## 28 **ABSTRACT**

29

30 Chikungunya virus (CHIKV) is a reemerging mosquito-borne virus that causes swift  
31 outbreaks. Major concerns are the persistent and disabling polyarthralgia in infected  
32 individuals. Here we present the results from a first-in-human trial of the candidate simian  
33 adenovirus vectored vaccine ChAdOx1 Chik, expressing the CHIKV full-length structural  
34 polyprotein (Capsid, E3, E2, 6k and E1).

35 24 adult healthy volunteers aged 18-50 years, were recruited in a dose escalation, open-label,  
36 non-randomised and uncontrolled phase 1 trial (registry NCT03590392). Participants  
37 received a single intramuscular injection of ChAdOx1 Chik at one of the three pre-  
38 established dosages and were followed-up for 6 months. The primary objective was to assess  
39 safety and tolerability of ChAdOx1 Chik. The secondary objective was to assess the humoral  
40 and cellular immunogenicity.

41 ChAdOx1 Chik was safe at all doses tested with no serious adverse reactions reported. The  
42 vast majority of solicited adverse events were mild or moderate, and self-limiting in nature. A  
43 single dose induced IgG and T-cell responses against the CHIKV structural antigens. Broadly  
44 neutralising antibodies against the four CHIKV lineages were found in all participants and as  
45 early as 2 weeks after vaccination. In summary, ChAdOx1 Chik showed excellent safety,  
46 tolerability and 100% PRNT<sub>50</sub> seroconversion after a single dose.

47

48

## 49 **INTRODUCTION**

50

51 Since its emergence in Tanzania in 1952<sup>1</sup>, and subsequent reemergence in a series of  
52 outbreaks in Kenya, the Indian Ocean (2004-2006)<sup>2</sup> and the Americas (2013-2017)<sup>3</sup>,  
53 Chikungunya virus (CHIKV) has become a major international health concern, with both  
54 acute and long-term impacts on public health. CHIKV has been identified in over 100  
55 countries across Africa, Asia, Europe and the Americas<sup>4</sup>.

56 CHIKV is an RNA alphavirus of the *Togaviridae* family that is transmitted to humans in  
57 urban settings by *Aedes aegypti* and *Aedes albopictus* mosquitoes. Both mosquito species  
58 have dispersed to all continents, with *Ae. aegypti* present mainly in tropical and sub-tropical  
59 regions and *Ae. albopictus* expanding through temperate regions<sup>5</sup>. Their rapid global

60 expansion accounts for the possibility of an even greater burden of chikungunya fever  
61 (CHIKF) beyond tropical regions.

62 Swift CHIKV outbreaks have recently taken place in Europe, where the East-Central-South  
63 African (ECSA) CHIKV lineage has been transmitted by the local *Ae. albopictus* vector<sup>6</sup>.

64 Examples of outbreaks occur in either, low and middle income (LMIC) or high income (HIC)  
65 countries. For instance, one of the largest recorded outbreaks occurred during 2004-2007 in  
66 islands of the Indian Ocean and India<sup>2</sup>. During this outbreak, 5,202 new CHIKV cases were  
67 reported in one month, between February and March 2005. Nevertheless, seroepidemiology  
68 studies indicated that nearly 215,000 people were actually infected within one month,  
69 corresponding to 63% of the total Grande Comore Island population, leaving 79% of the  
70 cases hospitalised or staying at home<sup>7</sup>. Nine months later, in December 2005 the outbreak  
71 had extended to the neighbouring region of Reunion Island resulting in approximately  
72 255,000 cases or 33% of the total population and an estimate of 225 deaths constituting a  
73 case-fatality rate for CHIKF of 1/1000 cases<sup>8</sup>. In Italy, an outbreak occurred in 2007,  
74 affecting 205 individuals in only two months<sup>9</sup>. Autochthonous cases of CHIKF have also  
75 been recorded in France in 2010, 2014 and 2017<sup>10-12</sup>, and have spread across local  
76 populations in 1-3 months after the identification of the index case. This demonstrates the  
77 need for effective actions to control outbreaks, and highlights the impact that CHIKV  
78 preventative vaccines would have if they are able to induce effective immunity rapidly after a  
79 single vaccine dose.

80 CHIKV infections result in a wide spectrum of clinical presentations, spanning from  
81 asymptomatic to chronic, severe and even disabling arthritis<sup>13</sup>. Infections are of major  
82 concern and have a significant economic impact. Studies have estimated 151,031 CHIKV-  
83 related chronic inflammatory rheumatism DALYs (Disability Adjusted Life Years) after the  
84 2014 outbreak in the Americas, roughly twice as many as the 69,000 dengue DALYs  
85 calculated in 2004 for the same region<sup>14</sup>.

86 We have developed a replication-deficient simian adenoviral vector from chimpanzee origin  
87 expressing the entire structural cassette polyprotein of CHIKV. ChAdOx1 Chik is a  
88 chimpanzee adenoviral vector vaccine expressing the CHIKV structural proteins: Capsid, E3,  
89 E2, 6K and E1. We have previously shown, by transmission electron microscopy, that  
90 expression of the CHIKV structural cassette in mammalian cells leads to the formation of  
91 virus-like particles (VLPs) that resemble wild-type CHIKV particles<sup>15</sup>. This suggests that  
92 vaccination with ChAdOx1 Chik can induce the formation of CHIKV VLPs, which mimic  
93 the tridimensional antigen structure of CHIKV particles released during CHIKV infections.

94 In pre-clinical mouse models, high levels of neutralizing antibodies have been induced upon  
95 a single, unadjuvanted ChAdOx1 Chik dose<sup>15,16</sup>, eliciting complete protection against a lethal  
96 CHIKV challenge<sup>16</sup>. ChAdOx1 vectored vaccines are currently in various stages of clinical  
97 development and have been assessed in more than 18,000 volunteers across 18 clinical trials  
98 spanning 10 diseases, including Zika (NCT04015648), Chikungunya (NCT03590392),  
99 MERS (NCT04170829, NCT04170829) and COVID-19 (NCT04324606, NCT04400838,  
100 NCT04444674, ISRCTN89951424). A consistent safe and immunogenic profile has been  
101 observed following vaccination with these ChAdOx1 vectored vaccines. Here we report  
102 safety and immunogenicity data from a first-in-human trial of the ChAdOx1 Chik candidate  
103 CHIKV vaccine.

104

105

## 106 **RESULTS**

107

### 108 **Study Population.**

109 Between 18 July 2018 and 18 October 2019, 24 twenty-four healthy adult subjects received a  
110 single dose of ChAdOx1 Chik at  $5 \times 10^9$ ,  $2.5 \times 10^{10}$  or  $5 \times 10^{10}$  vp (Fig. 1). Baseline  
111 characteristics are summarised in Table 1.

112

### 113 **Vaccine Safety.**

114 ChAdOx1 Chik was safe at doses up to  $5 \times 10^{10}$  vp with no serious adverse reactions  
115 reported. A total of 112 local and systemic solicited adverse events (AEs) were reported. The  
116 vast majority of solicited AEs were mild (79/112; 70.54%, 95%CI 61.53-78.18) or moderate  
117 (27/112; 24.11%, 95%CI 17.13-32.8) and self-limiting in nature. All solicited AEs were  
118 completely resolved within 7 days and 94.64% of them had their onset within the first 72h  
119 post vaccination (51.79% at D0, 39.29% at D1 and 3.57% at D2). Injection site pain was the  
120 most common local AE, reported by 79.17% of participants and was predominantly mild in  
121 severity. Fatigue was the most common systemic AE followed by headache, myalgia and  
122 feverishness. Frequencies of local and systemic solicited AEs reported during the first 7 days  
123 are summarised in Table 2. Median duration of solicited AEs is summarised in Table S1.  
124 Only one serious adverse event was reported but was deemed not related with ChAdOx1  
125 Chik.

126 Four participants reported a short-lived temperature above 37.5°C within the first 72h post  
127 vaccination (2 in the intermediate dose group and 2 in the high dose group). The highest  
128 temperature recorded was 38°C (classed as mild). All febrile episodes resolved within 24h.  
129 The proportion of moderate and severe AEs was significantly higher in group 3 compared to  
130 group 2 (relative risk 3.643, 95%CI 1.817-7.666,  $p < 0.001$ ), but there were no safety concerns  
131 despite the higher reactogenicity.  
132 Unsolicited AEs in the 28 days following vaccination considered possibly, probably or  
133 definitively related with ChAdOx1 Chik were predominantly mild in nature and resolved  
134 within the follow-up period (Table S3). Unsolicited AEs of note include: Shivering/Chills (1  
135 severe at D0 and D1, resolved by D2; 1 moderate at D0, resolved by D1 and 1 mild at D1,  
136 resolved by D2; all in Group 3); Insomnia (1 severe at D2, resolved by D3 - Group 3) and  
137 Lower Back Pain (1 severe at D0, resolved by D2 - Group 2) Laboratory AEs considered at  
138 least possibly related with the study intervention were self-limiting and predominantly mild  
139 in severity (Table S3).

140

#### 141 **Humoral immunogenicity.**

142 Neutralising antibody titers by PRNT<sub>50</sub> were blindly measured from all 24 participants. All  
143 doses were highly immunogenic upon a single immunisation, reaching a 100%  
144 seroconversion rate at 14 days against representative isolates from three CHIKV lineages:  
145 Indian Ocean Lineage (IOL), West African Lineage (Waf) and Asian Lineage (As). PRNT<sub>50</sub>  
146 titers to La Réunion (IOL), 37997 (Waf) and SV-0444 (As), were significantly increased  
147 from baseline and were maintained throughout the 182 days follow-up period. PRNT<sub>50</sub> to  
148 YO111213, from the Asian-American Lineage (AsAm), demonstrated a 100%  
149 seroconversion rate on day 28 but slightly lower seroconversion rates on days 14, 56 and 182  
150 (91.6%, 91.6% and 83.3%, respectively). By day 14, Geometric Mean Titers (GMT) between  
151 40 and 226.3 were measured across the four lineages. GMT peaked at day 28 for IOL (285.5,  
152 95% CI 161.2 - 504.3), Waf (369.7, 95% CI 217.2 - 629.3) and AsAm (71.3, 95% CI 49.6 -  
153 102.4); whereas titers peaked at day 56 for As (75.3, 95% CI 48.0 - 118.3) (Table 3 and Fig.  
154 2a). An analysis per dose group (Fig. 2b) indicated that all doses are effective at inducing  
155 broadly neutralising antibodies against all CHIKV isolates tested, with PRNT<sub>50</sub> GMT  
156 significantly higher than baseline at almost every time point. The best neutralisation was  
157 observed against IOL and Waf, with maximum PRNT<sub>50</sub> values of 1280, 1280 and 2560 at  
158 low, intermediate and high vaccine dosages, respectively. In comparison, maximum PRNT<sub>50</sub>

159 GMT for each dose group were 160, 320 and 1280 for As; 320, 640 and 320 for AsAm (Fig.  
160 S2).

161 Broad cross-neutralising and protective IgG antibodies which recognise epitopes on the  
162 CHIKV E2 protein have been found in convalescent individuals and in animals, shortly after  
163 infection<sup>17-21</sup>. A single ChAdOx1 Chik dose induced high antibody titers against CHIKV E2  
164 protein. Geometric mean ELISA units at the peak response were 80.99 (95% CI 38.65 -  
165 169.7); 205.90 (95% CI 92.66 - 457.6) and 169.70 (95% CI 71.94 - 400.3) for the low,  
166 intermediate and high dose, respectively (Table 4). Levels of anti-E2 antibodies showed a  
167 steady increase over time, reaching maximum seroconversion on day 182: 66.66% (4/6) for  
168 the low vaccine dose, 100% (9/9) for the intermediate dose and 77.77% (7/9) for the high  
169 dose (Table 4). Compared to day 0, anti-E2 IgG antibody levels started to increase by day 14  
170 ( $P= 0.089$ ), were significantly higher at day 28 ( $P= 0.0003$ ) and reached maximum levels at  
171 between day 56 and 182 ( $P= <0.0001$ ) following vaccination (Fig. 3a). Antibodies reached  
172 significantly higher levels than baseline as early as day 14 for the high dose group, day 28 for  
173 the intermediate dose group and day 56 for the low dose group (Fig. 3b). It was observed that  
174 the calculated cut-off threshold (mean on day 0 + 3 SDEV), was influenced by 4 participants  
175 with a relatively high ELISA background at baseline. Therefore, we decided to further  
176 validate the seronegativity of these individuals with two commercially available ELISA kits.  
177 Both anti-chikungunya virus IgG ELISA kits, from Abcam and Euroimmune, confirmed that  
178 none of the participants that had high background in our in-house ELISA were seropositive  
179 for CHIKV at baseline (data not shown).

180 PRNT<sub>50</sub> against CHIKV IOL showed a significant positive correlation with the measured  
181 ELISA units from all dose groups, being the intermediate dose group the most positively  
182 correlated (Spearman's Rho=0.699 [95%CI 0.5047-0.8269];  $P<0.0001$ ) (Fig. 3c). Within the  
183 intermediate dose group, a maximum correlation between PRNT<sub>50</sub> and ELISA units was  
184 reached at day 180 (Spearman's Rho=0.939 [95%CI 0.5047-0.8269];  $P<0.0003$ ) (Fig. 3d).

185

### 186 **Cellular immunogenicity.**

187 Cellular immunogenicity was measured from fresh peripheral blood mononuclear cells  
188 (PBMC) by an *ex vivo* IFN- $\gamma$  ELISpot assay, using pools of peptides spanning the structural  
189 CHIKV proteins (Capsid, E3, E2, 6k and E1) as stimuli. Total responses were quantified at  
190 days 0 (baseline), 14, 28, 56 and 182 after vaccination. At baseline, the geometric mean of  
191 IFN- $\gamma$  spot forming cells (SFC) per million PBMC was 180.1 (IQR 149.9 - 216.4), across all  
192 dosage groups. ChAdOx1 Chik significantly increased the number of IFN- $\gamma$  SFC, peaking at

193 day 14 post vaccination (1031, IQR 748.9 – 1420) and remained significantly higher than  
194 baseline throughout days 28 (541.1, IQR 411.6 - 711.13); 56 (398.2, IQR 298.6 -530.9) and  
195 182 (352.8, IQR 270.1 - 460.8) (Fig. 4a).

196 Breadth of responses against each of the five CHIKV structural antigens was measured by an  
197 *ex vivo* IFN- $\gamma$  ELISpot assay using pools of overlapping peptides. Responses to all structural  
198 proteins, except 6K, peaked at day 14 after vaccination (Fig. 4b). We observed the largest  
199 proportion of responses against E1 and E2, with E2 responses remaining high for a longer  
200 period as compared with the other proteins. However, the size of the proteins must be taken  
201 into consideration. While E1 and E2 have a similar size and were divided into a similar  
202 number of peptides (45 and 42, respectively), the other structural proteins are significantly  
203 smaller and had a smaller number of peptides. Capsid was the third largest protein with 26  
204 peptides, whereas E3 and 6K both had only 6 peptides each.

205 Intracellular Cytokine Staining (ICS) by flow cytometry was carried out at baseline and at  
206 day 28 after vaccination. PBMC were stimulated with pools of peptides covering the  
207 complete CHIKV structural polypeptide, and analysed for production of IFN- $\gamma$ , IL-2 or TNF-  
208  $\alpha$ . Analysis by the individual cytokines, demonstrated that only IFN- $\gamma$  producing CD4<sup>+</sup> T-  
209 cells were significantly increased from baseline. An increment on TNF- $\alpha$ <sup>+</sup> and IL-2<sup>+</sup>  
210 producing CD4<sup>+</sup> T cells was observed in a proportion of the participants but did not reach  
211 significance. CD8<sup>+</sup> T-cell responses did not show significant differences for any of the 3  
212 cytokines between baseline and day 28 (Fig. 4c).

213

214

## 215 **DISCUSSION**

216

217 We have shown safety and an excellent immunogenicity profile by a novel CHIKV vaccine  
218 using the replication-deficient chimpanzee adenoviral vector ChAdOx1 expressing the  
219 structural proteins capsid, E3, E2, 6k and E1 from CHIKV. Our findings demonstrate that the  
220 candidate ChAdOx1 Chik vaccine given as a single dose was safe and well tolerated across  
221 all doses tested, including  $5 \times 10^9$ ,  $2.5 \times 10^{10}$  and  $5 \times 10^{10}$  vp. Higher reactogenicity was  
222 observed at the highest dose of  $5 \times 10^{10}$  vp. No serious adverse reactions to ChAdOx1 Chik  
223 occurred. The majority of AEs reported were mild or moderate in severity, and all were self-  
224 limiting. We observed transient cases of leucopenia, neutropenia and lymphopenia in 5, 5 and  
225 1 volunteer, respectively. Most of these were mild and resolved by day 7, one was moderate

226 and resolved by day 28. None of them were severe. The profile of adverse events reported  
227 here is similar to the reported for other ChAdOx1 vectored vaccines expressing different  
228 antigens<sup>22,23</sup>.

229 CHIKV causes swift outbreaks, affecting large populations and spreading to neighbouring  
230 regions rapidly. This highlights the requirement for vaccines with capacity to rapidly  
231 stimulate immunity within days after immunisation. Nevertheless, most vaccines tested in  
232 clinical trials use prime-boost regimens, requiring several weeks to induce immune  
233 responses.

234 Animal and epidemiological studies have shown that protection from CHIKV disease is  
235 associated with the induction of neutralising antibodies<sup>18,24-26</sup>, primarily directed against  
236 structural proteins<sup>17-19</sup>. A virus-like particle (VLP) vaccine has reported to induce  
237 neutralising antibodies 8 weeks following a homologous prime-boost vaccination<sup>27</sup>.

238 Similarly, a measles vectored vaccine (MV-CHIK) which also requires prime boost regimens  
239 at 4- and 28-week intervals, demonstrated induction of immune responses after 8 and 32  
240 weeks, respectively<sup>28</sup>. Recently, a live attenuated vaccine (LAV) CHIKV vaccine based on an  
241 ECSA lineage has been reported to use a single dose to induce 100% homologous  
242 seroconversion at day 14 after a single administration<sup>29</sup>. Our data demonstrates that the  
243 ChAdOx1 Chik platform achieves equal levels of 100% seroconversion by PRNT<sub>50</sub> in only  
244 14 days after a single administration, with evidence of cross protective functional antibodies  
245 against 4 distinctive CHIKV lineages. To our knowledge, only one additional vaccine  
246 candidate in clinical trials has reported broad cross-neutralising responses against isolates  
247 from the 3 CHIKV genotypes (ECSA, Asian and West African) and the Indian Ocean sub-  
248 lineage<sup>30</sup>.

249 The role of T-cell immunity in clearance of CHIKV is not well understood and controversial.  
250 Although activation of CHIKV specific CD4<sup>+</sup> and/or CD8<sup>+</sup> T-cells has been observed upon  
251 vaccination and natural infection<sup>31-35</sup>, some publications have rejected that they might have a  
252 protective role<sup>18,24,36</sup>. Moreover, presence of reactive cytokine producing CD4<sup>+</sup> T-cells in the  
253 joints appear to exacerbate disease and lead into the development of arthritogenic disease<sup>37,38</sup>.  
254 IFN responses are likely not pathogenic, whereas TNF- $\alpha$  and Th2 cytokines might be<sup>39,40</sup>.

255 ChAdOx1 induced a CD4<sup>+</sup> IFN- $\gamma$ <sup>+</sup> biased cellular response towards CHIKV E1 and E2  
256 proteins but had no significant effect on CD8<sup>+</sup> T-cells. CD8<sup>+</sup> T-cells appear to have no  
257 protective role<sup>37</sup> and are of limited value in normal settings; only when antibodies are missing  
258 can a protective role be seen<sup>41</sup>.

259 Limitations of this study include the relatively short follow-up period of six months, small  
260 sample size and an open-labelled, non-randomised, uncontrolled study design. Generalisation  
261 of the study findings is limited, as this is a first-in-human study of healthy volunteers. Further  
262 studies should be conducted in older and younger age groups, adults with comorbidities and  
263 in populations considered to be at risk of developing chronic arthritis following CHIKV  
264 infection.

265 In conclusion, ChAdOx1 Chik was safe and well tolerated at all tested doses. A single dose  
266 showed compelling evidence of rapid stimulation of cellular responses and induction of high  
267 titers of functional antibodies with capacity to neutralise multiple CHIKV lineages. Since our  
268 platform does not require an adjuvant and shows to be immunogenic even at a low dose,  
269 ChAdOx1 Chik constitutes an attractive product for manufacturers and an affordable  
270 preventive vaccine for low-income countries. The ability to induce robust cellular and  
271 humoral immunity upon a single administration portrays ChAdOx1 Chik as a suitable  
272 candidate to limit swift outbreaks around the world. The results of this first-in-human clinical  
273 trial support clinical development progression into phase 1b and 2 trials in CHIKV-endemic  
274 regions, such as those in Latin America, India and Africa.

275

276

## 277 **METHODS**

278

### 279 **Trial objectives, participants and oversight.**

280 This is a first-in-human, dose escalation, open-label, non-randomised and uncontrolled  
281 clinical study of 24 healthy male and female subjects aged 18–50 years old. The sample size  
282 was selected based on other previous phase I trials using the same vector. This sample size  
283 was able to detect significant differences in immune responses from baseline while exposing  
284 a limited number of people to an investigational medicinal product that was being used for  
285 the first time.

286 The primary objective was to assess safety and tolerability of ChAdOx1 Chik in healthy  
287 volunteers, measured as: a) occurrence of solicited local reactogenicity signs and symptoms  
288 for 7 days following vaccination; b) occurrence of solicited systemic reactogenicity signs and  
289 symptoms for 7 days following vaccination; c) occurrence of unsolicited adverse events  
290 (AEs) for 28 days following vaccination; d) change from baseline for safety laboratory  
291 measures and; e) occurrence of serious adverse events (SAEs) during the whole study

292 duration. The secondary objective was to assess CHIKV structural antigen-specific humoral  
293 and cellular immune responses induced by ChAdOx1 Chik as measured by enzyme-linked  
294 immunosorbent assay (ELISA), plaque reduction neutralisation test (PRNT) and *ex vivo*  
295 interferon-gamma (IFN- $\gamma$ ) enzyme-linked immunospot (ELISpot).

296 Eligible volunteers were recruited at the Centre for Clinical Vaccinology and Tropical  
297 Medicine, Oxford, United Kingdom (CONSORT diagram, Fig. 1). All participants were  
298 healthy adults with negative pre-vaccination tests for HIV antibodies, hepatitis B surface  
299 antigen and hepatitis C antibodies. A negative urinary pregnancy test was required at  
300 screening and immediately before enrolment for all female subjects. Screening for previous  
301 CHIKV exposure was conducted on participants with significant travel history to CHIKV  
302 endemic areas, using a commercial ELISA kit (Anti-Chikungunya Virus IgG Human ELISA  
303 Kit, Abcam ab177835) and were excluded if positive. Full details of the eligibility criteria are  
304 described in the trial protocol provided in the Supplementary Materials.

305 The corresponding author had full access to all the data in the trial and had final  
306 responsibility for the decision to submit the manuscript for publication. All the trial data were  
307 available to all the authors.

308

### 309 **Study approvals.**

310 Written informed consent was obtained in all cases, and the trial was conducted in  
311 accordance with the principles of the Declaration of Helsinki and Good Clinical Practice  
312 (GCP). This study was approved within the UK by the Medicines and Healthcare Products  
313 Regulatory Agency (MHRA reference 21584/0394/001-0001) and the South Central Oxford  
314 A Research Ethics Committee (REC reference 18/SC/0004). Vaccine use was authorized by  
315 the Genetically Modified Organisms Safety Committee of the Oxford University Hospitals  
316 National Health Service Trust (GMSC reference number GM462.18.102). The trial is  
317 registered at [www.clinicaltrials.gov](http://www.clinicaltrials.gov) (identifier: NCT03590392). The first participant was  
318 enrolled on 02 October 2018 and the last participant was enrolled on 01 April 2019.

319

### 320 **Trial procedures.**

321 ChAdOx1 Chik was administered as a single intramuscular injection into the deltoid at a low  
322 dose of  $5 \times 10^9$  vp (group 1), intermediate dose of  $2.5 \times 10^{10}$  vp (group 2) and high dose of  $5 \times$   
323  $10^{10}$  vp (group 3). A staggered-enrolment approach was used for the first 3 participants in  
324 each group and interim safety reviews conducted prior to dose escalation (details provided in  
325 study protocol).

326 Blood samples were drawn and clinical assessments conducted for safety as well as  
327 immunology endpoints prior to vaccination at day 0 and subsequently at 2, 7, 14, 28, 56 and  
328 182 days following enrolment. Participants were observed in the clinic for one hour after the  
329 vaccination procedure and were asked to record any AEs using electronic diaries during the  
330 28-day follow-up period. Swelling at the injection site was objectively assessed by a member  
331 of the study team during the study visits.

332 Expected and protocol defined local site reactions (injection site pain, warmth, redness and  
333 pruritus) and systemic symptoms (malaise, myalgia, arthralgia, fatigue, nausea, headache,  
334 feverishness and temperature) were recorded for 7 days. Unsolicited AEs were recorded for  
335 28 days and SAEs were recorded throughout the follow-up period.

336 Severity of AEs was graded using the following criteria: (a) mild (short-lived or mild  
337 symptoms with no limitation to usual activity); (b) moderate (mild to moderate limitation in  
338 usual activity); and (c) severe (considerable limitation in activity, medication or medical  
339 attention required). Unsolicited AEs were reviewed for causality by an independent clinician  
340 and events considered possibly, probably or definitively related with the study vaccine were  
341 reported. Laboratory AEs were graded using site-specific toxicity tables which were adapted  
342 from the US Food and Drug Administration toxicity grading scale. An independent Local  
343 Safety Monitor (LSM) provided safety oversight. The relevant clinical data was recorded in a  
344 study database using OpenClinica (Enterprise Edition) v3.13.

345

#### 346 **ChAdOx1 Chik Vaccine.**

347 ChAdOx1 Chik uses the replication-deficient adenovirus vector derived from the E1 E3-  
348 deficient ChAdY25<sup>42</sup> and is currently a leading vaccine platform against COVID-19<sup>43</sup>.

349 ChAdOx1 Chik was engineered to express the full structural polyprotein genome of CHIKV  
350 that includes the Capsid, E3, E2, E1 and the 6K proteins. The synthetic gene was designed  
351 through an analysis of full-length structural polyprotein sequences from multiple CHIKV  
352 lineages. Sequences were collected from the NCBI database and aligned using Clustal Omega  
353 and a neighbour-joining tree (Juke-Cantor, 100 bootstraps). Intra- and inter-clade  
354 conservation was calculated using a sliding window approach with a sequence weighting  
355 method to enable equal representation of all lineages and variants. A synthetic gene cassette  
356 was produced by GeneArt® (ThermoFisher Scientific), which was subsequently cloned into a  
357 pMono plasmid to be driven by a CMV promoter expression<sup>15</sup>. The vaccine was  
358 manufactured to current Good Manufacturing Practice (cGMP) by the Clinical  
359 Biomanufacturing Facility (University of Oxford, Oxford, UK) in a HEK 293 cell line. The

360 vectored vaccine was purified and sterile filtered to generate a clinical lot at a concentration  
361 of  $1.57 \times 10^{11}$  viral particles per mL.

362

363 **ELISA.**

364 Total anti-CHIKV IgG was measured using a standardised in-house indirect ELISA<sup>44</sup>. To this  
365 end, 1 µg/ml of CHIKV E2 recombinant protein in phosphate buffered saline (PBS) were  
366 used to coat Nunc-immuno 96 well plates. Plates were incubated at 4°C for 18 h  
367 overnight<sup>15,45</sup>. Coated plates were washed six times with PBS-Tween followed by blocking  
368 with casein for 1 h at room temperature (RT). Serum samples were diluted at 1:100 or 1:500  
369 in casein to fit within the linear range of a standard curve prepared as indicated below, and  
370 then added to individual wells in triplicates. Plates were incubated at RT for 2 h, washed as  
371 described and then incubated at RT for 1 h with an alkaline phosphatase conjugated goat anti-  
372 human IgG (gamma-chain specific, Sigma). Plates were developed by adding 4-nitrophenyl  
373 phosphate (Sigma) in diethanolamine substrate buffer (Thermo Scientific). A standard curve  
374 was prepared from a serum sample of a convalescent individual, following a 2-fold serial  
375 dilution starting at 1:100 and generating 10 standard points to which arbitrary ELISA units  
376 (EUs) were assigned. The optical density (OD) values of the standard points were fitted to a  
377 4-parameter hyperbolic curve against the arbitrary EUs using the BioTek Gen5 v3.09  
378 software and the parameters estimated from the standard curve were used to convert  
379 absorbance values of individual test samples into EU. Each ELISA plate contained the  
380 samples in triplicates, an internal positive control at 1:1600 dilution of the standard pool in  
381 triplicates, 10 standard points in duplicates and 4 blank wells. Absorbance reading at 405 nm  
382 was performed using an ELx808 microplate reader (BioTek). The assay cut-off was  
383 determined from the analysis of the 24 pre-vaccinated (Day 0) samples of the trial volunteers.  
384 The seropositive cut-off was determined mathematically using the mean plus three standard  
385 deviations of the EU values reported for the 24 samples assayed. This value defined the  
386 threshold from which detection was feasible. A cut-off value of 51.1 EU was used as the  
387 analytical sensitivity of this assay.

388 Two commercially available ELISA kits were used to validate seronegativity of serum  
389 samples that had a higher background in our in-house E2 ELISA at baseline. The anti-  
390 chikungunya virus IgG ELISA kit from Abcam (ab177835) and the anti-chikungunya virus  
391 IgG ELISA kit from Euroimmune (EI 293a-9601G) were both performed according to  
392 manufacturer's instructions.

393

394 **Plaque Reduction Neutralisation Tests (PRNT).**

395 Induction of serum neutralising antibodies was evaluated with a plaque reduction  
 396 neutralisation tests (PRNT) on monolayers of Vero-cells (Vero ATCC CCL-81) cultured in  
 397 12-well plates using standard methods<sup>46,47</sup>. Neutralising antibody titers were recorded for four  
 398 CHIKV lineages including the chikungunya strains CHIKV-LR (Indian Ocean Lineage,  
 399 IOL), SV-0444 (Asian Lineage), 37997 (West African Lineage) and YO111213  
 400 (Asian/American Lineage), all obtained from the World Reference Center for Emerging  
 401 Viruses and Arboviruses at UTMB<sup>46</sup>. Titers were quantified as the highest serum dilution that  
 402 inhibited plaque formation in 50% (PRNT<sub>50</sub>). Seroconversion was considered positive in  
 403 samples with reciprocal titers of PRNT<sub>50</sub> ≥ 10<sup>48</sup>. Limits of detection were between 10 and  
 404 1280, and any samples without a detectable titer were listed as either 5 or 2560.

405

406 **ELISpot.**

407 Cellular immune responses were quantified at the selected timepoints using an ex-  
 408 vivo Enzyme-linked immunospot (ELISpot) for IFN- $\gamma$ <sup>43,44</sup>. PBMC were stimulated with  
 409 125 synthetic peptides (20mers overlapping by ten amino acids), divided into 13 peptide  
 410 pools spanning the entire vaccine insert of the CHIKV structural antigens: Capsid (3  
 411 pools=26 peptides), E3 (1 pool=6 peptides), E2 (4 pools=42 peptides), 6k (1 pool=6 peptides)  
 412 and E1 (4 pools=45 peptides). Peptide sequences and pooling are summarised in  
 413 supplementary Table S4. Data were analysed according to a quality control standard  
 414 operational procedure. The lower limit of detection for the assay was 4 spot-forming cells  
 415 (SFCs) for summed responses to the 13 CHIKV structural antigen peptide pools. The  
 416 following antibodies were used for ELISpot assay: anti-human IFN- $\gamma$  capture IgG1 mouse  
 417 monoclonal Ab (dil 1:100) and anti-human IFN- $\gamma$  biotinylated , detection mouse IgG1  
 418 monoclonal Ab (dil 1:1000).

419

420 **Flow cytometry.**

421 Intracellular cytokine staining for flow cytometry (ICS) was performed to quantify CD4<sup>+</sup> and  
 422 CD8<sup>+</sup> T-cell responses to the vaccine<sup>49</sup>. Five peptide pools from the structural CHIKV  
 423 cassette were used as stimuli (Table S4). Representative gating strategy is shown in Fig S1.  
 424 For the stimulation and staining, the following antibodies were used: anti-human CD14  
 425 eFluor450 (dil 1:100), anti-human CD19 eFluor450 (dil 1:100), anti-human CD3 AF700 (dil  
 426 1:50), anti-human CD4 APC (dil 1:25), anti-human CD8a APC eFluor780 (dil 1:10), anti-  
 427 human IFN- $\gamma$  FITC (dil 1:250), anti-human TNF- $\alpha$  PE-Cy7 (dil 1:500), anti-human IL-2 PE

428 (dil 1:50), anti-human CD28 (1 µg/mL) and anti-human CD49d (Integrin alpha 4) (1 µg/mL).  
429 Samples were ran in a LSRFortessa (Becton Dickinson); FACSDiva v 8.02 (BD Biosciences)  
430 and FlowJo v10.6.2 (BD Biosciences) were used for data recording and analysis,  
431 respectively.

432

### 433 **Statistics.**

434 Safety endpoints are described as frequencies with their respective percentages alongside  
435 95% confidence intervals (CI). The association between the frequency of moderate or severe  
436 solicited AEs and group allocation (groups 2 and 3) is reported as relative risk with the  
437 respective 95% CI and p value (Fisher's exact test). A Kruskal-Wallis test with Dunn's  
438 correction for multiple tests was used to assess the CHIKV *ex vivo* ELISpot IFN-γ responses,  
439 whereas a two-tailed Mann-Whitney test was used for ICS data. ELISA and PRNT data were  
440 analysed by either Kruskal-Wallis test or Friedman test with Dunn's correction for multiple  
441 parameters, as appropriate. A *P* value <0.05 was considered significant. Statistical analysis of  
442 safety and immunogenicity data was conducted using GraphPad Prism version 9.1 (GraphPad  
443 Software Inc., California, USA).

444

445

### 446 **DATA AVAILABILITY**

447 There is a restriction on the availability of the data presented on this manuscript due to the  
448 data being used to feed a patent application and because data will be linked to an ongoing  
449 Phase 1b blinded study funded by a different research award. Anonymised participant data  
450 may be available upon requests directed to the corresponding author  
451 (arturo.reyes@ndm.ox.ac.uk). Proposals will be reviewed and approved by the sponsor  
452 (CTRG- <https://researchsupport.admin.ox.ac.uk/ctrg#/>), principal investigator, and  
453 collaborators on the basis of scientific merit. If approved and upon signature of a data access  
454 agreement, data can be shared through a secure online platform. Data sharing may take a  
455 period of up to 6 weeks from receiving the request. All data will be made available for a  
456 minimum of 5 years from the end of the trial. The study protocol is available with this  
457 publication as part of the supplementary material.

584

## 585 **AUTHOR CONTRIBUTIONS**

586 PMF, AH, and ARS designed the study. PMF, FRL, DJ, IP and RR collected study data and  
587 oversaw participant visits. AL provided regulatory oversight, and MT, NT and RR provided  
588 project management. Immunogenicity testing was done and interpreted by KH, MB, LPL,  
589 AF, DB, RM, JS, KE and ARS. YCK produced purified protein for ELISA and performed  
590 immunopotency assay of the GMP batch. The analysis of samples by PRNT assays was  
591 designed, done and interpreted by SRA, RKC and SLR. Clinical trial data management was  
592 done by PMF and IP. Safety data analysis and interpretation were done by PMF. PMF, KH,  
593 LPL and ARS wrote the manuscript. AH was the chief investigator. EB was responsible for  
594 vaccine manufacture. ARS applied and obtained funding to support this project. All authors  
595 contributed to the reviewing and editing of the report and approved the final version.

596

597

598 **ACKNOWLEDGEMENTS**

599 The funders of the study had no role in the study design, data collection, data analysis, data  
 600 interpretation or writing of the report. This report is independent research funded by Innovate  
 601 UK (project No. 972212 and 971557). The views expressed in this publication are those of  
 602 the author(s) and not necessarily those of Innovate UK. PMF received financial support from  
 603 the Coordenacao de Aperfeicoamento de Pessoal de Nivel Superior, Brazil (finance code  
 604 001).

605 We would like to thank the support of Brian Angus (local safety monitor). Yrene  
 606 Themistocleous, Julia Marshall and Mehreen Dattoo (clinicians). Megan Baker, Celia Mitton,  
 607 Raquel Lopez Ramon and Lucy Kingham Page (nurses). Daniel Marshall Searson (data  
 608 manager). Yara Neves Silva (clinical trial assistant). Natalie Lella and Michelle Fuskova  
 609 (recruitment coordinators).

610

611

612 **COMPETING INTERESTS**

613 Pedro M. Folegatti is a consultant to Vaccitech, which is developing adenoviral vectored  
 614 vaccines. Adrian Hill is a co-founder of and consultant to Vaccitech Ltd and is named as an  
 615 inventor on a patent covering design and use of ChAdOx1-vectored vaccines. All other  
 616 authors declare no competing interests.

617

618

619 **FIGURE LEGENDS**

620 **Figure 1. Trial profile.** Study profile showing allocation of participants to 3 dosage groups:  
 621 Group 1 low dose at  $5 \times 10^9$  vp, Group 2 intermediate dose at  $2.5 \times 10^{10}$  vp and Group 3 high  
 622 dose at  $5 \times 10^{10}$  vp. None of the 24 recruited participants were lost in follow-up.

623

624 **Figure 2. PRNT<sub>50</sub> values over time.** PRNT<sub>50</sub> reciprocal titres are shown for each participant.  
 625 Arrows indicate when ChAdOx1 Chik was administered. Lower limit of detection (LLOD) is  
 626 5. **a)** Overall responses by timepoint in all trial volunteers ( $n = 24$ ). Geometric means and  
 627 95% CI; Kruskal-Wallis test with Dunn's correction. **b)** Same data as a) but analysed by  
 628 dosage groups: low dose was  $5 \times 10^9$  vp ( $n = 6$ ), intermediate (mid) dose was  $2.5 \times 10^{10}$  vp ( $n =$

629 9) and high dose was  $5 \times 10^{10}$  vp ( $n = 9$ ). Geometric means and 95% CI; Kruskal-Wallis test  
630 with Dunn's correction. One day 56 sample from the low dose group was excluded from  
631 analysis due to QC failure.

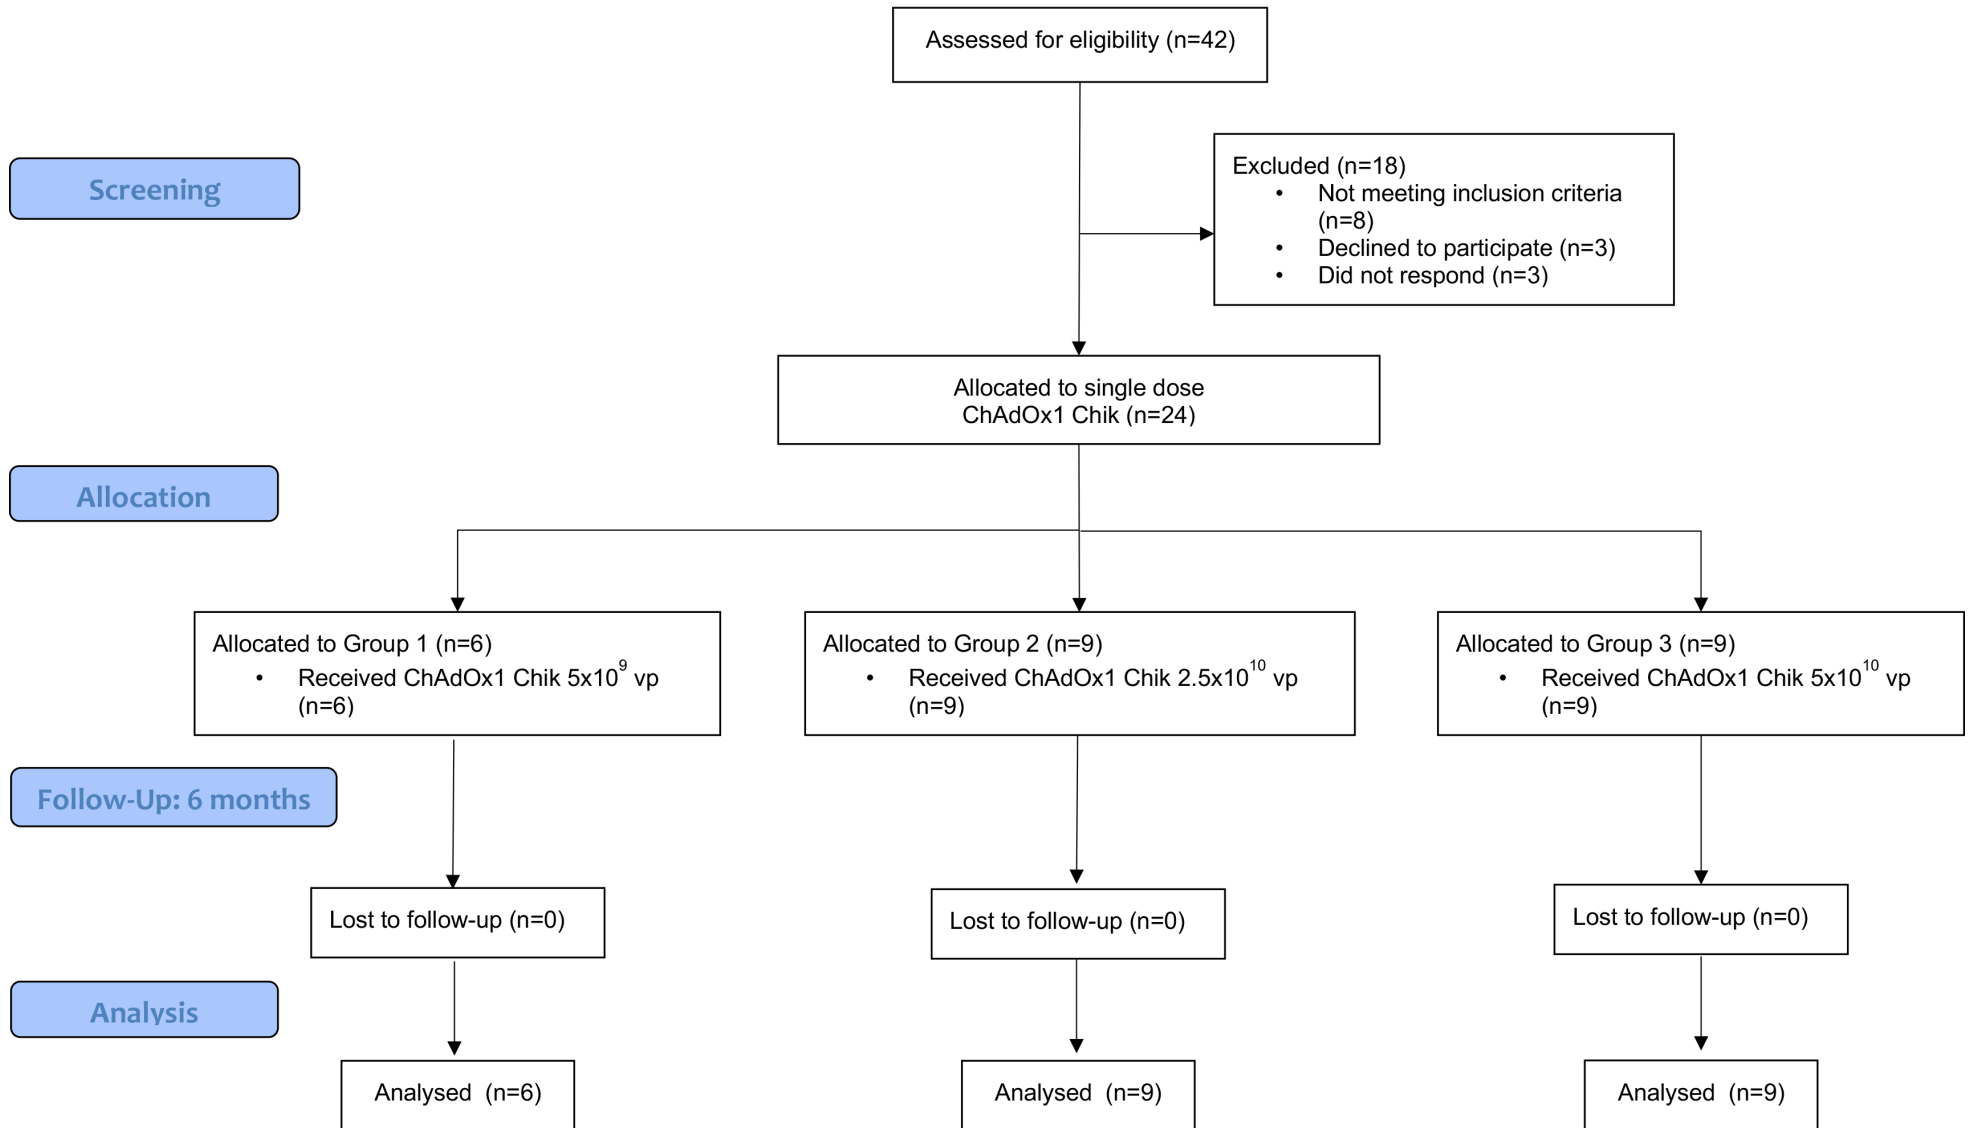

632

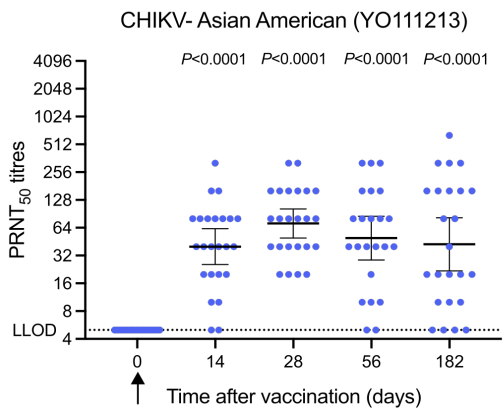

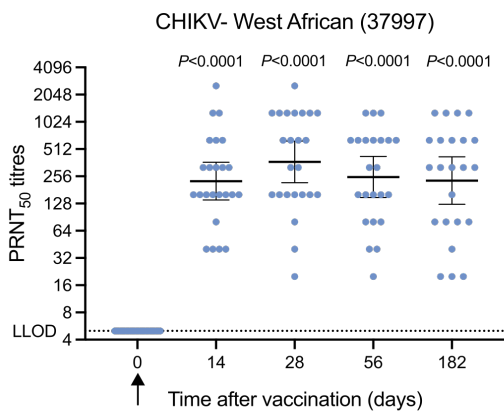

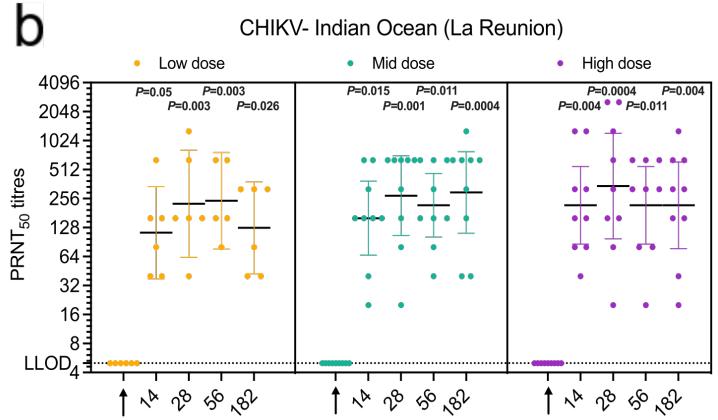

633 **Figure 3. ELISA titers over time.** CHIKV IgG response by standardised ELISA to E2  
634 protein in 120 serum samples of trial participants. **a)** Individual IgG titers over time ( $n = 24$ ).  
635 The dashed line represents the cut-off value for seropositivity. Geometric means and 95% CI;  
636 Friedman test with Dunn's correction. **b)** Same data as a) but represented as fold-change from  
637 baseline (day 0) and analysed by dosage group: low dose was  $5 \times 10^9$  vp ( $n = 6$ ), intermediate  
638 (mid) dose was  $2.5 \times 10^{10}$  vp ( $n = 9$ ) and high dose was  $5 \times 10^{10}$  vp ( $n = 9$ ). Geometric means  
639 and 95% CI; Friedman test with Dunn's correction. **c)** Correlation of PRNT<sub>50</sub> and IgG ELISA  
640 by dosage group at 5 time points. Low dose, 6 participants,  $n = 29$  (one day 56 sample was  
641 excluded due to QC failure); intermediate (mid) dose, 9 participants ( $n = 45$ ) and high dose, 9  
642 participants ( $n = 45$ ). Spearman correlation, two-tailed. **d)** Same data as c) but correlation is  
643 only shown for the 9 participants vaccinated at the intermediate (mid) dose ( $n = 9$  per  
644 timepoint). Spearman correlation, two-tailed.

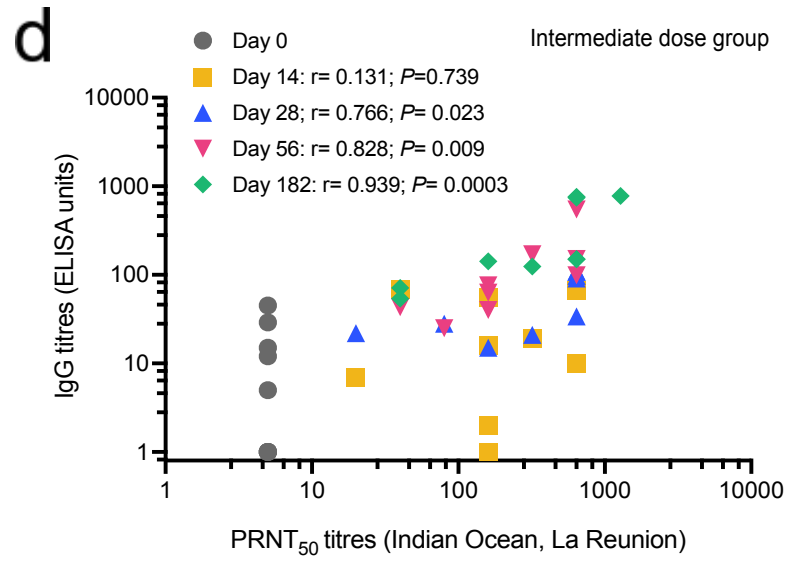

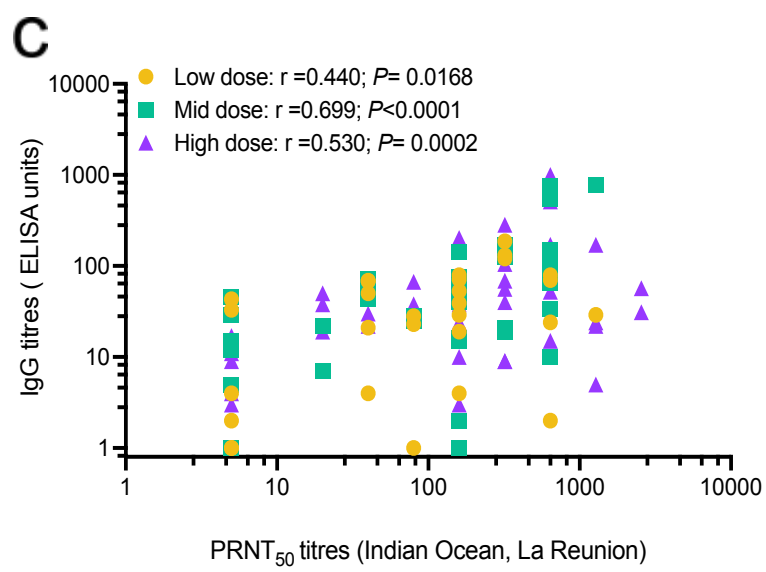

645

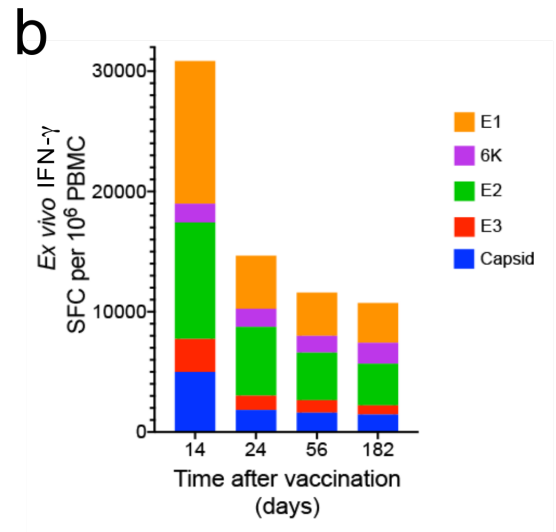

646 **Figure 4. T cell responses over time.** **a)** *Ex-vivo* Enzyme-linked immunospot (ELISpot) for  
647 IFN- $\gamma$  to CHIKV structural antigens measured as total responses to CHIKV peptides (sum of  
648 13 pools spanning C, E3, E2, 6K, E1). SFC per million PBMC during a 6-month follow-up  
649 period ( $n = 24$ ). Median and IQR; Kruskal-Wallis test with Dunn's correction. **b)** Proportion  
650 of spots contributed by C, E3, E2, 6K and E1 over time. **c)** Intracellular Cytokine Staining  
651 (ICS) by flow cytometry to assess CD4<sup>+</sup> and CD8<sup>+</sup> T-cell functionality. Percentage of  
652 cytokine producing CD4<sup>+</sup> and CD8<sup>+</sup> T-cells ( $n = 24$ ). Median and IQR; Mann-Whitney test  
653 two-tailed.

654

**Table 1. Summary of participants' baseline characteristics.**

\*Mixed: White and Asian.

Variable	Group 1 Low dose ( <i>n</i> = 6)	Group 2 Intermediate dose ( <i>n</i> = 9)	Group 3 High dose ( <i>n</i> = 9)	All Groups ( <i>n</i> = 24)

**Table 3. PRNT<sub>50</sub> against CHIKV lineages.**

PRNT<sub>50</sub> = serum dilution required to reduce viral plaques by 50% of the control value. Seroconversion was measured as PRNT<sub>50</sub> values of 10 or greater.

\*One day 56 sample, from the low dose group, was excluded from analysis due to QC failure.

PRNT <sub>50</sub>								
	Indian Ocean (La Reunion)		West African (37997)		Asian (SV044-95)		Asian/American (YO-111213)
