Abstract

Objective: Coronary artery diseases including atherosclerosis is considered as commonest problem worldwide. Ergosterols are the main components of vegetable oils and nuts. The objective of this study was to evaluate the potential hypolipidemic and hypocholesterolemic effects of ergosterol in combination with niacin in rats fed high fat diet (HFD).

Methods: Eighty male albino rats were included in this study divided into two main groups: Group I: Normal rats fed standard diet treated with either niacin (8.5 mg /kg b.w) or ergosterol (100 mg/Kg b.w) or both. Group II; rats fed HFD treated with either niacin (8.5 mg /kg b.w) or ergosterol (100 mg/Kg b.w) or both. The feeding and treatment lasted for 8 weeks.

Results: A significant elevation in the levels of total cholesterol, triacylglycerol, VLDL-c, LDL-c and atherogenic factor ($p < 0.001$) in rats fed on HFD compared with normal control while HDL-c was significantly reduced in HFD rats compared with control group. Supplementation of diet with niacin or ergosterol or combined exerts improvement in the studied parameters by lowering triacylglycerol, total cholesterol, LDL-c and atherogenic factor and elevate HDL-c near to the value of control. Niacin combined with ergosterol were effective in the reduction of hydroxy methyl glutaryl-CoA reductase (HMGCoA) compared with control ($p < 0.001$). The combined effect was more potent than individual alone.

Conclusion: Utilization of niacin and ergosterol may prevent the hypercholesterolemia and incidence of coronary heart diseases. These functional foods act as nutraceutical as dyslipidemics.

Keywords: Nicotinic acid, cholesterol, ergosterol.

Introduction

Cholesterol is non-calorigenic nutrient due to lack of enzymes that metabolize it. It is an essential for plasma membranes structure and formation of lipoproteins, aldosterone, bile salts, and cholecalciferol¹. Cholesterol in the body may be exogenous (from diet) or endogenous which synthesized from active acetate in the liver, testis, and ovary and controlled by the key enzyme hydroxy methyl glutaryl-CoA reductase (HMGCoA Rase). Blood cholesterol level determined by the balance be-

tween its rate of synthesis and rate of excretion. The liver is the only organ can eliminate the cholesterol by excretion via the bile².

Coronary artery diseases (CAD) including atherosclerosis considered as the commonest cause of death worldwide. Other risk factors including smoking, hypertension, lifestyle, diabetes and fast foods. Hypercholesterolemia especially elevated LDL-c and decreased HDL-c are the most valuable markers for CAD³. Atherosclerosis is indicated by the appearance of initial changes known as plaques. These plaques are made of lipid cores (cholesterol) surrounded by fibroid caps⁵. A clear cut correlation was found between dietary cholesterol and CAD by several previous studies in animal models and human. The risk for CAD is approximately three fold in diabetes mellitus compared with normal controls⁴.

Nicotinic acid or niacin is converted to important co-enzymes NAD⁺, or NADP⁺. These co-enzymes act as a hydrogen carrier involved in oxidation reduction reactions during metabolism of macromolecules as carbohydrate, lipids and proteins⁵.

Ergosterols are the main components of vegetable oils, nuts, cereal products, fruit and berries. The common types are β -sitosterol, campesterol and stigmasterol⁶. Phytosterol was found to act as anticancer and antioxidant agent. It was found in several studies that intake of foods as margarine or yoghurt supplemented with plant stanol lower serum total cholesterol and LDL-c. This is the principle hypocholesterolemic effect of drugs and exert a significance effect in lowering CAD⁷. There are different hypocholesterolemic agents available, these drugs act by different mechanisms. Efficacy relies on the lipid level of the subjects. These drugs have adverse effects varied from one to another. Thus, researches are promising to explore novel drugs that are more efficacies and more safe.

This study was designed to evaluate the potential hypolipidemic and hypocholesterolemic effect of ergosterol in combination with nicotinic acid in rats. For this purpose, this study aims to deduce a new regime for protection against CAD.

Materials and methods

Animals

This study was carried out on a total of 80 adult male albino rats weighing 100–120 g. The animals were housed in steel cages and left for one week before starting the experiment. The commercial diet supplemented with 2 % cholesterol, and 0.4% sodium cholate considered as high cholesterol diet⁸. The handling of animals according to ethical committee of the university.

Rats were grouped into two main groups (each 40 rats) as following: Group I: normal rats fed a standard diet and divided into 4 subgroups: Group Ia; normal untreated. Group Ib: rats treated orally with niacin (8.5 mg /kg b.w). Group Ic: rats treated orally with ergosterol (100 mg/Kg b.w). Group Id. rats treated orally with niacin (8.5 mg /kg b.w) and ergosterol (100 mg/Kg b.w). Group II: rats fed high HFD (1% cholesterol (w/w) and 0.2% sodium cholate (w/w) were well mixed with the finely-ground commercial diet) subdivided into 4 subgroups. Group IIa ; HFD untreated.

Group IIb: HFD treated orally with niacin (8.5 mg / kg b.w.) Group IIc: HFD rats treated orally with ergosterol (80 mg/Kg b.w). Group IId : HFD treated orally with niacin (8.5 mg /kg b.w) and ergosterol (80 mg/Kg b.w). The doses of ergosterol and niacin will given according to Takaku et al¹². Treatment was started on the day starting feeding high cholesterol and continued for 8 weeks. Rat were fasted for 12hr and anesthetized with 10% thiopental. Blood samples were collected and sera were separated by centrifugation and stored at -80°C until analysis. Liver was removed, rinsed from blood. Part of it was placed in sulphuric acid for total lipid assay and the remainder of liver will stored in at -80°C until analysis.

Biochemical assays

Serum total cholesterol, triacylglycerol, total lipid lipoproteins (VLDL-c, LDL-c and HDL-c) were estimated by colorimetric methods using kits from BIOLINE company (UK). Atherogenic index was calculated as following.

$$\text{Atherogenic index} = \text{LDL} + \text{VLDL} / \text{HDL}$$

Determination of liver microsomal HMGCoA reductase

One gram of liver was placed in 5 ml cold buffer (-4°C) at pH 7.4. The buffer contained 0.1 M triethanolamine. HCl, 0.02 M EDTA, and 2.0mM dithiothreitol, homogenized using glass homogenizer. The homogenate was centrifuged for 10 min at 12,000 g to remove mitochondria. Supernatant was centrifuged at 20,000 g for 30 min. The microsomes obtained were used for the assay of protein concentration and HMGCoA reductase. For assay 0.5-1 mg of microsomal protein, 100 nmoles of HMG CoA, and 2 μ moles of NADPH, 2 units of glucose-6-phosphate dehydrogenase, and 3 μ moles of glucose-6-phosphate. These components are added to 0.8 ml of 0.1 M triethanolamine-0.02 M EDTA buffer at pH 7.4 without dithiothreitol. The concentration of monothiol is determined by reacting DTNB with the reaction mixture in a cuvette placed in a recording spectrophotometer⁹.

The unit of HMGCoA reductase is defined as the micromole of mevalonate produced per unit of enzyme per second.

Statistical analysis

Data will be expressed as means \pm SD and t-test, p-value and Man-watany correlation will performed using SPSS version¹².

Results

Table (1) revealed the impact of niacin and ergosterol on normal rats fed normal diet. It was found that, normal rats supplemented with niacin, ergosterol or

combined showed a significant reduction in lipid profile including TG, total cholesterol and LDL-c while a significant increase in HDL-c compared with control group ($p < 0.01$).

Table (1): Serum levels of total-cholesterol, triacylglycerol, HDL-c, LDL-c, VLDL-c and atherogenic factor in normal rats supplemented with niacin and ergosterol (Mean+SD)

Groups Parameters	Normal	Normal +niac	Normal+Erg	N+niac+ERG
Body weight (gm) Mean +SD	295+11.7	309+50	282+26	293+15
T-cholesterol (mmol/l) Mean +SD	1.85+0.16	1.73+0.20	1.51+0.16	1.57+0.13
Triacylglycerol (mmol/l) Mean +SD	0.9+0.14	0.8+0.03	0.71+0.03	0.77+0.02
HDL-c (mmol/l) Mean +SD	0.44+0.03	0.52+0.08	0.50+0.07	0.51+0.06
LDL-c (mmol/l) Mean +SD	1.0+0.11	1.2+0.19	1.1+0.15	1.1+0.13
VLDL-c (mmol/l) Mean +SD	0.21+0.02	0.22+0.02	0.18+0.03	0.17+0.01
Atherogenic factor Mean +SD	0.081+0.01	0.12+0.02	0.033+0.01	0.01+0.001

HFD: High fat diet p : compared with control group. p^* : compared with HFD N.S.: non significant $p < 0.05$ was considered as significant Nia; Niacin ERG: ergosterol

In table (2), Rats fed high fat diet showed that, a significant elevation in the levels of total cholesterol, triacylglycerol, VLDL-c, LDL-c and atherogenic factor ($p < 0.001$) in rats fed on HFD compared with normal control while HDL-c was significantly reduced. Sup-

plementation of diet with niacin or ergosterol or combined exerts improvement in the studied parameters by lowering triacylglycerol, total cholesterol, LDL-c and atherogenic factor and elevating HDL-c till it reached near to the value of control as compared with HFD fed rats ($p < 0.001$).

Table (2): Serum levels of total-cholesterol, triacylglycerol, HDL-c, LDL-c, VLDL-c and atherogenic factor in hypercholesterolemic rats treated with niacin and ergosterol (Mean_±SD)

Groups Parameters	HFD	HFD +Nia	HFD + ERGO	HFD +Nia+ERG
Body weight Mean+SD	350+ 33	305+29	291+32	275+19 ^a

Group Ia; normal untreated. **Group Ib:** normal with niacin (8.5 mg /kg b.w). **Group Ic:** normal with ergosterol (100 mg/Kg b.w). **Group Id.** normal with niacin (8.5 mg /kg b.w) and ergosterol (100 mg/Kg b.w). **Group IIa;** HFD untreated. **Group IIb:** HFD with niacin (8.5 mg /kg b.w) **Group IIc:** HFD rats with ergosterol (80 mg/Kg b.w). **Group IId:** HFD with niacin (8.5 mg /kg b.w) and ergosterol (80 mg/Kg b.w).

Discussion

The HMG CoA reductase catalyses the rate limiting step in cholesterol synthesis¹⁰. The activity of HMG CoA reductase is regulated by the nutritional and hormonal state of animals. Feedback inhibition of cholesterol formation is mediated by the activity of HMG CoA reductase. Many chemically synthesized compounds called statins, have also been developed as effective cholesterol lowering agents through the inhibition of HMG CoA reductase. However, most hypocholesterolemic agents have been found to possess adverse effects, including rashes, gastrointestinal, hyperuricemia, hyperglycemia¹¹.

In the present study supplementing rats with niacin o, LDL-c and TG compared to control rats. Niacin was found to lower plasma total cholesterol and triglyceride levels by lowering VLDL-c and LDL-c levels¹². On the other hand it elevates HDL-c levels. Plant sterol possesses the ability to lower effect in a wide range of food products. The cholesterol and LDL-C lowering effect of ergosterol as well as safety of daily consumption of plant source was in accordance with different studies¹³. The most recent is evidence that intakes of ergosterol result in an enhanced decrease in LDL-c level comparable to that obtained by statins. The lowering of LDL-C was higher and is feasible as a range of food products are commercially available for consumption. LDL-c lowering effect contributes to beneficial effects in reducing the risk of cardiovascular diseases¹⁴. The decrease in the LDL-c level due to consumption of plant stanols in high doses (about 9 g) is of similar magnitude to that achieved by drugs lowering cholesterol via partly blocking cholesterol absorption¹⁵.

Changes in HMG-CoA reductase activity are accompanied to changes in the rate of cholesterol synthesis, suggesting the inhibition of HMG-CoA reductase is effective in lowering plasma cholesterol¹⁶.

On the basis of the present study, a significant LDL-c lowering effect can be done by a dietary supplementation of ergosterol. However, there was a dose-range effect of plant sterols and stanols on serum LDL-c lowering and it is reported that plant stanols showed a continuous dose-response in serum LDL-c lowering, whereas no further serum LDL-c was apparent with plant sterols at daily intakes exceeding 2 g/day^{17,18}.

Three of the studies with high daily plant stanol intake also reported serum plant stanol and sterol con-

centrations. Assmann et al.,¹⁹ demonstrated that a daily intake of 8.8 g plant stanols decreased cholesterol absorption markers. Similarly, Mensink et al.,²⁰ showed continuous decrease in plasma sitosterol and campesterol concentrations with 3, 6 and 9 g intakes of plant stanols in comparison to controls. With increasing plant stanol intake, the cholesterol absorption was reduced²¹. Nguyen²² reported a 40% lower campesterol and 50% lower sitosterol levels after daily consumption of 10 g of plant stanols.

The present study showed the role of niacin combined with ergosterol in reducing the cholesterol level by inhibiting the HMG CoA reductase activity. This finding can result in developing a nutraceutical agent and can be used in management of disorders of cholesterol for controlling the dyslipidemia.

Conclusion

Daily utilization of niacin and ergosterol may protect against hypercholesterolemia and decrease incidence of coronary heart diseases. These functional foods act as nutraceutical as dyslipidemics.
