**Abstract:** Cluster analysis is a formal study of methods and algorithms for natural grouping of objects according to the perceived intrinsic characteristics and the measure similarities in each group of the objects. The pattern of each cluster and the relationship for each cluster are identified, then they are related to the frequency of occurrence in the data set. Meanwhile, the mean and the mode are known as the measures of central tendency in a distribution. In clustering, the mean and the mode are applied as a technique to discover the existing of the cluster in the data set. Therefore, this study aims to compare the performance of  $K$ -means and  $K$ -modes clustering techniques in finding the group of cluster that exists in the numerical data. The difference between these methods is that the  $K$ -modes method is usually applied to categorical data, while  $K$ -means method is applied to numerical data. However, both methods would be used to cluster the numerical data in this study. Moreover, performance of these two clustering methods are demonstrated using the output from R software. The results obtained are compared such that the method giving the best output could be determined. In conclusion, the efficiency of the methods is highly presented.

**Keyword:** Performance; Central tendency;  $K$ -means clustering;  $K$ -modes clustering; Numerical data

## 1. Introduction

Mean and mode are two well-known measure of central tendency which are used as statistical measure to identify single value as representative of entire distribution. Mean is commonly used and the benefit of using mean is that this measure uses every value in the data to obtain its value. It was claimed that mean is the best measure of central tendency that resist fluctuation between different samples. However, it is very sensitive to extreme values and outliers; not suitable with data with skewed distribution. Meanwhile, mode is the most frequent in dataset. The mode is not affected by extreme values and can be used for both qualitative and quantitative data.

There are clustering techniques which are introduced based on central tendency deviation principle [1]. Clustering analysis is one of the most frequently used data mining techniques [2]. Clustering is an unsupervised learning task with purpose to make natural groupings based on similarity [3]. Clustering process will divide the data sets that have

similarities into same cluster group whereas objects that belong to the other clusters are as dissimilar as possible. Cluster analysis is used to separate data elements into groups by maximizing the homogeneity within elements of clusters and heterogeneity between clusters [4]. Clustering is also known as unsupervised learning algorithm because the actual number of clusters is unknown [5].

In this study, two clustering techniques are used, which are  $K$ -means clustering and  $K$ -modes clustering.  $K$ -means clustering was proposed by MacQueen (1967) and it is still been used by many researchers for many years due to its simplicity computations.  $K$ -means clustering is known as hard clustering since each data point belongs to one cluster only [6].  $K$ -means algorithm is based on the center of the associated cluster [7]. By using  $K$ -means clustering, the data is put into homogenous cluster which means that the groups have identical characteristics; in terms of intra-cluster similarity [8].

On the other hand,  $K$ -modes clustering uses similar concept of  $K$ -means but removes the limitation of numeric data.  $K$ -modes clustering is used for categorical data which

adjusting *K*-means method by substitute Euclidean distance metric with simple matching dissimilarity measure. This technique uses modes to represent cluster centers and updating modes with the most frequent categorical values in each iteration of clustering process. The advantages of *K*-modes is, it is scalable to very large data sets. However, random initial modes may lead to non-repetitive clustering structures formation [9]. In 2016, a study had implemented *K*-modes clustering on Iris dataset by transforming the data into binary data [10]. However, in this study, no modifications are made on data.

This study has three main objectives:

- i. To apply *K*-means and *K*-modes on numerical data.
- ii. To differentiate the clustering output using different methods.
- iii. To measure the efficiency of mean and mode as clustering methods.

Based on clustering output, the performance of these two techniques are differentiated and this study aims to show if these clustering methods obey central tendency measure.

## 2. Methodology

This study applies two clustering methods which are *K*-means and *K*-modes clustering methods in order to identify the differences of both methods. The clustering method minimizes the following function

$$F(U, Z) = \sum_{l=1}^k \sum_{i=1}^n \sum_{j=1}^m u_{i,l} d(x_{i,j}, z_{l,j}) \quad (1)$$

where

$U = u_{i,j}$  is an  $(n \times k)$  partition matrix,

$Z = \{Z_1, Z_2, \dots, Z_k\}$  is a set of mean or mode vectors ,

$d =$  distance

The selection of  $k$  cluster must be smaller than the number of object in the data set [11]. Usually, the number of  $k$  is started with the small value. In this study,  $k=3$  is chosen because it gave good clustering result for both data when *K*-means clustering is applied. Meanwhile, the same value of  $k$  is used in *K*-modes clustering. It is because this study wants to make comparison on the clustering result when the value of  $k$  is fixed. The methodology of each methods are further discussed in Sections 2.1 and 2.2. Both

clustering methods are performed by using the R Software.

### 2.1 *K*-means Clustering

In *K*-means clustering process, number of clusters is set to  $k=3$ . The centroids are selected randomly from the dataset for each cluster. The distance of data points to the centroid is calculated using selected distance measure. Each point is placed in the group based on the shortest distance to the centroid. The centroid value is then updated by finding the mean of the elements in the groups. The formal *K*-means clustering algorithm is given as follows:

- Step 1 Choose a value  $k$ .
- Step 2 Select points as initial centroids.
- Step 3 Calculate the distance of points to centroids.
- Step 4 Assign points to group based on distance computed.
- Step 5 Update the centroid by finding the means.
- Step 6 Repeat Steps 3, 4 and 5.
- Step 7 Stop the process when there is no more changes in each group.

### 2.2 *K*-modes Clustering

The process of *K*-modes clustering does not have so much different than *K*-means clustering. By setting the value of  $k$  cluster, number of initial centres is selected which correspond to the value of  $k$ . Then, distances are calculated. The mode values are updated and the process are continued until there is no changes in the clusters.

In this study, the number of cluster for *K*-modes clustering is set to  $k=3$ ; which is same with *K*-means clustering. However, the distance is calculated using simple-matching distance. The steps to perform the *K*-modes clustering are as below:

- Step 1 Choose a value of  $k$ .
- Step 2 Select initial centres (modes).
- Step 3 Calculate the distances between objects to the cluster modes.
- Step 4 Update the modes value and repeat the step to calculate the distances.

Step 5 Stop the process when no changes on cluster membership.

### 3. Results and Discussion

This study uses two data to make comparison of output using four types of distance measure. The first data is the Iris data from the UCI Machine Learning website which has four numeric, predictive attributes and class. The Iris data has been used widely for research purposes. Meanwhile, the second data used is the Malaysia household incomes data that have not been used for clustering purposes. The data were given by Micro Data UTHM which handled is in the Department of Mathematics and Statistics of Faculty of Science, Technology and Human Development. The household data have four numeric attributes which are employment incomes, self-employment incomes, property income and transfers received.

Table 1 shows two types of dataset information that have been used in this study. Both data are multivariate dataset. The Iris dataset has 150 instances, four real attributes and no missing value included. While, the household income dataset, which is also multivariate data, has 500 instances, four real attributes and no missing value in the dataset.

**Table 1** Dataset information.

Name of dataset	Iris	Income
Dataset Characteristics	Multivariate	Multivariate
Number of Instances	150	500
Number of Attributes	4	4
Missing Value	No	No
Attribute Characteristics	Real	Real
Area	Life	Economy

#### 3.1 Clustering on Iris Dataset

Both *K*-means and *K*-modes clustering methods are applied on the Iris dataset. The number of clusters  $k=3$  was set to both clustering processes. However, only two attributes were selected for clustering process which are petal length and petal width.

Fig. 1 shows distribution of the Iris data of petal length against petal width. Based on the figure, there are two main groups. However, the value of  $k$  was set to 3 because the types of the Iris data are known which are setosa, versicolor and virginica.

**Fig. 1** Iris data distribution figure.

#### 3.1.1 K-means Clustering on Iris Dataset

*K*-means clustering was performed on the Iris dataset. Fig. 2 shows the command used to call the Iris dataset from the library of the R software. The `head(iris)` command shows variables of the Iris dataset and the first six data values.

```
R Console
> library(datasets)
> head(iris)
  Sepal.Length Sepal.Width Petal.Length Petal.Width Species
1          5.1         3.5          1.4         0.2  setosa
2          4.9         3.0          1.4         0.2  setosa
3          4.7         3.2          1.3         0.2  setosa
4          4.6         3.1          1.5         0.2  setosa
5          5.0         3.6          1.4         0.2  setosa
6          5.4         3.9          1.7         0.4  setosa

Fig. 8 Cluster size and cluster modes value

Fig. 9 shows number of every species in each cluster. All setosa species are put into first cluster. The versicolor species are put into all the three clusters; 31 instances in the first cluster, 12 instances in the second cluster and 7 instances in the third cluster. Meanwhile, the virginica belongs to two clusters; 47 instances in the first cluster and 3 instances in the second clusters.

```
R Console
> table(iris$Species,irisCluster2$cluster)
      1  2  3
setosa 50  0  0
versicolor 31 12 7
virginica 47  3  0
> plot(iris[c("Petal.Length","Petal.Width")],col=irisCluster2$cluster)
> |
```

Fig. 9 Table of Iris species in each cluster

Fig. 10 shows the graph of the Iris dataset. The different colour of the data indicates different clusters. As shown in the

graph, most of the data belongs to the first cluster.

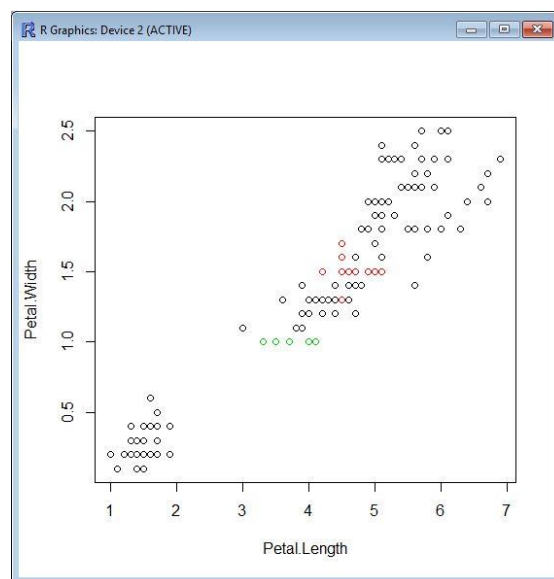

Fig. 10 Graph of Iris clusters

### 3.2 Clustering on Income Dataset

Clustering methods were applied on income dataset with  $n=500$ . Two variables were selected for this clustering process which are employment income and self-employment income. The result of the clustering processes are further discussed in Sections 3.2.1 and 3.2.2.

#### 3.2.1 K-means Clustering on Income Dataset

Although the number of classes of income is unknown, but the value of cluster  $k$  is set to 3. It is because this study wants to compare the clustering outputs with the Iris dataset clustering outputs.

Fig. 11 shows the income for K-means clustering output. The sizes of each cluster are 98, 368, and 34. The within cluster sum of squares was obtained. The percentage of between sum of squares over total sum of square is 62.4% which can be considered as good enough.

**Fig. 13** Graph of income data after *K*-modes clustering

### 3.3 Discussion

In this study, two numerical datasets are used to perform *K*-means and *K*-modes clustering methods. Both methods used different approach to find distance of the clusters. *K*-means clustering used sum of squares error value while *K*-modes used simple-matching coefficient to identify the distance. Using the Iris dataset, *K*-means clustering gave a better output than *K*-modes clustering. It is because the clusters formed are clear and the percentage of between cluster sum of square over total sum of square is also high. Besides, the clusters formed by using *K*-modes cannot differentiate the Iris species as well.

Meanwhile, using income dataset, *K*-means clustering is well performed with 62.4% which is percentage of between cluster sum of square over total sum of square. It indicates that difference of each cluster to the other cluster is maximized. It shows that the *K*-means clustering on income dataset gave a better output as *K*-modes clustering put 99.6% into the same cluster.

### 4. Conclusion

It was known that mean and mode are two types of measure of central tendency. Thus, this study wanted to investigate how both mean and mode work on clustering process. As this study used two numerical data, the results were compared and discussed. It shows that *K*-means performed better clustering process

than *K*-modes. The distance formulae applied on *K*-means and *K*-modes also contribute on the difference performance of clustering process. The sum of square and mean value calculation in *K*-means clustering gave better output than *K*-modes clustering which used simple-matching distance and mode value as their centroid. Although in measuring central tendency the mode can be used both on numerical and binary data, however, it was found that *K*-modes clustering cannot perform well on numerical data. Thus, it is suggested that the data should be transformed into binary data if the *K*-modes clustering is used.

In conclusion, *K*-means clustering gives a better output than *K*-modes clustering on numerical datasets.

### Acknowledgements

Authors would like to express greatest gratitude to Research, Innovation, Commercialization, Consultancy Office UTHM (ORICC) for giving the chance to carry out the research by using Geran Penyelidikan Pascasiswazah (GPPS). Authors were extremely thankful to reviewers for their beautiful remarks.
