## INTRODUCTION

The UK Acid Waters Monitoring Network (UKAWMN) has been in continuous operation since 1988. For the first ten years biological and chemical data were summarised in an annual series of printed reports and these were followed by a detailed analysis of data in an interpretative report (Monteith and Evans, 2000), which is available on the [UKAWMN](#) web page. From the year 2000 annual data reports have been available from the [UKAWMN](#) web page. These are of a similar format to earlier annual reports but focus on graphical representations of time trends in raw data and diagnostic statistics (e.g. species richness and diversity indices). An analytical report, providing an interpretation of the first 15 years of data will be completed and made available on the project web page in the near future. A full description of sampling methods and analytical procedures, together with site descriptions, is presented in Patrick *et al.* (1991).

## THE MONITORING NETWORK

The UKAWMN, funded by the UK Department of the Environment, originally consisted of 10 stream sites and 10 lakes, situated in those parts of the country most susceptible to acidification (see map, page 14). In 1990, two additional sites, Blue Lough and Coneyglen Burn, were added to the Network with funding from the Department of Environment (Northern Ireland). In January 1991 site 18, the Nant y Gronwen, was withdrawn from the Network at the request of the landowner and was replaced by a nearby moorland stream, the Afon Gwy. Due to water abstraction and damming by a local fish farm at site 1, Coire nan Arr, a nearby replacement control site has been chosen, site 23, named Loch Coire Fionnaraich. Data for this site will be included within the next annual report. Since 2001 the entire network has been funded by the UK Department of the Environment Food and Rural Affairs ([DEFRA](#)).

All sites are monitored chemically and biologically according to methodologies described by Patrick *et al.* (1991). Water samples are collected monthly at stream sites and quarterly at lake sites. Epilithic diatoms and benthic invertebrates are sampled annually. Aquatic macrophytes are surveyed bi-annually between June and September. Stream sites and the outflow streams of lake sites are electro-fished annually in the autumn.

In addition to the annual surveys, sediment cores were taken from all lake sites during the first five years of monitoring. These were radiometrically dated and analysed for diatoms, carbonaceous particles (derived from the combustion of fossil fuels) (Rose *et al.* 1995) and trace metals. Results of this work are presented in Patrick *et al.* (1995). Sediment traps have now been installed in all lakes and are emptied annually. The contents are analysed for diatom species composition and the flux of carbonaceous particles, allowing direct comparisons to be made with the historical (sediment core) record.

Water chemistry and macroinvertebrate sampling was prevented at several sites in the spring of 2001 by foot-and-mouth related access restrictions. Sampling was resumed across the Network in June 2001.

All chemical, physical and biological data are stored in a database managed by the Centre for Ecology and Hydrology and ENSIS. Summary data are available to scientific and other interested organisations on request. Further information on the UKAWMN, including site descriptions and photographs, is available via the Internet at the new address: <http://www.ukawmn.ucl.ac.uk>

## DATA FORMAT

The chemical and biological data are presented in a series of sections, summarised below, on a site-by-site basis.

- Section 1: Time series graphs of key spot sampled chemical determinands for individual samples.  
Summary table for key chemical determinands including: the mean over the 1988-1993 baseline period; the mean for the current year (2001-2002), the standard deviation for the current year; the Seasonal Kendall (Hirsch *et al.*, 1982) slope estimate for the period 1988-2002; and, the Seasonal Kendall trend significance level (p) (we consider values of less than 0.05 as evidence for a significant temporal trend). The normal number of observations per year is 4 for lakes and 12 for streams.
- Section 2: Macroinvertebrates. Time series of macroinvertebrate taxon % abundance in annual aggregated samples (5 kick samples from lake littoral habitats or from riffle areas in streams), and annual total number of individual animals. Some species occurring at less than 1% relative abundance are omitted.  
Macroinvertebrate summary statistic time series:  
1) total number of individuals;  
2) number of individuals identified at Genus level only (excludes some ubiquitous groups such as the chironomids and oligochaetes);  
3) total number of taxa;  
4) Diversity Indices. Although we have observed a general between-site relationship between acidity and the total number of macroinvertebrate species found, it is difficult to predict how chemical recovery might influence measures of diversity at specific sites. However, trends in the diversity scores described below should provide an indication of directional changes in community structure.  
a) Hill's  $N_1$ , the exponent of Shannon's Index and a measure of the number of abundant species in a sample (Hill, 1973).  
b) Hill's  $N_2$ , the reciprocal of Simpson's Index and a measure of the number of very abundant species in a sample (Hill, 1973).  
c)  $E_5$ , a measure of evenness based on the ratio  $(N_2-1):(N_1-1)$ . As a single species becomes more and more dominant,  $E_5$  tends to zero.
- Section 3: Salmonids. Summary histogram of mean density of trout and salmon, if present, in three 50m reaches (number of individuals caught per  $100\text{m}^2$  survey area) for each year of the monitoring period. ( $0+$  = new recruits,  $>0+$  = all fish over one year of age).
- Section 4: Epilithic diatoms. Time series of annual mean percentage frequency (from 3-4

replicate samples) of taxa occurring at greater than 2 % abundance in any one sample.

Epilithic diatom summary statistic time series. Mean, maximum and minimum for:

- a) Hill's  $N_1$  (see above)
- b) Hill's  $N_2$  (see above)
- c)  $E_5$  (see above)
- d) Diatom inferred pH (Di pH), based on the weighted average of species pH optima in the surface sediments of the 167 lake Surface Water Acidification Project dataset (Stevenson *et al.* 1991).

pH reconstructions are intended only for application to sedimentary diatoms but directional trends in inferred pH of epilithic assemblages should provide an indication of the direction of a response to changing acidity.

#### Section 5:

Aquatic macrophytes. For lakes relative species abundance was determined on a five point scale (comparable to the DAFOR scoring system, Palmer *et al.* 1992) following shoreline survey, shore transects and deep water grapnel trawls, as follows:

1. rare/infrequent
2. occasional but not abundant
3. widespread but not abundant
4. locally abundant
5. widespread and abundant

For streams, total macrophyte cover was estimated for 5m sections of a 50m survey stretch and each was then partitioned into proportional species abundance to provide percentage cover for each species. Data analysed for this report are the mean species cover estimates for the 50m stretches.

#### Section 6:

For lake sites only. Histogram of diatom species composition and carbonaceous particle flux estimated from annually retrieved sediment traps. Species occurring at less than 1% abundance in all years are omitted. Carbonaceous particle flux data presented in units of number of particles accumulated per trap (uniform trap size for all sites) per day.
