(s+t)}{t-s} \right).$$

11.9 Note 9

- **Asymptotic study of $r(t)$, $t \rightarrow 0$, and $t \rightarrow \infty$.**

a) ($t \rightarrow 0$) : We use

$$r(t) = \mathbb{E}_1^{(3)} \left[\left(\frac{1}{X_t} - 1 \right)^+ \right] \underset{t \rightarrow 0}{\sim} \mathbb{E}_1^{(3)} [(1 - X_t)^+].$$

Now, using the decomposition :

$$X_t = 1 + \beta_t + \int_0^t \frac{ds}{X_s},$$

with (β_t) a one-dimensional Brownian motion starting from 0, one obtains :

$$r(t) \underset{t \rightarrow 0}{\sim} \mathbb{E}_1^{(3)} \left[\left(-\beta_t - \int_0^t \frac{ds}{X_s} \right)^+ \right],$$

and, it is now easily seen that :

$$\begin{aligned} r(t) &\sim \mathbb{E} [(-\beta_t)^+] \\ &\sim \sqrt{t} \left(\frac{1}{2} \right) \mathbb{E} [|\mathbf{N}|] \\ &\sim \sqrt{\frac{t}{2\pi}} \end{aligned}$$

b) ($t \rightarrow \infty$) : From (72), we obtain :

$$\begin{aligned}
r(t) &= \mathbb{P} \left(|B_1| \leq \frac{1}{\sqrt{t}} \right) - \mathbb{P} \left(|B_1| \leq \frac{2\mathbf{U}}{\sqrt{t}} \right) \\
&= \sqrt{\frac{2}{\pi}} \left(\int_0^{\frac{1}{\sqrt{t}}} dx e^{-\frac{x^2}{2}} - \mathbb{E} \left[\int_0^{\frac{2\mathbf{U}}{\sqrt{t}}} dx e^{-\frac{x^2}{2}} \right] \right) \\
&\sim \sqrt{\frac{2}{\pi t}} \left(\int_0^1 dy e^{-\frac{y^2}{2t}} - \mathbb{E} \left[2\mathbf{U} \int_0^1 dy e^{-2\frac{y^2\mathbf{U}^2}{t}} \right] \right) \\
&= \sqrt{\frac{2}{\pi t}} \left(\int_0^1 dy \left(e^{-\frac{y^2}{2t}} - 1 \right) - \mathbb{E} \left[2\mathbf{U} \int_0^1 dy \left(e^{-2\frac{y^2\mathbf{U}^2}{t}} - 1 \right) \right] \right) \\
&\sim \sqrt{\frac{2}{\pi t}} \left(\int_0^1 dy \frac{-y^2}{2t} - \mathbb{E} \left[(2\mathbf{U}) \int_0^1 dy \left(-\frac{2y^2\mathbf{U}^2}{t} \right) \right] \right)
\end{aligned}$$

Hence :

$$\begin{aligned}
r(t) &\sim \sqrt{\frac{2}{\pi t}} \left(\mathbb{E} \left[\frac{4\mathbf{U}^3}{t} \int_0^1 dy y^2 \right] - \frac{1}{2t} \left(\frac{1}{3} \right) \right) \\
&= \sqrt{\frac{2}{\pi t^3}} \left(\mathbb{E} [4\mathbf{U}^3] \left(\frac{1}{3} \right) - \frac{1}{6} \right) \\
&= \sqrt{\frac{2}{\pi t^3}} \left(\frac{1}{6} \right)
\end{aligned}$$

From the representation (72) of $r(t)$:

$$r(t) = \mathbb{P} \left(|B_1| \leq \frac{1}{\sqrt{t}} \right) - \mathbb{P} \left(|B_1| \leq \frac{2\mathbf{U}}{\sqrt{t}} \right),$$

we can show :

$$r(t) = \sqrt{\frac{2}{\pi t}} \sum_{n=1}^{\infty} \frac{r_n}{t^n},$$

with :

$$r_n = \frac{(-1)^n}{n!(2n+1)} \left(\frac{1}{2^n} - \frac{2^n}{n+1} \right).$$

(Note : $r_1 = \frac{1}{6}$, $r_2 = -\frac{13}{120}$).

c) We recall that :

$$r(t) \equiv \mathbb{W}_1(T_0 \geq t) - \mathbb{W}_1(\gamma \geq t).$$

Figure 1: Graph of ρ

Let θ_0 and θ_1 denote the respective densities of T_0 and γ ; then :

$$r'(t) = -\theta_0(t) + \theta_1(t),$$

hence, $r'(t) = 0$ if and only if : $\theta_0(t) = \theta_1(t)$. To be continued...

d) A simple integral formula and a graph.

From (72), it is easy enough to obtain :

$$r(t) = \sqrt{\frac{2}{\pi}} \rho\left(\frac{1}{\sqrt{t}}\right),$$

with :

$$\rho(u) = \frac{1}{2u} \left(1 - e^{-2u^2}\right) - \int_u^{2u} dx e^{-\frac{x^2}{2}}.$$

We now show the graph of ρ , for which we thank G. Pagès.

e) Other properties of r :

- We note that $(r(t), t \geq 0)$ is integrable over \mathbb{R}^+ , since : $r(t) \sim \frac{C}{t^{3/2}}$, as $t \rightarrow \infty$. More precisely, we have :

$$\int_0^\infty dt r(t) = \int_0^\infty dt \mathbb{W}_1(\gamma \leq t \leq T_0) = \mathbb{W}_1(T_0 - \gamma) = \mathbb{E}_0^{(3)}(T_1) = \frac{1}{3}.$$

- Moreover, $\int_0^\infty dt t^\alpha r(t) < \infty$ iff $-\frac{3}{2} < \alpha < \frac{1}{2}$.
- We note that $\tilde{r}(t) = 3r(t)$, is a probability density, and we denote by \tilde{R} a random variable such that:

$$\mathbb{P}(\tilde{R} \in dt) = 3r(t) dt.$$

The Laplace transform of \tilde{R} is given by :

$$\begin{aligned} \mathbb{E} \left[e^{-\lambda \tilde{R}} \right] &= \int_0^\infty dt 3e^{-\lambda t} \mathbb{W}_1(\gamma \leq t \leq T_0) \\ &= \frac{3}{\lambda} \mathbb{W}_1(e^{-\lambda \gamma} - e^{-\lambda T_0}) \\ &= \frac{3}{\lambda} \mathbb{W}_1(e^{-\lambda \gamma}) \mathbb{W}_1(1 - e^{-\lambda(T_0 - \gamma)}) \end{aligned}$$

Since :

$$\mathbb{W}_1(e^{-\lambda(T_0 - \gamma)}) = \mathbb{E}_0^{(3)}[e^{-\lambda T_1}] = \frac{\sqrt{2\lambda}}{\sinh(\sqrt{2\lambda})},$$

and :

$$\mathbb{W}_1(e^{-\lambda \gamma}) \mathbb{W}_1(e^{-\lambda(T_0 - \gamma)}) = e^{-\sqrt{2\lambda}},$$

we finally obtain :

$$\mathbb{E} \left[e^{-\lambda \tilde{R}} \right] = \frac{3 \left(1 - e^{-2\sqrt{2\lambda}} - 2\sqrt{2\lambda} e^{-\sqrt{2\lambda}} \right)}{(2\lambda)^{3/2}}.$$

Can we exhibit a “natural” Brownian variable which is distributed as \tilde{R} ?

Acknowledgments

What started it all is M. Qian's question (15/08/2007).

M. Yor is also very grateful to D. Madan and B. Roynette for several attempts to solve various questions, rewriting, and summarizing...

J. Akahori gave the stimulation for Section 6.

C. Ewald sent the preprint [6] very early on.

The graph of ρ (see A-9) is due to G. Pagès.

Lecturing in Osaka and Ritsumeikan (October 2007), Melbourne and Sydney (December 2007), then finally at the Bachelier Séminaire (February 2008) has been a great help.

We gave further lectures in Oxford and at Imperial College, London, both in May 2008 and in Amsterdam at VU University in June 2008.
