## ON THE TOPOLOGICAL COMPLEXITY OF INFINITARY RATIONAL RELATIONS

OLIVIER FINKEL<sup>1</sup>

**Abstract.** We prove in this paper that there exists some infinitary rational relations which are analytic but non Borel sets, giving an answer to a question of Simonnet [Sim92].

**1991 Mathematics Subject Classification.** 68Q45; 03D05; 03D55; 03E15.

### 1. INTRODUCTION

Acceptance of infinite words by finite automata was firstly considered by Büchi in order to study decidability of the monadic second order theory of one successor over the integers [Büc62]. Then the so called  $\omega$ -regular languages have been intensively studied and many applications have been found, see [Tho90] [Sta97] [PP01] for many results and references.

Rational relations on finite words were studied in the sixties and played a fundamental role in the study of families of context free languages [Ber79]. Their extension to rational relations on infinite words was firstly investigated by Gire and Nivat [Gir81] [GN84]. Infinitary rational relations are subsets of  $\Sigma_1^\omega \times \Sigma_2^\omega$ , where  $\Sigma_1$  and  $\Sigma_2$  are finite alphabets, which are recognized by Büchi transducers or by 2-tape finite Büchi automata with asynchronous reading heads (there exists an extension to subsets of  $\Sigma_1^\omega \times \Sigma_2^\omega \times \dots \times \Sigma_n^\omega$  recognized by  $n$ -tape Büchi automata, with  $\Sigma_1, \dots, \Sigma_n$  some finite alphabets, but we shall not need to consider it). Since then they have been much studied, in particular in connection with the rational functions they may define, see for example [CG99] [BC00] [Sim92] [Sta97] [Pri00] for many results and references.

---

*Keywords and phrases:* Infinitary rational relations; topological properties; Borel and analytic sets.

The question of the complexity of such relations on infinite words naturally arises. A way to investigate the complexity of infinitary rational relations is to consider their topological complexity and particularly to locate them with regard to the Borel and the projective hierarchies. It is well known that every  $\omega$ -language accepted by a Turing machine with a Büchi or Muller acceptance condition is an analytic set, [Sta97], thus every infinitary rational relation is an analytic set. Simonnet asked in [Sim92] whether there exists some infinitary rational relation which is an analytic but non Borel set. We give in this paper a positive answer to this question showing that there exists some non Borel (and even  $\Sigma_1^1$ -complete) infinitary rational relation. The paper is organized as follows. In section 2 we introduce the notion of transducers and of infinitary rational relations. In section 3 we recall definitions of Borel and analytic sets, and we prove our main result in section 4.

## 2. INFINITARY RATIONAL RELATIONS

Let  $\Sigma$  be a finite alphabet whose elements are called letters. A non-empty finite word over  $\Sigma$  is a finite sequence of letters:  $x = a_1 a_2 \dots a_n$  where  $\forall i \in [1; n] a_i \in \Sigma$ . We shall denote  $x(i) = a_i$  the  $i^{\text{th}}$  letter of  $x$  and  $x[i] = x(1) \dots x(i)$  for  $i \leq n$ . The length of  $x$  is  $|x| = n$ . The empty word will be denoted by  $\lambda$  and has 0 letter. Its length is 0. The set of finite words over  $\Sigma$  is denoted  $\Sigma^*$ .  $\Sigma^+ = \Sigma^* - \{\lambda\}$  is the set of non empty words over  $\Sigma$ . A (finitary) language  $L$  over  $\Sigma$  is a subset of  $\Sigma^*$ . The usual concatenation product of  $u$  and  $v$  will be denoted by  $u.v$  or just  $uv$ . For  $V \subseteq \Sigma^*$ , we denote  $V^* = \{v_1 \dots v_n / n \in \mathbb{N} \text{ and } v_i \in V \forall i \in [1; n]\}$ .

The first infinite ordinal is  $\omega$ . An  $\omega$ -word over  $\Sigma$  is an  $\omega$ -sequence  $a_1 a_2 \dots a_n \dots$ , where  $a_i \in \Sigma, \forall i \geq 1$ . When  $\sigma$  is an  $\omega$ -word over  $\Sigma$ , we write  $\sigma = \sigma(1)\sigma(2) \dots \sigma(n) \dots$  and  $\sigma[n] = \sigma(1)\sigma(2) \dots \sigma(n)$  the finite word of length  $n$ , prefix of  $\sigma$ . The set of  $\omega$ -words over the alphabet  $\Sigma$  is denoted by  $\Sigma^\omega$ . An  $\omega$ -language over an alphabet  $\Sigma$  is a subset of  $\Sigma^\omega$ . For  $V \subseteq \Sigma^*$ ,  $V^\omega = \{\sigma = u_1 \dots u_n \dots \in \Sigma^\omega / u_i \in V, \forall i \geq 1\}$  is the  $\omega$ -power of  $V$ . The concatenation product is extended to the product of a finite word  $u$  and an  $\omega$ -word  $v$ : the infinite word  $u.v$  is then the  $\omega$ -word such that:  $(u.v)(k) = u(k)$  if  $k \leq |u|$ , and  $(u.v)(k) = v(k - |u|)$  if  $k > |u|$ . The prefix relation is denoted  $\sqsubseteq$ : the finite word  $u$  is a prefix of the finite word  $v$  (respectively, the infinite word  $v$ ), denoted  $u \sqsubseteq v$ , if and only if there exists a finite word  $w$  (respectively, an infinite word  $w$ ), such that  $v = u.w$ .

We assume the reader to be familiar with the theory of formal languages and of  $\omega$ -regular languages, see [Büc62] [Tho90] [EH93] [Sta97] [PP01] for many results and references. We recall that  $\omega$ -regular languages form the class of  $\omega$ -languages accepted by finite automata with a Büchi acceptance condition and this class is the omega Kleene closure of the class of regular finitary languages.

We are going now to introduce the notion of infinitary rational relation which extends the notion of  $\omega$ -regular language, via definition by Büchi transducers:

**Definition 2.1.** A Büchi transducer is a sextuple  $\mathcal{T} = (K, \Sigma, \Gamma, \Delta, q_0, F)$ , where  $K$  is a finite set of states,  $\Sigma$  and  $\Gamma$  are finite sets called the input and the output alphabets,  $\Delta$  is a finite subset of  $K \times \Sigma^* \times \Gamma^* \times K$  called the set of transitions,  $q_0$  is the initial state, and  $F \subseteq K$  is the set of accepting states.

A computation  $\mathcal{C}$  of the transducer  $\mathcal{T}$  is an infinite sequence of transitions

$$(q_0, u_1, v_1, q_1), (q_1, u_2, v_2, q_2), \dots (q_{i-1}, u_i, v_i, q_i), (q_i, u_{i+1}, v_{i+1}, q_{i+1}), \dots$$

The computation is said to be successful iff there exists a final state  $q_f \in F$  and infinitely many integers  $i \geq 0$  such that  $q_i = q_f$ .

The input word of the computation is  $u = u_1.u_2.u_3 \dots$

The output word of the computation is  $v = v_1.v_2.v_3 \dots$

Then the input and the output words may be finite or infinite.

The infinitary rational relation  $R(\mathcal{T}) \subseteq \Sigma^\omega \times \Gamma^\omega$  recognized by the Büchi transducer  $\mathcal{T}$  is the set of couples  $(u, v) \in \Sigma^\omega \times \Gamma^\omega$  such that  $u$  and  $v$  are the input and the output words of some successful computation  $\mathcal{C}$  of  $\mathcal{T}$ .

The set of infinitary rational relations will be denoted  $RAT$ .

**Remark 2.2.** An infinitary rational relation is a subset of  $\Sigma^\omega \times \Gamma^\omega$  for two finite alphabets  $\Sigma$  and  $\Gamma$ . One can also consider that it is an  $\omega$ -language over the finite alphabet  $\Sigma \times \Gamma$ . If  $(u, v) \in \Sigma^\omega \times \Gamma^\omega$ , one can consider this couple of infinite words as a single infinite word  $(u(1), v(1)).(u(2), v(2)).(u(3), v(3)) \dots$  over the alphabet  $\Sigma \times \Gamma$ . We shall use this fact to investigate the topological complexity of infinitary rational relations.

### 3. BOREL AND ANALYTIC SETS

We assume the reader to be familiar with basic notions of topology which may be found in [Kur66] [Mos80] [Kec95] [LT94] [Sta97] [PP01].

For a finite alphabet  $X$  having at least two letters we shall consider  $X^\omega$  as a topological space with the Cantor topology. The open sets of  $X^\omega$  are the sets in the form  $W.X^\omega$ , where  $W \subseteq X^*$ . A set  $L \subseteq X^\omega$  is a closed set iff its complement  $X^\omega - L$  is an open set. We define now the next classes of the Borel Hierarchy:

**Definition 3.1.** The classes  $\Sigma_n^0$  and  $\Pi_n^0$  of the Borel Hierarchy on the topological space  $X^\omega$  are defined as follows:

$\Sigma_1^0$  is the class of open sets of  $X^\omega$ .

$\Pi_1^0$  is the class of closed sets of  $X^\omega$ .

And for any integer  $n \geq 1$ :

$\Sigma_{n+1}^0$  is the class of countable unions of  $\Pi_n^0$ -subsets of  $X^\omega$ .

$\Pi_{n+1}^0$  is the class of countable intersections of  $\Sigma_n^0$ -subsets of  $X^\omega$ .

The Borel Hierarchy is also defined for transfinite levels. The classes  $\Sigma_\alpha^0$  and  $\Pi_\alpha^0$ , for a countable ordinal  $\alpha$ , are defined in the following way:

$\Sigma_\alpha^0$  is the class of countable unions of subsets of  $X^\omega$  in  $\cup_{\gamma < \alpha} \Pi_\gamma^0$ .

$\Pi_\alpha^0$  is the class of countable intersections of subsets of  $X^\omega$  in  $\cup_{\gamma < \alpha} \Sigma_\gamma^0$ .

There are also some subsets of  $X^\omega$  which are not Borel sets. In particular the class of Borel subsets of  $X^\omega$  is strictly included into the class  $\Sigma_1^1$  of **analytic** subsets of  $X^\omega$ . A subset  $A$  of  $X^\omega$  is an **analytic** set iff there exists another finite set  $Y$  and a Borel subset  $B$  of  $(X \times Y)^\omega$  such that  $x \in A \leftrightarrow \exists y \in Y^\omega$  such that  $(x, y) \in B$ , where  $(x, y)$  is the infinite word over the alphabet  $X \times Y$  such that  $(x, y)(i) = (x(i), y(i))$  for each integer  $i \geq 1$ .

Recall also the notion of completeness with regard to reduction by continuous functions. If  $\alpha$  be a countable ordinal, a set  $F \subseteq X^\omega$  is said to be a  $\Sigma_\alpha^0$  (respectively  $\Pi_\alpha^0, \Sigma_1^1$ )-complete set iff for any set  $E \subseteq Y^\omega$  (with  $Y$  a finite alphabet):  $E \in \Sigma_\alpha^0$  (respectively  $E \in \Pi_\alpha^0, \Sigma_1^1$ ) iff there exists a continuous function  $f : Y^\omega \rightarrow X^\omega$  such that  $E = f^{-1}(F)$ .

A  $\Sigma_\alpha^0$  (respectively  $\Pi_\alpha^0, \Sigma_1^1$ )-complete set is a  $\Sigma_\alpha^0$  (respectively  $\Pi_\alpha^0, \Sigma_1^1$ )-set which is in some sense a set of the highest topological complexity among the  $\Sigma_\alpha^0$  (respectively  $\Pi_\alpha^0, \Sigma_1^1$ )-sets.  $\Sigma_n^0$  (respectively  $\Pi_n^0$ )-complete sets, with  $n$  an integer  $\geq 1$ , are thoroughly characterized in [Sta86].

The  $\omega$ -language  $\mathcal{A} = (0^*.1)^\omega$  is a well known example of  $\Pi_2^0$ -complete set which will be used below. It is the set of  $\omega$ -words over the alphabet  $\{0, 1\}$  with infinitely many occurrences of the letter 1.

#### 4. $\Sigma_1^1$ -COMPLETE INFINITARY RATIONAL RELATIONS

We can now state our main result:

**Theorem 4.1.** *There exists some  $\Sigma_1^1$ -complete (hence non Borel) infinitary rational relations.*

*Proof.* We shall use here results about languages of infinite binary trees whose nodes are labelled in a finite alphabet  $\Sigma$ .

A node of an infinite binary tree is represented by a finite word over the alphabet  $\{l, r\}$  where  $r$  means "right" and  $l$  means "left". Then an infinite binary tree whose nodes are labelled in  $\Sigma$  is identified with a function  $t : \{l, r\}^* \rightarrow \Sigma$ . The set of infinite binary trees labelled in  $\Sigma$  will be denoted  $T_\Sigma^\omega$ .

There is a natural topology on this set  $T_\Sigma^\omega$  [Mos80], [LT94], [Sim92]. It is defined by the following distance. Let  $t$  and  $s$  be two distinct infinite trees in  $T_\Sigma^\omega$ . Then the distance between  $t$  and  $s$  is  $\frac{1}{2^n}$  where  $n$  is the smallest integer such that  $t(x) \neq s(x)$  for some word  $x \in \{l, r\}^*$  of length  $n$ .

The open sets are then in the form  $T_0.T_\Sigma^\omega$  where  $T_0$  is a set of finite labelled trees.  $T_0.T_\Sigma^\omega$  is the set of infinite binary trees which extend some finite labelled binary tree  $t_0 \in T_0$ ,  $t_0$  is here a sort of prefix, an "initial subtree" of a tree in  $t_0.T_\Sigma^\omega$ .

For an alphabet  $\Sigma$  having at least two letters the topological space  $T_\Sigma^\omega$  is homeomorphic to the Cantor set  $\Sigma^\omega$ . Borel and analytic subsets of  $T_\Sigma^\omega$  are defined from open sets in the same manner as in the case of the topological space  $\Sigma^\omega$ .

Let  $t$  be a tree. A branch  $B$  of  $t$  is a subset of the set of nodes of  $t$  which is linearly ordered by the tree partial order  $\sqsubseteq$  and which is closed under prefix relation, i.e. if  $x$  and  $y$  are nodes of  $t$  such that  $y \in B$  and  $x \sqsubseteq y$  then  $x \in B$ .

A branch  $B$  of a tree is said to be maximal iff there is not any other branch of  $t$  which strictly contains  $B$ .

Let  $t$  be an infinite binary tree in  $T_\Sigma^\omega$ . If  $B$  is a maximal branch of  $t$ , then this branch is infinite. Let  $(u_i)_{i \geq 0}$  be the enumeration of the nodes in  $B$  which is strictly increasing for the prefix order.

The infinite sequence of labels of the nodes of such a maximal branch  $B$ , i.e.  $t(u_0)t(u_1)\dots t(u_n)\dots$  is called a path. It is an  $\omega$ -word over the alphabet  $\Sigma$ .

Let then  $L \subseteq \Sigma^\omega$  be an  $\omega$ -language over  $\Sigma$ . We denote  $Path(L)$  the set of infinite trees  $t$  in  $T_\Sigma^\omega$  such that  $t$  has at least one path in  $L$ .

It is well known that if  $L \subseteq \Sigma^\omega$  is an  $\omega$ -language over  $\Sigma$  which is a  $\mathbf{\Pi}_2^0$ -complete subset of  $\Sigma^\omega$  (or a Borel set of higher complexity in the Borel hierarchy) then the set  $Path(L)$  is a  $\mathbf{\Sigma}_1^1$ -complete subset of  $T_\Sigma^\omega$ . Hence in particular  $Path(L)$  is not a Borel set, [Niw85] [Sim93] [Sim92].

Whenever  $B \subseteq \Sigma^\omega$  is a regular  $\omega$ -language, we shall find a rational relation  $R \subseteq (\Sigma \cup \{A\})^\omega \times (\Sigma \cup \{A\})^\omega$  and a continuous function

$$h : T_\Sigma^\omega \rightarrow ((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))^\omega$$

such that  $Path(B) = h^{-1}(R)$ . For that we shall code trees labelled in  $\Sigma$  by words over the finite alphabet  $(\Sigma \cup \{A\}) \times (\Sigma \cup \{A\})$  where  $A$  is supposed to be a new letter not in  $\Sigma$ .

Consider now the set  $\{l, r\}^*$  of nodes of binary infinite trees. For each integer  $n \geq 0$ , call  $C_n$  the set of words of length  $n$  of  $\{l, r\}^*$ . Then  $C_0 = \{\lambda\}$ ,  $C_1 = \{l, r\}$ ,  $C_2 = \{ll, lr, rl, rr\}$  and so on.  $C_n$  is the set of nodes which appear in the  $(n+1)^{th}$  level of an infinite binary tree. The number of nodes of  $C_n$  is  $card(C_n) = 2^n$ . We consider now the lexicographic order on  $C_n$  (assuming that  $l$  is before  $r$  for this order). Then, in the enumeration of the nodes with regard to this order, the nodes of  $C_1$  will be:  $l, r$ ; the nodes of  $C_3$  will be:  $lll, llr, lrl, lrr, rll, rlr, rrl, rrr$ .

Let  $u_1^n, \dots, u_j^n, \dots, u_{2^n}^n$  be such an enumeration of  $C_n$  in the lexicographic order and let  $v_1^n, \dots, v_j^n, \dots, v_{2^n}^n$  be the enumeration of the elements of  $C_n$  in the reverse order. Then for all integers  $n \geq 0$  and  $i$ ,  $1 \leq i \leq 2^n$ , it holds that  $v_i^n = u_{2^n+1-i}^n$ .

We define now the code of a tree  $t$  in  $T_\Sigma^\omega$ . Let  $A$  be a new letter not in  $\Sigma$ . The code of the tree  $t$  is an  $\omega$ -word  $\sigma$  over the alphabet  $(\Sigma \cup \{A\}) \times (\Sigma \cup \{A\})$  which may

be written in the form  $(\sigma_1, \sigma_2)$ , where  $\sigma_1$  and  $\sigma_2$  are  $\omega$ -words over the alphabet  $(\Sigma \cup \{A\})$ .

The  $\omega$ -word  $\sigma_1$  enumerates the labels of the nodes of the tree  $t$  which appear at levels 1, 3, 5,  $\dots$ ,  $2n+1$ ,  $\dots$ , i.e. at odd levels. More precisely the word  $\sigma_1$  begins with the label  $t(v_1^0)$  of the node at level 1, followed by an  $A$ , followed by the labels of the nodes of the third level enumerated in the **reverse lexicographic order**, i.e.  $t(v_1^2)t(v_2^2)t(v_3^2)t(v_4^2)$ , followed by an  $A$ , followed by the labels of the nodes of the 5<sup>th</sup> level enumerated in the reverse lexicographic order, i.e.  $t(v_1^4)t(v_2^4)t(v_3^4)\dots t(v_{16}^4)$ , and so on  $\dots$ .

For each integer  $n \geq 0$ , the labels of the nodes of  $C_{2n}$ , enumerated in the **reverse lexicographic order**, are placed before those of  $C_{2n+2}$  and these two sets of labels are separated by an  $A$ .

The construction of the  $\omega$ -word  $\sigma_2$  is very similar but it successively enumerates, in the **lexicographic order**, the labels of nodes occurring at even levels. So the word  $\sigma_2$  is in the form

$$\sigma_2 = t(u_1^1)t(u_2^1)At(u_1^3)t(u_2^3)t(u_3^3)t(u_4^3)t(u_5^3)t(u_6^3)t(u_7^3)t(u_8^3)A\dots$$

For each integer  $n \geq 0$ , the labels of the nodes of  $C_{2n+1}$  are enumerated before those of  $C_{2n+3}$  and these two sets of labels are separated by an  $A$ . Moreover the labels of the nodes of  $C_{2n+1}$ , for  $n \geq 0$ , are enumerated in the **lexicographic order** (for the nodes).

Let then  $h$  be the mapping from  $T_\Sigma^\omega$  into  $((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))^\omega$  such that for every labelled binary infinite tree  $t$  of  $T_\Sigma^\omega$ ,  $h(t)$  is the code  $(\sigma_1, \sigma_2)$  of the tree as defined above. It is easy to see, from the definition of  $h$  and of the order of the enumeration of labels of nodes (they are enumerated level after level in the increasing order), that  $h$  is a continuous function from  $T_\Sigma^\omega$  into  $((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))^\omega$ .

Now we are looking for a rational relation  $R$  such that for every tree  $t \in T_\Sigma^\omega$ ,  $h(t) \in R$  if and only if  $t$  has a path in  $B$ . Then we shall have  $Path(B) = h^{-1}(R)$ .

We shall first describe the rational relation  $R$  which is an  $\omega$ -language over the alphabet  $((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))$ . Every word of  $R$  may be seen as a couple  $y = (y_1, y_2)$  of  $\omega$ -words over the alphabet  $\Sigma \cup \{A\}$ . Now  $y = (y_1, y_2)$  is in  $R$  if and only if it is in the form

$$\begin{aligned} y_1 &= x(1).u_1.A.v_2.x(3).u_3.A.v_4.x(5).u_5.A.\dots A.v_{2n}.x(2n+1).u_{2n+1}.A\dots \\ y_2 &= v_1.x(2).u_2.A.v_3.x(4).u_4.A.\dots A.v_{2n+1}.x(2n+2).u_{2n+2}.A\dots \end{aligned}$$

where for all integers  $i \geq 1$ ,  $x(i) \in \Sigma$  and  $u_i, v_i \in \Sigma^*$  and

$$|v_i| = 2|u_i| \quad \text{or} \quad |v_i| = 2|u_i| + 1$$

and the  $\omega$ -word  $x = x(1)x(2)\dots x(n)\dots$  is in  $B$ .

If such an  $\omega$ -word  $y = (y_1, y_2)$  is the code  $h(t)$  of a tree  $t \in T_\Sigma^\omega$ , then  $x(1) = t(v_1^0)$  and  $u_1 = \lambda$ , then  $|v_1| = 2|u_1| = 0$  or  $|v_1| = 2|u_1| + 1 = 1$ . Therefore if  $|v_1| = 0$  then  $x(2) = t(u_1^1)$  and if  $|v_1| = 1$  then  $x(2) = t(u_2^1)$ . Then the choice of  $|v_1| = 2|u_1|$  or of  $|v_1| = 2|u_1| + 1$  implies that  $x(2)$  is the label of the left or the right successor of the root node  $v_1^0 = \lambda$ .

By construction this phenomenon will happen for further levels. The choice of  $|v_i| = 2|u_i|$  or of  $|v_i| = 2|u_i| + 1$  determines one of the two successor nodes of a node at level  $i$  thus the successive choices determine a branch of  $t$  and the labels of nodes of this branch form a path  $x(1)x(2)x(3)\dots x(n)\dots$  which is in  $B$ . Thus for a tree  $t \in T_\Sigma^\omega$ ,  $h(t) \in R$  if and only if  $t \in Path(B)$  then  $Path(B) = h^{-1}(R)$ . Remark that  $R$  does not contain only codes of trees but such a code  $h(t)$  is in  $R$  iff  $t \in Path(B)$  and this fact suffices for our proof.

Hence if  $B$  is a Borel set which is a  $\mathbf{\Pi}_2^0$ -complete subset of  $\Sigma^\omega$  (or a set of higher complexity in the Borel hierarchy), the language  $h^{-1}(R) = Path(B)$  is a  $\mathbf{\Sigma}_1^1$ -complete subset of  $T_\Sigma^\omega$ . Then the  $\omega$ -language  $R$  is at least  $\mathbf{\Sigma}_1^1$ -complete because  $h$  is a continuous function.

Note that here  $h$  is a continuous function:  $T_\Sigma^\omega \rightarrow ((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))^\omega$  and the preceding definition of  $\mathbf{\Sigma}_1^1$ -complete set involves continuous reductions:  $X^\omega \rightarrow Y^\omega$ ; but the two topological spaces  $T_\Sigma^\omega$  and  $Y^\omega$  have good similar properties (they are zero-dimensional polish spaces, see [PP01] [Kec95] [Sim92], in fact they are homeomorphic) which enable to extend the previous definition to this new case. Indeed  $R$  is a  $\mathbf{\Sigma}_1^1$ -complete subset of  $((\Sigma \cup \{A\}) \times (\Sigma \cup \{A\}))^\omega$  because every infinitary rational relation is a  $\mathbf{\Sigma}_1^1$ -set.

Then in that case  $R$  is not a Borel set because a  $\mathbf{\Sigma}_1^1$ -complete set is not a Borel set. This gives infinitely many non Borel infinitary rational relations, because there exist infinitely many  $\mathbf{\Pi}_2^0$ -complete  $\omega$ -regular languages.

It remains to show that if  $B$  is an  $\omega$ -regular language then  $R$  is an infinitary rational relation. In fact this is easy to see from the definition of  $R$ . We shall explicitly give a Büchi transducer defining  $R$  in the following simple case:  $\Sigma = \{0, 1\}$  and  $B = (0^*.1)^\omega$  is a well known example of  $\mathbf{\Pi}_2^0$ -complete  $\omega$ -regular language.

The infinitary rational relation  $R$  is then recognized by the following Büchi transducer  $\mathcal{T} = (K, (\Sigma \cup \{A\}), (\Sigma \cup \{A\}), \Delta, q_0, F)$ , where

$$K = \{q_0, q_1, q_2, q_3, q_4, q_1^0, q_1^1, q_2^0, q_2^1\}$$

is a finite set of states,  $\{0, 1, A\}$  is the input *and* the output alphabet,  $q_0$  is the initial state, and  $F = \{q_1^1, q_2^1\}$  is the set of accepting states. Moreover  $\Delta \subseteq K \times (\Sigma \cup \{A\})^* \times (\Sigma \cup \{A\})^* \times K$  is the finite set of transitions, containing the following transitions:

$(q_0, 0, \lambda, q_1)$  and  $(q_0, 1, \lambda, q_1)$ ,  
 $(q_1, u, v, q_1)$ , for all words  $u, v \in \Sigma^*$  with  $|u| = 1$  and  $|v| = 2$ ,  
 $(q_1, \lambda, v, q_2)$ , for  $v \in \{0, 1, \lambda\}$ ,  
 $(q_2, A, 0, q_1^0)$  and  $(q_2, A, 1, q_1^1)$ ,  
 $(q, u, v, q_3)$ , for all  $u, v \in \Sigma^*$  with  $|u| = 2$  and  $|v| = 1$  and  $q \in \{q_1^0, q_1^1, q_3\}$ ,  
 $(q, u, \lambda, q_4)$ , for  $u \in \{0, 1, \lambda\}$  and  $q \in \{q_1^0, q_1^1, q_3\}$ ,  
 $(q_4, 0, A, q_2^0)$  and  $(q_4, 1, A, q_2^1)$ ,  
 $(q_2^0, \lambda, \lambda, q_1)$  and  $(q_2^1, \lambda, \lambda, q_1)$ . □

**Remark 4.2.** We could of course have avoided the set of transitions to contain some transitions with both the input and the output words being empty, like the two last ones:  $(q_2^0, \lambda, \lambda, q_1)$  and  $(q_2^1, \lambda, \lambda, q_1)$ .

**Remark 4.3.** We have shown that there exists some infinitary rational relations which are  $\Sigma_1^1$ -complete hence non Borel. In particular this implies that these infinitary rational relations are not arithmetical sets because every arithmetical set is a Borel set (of finite rank). We refer to [Sta86] [Sta97] for definitions and results about the arithmetical hierarchy over sets of infinite words over a finite alphabet  $\Sigma$ .

**Remark 4.4.** From the preceding example we can easily find a  $\Sigma_1^1$ -complete infinitary rational relation in the form  $S^\omega$  where  $S$  is a rational relation over finite words, see [Ber79] [Gir81] [Pri00] about finitary rational relations.

**Acknowledgements.** Thanks to Jean-Pierre Ressayre and Pierre Simonnet for useful discussions.
