

**DEVELOPING PHOTOCHEMICAL PRECURSORS FOR
INDEPENDENT GENERATION OF NEUTRAL PURINE RADICALS
AND INVESTIGATING THE REACTIVITY OF 2'-
DEOXYADENOSIN-N6-YL RADICAL IN DNA**

Abstract

DNA damage is deleterious to cells and can lead to cell death or cancer. The cytotoxicity of DNA damage is exploited by cancer treatments such as radiotherapy. Ionizing radiation damages DNA indirectly by reacting with hydroxyl radicals to generate reactive intermediates, e.g., nucleobase and deoxyribose radicals; or by directly generating nucleobase radicals. Neutral purine radicals ($\text{dA}\cdot$, $\text{dG(N1-H)}\cdot$, and $\text{dG(N2-H)}\cdot$) generated by formal hydrogen atom abstraction of purines are believed to play a prominent role in oxidative DNA damage and DNA hole migration. However, very little is known about their reactivity.

Studying these intermediates via radiolysis is complicated due to the concomitant formation of other reactive species. To overcome the dearth of methods for photochemically generating neutral purine radicals, we developed two general strategies. The first type of precursors utilized photoinduced homolytic cleavage of weak covalent bonds (**3**, **4** and **5**). The second type of precursors (**6** and **7**) underwent a Norrish Type I photocleavage and β -fragmentation cascade to form neutral purine radicals and acetone. These precursors allowed mechanistic studies on the reactivity of neutral purine radicals as monomers in solutions or within DNA.

Herein, we report that $\text{dA}\cdot$ initiates tandem lesion formation in 5'-d(GTA) sequences but does not induce DNA hole migration. We propose that the tandem lesion formation is initiated by $\text{dA}\cdot$ abstracting the hydrogen atom from the C5-methyl group of the 5'-adjacent thymidine. $\text{dA}\cdot$ is converted to dA in this process, and thus the involvement of $\text{dA}\cdot$ in the tandem lesion formation is traceless by typical product analysis. Furthermore, we demonstrate, for the first time, that $\text{dA}\cdot$ is protonated at neutral pH when flanked by

dA. The formation of $\text{dA}^{\bullet+}$ by this protonation results in DNA damage arising from hole transfer. Finally, we disprove the published mechanism for the formation of strand damage observed during DNA hole migration in poly(dA-T) sequences and provide support for an alternative mechanism, in which the strand damage is tracelessly induced by dA^{\bullet} .

Acknowledgments

I am very thankful to all the people who have helped me through this journey. Thanks to all the members of the Greenberg lab, current and former, for their help. Thanks to Liwei Weng, Josh, Rakesh and Arnab for their help during my early years in graduate school. Special thanks to my best friend Danny who has been by my side through highs and lows. Thanks to Huabing, Shelby, Marco, and Kun for all their help, support, and advice. Thanks to Haozhe and Tingyu for their friendship and tremendous help during my final days in graduate school. I am also very thankful to Dr. Greenberg for his mentorship. I am impressed by his professionalism and enthusiasm for science. I am so grateful for not only the guidance and help in the research but also for his advises for my career path. Without his help, I surely would have never made it this far.

I also would like to thank Dr. Tovar and Dr. Rokita for their valuable suggestions and comments on this thesis. Thanks to Dr. Rokita and Dr. Klausen for their help during my search for a post-doctoral position. Thanks to Dr. Mortimer for his help in the UPLC-MS/MS studies. Thanks to all the collaborators for making this project come into fruition.

Thanks to my parents and parents-in-law who have always been supportive. My deepest appreciation goes to my wife, Yujia, who has always been extremely supportive and understanding. Although I could not be by her side most of the time, her encouragement and unconditional love have always motivated me.

1. Introduction

Deoxyribonucleic acid (DNA), the storage medium of genetic information, is constantly exposed to potentially damaging reactive species, which are either generated endogenously by normal cellular metabolism or exogenously by, for example, ionizing radiation.¹⁻³ DNA damage is deleterious to cells and can lead to cell death or cancer. Cancer treatments such as radiotherapy exploit the cytotoxicity of DNA damage.

Among the four naturally occurring 2'-deoxyribonucleosides, 2'-deoxyadenosine (dA) and 2'-deoxyguanosine (dG) are more prone to oxidation than 2'-deoxycytidine (dC), and thymidine (T) due to their low oxidation potentials.⁴⁻⁵ Oxidation of dA and dG by one-electron oxidants and the direct effect of ionizing radiation generates radical cations ($\text{dA}^{\bullet+}$ and $\text{dG}^{\bullet+}$).⁶⁻⁷ The pK_{a} s of these radical cations are lower than their parent molecules.⁸ For example, the pK_{a} of $\text{dA}^{\bullet+}$, although somewhat controversial, is believed to be as low as -0.3.⁶ At neutral pH, purine radical cations rapidly deprotonate to generate neutral purine radicals (Scheme 1, dA^{\bullet} and dG^{\bullet}). Moreover, deprotonation of $\text{dG}^{\bullet+}$ can generate two isomeric radicals: $\text{dG}(\text{N1-H})^{\bullet}$ and $\text{dG}(\text{N2-H})^{\bullet}$, and the tautomerization between them remains controversial. Neutral purine radicals are also generated by the indirect effect of ionizing radiation via the addition of hydroxyl radical ($\bullet\text{OH}$) at the C4 position of purines to yield **1** and **2**, which eliminate a water molecule to generate neutral purine radicals (Scheme 1).^{6, 9-10}

Scheme 1. The formation of neutral purine radicals.

While $\text{dG}^{\bullet+}$ is generally considered to be the major hole carrier in DNA hole migration, the role of $\text{dA}^{\bullet+}$ in hole migration has only gained attention more recently.¹¹⁻¹⁹ Hole migration can occur in dA-T tracts over long distances, which seemingly contradicts the low pK_a of $\text{dA}^{\bullet+}$ which would lead to spontaneous deprotonation of $\text{dA}^{\bullet+}$ and attenuation of hole migration.²⁰ To address these two conflicting observations, it has been proposed that a flanking dA increases the pK_a of $\text{dA}^{\bullet+}$ to ~ 7 .²¹⁻²³ However, this proposal has only been corroborated by computation and low-temperature electron paramagnetic

resonance (EPR) experiments.²¹ Furthermore, it is interesting to note that, in the absence of guanine, hole migration in dA-T tracts led to strand damage on T.²⁴⁻²⁸ This observation was explained by kinetically favorable irreversible trapping of the radical cation at T, despite the thermodynamically unfavorable electron transfer from T to dA^{•+}.²⁹ However, the proposed mechanism was not fully consistent with the sequence specificity of the formation of strand damage.

Little is known about the reactivity of neutral purine radicals. Much of the knowledge about the reactivity of purine radicals has been obtained from pulse radiolysis experiments on the nucleoside or dinucleotides. These experiments established that purine radicals react slowly with O₂ and H₂O.³⁰⁻³¹ These studies also lead to the proposal that dA[•] oxidizes dG to initiate hole migration.³²⁻³⁴ Additionally, the tautomerization of dG[•] and the involvement of this tautomerization during DNA oxidation are also controversial.^{23, 35-40} Furthermore, the information regarding the downstream products generated from neutral purine radicals, especially dA[•], are limited, despite their frequent occurrence during oxidative DNA damage. Therefore, independent, site-specific generation of purine radicals in DNA will greatly advance the understanding of the reactivity of these reactive intermediates.

To overcome the dearth of methods for photochemically generating neutral purine radicals we developed two general strategies. The first approach utilizes photoinduced homolytic cleavage of weak covalent bonds in precursors **3**, **4** and **5**.⁴¹ The second type of precursors (**6** and **7**) undergoes a Norrish Type I photocleavage and β -fragmentation cascade to form neutral purine radicals and acetone.⁴² Furthermore, incorporation of **6** into DNA provided significant insight into the reactivity of dA[•], including bringing to light the

traceless involvement of $\text{dA}\cdot$ in tandem lesion formation.⁴³ It also enabled us to demonstrate the sequence-dependent protonation of $\text{dA}\cdot$ to form $\text{dA}\cdot+$ in an aqueous environment at room temperature and thus validated the results obtained by calculation and EPR in low-temperature matrices.⁴⁴ Finally, we disproved the aforementioned proposed mechanism for the formation of strand damage observed during DNA hole migration in poly(dA-T) sequences and provided support for an alternative mechanism, in which the strand damage is induced by $\text{dA}\cdot$.⁴⁵

2. Background

2.1 DNA damage induced by ionizing radiation

Ionizing radiation damages DNA via two pathways: the indirect effect and the direct effect. The indirect effect of ionizing radiation refers to DNA damage induced by reactive oxygen species (ROS) generated by radiolysis of water.² Ionizing radiation can also directly excite electrons within a nucleic acid molecule. The direct effect results in the

formation of radical cations, particularly in the nucleobases. The components of a mixture absorb the energy of ionizing radiation approximately proportional to their weight.² Thus, under low DNA concentration ($0.5 \mu\text{g mL}^{-1}$), radicals generated by the radiolysis of water are the major contributors to DNA damage, and direct ionization of DNA accounts for a negligible part of the damage events. It is also worth noting that DNA damage induced by the direct effect accounts for 30 – 50 % of the DNA damage *in vivo*.⁴⁶⁻⁴⁷ The relative contribution of the direct effect to DNA damage is higher *in vivo* because protein scavenges a significant fraction of the $\bullet\text{OH}$.

The direct effect of ionizing radiation occurs when DNA absorbs the energy from ionizing radiation. The direct effect results in the formation of solvated electrons, electronically excited DNA, and most importantly, radical cations. DNA radical cations can also be accessed via reaction of DNA with one electron oxidants, such as $\text{SO}_4\bullet^-$,^{31, 48} $\text{CO}_3\bullet^-$,⁴⁹⁻⁵¹ and $\text{Br}_2\bullet^-$.⁵² Photosensitization of DNA by irradiating 2-methyl-1,4-naphthoquinone,⁵³⁻⁵⁵ benzophenone,⁵⁶ anthraquinone,²⁴ and riboflavin⁵⁷ also generates radical cations.

When a water molecule is excited by ionizing radiation, it can either release an electron to generate a water radical cation or occasionally yield an electronically excited water molecule (eqn. 1 and 2) . The $\bullet\text{OH}$ is generated by the deprotonation of the H_2O^+ radical cation, or the homolytic decomposition of the excited water molecule (eqn. 3 and 4).² $\bullet\text{OH}$ is also generated from the reduction of H_2O_2 by Fe^{2+} or Cu^+ , via Fenton chemistry.⁵⁸⁻⁵⁹

The highly electrophilic $\cdot\text{OH}$ readily adds to the C-C and C-N double bonds. Approximately 90% of the pyrimidine nucleoside reactive intermediates generated by $\cdot\text{OH}$ result from addition to carbon-carbon double bonds in the nucleobases. $\cdot\text{OH}$ undergoes addition to the C-C π -bonds at a nearly diffusion-controlled rate ($k = 3\text{-}10 \times 10^9 \text{ M}^{-1}\text{s}^{-1}$).⁶⁰⁻
⁶¹ However, these reactions are regioselective due to the electrophilic nature of $\cdot\text{OH}$. For example, the electron-rich C5 of pyrimidines is preferably attacked by $\cdot\text{OH}$.⁶² The remaining 10% of reactive intermediates arise from the hydrogen atom abstraction from the C5-methyl group of thymine or the deoxyribose.²

The susceptibility of nucleobases towards exogenous oxidants, such as ionizing radiation and one-electron oxidants is determined by the reduction potentials of one-electron deficient bases.⁴ The reduction potentials of the radical of the four native DNA nucleosides have been measured in aqueous solution by pulse radiolysis (Table 1). Among the four DNA nucleobases, adenine and guanine have relatively low reduction potentials and are preferentially oxidized to their radical cation. The local environment, in which the nucleosides also reside profoundly affects the redox properties of nucleobases. For instance, hydrogen bonding to cytosine reduces the reduction potential of guanine by 100 mV.⁶³⁻⁶⁴ On the other hand, π -stacking in dGGG sequences reduces the reduction potential of

guanine by 77 ± 5 mV, and this reduction makes dGGG triplets the thermodynamic sinks for “holes” (radical cations) in DNA charge transfer (Section 2.3).⁶⁵⁻⁶⁶

2.1 Generation of purine radicals

2.1.1 Generation of adenine radicals

One-electron oxidation of adenosine by the direct effect of ionizing radiation or one-electron oxidants generates adenine radical cations, dA•⁺ ($pK_a < 4$), which readily deprotonates to yield dA•.^{6,21} This deprotonation is less affected by base pairing than dG•⁺ in a d(G-C) base pair (see Section 2.1.2) because T is a poor proton acceptor (the pK_a of T(H)⁺ is -5).⁶⁷ However, this equilibrium is significantly affected by π -stacking in poly(dA-T) sequences (Section 2.3.3.2).²¹⁻²² dA• is also generated by the indirect effect of ionizing radiation via the reaction with •OH.¹⁰ Generally, •OH readily adds to double bonds but does not undergo electron transfer. •OH adds to dA at the C8 position (37%), the C4 position (50%) and the C5 position (<5%) (Scheme 2).¹⁰ •OH also abstracts hydrogen atom from the deoxyribose (8%). The C4-OH adduct (**1**) dehydrates to generate dA• with a rate constant of 1.9×10^4 s⁻¹. The C8-OH adduct (**8**) is also generated from the hydration of A•⁺ at C8 position.

Scheme 2. The generation of adenine radicals.

2.1.2 Generation of guanine radicals

Deprotonation of $\text{dG}\cdot^+$ ($\text{pK}_a = 3.9$) can generate two isomeric radicals: $\text{dG}(\text{N1-H})\cdot$ resulting from deprotonation from N1 and $\text{dG}(\text{N2-H})\cdot$ resulting from deprotonation from N2 (Scheme 3).^{6, 68} $\text{dG}(\text{N1-H})\cdot$ is only slightly more stable than $\text{dG}(\text{N2-H})\cdot$ because the radical cations derived from dG and 1-methyl-2'-deoxyguanosine have similar pK_a values of 3.9 and 4.7, respectively.⁷ The B3LYP/6-31G(d) level of theory also suggests that $\text{dG}(\text{N1-H})\cdot$ is $3.26 \text{ kcal mol}^{-1}$ more stable than $\text{dG}(\text{N2-H})\cdot$ upon hydration by seven water molecules.⁶⁹

Scheme 3. The generation of guanine radicals.

In double-stranded DNA, it is proposed that $dG^{\bullet+}$ is stabilized by sharing the N1-proton with the N3-site of C in the $d[G^{\bullet+}-C]$ base pair to form $d[G(N1-H)^{\bullet}-H^+C]$ (Scheme 4a). Given the pK_a values of $dG^{\bullet+}$ (3.9) and dC (4.3), the ratio between $[G^{\bullet+}-C]$ and $[G(N1-H)^{\bullet}-H^+C]$ is approximately 3:7.^{20, 38, 67, 70} The deprotonation from $[G(N1-H)^{\bullet}-H^+C]$ base pair to water generates $d[G(N2-H)^{\bullet}-C]$, which is proposed to tautomerize to yield $d[G(N1-H)^{\bullet}-C]$. However, Anderson et al. proposed an alternative mechanism for deprotonation of $d[G^{\bullet+}-C]$ that did not involve the tautomerization of $d[G(N2-H)^{\bullet}-C]$ (Scheme 4b).⁴⁰ They suggested that the oxygen-centered $G(N1-H)^{\bullet}$ abstracts a hydrogen atom from the N4 aminyl group of dC to transiently generate $d[G-C^{\bullet+}]$. The ensuing deprotonation of the N4 aminyl proton in $d[G-C^{\bullet+}]$ gave rise to $d[G-C_{im}^{\bullet}]$, which abstracted the hydrogen atom

from guanine yielding $d[G(N1-H)\bullet-C]$. The DFT calculations suggested that $dC_{im}\bullet$ is 9.01 kcal mol⁻¹ more stable than the aminyl tautomer of $dC\bullet$.⁷¹⁻⁷²

Scheme 4. Deprotonation of $dG\bullet+$ in the $d[G-C]$ base pair.

Similar to the reaction between $\bullet OH$ and dA (Scheme 2), $\bullet OH$ adds to dG (Scheme 3) at the C8 position (**9**, 17%) and the C4 position (**2**, 65-70%).⁷³ It is commonly accepted that dehydration of **2** is the major pathway contributing to the formation of $dG(N1-H)\bullet$. Recently, however, Chatgililoglu^{35, 37, 74} and co-workers reevaluated the reaction of $\bullet OH$ with dG by pulse radiolysis. They proposed that $\bullet OH$ directly abstracts the hydrogen atom

from the exocyclic NH₂ group of guanine to form of dG(N2-H)•, which undergoes a water-assisted tautomerization to generate dG(N1-H)•. The controversy regarding this proposal will be discussed in Section 2.3.2.1.

2.2 Reactivity of purine radicals

Purine radical cations (dA•+, dG•+) have much lower pK_a values than their parent nucleosides, and readily deprotonate to form neutral purine radicals.^{5, 52, 67} Neutral purine radicals, e.g., dA•, dG(N1-H)•, and dG(N2-H)• carry the spin predominantly at oxygen and nitrogen atoms.⁷⁵ Carbon-centered radicals react with oxygen at nearly diffusion-controlled rates ($k \sim 10^9 \text{ M}^{-1}\text{s}^{-1}$). In contrast, purine radicals have a drastically decreased reactivity towards molecular oxygen ($k \sim (1 - 5) \times 10^2 \text{ M}^{-1}\text{s}^{-1}$) due to their reduced electron density on the carbon atoms.⁷⁶ In addition, neutral radicals do not undergo hydration like radical cations. According to DFT calculations done on the nucleobases, the reaction of guanine radical cation (Gua•+) with water is exothermic by 75 kcal mol⁻¹, while a corresponding reaction of the guanine radical (Gua•) is endothermic by 29 kcal mol⁻¹.⁷⁷ At neutral pH, dG• reacts only slowly with H₂O and lives for ~70 ms in the absence of oxidants, including other radicals.³¹

2.2.1 Reactivity of adenine radicals

2.2.1.1 Acid-base equilibria of adenine radicals

The pK_a of nucleobase radical ions affects a variety of biologically significant processes, including DNA hole transfer, and formation of DNA lesions. While the pK_a values of $dG^{\bullet+}$ (3.9), $dC^{\bullet+}$ (~ 4.0), and $T^{\bullet+}$ (3.6) are generally accepted,^{4, 6, 8, 20, 78} the pK_a of $dA^{\bullet+}$ is still open to question. Steenken and co-workers produced $dA^{\bullet+}$ from dA in aqueous solution employing 248 nm laser photolysis and estimated the pK_a of $dA^{\bullet+}$ to be ≤ 1 .^{6, 20} This pK_a value is significantly lower than that of dA (≥ 14). Sevilla et al. calculated the deprotonation of an adenine radical cation in the presence of a seven water molecule hydration shell ($dA^{\bullet+} + 7 H_2O$) and concluded that the pK_a of $dA^{\bullet+}$ was -0.3 .²¹ However, in another study, the rates of hole migration in dinucleotide 5'-d(ApG) and 5'-d(GpA) decreased from pH 2.3 to 7, which indicated the population of $dA^{\bullet+}$ changes within this pH range.⁷⁹ This is inconsistent with the aforementioned pK_a of $dA^{\bullet+}$ (≤ 1). In a more recent transient spectroscopic study, the pK_a of $dA^{\bullet+}$ is reported to be 4.2.⁸⁰ NMR spectral study of one-electron-oxidized adenine produced via laser CIDNP in 5'-AMP suggests that the pK_a of $A^{\bullet+}$ in aqueous (D_2O) solution is 4 ± 0.2 .⁸¹ Furthermore, the recent theoretical calculation by Close predicted the pK_a of $A^{\bullet+}$ to be 3.9.⁸ Additionally, the rate at which $dA^{\bullet+}$ deprotonates is also controversial. Steenken et al. initially estimated that the deprotonation occurred in less than 1 ps.⁶ However, Kobayashi recently reported that $dA^{\bullet+}$ deprotonated to form dA^{\bullet} in phosphate buffer (20 mM, pH = 7.0) with a rate constant of $2.0 \times 10^7 \text{ s}^{-1}$.⁸⁰

Given the pK_a value of $dA^{\bullet+}$, the deprotonation rate of $dA^{\bullet+}$ ($< 1 \text{ ps}$) is faster than the rate constants of hole transfer between adjacent adenine ($k = 10^8 \text{ to } 10^{10} \text{ s}^{-1}$).⁸² This

deprotonation leads to charge-spin separation, which attenuates hole migration.²⁰ However, this is inconsistent with experiments, which showed that holes efficiently migrate over long dA-T tracts with little distance dependence.^{12, 83-86} It has been proposed that

the rate of hole transfer in dA-T tracts is faster than the rate of the deprotonation of $\text{dA}\bullet+$. Pulse radiolysis study determined the deprotonation rate of $\text{dA}\bullet+$ to be $0.9\text{--}1.1 \times 10^7 \text{ s}^{-1}$ in poly(dA-T) tracts, which is slower than the rate of hole transfer in these sequences.⁸⁰ In addition, in the same study, the monomeric $\text{dA}\bullet+$ was reported to deprotonate with a rate constant of $(2.0 \pm 0.2) \times 10^7 \text{ s}^{-1}$, which is only two times faster than that in poly(dA-T) tracts and significantly slower than that of hole transfer. This result contradicts the previously measured deprotonation rate ($< 1 \text{ ps}$) and the observation made in DNA that alternating dA-T sequences serve as insulators in DNA hole migration.^{6, 13}

D., Effect of Base Stacking on the Acid–Base Properties of the Adenine Cation Radical $[\text{A}\bullet+]$ in Solution: ESR and DFT Studies. *J. Am. Chem. Soc.* 2008, 130 (31), 10282-10292. Copyright 2008. American Chemical Society.

Another plausible explanation is that the hole within these adenine tracts is delocalized over several stacked adenine bases.²¹ Conwell proposed that a hole injected into an extended dA-tract leads to the formation of a polaron delocalized over 3–5 dA-T base pairs.⁸⁴ Barton and co-workers suggested that hole delocalization in A-tracts stabilizes the hole towards deprotonation.⁸⁵⁻⁸⁶ Sevilla and co-workers examined this proposal by DFT calculation and EPR.²¹ The geometry of adenine dimer radical cation with an 18 water molecule hydration shell ($\text{Ade}_2^{\bullet++} + 18 \text{H}_2\text{O}$) was optimized at the B3LYP/6-31G* level of theory, and the potential energy surface for the stretching of N-H bond was scanned from equilibrium bond length (1.12 Å) to 1.45 Å (Figure 1). Unlike $\text{dA}^{\bullet++} + 7 \text{H}_2\text{O}$, which showed no barrier for deprotonation, deprotonation of $\text{Ade}_2^{\bullet++} + 18 \text{H}_2\text{O}$ was endothermic, and the proton binding energy was calculated to be 12-16 kcal mol⁻¹. The computational studies were validated by generating $\text{dA}^{\bullet+}$ by one-electron oxidation of dA monomer and the oligomer $(\text{dA})_6$ by $\text{Cl}_2^{\bullet-}$ in aqueous glass at 150 K. Utilizing EPR, the presence of $\text{dA}^{\bullet+}$ was detected in the pH range of 3-7, and dA^{\bullet} was detected in the pH range of 9-12. These results suggested that the pK_a value of $\text{dA}^{\bullet+}$ was about 8, which was very different from Steenken's estimate (< 1).^{6, 20} This contradiction was rationalized by the dimerization of dA in a stacked conformation at millimolar concentration, which stabilized the radical cation.⁸⁷⁻⁸⁹ Similar behavior of $\text{dA}^{\bullet+}$ was also observed in $(\text{dA})_6$, which is known to adopt a stacked conformation.⁸⁸ More recently, $\text{dA}_n^{\bullet+}$ ($n > 3$) was directly observed in diphenylacetylenedicarboxamide (DPA) capped DNA hairpins using femtosecond transient absorption spectroscopy and $\text{dA}_n^{\bullet+}$ showed a distinct absorbance at 565 nm.⁸³ The delocalization of $\text{dA}^{\bullet+}$ in stacks of adenines is unique. Similar delocalization of $\text{dG}^{\bullet+}$ in stacks of guanine was not observed. The spin density of $\text{d}(\text{G}^{\bullet+}\text{pG})$ and $\text{d}(\text{ApA})^{\bullet+}$ were

simulated at the M06-2X/6-31G* level of theory (Figure 2).⁹⁰ The calculations suggested that in $d(G^{\bullet+}pG)$, the spin density was localized at the 5'-guanine. In the $d(ApA)^{\bullet+}$, the spin density was equally delocalized on both of the adenines.

D., Density Functional Theory Studies of the Extent of Hole Delocalization in One-Electron Oxidized Adenine and Guanine Base Stacks. *J. Phys. Chem. B* 2011, 115 (17), 4990-5000. Copyright 2011. American Chemical Society.

2.2.1.2 Products formed from adenine radicals

Two major products arise from adenine derived radicals are 8-oxo-7,8-dihydro-2'-deoxyadenosine (8-oxo-dA, Scheme 5) and *N*6-(2-deoxy- α,β -d-erythro-pentofuranosyl)-4,6-diamino-5-formamidopyrimidine (FapydA, Scheme 5).⁹¹ Their formation can be explained by the oxidation and reduction of **8**, which is either generated by hydration of $dA^{\bullet+}$ or the addition of $\bullet OH$ at the C8 position of dA (Scheme 2). Another modified nucleoside that was found to be generated upon one-electron oxidation by photoexcited riboflavin or menadione is 2'-deoxyinosine (dI), which likely arises from deamination of dA^{\bullet} (Scheme 5).⁹² However, the mechanism for the generation of dI is unclear at this point. The yields of 8-oxo-dA and FapydA are about eight- to tenfold lower than the yields of 8-oxo-7,8-dihydro-2'-deoxyadenosine (8-oxo-dG) and *N*6-(2-deoxy- α,β -d-erythro-pentofuranosyl)-2,6-diamino-4-hydroxy-5-formamidopyrimidine (FapydG).⁹³ This may

be explained by the lower oxidation potential of guanine, which can result in the transfer of an electron from guanine to radicals in close proximity.⁹⁴

Scheme 5. Products generated from adenine radicals.

2.2.2 Reactivity of guanine radicals

2.2.2.1 Tautomerization of neutral guanine radical

Recently, Chatgililoglu and co-workers demonstrated the tautomerization between $\text{dG(N2-H)}\cdot$ and $\text{dG(N1-H)}\cdot$. Upon reaction with a solvated electron, 8-bromo-2'-deoxyguanosine (**10**) was converted to its radical anion (**11**), which lost a bromide ion to generate $\text{dG(N2-H)}\cdot$ (Scheme 6).^{36-37, 95} However, the author did not address the mechanism by which the initially generated vinyl radical ($\text{dG(C8-H)}\cdot$) tautomerized to $\text{dG(N2-H)}\cdot$ (Scheme 6). The transient spectrum recorded 2 μs after the pulse had an absorbance at around 600 nm, which was consistent with the DFT simulated spectrum of $\text{dG(N2-H)}\cdot$. The absorbance decayed by a first-order rate constant of $5 \times 10^4 \text{ s}^{-1}$ to generate

dG(N1-H)•, which showed absorbances around 500 nm and 400 nm. The activation energy of this tautomerization was experimentally measured to be $23.0 \pm 2.5 \text{ kJ mol}^{-1}$. DFT calculations performed in the same study suggested that the energy barrier for direct tautomerization from dG(N2-H)• to dG(N1-H)• is $183.7 \text{ kJ mol}^{-1}$. The energy barrier was lowered to 18.8 kJ mol^{-1} by a water-assisted proton transfer, which was consistent with the experimental measurements.

Scheme 6. Generation of dG(N2-H)• via one-electron reduction of 8-bromo-2'-deoxyguanosine (**10**) and tautomerization between dG(N2-H)• and dG(N1-H)•.

However, the same calculation was performed by Sevilla et al. using the same level of theory (B3LYP/6-31G*), and the activation energy was found to be $18.9 \text{ kcal mol}^{-1}$, which suggested that units may have been misreported in Chatgililoglu's original paper (Figure 3). At 298 K, the rate constant of tautomerization based on Chatgililoglu's calculation was $\sim 3.7 \times 10^{10}$ times greater than that derived from Sevilla's calculation. The

calculation performed by Sevilla et al. suggested that the hydrogen atom abstraction, tautomerization pathway was unlikely to be competitive against addition, elimination pathway at room temperature.⁶⁹

Figure 3. Water-assisted tautomerization between dG(N2-H)• and dG(N1-H)•. Reprinted with permission from Adhikary, A.; Kumar, A.; Becker, D.; Sevilla, M. D., The Guanine Cation Radical: Investigation of Deprotonation States by ESR and DFT. *J. Phys. Chem. B* 2006, *110*, 24171-24180. Copyright 2006. American Chemical Society.

Having assigned the transient spectra of the two tautomers of dG•, Chatgililoglu et al. reevaluated the reactivity of guanine towards hydroxyl radicals.^{35, 74} The transient spectrum obtained from the pulse radiolysis of dG showed an absorbance at around 600 nm, which suggested that the species initially generated by the reaction between hydroxyl radicals and guanine was dG(N2-H)•. This observation led to the proposal that hydroxyl radicals react with guanine via hydrogen atom abstraction from the exocyclic aminyl group. Sevilla et al. also investigated the direct hydrogen abstraction from the exocyclic NH₂ of guanine by •OH and calculated that the activation barrier for hydrogen abstraction was 7

kcal mol⁻¹.⁶⁹ Sevilla and co-workers considered an alternative mechanism, the addition elimination mechanism (Scheme 3). They calculated that the initial addition of the •OH at C4-C5 π-bond of guanine is barrier-free, and the C4-OH adduct (Gua(C4-OH)•) has only a small activation barrier of 1–6 kcal mol⁻¹ to form a metastable ion-pair intermediate (Gua•+ --- OH⁻, Figure 4).^{39, 69} The ion-pair deprotonates to form H₂O and neutral dG radicals favoring Gua(N1-H)• with an activation barrier of 5 kcal/mol. The overall process from **2** to Gua(N1-H)• and water was found to be exothermic by more than 13 kcal/mol. These results suggested the generation of Gua(N2-H)• is not necessary for the formation of Gua(N1-H)•, and the formation of Gua(N1-H)• more likely goes through the low-energy addition elimination pathway. Interestingly, calculations also suggest that the (Gua•+ --- OH⁻) ion-pair has a long wavelength absorption peak (λ_{max} = 665 nm) which was previously assigned to absorption of dG(N2-H)•.⁶⁹

Figure 4. The Metastable ion-pair intermediate (Gua•+ --- OH⁻) generated by the dehydration of Gua(C4-OH)•. Reprinted with permission from Kumar, A.; Pottiboyina, V.; Sevilla, M. D., Hydroxyl Radical (OH•) Reaction with Guanine in an Aqueous Environment: A DFT Study. *J. Phys. Chem. B* 2011, *115*, 15129-15137. Copyright 2011. American Chemical Society.

2.2.2.2 Products formed from guanine radicals

Guanine is susceptible to one-electron oxidation, which gives rise to $\text{dG}^{\bullet+}$ and the deprotonated neutral radical $\text{dG}(\text{N1-H})^{\bullet}$.⁵⁻⁷ The two major decomposition pathways involve (i) oxidation of dG^{\bullet} by O_2 (ii) hydration of $\text{dG}^{\bullet+}$ and subsequent oxidation or reduction. The first pathway leads to the formation of 2,2-diamino-4-[(2-deoxy- β -D-erythro-pentofuranosyl)amino]-5(2H)-oxazolone (dOz, Scheme 7) and its precursor 2-amino-5-[(2-deoxy- β -D-erythro-pentofuranosyl)amino]-4H-imidazol-4-one (dlz).⁹⁶⁻⁹⁹ The formation of these products can be rationalized by $\text{dG}(\text{N1-H})^{\bullet}$ which can be generated by deprotonation of dG radical cation or dehydration from the predominant $\bullet\text{OH}$ C-4 adduct of the guanine moiety (**2**, Scheme 3).⁷³ In a subsequent step, $\text{dG}(\text{N1-H})^{\bullet}$ reacts with O_2 or more likely $\text{O}_2^{\bullet-}$ to form peroxide **12**.⁷³ The addition of water takes place at the 7,8-double

Scheme 7. The generation of dlz and dOz from $\text{dG}(\text{N1-H})^{\bullet}$.

bond of **12** to generate **13**, followed by ring opening of the pyrimidine and loss of CO₂ to generate **14**.⁹⁸ The release of formamide leads to the formation of dIz which hydrolyzes to generate dOz (Scheme 7). It is also worth noting regarding that DNA containing dOz or dIz is readily cleaved upon hot piperidine treatment whereas 8-oxo-dG is stable under similar conditions.^{96, 100-101}

Scheme 8. Products generated from 8-hydroxy-7,8-dihydroguanyl radical (**9**).

The second major radical-induced decomposition pathway of dG involves 8-hydroxy-7,8-dihydroguanyl radical (**9**) that arises from either the hydration of dG^{•+} or addition of [•]OH at C-8 of dG (Scheme 3).⁶ This pathway leads to the predominant formation of 8-oxo-dG together with small amounts of FapydG in aerated aqueous solution (Scheme 8).^{73, 102-103} Oxidation of transiently formed **9** leads to the formation of 8-oxo-dG, whereas competitive reduction gives rise to FapydG. However, the formation of 8-oxo-dG

upon exposure of dG and single-stranded DNA to one-electron oxidants is only a minor process. This is caused by the rapid deprotonation of dG^{•+} at neutral pH since its pK_a is 3.9.^{6, 38} In contrast, hydration of dG^{•+} is more efficient within double-stranded DNA, in which guanine radical cations are likely to be stabilized through base stacking and base pairing. This stabilization leads to higher yields of products resulting from hydration of dG^{•+}.^{38, 104}

The two-electron oxidized product of guanine—8-oxo-dG, which has an oxidation potential about 0.5 eV lower than that of dG,¹⁰⁵ is a preferential target for one-electron oxidizing agents.¹⁰⁶⁻¹⁰⁸ For instance, the rate constant describing the reaction of dG[•] with 8-oxo-dG was found to be $4.6 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ at pH 7.0.¹⁰⁹ This fast reaction, together with the slow addition of O₂ to dG[•] ($k < 10^2 \text{ M}^{-1} \text{ s}^{-1}$), could explain the low yield of 8-oxo-dG during γ -radiolysis of an aerated aqueous solution of dG. Instead of 8-oxo-dG, the two diastereomers of spiroiminodihydroantoin 2'-deoxynucleosides (dSp, Scheme 9) resulting from two-electron oxidation of 8-oxo-dG were the predominant oxidized products of dG at higher pH (pH > 5.8).^{107, 110-112} The formation of dSp containing products was rationalized by the transient generation of 5-hydroxy-8-oxo-7,8-dihydroguanine (**15**) that rearranges via an acyl shift (Scheme 9a). Under slightly acidic conditions (pH < 5.8) or sterically encumbered environments such as double-stranded DNA, **15** undergoes opening of the 5,6-pyrimidine ring followed by a decarboxylation reaction and formation of the two diastereomers of guanidinohydroantoin derivatives (dGh, Scheme 9b).^{107, 110-113} It is also worth mentioning that **15** is at the same oxidation state as **13** which generates dOz and dIz, (Scheme 9c). However, dOz and dIz are generated in lower yields than dSp and dGh.¹⁰⁸

Scheme 9. Products generated from two-electron oxidation of 8-oxo-dG.

2.2.1 Mechanism of DNA hole migration

2.2.1.1 Hopping mechanism

Over a half century ago, Eley and Spivey demonstrated the semiconductivity of duplex DNA.¹¹⁴ In 1993, Barton and co-workers reported that holes rapidly migrate through DNA duplexes.¹¹⁵ DNA hole migration helps to explain how initial oxidation events induce DNA damages at distal positions.^{13, 29, 115-117} Furthermore, DNA hole migration chemistry can also be utilized to sense changes in DNA including DNA lesions, mismatches, and protein binding.¹¹⁸⁻¹²² For instance, more recently Barton and co-workers demonstrated that binding of human DNA primase is controlled by the oxidation state of the [4Fe4S] cluster that is modulated by DNA hole migration.¹²³ As a biologically significant process, the mechanism of DNA hole migration was thoroughly investigated. DNA hole migration was initially proposed to occur via a superexchange mechanism, a process in which the charge transportation is considered as a unistep coherent orbital-mediated tunneling without the oxidation of bridging nucleotides (Figure 5a).^{115, 124-125} The superexchange mechanism predicts that the rate of charge transport decreases exponentially as the distance increases (eqn. 5).¹²⁶⁻¹²⁸

$$\ln k = -\beta \ln \Delta r \quad \text{eqn. 5}$$

Figure 5. Comparison of photoinduced DNA-mediated hole transfer via (a) the superexchange mechanism and (b) the hopping mechanism (D = donor, A = acceptor, B = base, HT = hole transfer, HOP = hopping).

The β value was independently determined by PAGE analysis of strand-cleavage and femtosecond time-resolved transient-absorption spectroscopy to be $0.7 \pm 0.1 \text{ \AA}^{-1}$.^{13, 126, 129} This strong distance dependence suggests that a single step charge transfer via superexchange over long distance is too slow to compete with trapping reaction of $dG^{\bullet+}$ by water and deprotonation of $dG^{\bullet+}$.^{11, 130} Alternatively, the hopping mechanism is generally considered as the more plausible mechanism to explain the observed hole migration over long distances (e.g. 50 Å) (Figure 5b).^{11, 130} Giese and co-workers demonstrated that the overall hole migration over long distances occurs as a multistep hopping process during which holes reversibly “hop” between hole carriers ($dG^{\bullet+}$, Figure 2b). Each hopping step can be viewed as a discrete superexchange process and is

competitive with hydration and deprotonation.¹³¹⁻¹³² The efficiency of hole migration by hopping shows a shallow distance dependence and can be described by eqn. 6, in which E is the efficiency of the hole migration, and N is the number of the equidistant hopping steps.^{11, 130, 133-134}

$$\ln E \propto -\ln N \quad \text{eqn. 6}$$

2.2.1.2 “A-Hopping” and polaron formation in poly(dA) sequences

In the previous section, the discussion was based on the assumption that $dG^{\bullet+}$ is the hole carrier, and the superexchange between guanines separated by poly(dA-T) tracts does not lead to any oxidation within the poly(dA-T) regions. Based on the distance dependence of the rate of superexchange (eqn. 5), one may mistakenly conclude that hole transfer will collapse when the length of the poly(dA-T) tracts increase, which is not the case.^{85, 135-137} Giese and co-workers investigated sequences bearing different lengths of $(dA-T)_n$ tracts between $dG^{\bullet+}$ and $dGGG$ triplets (Figure 6).¹² For $n = 1-3$ the alkali-labile lesion yield ratio P_{GGG}/P_G decreased from 250 to 4, which is consistent with the exponential distance dependence of single step superexchange. However, when the number n of $(dA-T)_n$ base pairs increased further, P_{GGG}/P_G only decreased slightly. It was proposed that when the length of $(dA-T)_n$ increases, the rate of superexchange between the $dG^{\bullet+}$ and the $dGGG$ triplets was so slow that endothermic oxidation of the adjacent adenine by thermally excited $dG^{\bullet+}$ to generate $dA^{\bullet+}$ became competitive.¹³⁸⁻¹⁴⁰ Once the $dA^{\bullet+}$ is generated, the hole rapidly migrates through the dA-T base pairs until it reaches the $dGGG$ triplets, the thermodynamic sink for the hole.⁶⁵ This nearly distance-independent hole transfer over $(dA-T)_n$ sequences where adenines are charge carriers is named “A-hopping”.¹¹⁷ Giese originally proposed that hole migration occurred in poly(dA-T) tracts via tunneling.¹² As

previously discussed in section 2.2.1.1, this rapid hole migration can also be explained by the delocalization of positive charge over multiple (dA-T)_n base pairs to form polarons, which have been directly observed in DNA hairpins.⁸³⁻⁸⁴ Furthermore, since the calculated polaron size is approximately four adenines, the strong distance dependence that has been found for tracts shorter than this length is consistent with these sequences not supporting polaron formation.¹⁴¹

2.2.2 Strand damage induced by DNA hole migration

2.2.2.1 Hole migration induced strand damage at guanine base stacks

As previously mentioned, dGG and dGGG sites are more easily oxidized than isolated guanine sites and are preferred hot spots for hole localization during hole DNA transfer. Experimental and theoretical studies suggested that there is a distinct preference for hole localization at the 5'-dG in dGG and dGGG sequences.¹⁴ EPR studies suggested

that 60% of holes localize at the 5'-dG of a dGGG triplets at 77 K.⁷⁰ However, this localization of holes was not fully consistent with observations made in some strand cleavage assays, in which the central dG was often preferentially damaged. To explain this phenomenon, it has been proposed that the preferential site of strand cleavage is dictated by the stability of neutral radical species.¹⁴² For example, computational studies showed that 5'-d(TG₁G₂•G₃T) was more stable than 5'-d(TG₁•G₂G₃T) by 2.4 kcal mol⁻¹. This was consistent with the strand cleavage assay, in which dG₂ of 5'-d(TG₁G₂G₃T) is more reactive than dG₁. The same correlation was also found in the 5'-d(CG₁G₂G₃C) sequence. If this proposal is correct, one has to assume that the strand cleavages are induced by alkali-labile lesions generated from the neutral guanine radicals, such as dOz and dIz.⁹⁷ However, other reactions at sites where the hole is stabilized, such as nucleophilic addition of H₂O at C8 in the guanine moiety, followed by one-electron oxidation leading to the formation of 8-oxo-dG have also been suggested.¹⁴³ These proposals raised the question which is yet to be answered. What is/are the structure(s) of hole migration induced guanine lesion(s)?

2.2.2.2 Hole migration induced strand damage in the absence of guanine

Although the majority of literature has focused on hole migration induced strand damage on dG, strand damage induced via hole migration in poly(dA-T) sequences in the absence of guanine has been investigated by Schuster and co-workers.^{25-26, 28-29} After holes were introduced by photoexcited anthraquinone (AQ),¹⁴⁴ the alkali-labile lesions detected in duplex **16** were localized at the GG step as one would expect. However, in duplex **17** and **18** which lack guanine, the alkali labile lesions are predominantly generated at the 5'-thymidine in TT steps (in **17**) and the central thymidine in TTT steps (in **18**). These

observations are surprising because dAs are more easily oxidized and are the major hole carriers in these duplexes.^{4, 12} The authors proposed that charge transfer from $\text{dA}^{\bullet+}$ on the opposite strand resulted in the formation of $\text{T}^{\bullet+}$, which was the precursor for the observed alkali-labile lesions.²⁵ The Curtin–Hammett principle was invoked to explain the product formation. Despite the high population of $\text{dA}^{\bullet+}$, $\text{T}^{\bullet+}$ was irreversibly trapped by oxygen and water, and $\text{dA}^{\bullet+}$ did not generate alkali-labile products. The strand damage in TT steps was attributed to tandem lesions (Scheme 10). When the $\text{T}^{\bullet+}$ is localized on the 5' end of a TT step, the hole is trapped by water and oxygen to give peroxy radical (Scheme 10a), which abstracts a hydrogen atom from the C5-methyl hydrogen of the 3'-T. The resulting carbon-centered radical (T^{\bullet}) is trapped by O_2 and ultimately generates tandem lesion **20**. Alternatively, $3'\text{-T}^{\bullet+}$ deprotonates to generate T^{\bullet} , which reacts with oxygen to yield 5-fdU

Scheme 10. The mechanism for tandem lesion generation in 5'-TT steps induced by hole migration.

or 5-hmdU single lesions **21** (Scheme 10b). The peroxy radical (Tp•, Scheme 10b) generated from the 3'-T•+ was proposed to not contribute to the strand damage due to the unfavorable distance for hydrogen atom abstraction from C5-methyl hydrogen of the 5'-T (see Section 3.2.5.1). In addition, alkali-labile lesion formation was sequence specific. For instance, alkali-labile cleavage was observed at TT and 5'-d(UT) steps, but no damage was detected at 5'-d(TU) sequences (**19**). This is consistent with the proposed mechanism that the absence of C5- methyl hydrogen of the 5'-dU inhibits both pathways of strand damage formation (Scheme 10), but the absence of the C5-methyl hydrogen of the 3'-dU does not have such effect. LC-MS analysis of the enzyme digest of the photolyzed oligonucleotides revealed the formation of 5-fdU, 5-hmdU, and Tg, which agreed with the proposed mechanism. The authors also rationalized the preferential damages at the central T in 5'-TTT segments, but the proposal was inconsistent with the observation (see Section 3.2.5.1).

2.3 Tandem lesions

It has been proposed that the cytotoxicity of ionizing radiation largely arises from the formation of clustered lesions.¹⁴⁵⁻¹⁴⁷ A clustered lesion is defined as two or more lesions, such as oxidized bases, abasic sites, or strand breaks formed within 20 bp. Tandem lesions, e.g., **20**, are a subset of cluster lesions in which two adjacent nucleotides on the same strand are damaged.¹⁴⁷ The formation of tandem lesions was first reported by Box and co-workers from X-ray irradiated 5'-d(GpT) in the presence of oxygen.¹⁴⁸ A damaged residue containing an 8-oxo-dG and N-(2-deoxy-d-erythropentofuranosyl)formylamide (**22**, Scheme 11) was isolated. Formation of **22** was proposed to arise from **23**, which resulted from the addition of •OH to the thymidine π -bond (Scheme 10). The resulting carbon-centered radical was trapped by oxygen to form peroxy radical **24**, which adds to the C8

of 5'-dG. A subsequent breakdown of the peroxide **25** and β -fragmentation of **26** generates the tandem lesion (Scheme 11).¹⁴⁹ Cadet identified and characterized **22** in enzyme-digested (snake venom phosphodiesterase and calf spleen phosphodiesterase) calf thymus DNA that was γ -irradiated utilizing HPLC-ESI-MS/MS.¹⁵⁰ The proposed mechanism for the tandem lesion formation was supported by an isotopic labeling experiment, in which one ¹⁸O atom was incorporated in the tandem lesion.¹⁴⁹

Scheme 11. The mechanism for tandem lesion generation in 5'-GT.

Wang and co-workers identified another tandem lesion (**27**) in calf thymus DNA exposed to Cu(II)/ascorbate/H₂O₂.¹⁵¹ The oxidized DNA was digested by nuclease P1, which does not hydrolyze the phosphodiester bond 3' to the thymidine glycol (Tg), enabling the detection of the tandem lesion. The tandem lesion with reversed directionality (**28**) was not detected. However, nuclease P1 used to digest the DNA was previously shown to digest

22 that had the same directionality.¹⁴⁹ Hence, the formation of **28** may be masked by the nuclease treatment.

Scheme 12. The mechanism for generation of intrastrand [G-T] cross-links.

Another example of a tandem lesions is [G-T] (Scheme 12), which has been detected following one-electron oxidation of 5'-d(CCTACGCTACC) by photochemically generated $\text{CO}_3^{\bullet-}$.¹⁵²⁻¹⁵⁴ The structure of this tandem lesion was characterized by LC-MS/MS following enzymatic digestion, 1D, and 2D NMR studies.¹⁵³ The formation of [G-T] cross-links is most efficient in the case of 5'-d(GpCpT). However, the central dC was hydrolyzed by alkaline phosphatase and snake venom phosphodiesterase. Cross-link 5'-

d(GpT) was observed in 5'-d(TTACGTACGTAA) following exposure to $\text{CO}_3^{\bullet-}$. The phosphodiester bond in the 5'-d(GpT) crosslink was resistant toward enzymatic treatment. The tandem lesion was proposed to be generated by addition of thymine N3 atom to guanine radical at the C8 position (Scheme 12). The pH dependence of crosslink yields supported nucleophilic attack by N3. The yields of crosslinks were 22% at pH 10, ~5% at pH 7, and no crosslinks were observed at pH 5. This is consistent with the fact that the pK_a of T is 9.8, and N3-deprotonated thymine is a better nucleophile.¹⁵²

Scheme 13. The mechanism for the generation of intrastrand G[8-5m]T and G[8-5]C crosslinks.

In the absence of O_2 , carbon-centered pyrimidine radicals (**29**, **30**, Scheme 13) also react with adjacent bases to generate crosslinks, such as G[8-5m]T and G[8-5]C (Scheme 13).¹⁵⁵⁻¹⁵⁷ These products were quantified using nuclease P1 digestion followed by highly sensitive HPLC-ESI/MS³ due to their low frequency of generation. In the presence of O_2 ,

the carbon-centered radicals are efficiently trapped, which significantly limits the formation of these lesions.¹⁵⁷

Furthermore, it is worth noting that most of the studies on tandem lesion formation rely on enzymatic digestion followed by LC-MS/MS studies, or structural characterization of oxidatively damaged short model oligonucleotides (< 4 nt).^{149, 153-154} The enzymatic digestions take advantage of the resistance of the tandem lesion toward hydrolysis.^{149, 151} However, evidence for the formation of some tandem lesions is lost during digestion because they are the substrates for the enzyme. Using short model oligonucleotides circumvents the enzymatic digestion, and thus preserves the sequence information of the tandem lesions. However, extra caution should be exercised in extrapolating the results obtained in short oligonucleotides to double-stranded DNA due to the complexity of sequence effects and structural flexibility of long double-stranded DNA.¹⁵⁸

2.4 Photochemical generation of Heteroatom-centered radicals

2.4.1 Oxygen-centered radicals

O-centered radicals are reactive intermediates that exhibit electrophilic properties in hydrogen atom abstractions and addition reactions to C-C double bonds.¹⁵⁹⁻¹⁶⁰ The main advance in the photochemical generation of O-centered radicals was made by Beckwith, who showed in 1988 that molecules of the general type **31** were sources of alkoxy radicals (Scheme 14a).¹⁶¹ However, the synthesis of N-alkoxy-pyridine-2(1H)-thiones is hampered by poor chemoselectivity between competitive O-substitution and S-substitution.¹⁶² Furthermore, some pyridinethiones decompose at room temperature, and others rearrange to form the thermodynamically more stable 2-(alkylsulfanyl)pyridine N-oxides (**32**), which are not precursors for alkoxy radicals (Scheme 14a).¹⁶³ To overcome some of the

disadvantages of pyridinethiones, N-alkoxy-2(1H)-pyridone precursors (**33**) were synthesized (Scheme 14b).¹⁶⁴ The synthesis of **33** is simplified because the keto form of N-hydroxy-2(1H)-pyridone (**36**, Scheme 14c) predominates over the enol tautomer (**37**, Scheme 14c).¹⁶⁵ In addition, the 2-pyridyloxyl radical (**34**) generated along with RO• by UV-irradiation, was found to be much less reactive than 2-pyridylthiyl radical (**35**, Scheme 14a).¹⁶⁴ This reduced reactivity is particularly advantageous for using **33** as selective precursors to generate alkoxy radicals for mechanistic studies.

Scheme 14. N-Alkoxy-2(1H)-thione precursors and related precursors for photochemical generation of oxygen-centered radicals.

Hartung and co-workers developed another method to access alkoxy radicals via alkoxy-4-arylthiazole-2(3H)-thiones (**38**, Scheme 14d).¹⁶⁶ Precursors **38** were synthesized in good yields in two steps because N-(hydroxy)-4-arylthiazole-2(3H)-thiones exhibited higher reactivity for O-substitution against S-substitution. Moreover, N-hydroxy-

thiazolethiones demonstrated improved thermal stability. The effectiveness of these precursors (**38**) was demonstrated by laser flash photolysis and product analysis, in which disulfide **40** resulting from recombination of thiyl radical **39** was identified as the primary product.¹⁶⁷ Upon irradiation (300 nm) of thiazolethione **41** in aqueous media, only isopropoxyl radical was formed, as confirmed by the generation of **42** that resulted from trapping of isopropoxyl radical by 5,5-dimethyl-1-pyrroline N-oxide (DMPO) and EPR spectroscopy.¹⁶⁸

N-hydroxy-phthalimide derivatives, such as **43**, are another type of photochemical precursors of oxygen-centered radicals (Scheme 15).¹⁶⁹ Although typically activated by one-electron reduction (Scheme 15 a),¹⁷⁰ **43** can also be activated by UV (medium-pressure mercury lamp with Pyrex filter, Scheme 15b).¹⁷⁰ However, the photochemistry is inefficient, possibly because of the low absorbance of the phthalimide chromophore. In order to overcome this shortcoming, N-hydroxy-naphthalimide derivatives have been used as precursors for oxygen-centered radicals via homolytic cleavage of the labile N-O bonds.¹⁷¹ The extended conjugation shifts the absorbance to around 350 nm, which improves the compatibility with other functional groups. N-hydroxynaphthalimide triflate (**44**, Scheme 15) is used as a photo-acid generator, which is one of the key materials in the field of photoresists for semiconductor fabrication.¹⁷²

Scheme 15. N-hydroxy-phthalimide precursors and related precursors for photochemical generation of oxygen-centered radicals.

2.4.2 Nitrogen-centered radicals

Compared to carbon-centered radicals, nitrogen-centered radicals are underutilized reactive intermediates in organic synthesis owing to the lack of convenient methods for producing these radical species. Two of the most characteristic reactions of N-centered radicals are hydrogen atom abstraction and amination of unsaturated substrates.¹⁷³⁻¹⁷⁵ With the recent development of visible light photoredox catalysis, synthetic methods utilizing nitrogen-centered radicals attracted increasing attention.¹⁷⁶ To independently generate nitrogen-centered radicals in the biopolymers, unimolecular photochemical processes are more feasible. However, the examples of these methods are rather limited.¹⁷⁷

N-O bonds are generally weaker than N-C and N-N bonds, and their cleavage serves as the basis of several methods to produce nitrogen-centered radicals. Walton et al.

recently studied the photochemistry of oxime carbamates (Scheme 16a).¹⁷⁴ Upon photolysis, the oxime carbamate **45** underwent homocleavage of the labile N-O bond which generated an iminyl radical **46**. The subsequent decarboxylation of carbonyloxy radical **47** yielded an aminyl radical **48**. Methods based on modified Barton decarboxylation were also reported. This concept was demonstrated by the photochemical behavior of carbamate derivative **49** upon irradiation with visible light in the presence of trifluoroacetic acid (Scheme 16b).¹⁷⁸ Homolysis of the N-O bond is followed by a rapid fragmentation of the carbonyloxy radical (**50**) to give a molecule of carbon dioxide and the desired protonated aminyl radical **51**.

Scheme 16. The generation of nitrogen-centered radical via the cleavage of N-O bonds.

Methods based on a cascade of photocleavage of N-O bond and β -fragmentation have also been explored. Newcomb and co-workers reported a tandem Barton decarboxylation, β -fragmentation reaction.¹⁷⁹ The photocleavage of the N-O bond of an ester of N-hydroxypyridinethione (**52**) resulted in the formation of the carboxyl radical **53**, which decarboxylated to generate β -(dialkylamino)alkyl radical **54**. The ensuing β -fragmentation with a rate constant of 10^4 s^{-1} generated the desired aminyl radical (**55**,

Scheme 17a). Similarly, amidyl and iminyl radicals have been generated by β -fragmentation of the N-O bond. Zard and co-workers also applied Barton decarboxylation of N-hydroxypyridinethione ester **56** followed by loss of formaldehyde via β -fragmentation to give the expected iminyl radical **57** (Scheme 17b).¹⁸⁰ Furthermore, an amidyl radical was generated by Begley and co-workers via a similar strategy by the photolysis of hydroxamate **58** (Scheme 17c).¹⁸¹ The rate constant for β -fragmentation of the N-O bond is measured in compound **61** by the competition between the ring opening of the cyclopropyl group generating radical **62** and the cleavage of the N-O bond generating amidyl radical **59** (Scheme 17d). In the presence of *t*-BuSH, the photolysis of **60** only generated the amide **64**. Product **63** resulting from the opening of the cyclopropyl ring of **61** was not detected. Based on the assumption that the ring-opening rate of radical **61** was $2 \times 10^7 \text{ s}^{-1}$, the author estimated that the rate of β -fragmentation was greater than $2 \times 10^8 \text{ s}^{-1}$.

Scheme 17. Generation of nitrogen-centered radical via tandem Barton decarboxylation, β -fragmentation.

Fewer examples of the photochemical generation of nitrogen-centered radicals via N-N and N-C bond cleavages have been reported because these bonds have higher bond dissociation energies. Steenken et al. demonstrated that upon UV (248 or 308 nm) irradiation in acetonitrile and hexanes, N-(triphenylmethyl)anilines (**65**) exclusively undergo C-N bond homolysis to generate the triphenylmethyl radicals (**67**) and aniliny radicals (**66**, Scheme 18a).¹⁸² Similarly, tetraphenylhydrazine (**68**), which has N-N bond dissociation energy of 30 kcal/mol undergoes homolysis of the N-N bond both thermally and photochemically yielding diphenylaminyl radicals (Scheme 18b), which were detected by EPR.¹⁸³ In addition, triphenylhydrazine (**70**) undergoes a similar process upon UV excitation generating an aniliny radical (**66**) and a diphenylaminyl radical (**69**, Scheme 18c).

Scheme 18. Generation of nitrogen-centered radical via cleavage of N-C and N-N bonds.

2.5 Independent generation of reactive intermediates in DNA

2.5.1 Investigating reactivity of reactive intermediates via their independent generation

Mechanistic studies of reactive intermediates in biopolymers by non-selective methods, such as pulse radiolysis are hampered by simultaneous generation of multiple reactive intermediates and the lack of site-selectivity. Independent generation of reactive intermediates involved in DNA allows studies of the reactivity of a single reactive intermediate in certain sequence context without producing other reactive intermediates. Unambiguous generation of reactive intermediates at a defined site in a biopolymer can also improve the resolution of complex DNA lesions that would otherwise be masked due to the simultaneous generation of multiple lesions in the same region of DNA. Lastly, in the course of such a mechanistic investigation, it is possible to discover new reaction

processes. In the realm of nucleic acid damage, these processes could have significant relevance to human health.

Our group and Giese's group pioneered independent generation of nucleoside radicals using Norrish Type I photocleavage of ketones **71** and **75**.¹⁸⁴⁻¹⁸⁵ The ketones produced the carbon-centered radicals via α -cleavage and ensuing decarbonylation generating one equivalent of alkyl radical and carbon monoxide.¹⁸⁶ The photolysis of **71** generated the deoxyribose C-4' radical **72** (Scheme 19a), which is one of the key intermediates involved in bleomycin or neocarzinostatin induced DNA damage. The cleavage of the β -C-O bond generates enol ether radical cation **73** which oxidizes dG generating dG^{•+} and **74**. This chemistry was used as a hole injection method for DNA charge transfer studies.¹⁸⁷ Precursor **75** was synthesized to independently generate 5,6-dihydro-2'-thymidin-6-yl radical **76** (Scheme 19b), which is the formal product of hydrogen atom addition to thymidine.¹⁸⁵

Scheme 19. Examples for independent generation of reactive intermediates in DNA.

2.5.2 Examples for independent generation of purine radicals

Selective generation of carbon-centered nucleobase and sugar radicals has yielded significant insight into the reactivity of these species. However, the use of photolabile precursors for the site-selective generation of neutral purine radicals has had limited success, owing to the lack of means for the photochemical generation heteroatom-centered radicals.

Photolysis of **77** was designed to produce dG(N1-H)•.¹⁸⁸ However, instead of forming the desired precursor, pyridine-2-thiol 1-oxide **78** was the only observed product. It was proposed that **78** can isomerize to form **77**, which is the photochemical precursor of dG(N1-H)• (Scheme 20a). The generation of dG(N1-H)• was supported by product analysis, in which the presence of H-atom donor increased the yield of dG. However, no transient absorption of dG(N1-H)• was obtained by laser flash photolysis. The author proposed an alternative precursor (**79**) by replacing the pyridinethione moiety with a pyridone.¹⁸⁹ This change not only granted the authors access to the desired precursors but also simplified the analysis of the photochemical processes. The generation of dG(N1-H)• was supported by laser flash photolysis. The author also utilized ring opening of the cyclopropyl group in **80** to support the generation of dG(N1-H)• (Scheme 20b).¹⁸⁹⁻¹⁹⁰ It is worth noting that the authors did not comment on that the ring opening would require the tautomerization of dG(N1-H)• analogue to form **81** (Scheme 20b). No data regarding the effects of hydrogen atom donors was reported, and the authors did not address the formation of dG (38 %) in the absence of hydrogen atom donors. Furthermore, studies on the formation of dG(N1-H)• from **78** and **79** in oligonucleotides have not yet been reported.¹⁸⁸

Scheme 20. Photochemical generation of dG(N1-H)•.

dA• has also been produced from a photochemical precursor (**82**) but not within DNA (Scheme 21).¹⁹¹ Photolysis (315 nm) of phenylhydrazone **82** in the absence of thiol yielded 32% of dA. In the presence of GSH (50 mM) a 73% yield of dA was observed, as expected. Formation of dI was also observed, which is consistent with the literature.¹⁹²

Scheme 21. Photochemical generation of dA•.

3. Results and discussion

3.1 Photochemical precursors to generate neutral purine radicals

3.1.1 Generation of neutral purine radicals via homolytic cleavage of N-N and N-C bonds

3.1.1.1 Design and synthesis of precursors

Inspired by the photochemistry of N-(triphenylmethyl)aniline (**65**),^{182, 193} we speculated that the structurally similar tritylated purine nucleosides **83a-c** and **84a-c**

65

may undergo homolytic cleavage of the N-O bonds to yield purine radicals. The tritylated purine nucleosides were synthesized by reacting disilylated dA (**85**) and dG (**86**) with the corresponding trityl chloride **87-89** followed by desilylation (Scheme 22).¹⁹⁴⁻¹⁹⁵ However, the syntheses of compounds **83c**, **84b**, and **84c** were unsuccessful because they were moisture sensitive and decomposed during chromatography. Precursor **83b** could be

isolated but hydrolyzed in aqueous buffer. In contrast, **83a** and **84a** were stable in phosphate buffer and were used for the subsequent photochemical studies.

Scheme 22. Syntheses of precursors **83a-c** and **84a-c**.

Precursors **83a** and **84a** were photolyzed with 300 nm broadband irradiation. Low yields of dA and dG (~18%) were observed under aerobic or anaerobic conditions, and the generation of dA and dG was independent of the presence of β -mercaptoethanol (BME). These results suggested that the photoinduced dissociation of the C-N bonds were likely to be heterolytic (Scheme 23, pathway a). Alternatively, electron transfer between dA \cdot and Ph₃C \cdot (**67**) following the generation of the radical pair is also consistent with the absence

of any effect of BME on the yields of dA and dG (Scheme 23, pathway b). The difference between Steenken's report and our observations may be caused by aqueous solution favoring heterolytic cleavage by stabilizing charged transition states. Furthermore, Steenken et al. pointed out that the electron transfer within the radical pairs is thermodynamically favorable.¹⁸²

Scheme 23. Proposed mechanism for the generation of dA by the photolysis of **83a**.

Considering that the polar C-N bonds in **83a** and **84a** favor heterolytic bond cleavage, we designed precursor **90** (Scheme 24), which has a weak non-polar N-N bond (the BDE of N-N bond in 1,2-diphenyl hydrazine is 45.2 kcal mol⁻¹).¹⁹⁶⁻¹⁹⁹ We envisioned that the non-polar N-N bonds would favor homolytic cleavage and suppress electron transfer within the radical pairs.¹⁹⁸ Although there was no report on the photoinduced bond dissociation of a 1,2-diarylhydrazine, *N*6-aniliny-2'-deoxyadenosine (**90**) was chosen due to its synthetic accessibility. Aromatic nucleophilic substitution on Lakshman's *O*6-

(benzotriazole-1-yl)-2'-deoxyinosine derivatives (**91**) by phenylhydrazine gave **92** quantitatively,²⁰⁰ and the TBS protecting group was removed to provide **90** (Scheme 24).

Scheme 24. Synthesis of N6-anilinyl-2'-deoxyadenosine (**90**).

The anaerobic photolysis of **90** (350 nm, 8 h) generated a trace amount of dA, the yield of which was independent of the presence of BME. In the absence of hydrogen atom donor, diazene **93** was detected. While the mechanism involving heterolytic cleavage is plausible, the generation of **93** suggests that **90** can serve as the reducing reagent for $\text{dA}\cdot$. Furthermore, the photochemistry in the presence of O_2 was complicated by the oxidation of **90** to form **93**.

In order to eliminate the possibility for photooxidation, we designed precursor **3** by introducing an additional phenyl group. We also speculated that the introduction of an additional phenyl group would weaken the N-N bond (the BDE of the N-N bond in tetraphenyl hydrazine is $37.3 \text{ kcal mol}^{-1}$).¹⁹⁹ We also were encouraged to pursue the

photolysis of **3** because condensed phase spectroscopy experiments demonstrated that photoexcited tetraphenylhydrazine and triphenylhydrazine underwent N-N homolytic cleavage.²⁰¹⁻²⁰⁴ Another advantage of hydrazine precursors is that the simultaneously produced diphenylaminyl radical (**69**) is less reactive, due to the low BDE of the N-H bond in diphenylamine **94** (<85 kcal/mol).²⁰⁵⁻²⁰⁶ Therefore, diphenylaminyl radical (**69**) is less likely to induce side reactions in DNA which would be useful when using these precursors in polymer studies.

We attempted to synthesize the precursor via nucleophilic aromatic substitution, which was used in the synthesis of **92** and other *N6*-substituted purines.²⁰⁷⁻²⁰⁸ Nucleophilic substitution on **91** using the hydrochloride salt of 1,1-diphenylhydrazine (**95**) as nucleophile did not yield any desired product (**96**, Scheme 25a).²⁰⁰ Additionally, no product was generated when the reaction was carried out at elevated temperature (80 °C) in 1,2-dimethoxyethane (DME). Because the hydrochloride salt of **95** was not soluble in THF or DME, the reaction was also carried out in methanol, which dissolves the salt of **95** (Scheme 25a). However, no desired product was observed. Following these unsuccessful attempts, we turned our attention to other leaving groups. Reacting **95** with disilylated 6-bromopurine-2'-deoxynucleoside (**97**) which readily reacts with a variety of arylamines,²⁰⁹⁻²¹⁰ did not yield **96** (Scheme 25b). Disilylated *O*⁶-mesitylenesulfonate 2'-deoxyinosine (**98**), which undergoes nucleophilic aromatic substitution when activated by DABCO,²¹¹ also

did not react with **95** (Scheme 25c). These results suggested that the nucleophilicity of **95** may be too weak for the nucleophilic aromatic substitution. The poor nucleophilicity might be attributed to the steric hindrance of two phenyl groups.

Scheme 25. Attempts to synthesize **96**.

Following the unsuccessful attempts with nucleophilic aromatic substitution, we turned our attention to Buchwald-Hartwig amination.²¹²⁻²¹³ A variety of 6-substituted purines and *N*6-amino substituted adenosines have been prepared from **97** using Pd catalysts.²¹⁴⁻²¹⁵ However, there were few reports on the reactions using hydrazines as the

coupling partner with aryl bromides.²¹⁶⁻²¹⁷ Use of Pd(OAc)₂ and BINAP ligand gave only trace amounts of the desired product (**96**) (Scheme 26a).²¹⁸ It has been proposed that bidentate phosphine ligands with large bite angles promote reductive elimination, and thus would improve the yield.²¹⁹ Indeed, switching to Xantphos, a phosphine ligand with wide bite angle and Pd₂dba₃ as catalyst produced **96** in 48% yield (Scheme 26a). Desilylation provided the photochemical hydrazine precursor (**3**).

Scheme 26. Synthesis of precursor **3** and **4**.

Similarly, the corresponding precursor (**4**) for dG(N2-H) \bullet was also synthesized via cross-coupling (Scheme 26b). This was accomplished by protecting the O6 position of disilylated dG with benzyl alcohol via a Mitsunobu reaction. The O6-protected dG (**99**) was brominated according to the method reported by Hopkins et al.²²⁰ Cross-coupling between **100** and 1,1-diphenylhydrazine (**95**) followed by hydrogenolysis and desilylation afforded the desired precursor **4**. It is also worth mentioning that synthesizing **4** via substitution of the 2-fluoro-2'-deoxyinosine derivative (**103**) was unsuccessful, which corroborated the aforementioned poor nucleophilicity of 1,1-diphenylhydrazine (**95**).

3.1.1.2 Photochemical properties of the diphenyl hydrazine type precursors

Hydrazine **3** had a $\lambda_{\text{max}} = 267 \text{ nm}$ ($\epsilon = 1.81 \pm 0.01 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$ in water) and its absorption tailed into the $>300 \text{ nm}$ region at the concentration (100 μM) at which it was present during photolysis. Hydrazine **3** was completely consumed after photolysis for 4 h. dA was the major product detected under all irradiation conditions (Table 2). The only

Table 2. Product analysis for the photolyses of hydrazine 3.

^aAverage \pm std. dev. of 3 experiments.

other product detected was formal recombination product **104** (Scheme 27), which was initially identified by UPLC-MS/MS analysis in the photolysates of **3**. It exhibited (Figure 7b) a molecular ion that had identical m/z as **3** (Figure 7a). However, in contrast to **3** (Figure 7a), fragmentation of the diphenylamino group was not observed (calculated $m/z = 168.0808$, observed $m/z = 168.0809$). Finally, the yield of **104** was independent of the presence of reducing agents or their concentration, and substrate concentration, suggesting that it could result from a radical pair process.

Scheme 27. Proposed mechanism for the formation of recombination product **104**.

Attempted synthesis of **104** via cross-couplings of the disilylated 8-bromo-2'-deoxyadenosine (**105**) with diphenylamine (**94**) was unsuccessful (Scheme 28a).²²¹ Consequently, support for the structural assignment of **104** was obtained via UPLC-MS/MS analysis of photolyzed 8-²H-**3** (Figure 4c), which was prepared from **3** via Et₃N-

catalyzed deuterium exchange.²²² The recombination product formed from 8-²H-**3** (Figure 4d) lacked deuterium, consistent with the proposed structure (**104**, Scheme 27). The formation of this rearranged recombination product is consistent with the homolytic cleavage of the N-N bond (Scheme 27). Structurally similar **106** was synthesized (Scheme 28b), and its extinction coefficient at 260 nm was measured. The extinction coefficient of **106** was compared to that of **3**, whose response factor against thymidine was independently measured to approximate the yield of **104** by HPLC (Table 2).

Figure 7. Mass spectrometric characterization of the photolysis of **3**. (a) **3**, (b) recombination product **104** formed from photolysis **3**, (c) 8-²H-**3**, (d) recombination product **104** formed from photolysis 8-²H-**3**. dR = 2'-deoxyribose.

Scheme 28. Synthesis of the recombination product (**104**) and its analogue **106**.

The yield of dA in the absence of reducing agents was 64%, and the presence of BME did not increase the yield of dA (Table 2). Ferrous ion and PhSH only increased the yield of dA by approximately 10%. Furthermore, in the presence of PhSH, there was an inverse relationship between dA yield and concentration of **3**. We proposed that the precursor (**3**) serves as a reducing agent for dA• and effectively competes with other reducing agents, such as PhSH and ferrous ion. Evidence in support of hydrazine **3** serving as a viable reductant for dA• was obtained from cyclic voltammetry (Table 3). The oxidation potential suggests that **3** is more readily oxidized than dG ($E(dG^{\bullet+}/dG) = 1.49$ V versus NHE in acetonitrile), the most electron rich native nucleotide, and 8-oxo-dG, a DNA lesion that is susceptible to further oxidation (Table 3).¹⁰⁹ However, the yield of dA in the absence of any exogenous reducing agents is >50%, indicating that a species other than **3** also reduces dA•. Given the oxidative nature of dA, it is reasonable to propose that the radical pair also undergoes electron transfer (Scheme 29).

Scheme 29. Proposed mechanism for the generation dA via the photolysis of **3**.

Table 3. Reduction potentials measured by cyclic voltammetry.

Redox couple	E ^a (V)
3^{•+} / 3	0.82
4^{•+} / 4	0.77
8-oxo-dG ^{•+} / 8-oxo-dG	1.16 ⁴¹

^a Versus NHE in CH₃CN.

Photoconversion of **4** was less efficient than that of **3**, requiring 8 h photolysis for complete conversion compared to 4 h for **3**. dG was the major product from the photolysis of **4** (Table 4). Hydrazine **4** is more readily oxidized than **3**, and cyclic voltammetry indicated that the reduction potential of **4** was 0.77 V vs. NHE (Table 3). Therefore, **4** can also serve as the reducing agent for dG(N₂-H)[•]. However, the yield of dG and mass balance in the absence of exogenous reducing agent were closer to 50%, which would be the maximum yield if **4** is the sole reducing agent of dG(N₂-H)[•]. This could reflect less efficient electron transfer within the radical pair formed upon photodissociation (Scheme 30). This correlates with the smaller thermodynamic driving force for dG(N₂-H)[•] reduction (Table 1). Similar to the photolysis of **3**, the presence of PhSH and ferrous ion moderately increased the yields of dG (Table 4). Interestingly, BME, an inefficient trap for dA[•], also increased the yield of dG (Table 4). These observations were attributed to a polarity-matching effect in hydrogen atom transfer reactions (see Section 3.1.2.2).

Scheme 30. Proposed mechanism for the generation dG via the photolysis of **4**.

3.1.2 Generation of neutral purine radicals via tandem Norrish type I β -fragmentation reactions

3.1.2.1 Design and synthesis of the precursors for independent generation of dA•

Based on Newcomb's original report on the generation of aminyl radicals via tandem Barton decarboxylation, β -fragmentation,^{179, 223} we envisioned combining the

Norrish Type I photocleavage of a ketone with β -fragmentation to generate dA• (Scheme 31).⁴² Aminoketone **107** was an attractive potential precursor due to its stability and the reliability of the Norrish Type I photocleavage of benzyl ketones. The feasibility of β -fragmentation from **108** to yield dA• and isobutylene was uncertain, as there were conflicting reports in the literature. Newcomb reported that the rate constant for generating a dialkylaminy radical via ethylene elimination was $\sim 4 \times 10^4 \text{ s}^{-1}$ at 27 °C. However, subsequent experimental and computational experiments argued against aminyl radical formation via alkyl radical β -fragmentation.²²⁴⁻²²⁵ If the rate constant reported by Newcomb was correct, O₂ trapping of the carbon-centered radical ($k[\text{O}_2] \sim 10^6 \text{ s}^{-1}$) would compete with the β -fragmentation. However, it is still possible that **107** would provide a source of dA• under anaerobic conditions.

Scheme 31. Generation of dA• via a tandem Norrish type I reaction, β -fragmentation.

Precursor **107** was readily prepared using the method for synthesizing N6-purine derivatives developed by Lakshman (**91**, Scheme 32).²⁰⁰ β -Aminylketone (**111**) was synthesized using a reported approach.²²⁶ The α -nitrile ketone **109** was synthesized via nucleophilic addition of ethyl phenylacetate and isobutyronitrile. Both the carbonyl group and nitrile group of **109** was reduced by LiAlH₄. The resulting amine was protected with a *t*-butyloxycarbonyl group (Boc) to afford **110**, and the ketone in was restored by oxidation

prior to removing the amine protecting group to generate β -aminoketone (**111**). Displacement of the *O*-benzotriazole group in **91** was carried out at room temperature with **111** to provide the disilylated precursor (**112**), which was deprotected to give **107**.

Scheme 32. Synthesis of precursor **107**.

Photolysis of **107** (0.1 mM) by UV irradiation ($\lambda_{\max} = 350$ nm) did not yield detectable amounts of dA under either aerobic or anaerobic conditions. Low yields of the compound with m/z corresponding to **113** and **114** were identified by LC/MS following photolysis under aerobic conditions (Scheme 32). These products may result from O_2 trapping the intermediates (**115**, **108**) produced upon irradiation. The generation of **114** is consistent with the aforementioned competition between O_2 and β -fragmentation. Similarly, **116** was detected by LC/MS following anaerobic photolysis in the presence of

BME (10 mM). These results suggested that β -fragmentation from **108** is too slow to generate $\text{dA}\cdot$.²²⁴⁻²²⁵

Scheme 33. Products generated from the photolysis of **107**.

Replacing the methylene group in **108** with oxygen (**118**, Scheme 34) increases the thermodynamic driving force for β -fragmentation to $\text{dA}\cdot$ by producing a stronger carbon-oxygen π bond (BDE of $\pi_{\text{C-O}} \approx 80 \text{ kcal mol}^{-1}$, BDE of $\pi_{\text{C-C}} \approx 63 \text{ kcal mol}^{-1}$) and requiring cleavage of a weaker nitrogen-oxygen σ bond (BDE of $\sigma_{\text{C-N}} \approx 73 \text{ kcal mol}^{-1}$, BDE of $\sigma_{\text{N-O}} \approx 50 \text{ kcal mol}^{-1}$).¹⁹⁶ As discussed in Section 2.4.2, methods based on Barton decarboxylation involving carbon-center radical intermediates similar to **105** have been reported.¹⁸⁰⁻¹⁸¹ Furthermore, Begley estimated that the rate constant for a similar β -fragmentation to form a hydroxamate radical (**61**, Scheme 17) is $> 2 \times 10^8 \text{ s}^{-1}$.¹⁸¹ In addition,

more recently, Baran and co-workers used single electron transfer chemistry to generate a carbon-centered radical intermediate that fragmented to yield aminyl radicals.²²⁷ Due to the ease of synthesis, we designed the acyloin type precursor **117** (Scheme 34), which has been reported to undergo α -cleavage upon UV excitation.²²⁸

Scheme 34. Generation of dA• via tandem Norrish type I and β -fragmentation reactions.

We initially attempted a similar strategy used in the synthesis of **107** by reacting hydroxylamine (**121**) with Lakshman's compound (**91**, Scheme 35a).²⁰⁰ The α -bromoketone **119** derived from commercially available isopropyl phenyl ketone was substituted by N-Boc-hydroxylamine to yield **120**. After cleavage of the Boc protecting group, **121** was reacted with **91**. However, no desired product **122** was formed (Scheme 35a). Given that the nucleophilic substitution on brominated ketone with N-Boc-hydroxylamine proceeded effectively, we proposed an alternative synthetic route based on the disconnection of oxygen and the α -carbon of the ketone moiety (Scheme 35b). The disilylated *N*6-hydroxy-2'-deoxyadenosine (**123**) was synthesized via the reaction between hydroxylamine hydrochloride and **97**. The purification of **123** required washing with EDTA in MeOH to remove unidentified metals that bound the product, producing an intensely colored complex.²²⁹ The hydroxyl group of **123** was deprotonated by NaH and reacted with **119** to afford desired product **122** in 20% yield.

Scheme 35. Synthesis of precursor **117**.

dA was the major product generated by the photolysis of **117** under UV irradiation ($\lambda_{\text{max}} = 350 \text{ nm}$). The yield of dA was 48% under anaerobic condition in the absence of reducing agents (Table 5). The presence of 10 mM BME did not increase the yield of dA. This corroborates our hypothesis that BME is an inefficient hydrogen atom donor for dA•.

In contrast, the presence of Et₃N or (NH₄)₂Fe(SO₄)₂ as reductant increased the yields of dA to 78% and 71%, respectively. This is consistent with the generation of dA• during photolysis. In addition, a product with *m/z* corresponding to **124** was identified by UPLC-MS. Although we initially attributed the formation of **124** to recombination of radical dA• and **125**, the mechanism involving Norrish type II reaction was also possible (Scheme 36).²³⁰ The excited carbonyl abstracts the hydrogen atom from N6 generating the 1,4-diradical intermediate **126**, which undergoes an intermolecular recombination to form the Yang-type product (**127**).²³¹ The Yang-type cyclized product (**127**) can then decompose to release acetone and produce **124**.

Scheme 36. Formation of **124** via Norrish type II reaction.

Table 5. Product analysis of the photolysis of 117.

Reducing agent (10 mM)	Yield of dA
-	48%
ascorbic acid	15.6%
dG	52.2%
Fe ²⁺	70.7%
Et ₃ N	78.0%
isopropanol	38.7%

The photolysis in the presence of Et₃N was further investigated by time course experiments. These experiments revealed that the precursor was consumed after 1 h of photolysis, whereas dA grew in over 5 h. We hypothesized two possible causes for this observation: (1) a nonphotochemical reaction of the precursor generates dA; (2) the precursor is converted into other intermediates, which convert to dA photochemically. The possibility of a nonphotochemical reaction was ruled out by an experiment during which the precursor was photolyzed for 1 h and analyzed 4 h after the photolysis. The yield of dA was the same as in the sample analyzed immediately after 1 h photolysis. Furthermore, we were unable to identify any intermediates to support the second hypothesis. Most importantly, the results obtained from the time course experiments cannot be explained by tandem Norrish type I cleavage, β -fragmentation. We believe that the acyloin moiety in **117** may undergo reactions other than Norrish type I reaction, but the process by which this happens is unknown.

Scheme 37. Synthesis of precursor **6**.

Consequently, we designed precursor **6**, in which the phenyl group was replaced by a *t*-butyl group. The Norrish Type I photochemical cleavage of *t*-butyl ketones has been used successfully to generate a number of DNA and RNA carbon radicals in high yield.¹⁸⁴⁻¹⁸⁵ The same strategy for the synthesis of **117** was used in the synthesis of **6** (Scheme 37). β -Ketoester (**128**) was synthesized via a TiCl_4 -catalyzed Claisen-type condensation.²³² The *t*-butyl bromoketone (**130**) was prepared from **129** via decarboxylation and bromination. The yield of **131** via the substitution of **130** by **123** was significantly improved to 71 % by using DMF as the solvent instead of THF . Precursor **6** showed a $\lambda_{\text{max}} = 270 \text{ nm}$ ($\epsilon = 1.20 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) which tails to approximately 350 nm.

Figure 8. Solvent-dependent tautomerization of **6**. (a) Aminyl (**6**) and iminyl (**6-im**) tautomers. (b) ^1H NMR in CDCl_3 (c) ^1H NMR in CD_3CN .

Ketone **6** exists as a mixture of tautomers (Figure 8a). The iminyl tautomer (**6-im**) is slightly favored in CDCl_3 (Figure 8b) but dominates in CD_3CN (Figure 8c) and protic solvents, such as MeOH-d_4 . The protons in the aminyl tautomer have higher chemical shifts in the spectrum relative to the corresponding protons in **6-im**, which is consistent with trends reported in the literature.²³³ The relevance of the tautomeric equilibrium to the photochemistry of **6** is discussed below.

3.1.2.2 Photochemical properties of **6**

Laser flash photolysis of **6** with the 308 nm emission of a nanosecond-pulsed XeCl excimer laser was carried out to obtain direct evidence for the transient formation of the aminyl radical dA•.

Unfortunately, photolysis (~12 mJ/pulse) in several solvents (e.g., acetonitrile, MeOH, aqueous buffer) did not afford any detectable transients. The failure to detect dA• was consistent with the low quantum yield for **6** disappearance ($\Phi = 0.0015$) that was determined using 2-hydroxy-2-methylpropiophenone (**132**) as an actinometer, which led us to explore photosensitization conditions. Addition of low triplet energy sensitizers (e.g. benzophenone) did not yield detectable transients. However, photolysis in the presence of acetone (200 mM in acetonitrile) yielded a prominent peak centered around 340 nm and a broader, weaker peak that stretches from 500-600 nm (Figure 9a). These data are consistent with previously reported spectra of dA•, which also feature a broad absorbance centered around 590 nm.^{32, 234} Since the alkoxyamine **6** is in equilibrium with the oxime ether (**6-im**), we calculated the UV-vis spectra of both the expected aminyl radical dA• and that of its iminyl tautomer (dA•-im) (Figure 9b). These calculations indicate that it is unlikely the observed transient corresponds to the iminyl radical, which lacks a long wave absorption. The calculations, using a N9-methyladenine analog of dA• (**133**) and dA•-im (**133-im**), indicate that the iminyl radical is 13.0 kcal/mol higher in energy in the gas phase than the aminyl radical (Figure 10). This result suggests that the dA•-im will rapidly tautomerize to dA•.

Figure 9. Transient spectroscopic studies of $dA\cdot$. (a) Transient absorption spectrum obtained 40 μ s after photolysis of a solution of (0.2 mM) in acetonitrile containing acetone (200 mM). Inset: the growth of absorption at 340 nm. (b) Calculated absorption spectra for $dA\cdot$ and its iminyl tautomer ($dA\cdot$ -im) (TD-B3LYP/6-311++G(d,p)).

Figure 10. Calculated transition state structures for the fragmentation reactions of **133** and **133-im** (energies given in kcal mol^{-1}).

The accumulation of signal at or around 340 nm was attributed to β -fragmentation of the intermediate alkyl radical **118** to produce dA•. Intermediate **118** is not expected to absorb strongly above 300 nm, and its formation is presumably too fast to detect on the μs timescale. The rate constant for formation of dA• was fit to first order growth kinetics, yielding a rate constant of $(2 \pm 2) \times 10^5 \text{ s}^{-1}$ (Figure 9a); more than 10^4 - and 10^7 -fold slower than the rate of β -fragmentation computed from either **133** or **133-im**, respectively (Figure 10). However, the rate constant derived from the growth rate of dA• is likely underestimated due to the relatively fast concurrent consumption of the radical that suppresses the transient signal. Furthermore, if the rate constant of the β -fragmentation was only $\sim 10^5 \text{ s}^{-1}$, reaction with O_2 would be competitive ($k[\text{O}_2] \sim 10^6 \text{ s}^{-1}$), which does not appear to be the case (see below). Once the absorption at 340 nm reaches a maximum intensity around 80 μs after photolysis, the transient slowly decays with a half-life of ca. 200 μs (Figure 11). This decay could not be fit to a second-order function, indicating that multiple decay paths are available to the radical under these conditions.

In an attempt to slow the decay of the dA• and possibly obtain cleaner decay kinetics we carried out photolyses of **6** in acetonitrile-buffer mixtures. Unfortunately, this led to a significant reduction in signal intensity (Figure 11). This is consistent with the shorter lifetime of the acetone triplet state in aqueous solution as compared to acetonitrile, rendering photosensitization less efficient and precluding generation of radical **105**.²³⁵ This hypothesis is also consistent with acetone sensitized photochemical conversion of **6** during continuous irradiation in various solvent conditions (Table 6). We found that **6** is converted

approximately 3-times more efficiently upon broadband UV-irradiation ($\lambda_{\max} = 350$ nm) in acetonitrile than in phosphate buffer in the absence of acetone. Acetone enhances the photoconversion efficiency in both solvents, notably more than 6-fold in acetonitrile, the conditions under which laser flash photolysis experiments were most successful.

Figure 11. Transient absorption traces of a solution of **6** (0.2 mM) in acetonitrile and different mixtures with buffer (phosphate 10 mM, pH 7.4) in the presence of acetone (200 mM) at 340 nm.

Table 6. Photochemical conversion efficiency of 6 during continuous UV-irradiation.

Solvent	Acetone ^a	Photolysis time (min)	Conversion (%)	Average conversion rate (% min ⁻¹)
Aq. buffer ^b	-	60	30 ± 1	0.5
Aq. buffer ^b	+	30	51.4 ± 0.2	1.7
CH ₃ CN	-	30	45.2 ± 0.2	1.5
CH ₃ CN	+	1	10 ± 1	10

^a[Acetone] = 0.2 M ^bPhosphate (10 mM, pH 7.2)

Although **6** was converted more efficiently in acetonitrile, the product studies involving the photolysis of **6** were carried out in phosphate buffer to mimic the conditions under which dA• would be produced in DNA. Inferential support for the intermediacy of

dA• was obtained from the detection of **134** which was formed by DMPO trapping dA•. Trapping product (**135**) generated by t-butyl radical and DMPO was also observed.²³⁶

Minor amounts of *t*-butyl amide (**136**) and *N*6-*t*-butyl-2'-deoxyadenosine (**137**) were also detected by LC/MS. The former product was observed under aerobic and anaerobic conditions and was likely to result from a competing Norrish Type II reaction similar to that observed in the photolysis of **117**. Product **137** was only detected under anaerobic conditions and was attributed to the recombination of dA• and *t*-butyl radical.

The formation of dA served as the strongest evidence for the formation of dA•. Modest yields of dA were formed following photolysis of **6** in aqueous buffer under aerobic or anaerobic conditions in the absence of exogenous reducing agent (Table 7). The yield almost doubled under anaerobic conditions in the presence of Fe(NH₄)₂(SO₄)₂ (10 mM) and increased further when the concentration of **6** was reduced to 25 μM from 100 μM. The reduced dA yield and mass balance in the absence of reductant could be due to a reaction between dA• and **6**. The inverse relationship between the yield of dA and mass

balance with the concentration of **6** is consistent with this proposal. Under aerobic conditions, dI was also formed in yields (11.6 ± 0.7 %) comparable to those reported by Wagner upon irradiation of **82**. The yields of dI were not affected by the presence of ferrous ion. The mass balance determined by the amounts of **6**, dA, and dI varied from 73 to 86% in the presence of ferrous ion.

Table 7. Effect of reaction conditions on dA yield from the photolysis of **6 in phosphate buffer (pH = 7.2).**

[6] (μM)	O ₂	Reducing agent (mM)	% Yield of dA ^a	% Mass balance ^a

^aAverage \pm std. dev. of 3 experiments.

The lack of an O₂ effect on the yield of dA from **6** is consistent with the slow reaction of dA• with O₂.³⁰ However, this also suggests that O₂ does not compete with β-fragmentation in **118**. To further support this, we set out to search for potential products generated by O₂ trapping of **118**. The trapping of **118** is likely to give rise to products such as **138** and **139** (Scheme 38a). Indeed, a product with the *m/z* matching **138** was detected by LC/MS. We independently synthesized **138** (Scheme 38b). However, the aforementioned product observed upon photolysis of **6** had a different reverse phase HPLC retention time than **138**. The absence of detectable levels of **138** is consistent with rapid loss of acetone. We also attempted to trap **118** with hydrogen atom donor, which was expected to react with **118** to generate **141**. However, **141** was not detected by LC/MS in the presence of BME (as high as 0.5 M) under anaerobic conditions. The absence of **141** was further confirmed by independently synthesizing it (Scheme 38c). These experiments enable us to propose that β-fragmentation is significantly greater than 10⁶ s⁻¹, and are consistent with the Begley's results for hydroxamate radical formation ($k > 2 \times 10^8$, Scheme 17) and the computational studies described above ($k > 2 \times 10^{10}$ s⁻¹).¹⁸¹

Moreover, there is no evidence for BME trapping dA•. Increasing the BME concentration from zero to 0.1 M to 0.5 M does not affect the yield of dA, and a slight decrease in the mass balance is observed (Table 7). In contrast, the presence of cysteine (Cys) and glutathione (GSH) during photolysis of **6** yield modestly higher dA yields and increased mass balances. The greatest dA yield and mass balance are observed when the even more reactive thiophenol (PhSH) is employed. PhSH (10 mM) was even more effective when **6** (0.1 mM) was photolyzed in acetonitrile, where the yield of dA was (90 ± 5 %), and the mass balance was 94 ± 5 % (3 replicates).

Scheme 38. Proposed products generated by trapping of **118** and their independent synthesis

The lower yield of dA in reactions between dA• and thiols other than PhSH cannot be rationalized simply by consideration of the corresponding bond dissociation energies. The thiol bond strength in BME could be as low as 88 kcal/mol, and the BDE of N6-H is greater than 97 kcal/mol in 9-methyladenine.²³⁷⁻²³⁹ Hence, hydrogen atom transfer from BME to dA• is thermodynamically favorable. The slightly more favorable reactivity of dA• with Cys and GSH could be due to a variety of factors, including polarity of the thiol bonds. We suggest that the reactions are kinetically controlled and are a consequence of a polarity mismatch between the electrophilic dA• radical and the polarity of the hydrogen atom donor. Nucleophilic aminyl radicals react readily with alkyl thiols or PhSH.²⁴⁰ The rate constants for their reaction with thiols are comparable to those of their alkyl radical

counterparts.²⁴⁰ However, the aminyl radical in dA• is conjugated to the electron withdrawing purine ring, which increases its electrophilic character. The reactivity of dA• is more similar to an amidyl radical than an alkylamine radical. Amidyl radicals react more rapidly with electron-rich donors, such as Bu₃SnH than even PhSH.²⁴¹ Hence, dA• reacts slowly with thiols other than PhSH because of polarity mismatching between the electrophilic radical and the relatively electronegative hydrogen atom donor.^{240, 242} Unfortunately, testing this hypothesis by examining the reaction of dA• with less electronegative hydrogen atom donors, such as Bu₃SnH is not possible due to the incompatible solubilities of **6** and the tin hydride. Moreover, attempts to measure the rate of reduction of dA• by thiophenol were unsuccessful. The phenylthiyl radical absorbs in the same region as dA• ($\lambda_{\text{max}} = 450 \text{ nm}$),²⁴³ which may be produced in this experiment by the desired hydrogen atom transfer, hydrogen atom donation to the acetone triplet, and photolysis of residual diphenyldisulfide in the thiophenol.

Furthermore, with the success in utilizing acetophenone to sensitize precursor **7** (see Section 3.1.2.3), we demonstrated that acetophenone was also able to sensitize the photolysis of **6**. In the presence of 1% (v/v, 86 mM) acetophenone, the photolysis in phosphate buffer containing 10% acetonitrile resulted in $75 \pm 2 \%$ conversion of **6** in 5 min. While sensitization by acetone (2% v/v) led to less than 10% conversion of the precursor within 5 min. Compared to the conditions under which the transient spectra of dA• was obtained (200 mM acetone in acetonitrile, Table 6), the consumption of **6** when sensitized by acetophenone in 90% aqueous buffer was 1.5-times faster. In addition, the fidelity of **6** was not affected by acetophenone sensitization, and $82 \pm 3\%$ of dA was generated in the presence of PhSH (10 mM). Hence, we expect that using acetophenone as sensitizer will

enable us to carry out transient spectroscopic studies in buffer-acetonitrile mixtures which are a better approximation of pure aqueous buffer, where DNA naturally exists.

3.1.2.3 Synthesis of the precursors for independent generation of dG(N2-H)•

Based on the same strategy for the generation of dA•, we designed precursor **7** to generate dG(N2-H)• photochemically (Scheme 39). We attempted to synthesize **142** from *O*6-benzyl-2-bromo-2'-deoxyinosine (**100**) under the same conditions for synthesizing *N*6-hydroxy-2'-deoxyadenosine (**123**, Scheme 35). However, the reaction only yielded a trace amount of **142** after 24 h, which was attributed to the low reactivity of electron-rich guanine towards nucleophilic aromatic substitution. Furthermore, carrying out the reaction in DMF under 100 °C led to hydrolysis of the bromide, which may be caused by water residue in DMF. Consequently, we used dioxane as the solvent, which allowed the reaction to be carried out under elevated temperature (100 °C) without hydrolyzing the substrate. The reaction was still inefficient and required 36 h to complete. The ensuing substitution with **130** using NaH as the base was unsuccessful and generated an unidentified side product. By switching the base to Cs₂CO₃, the formation of this side product was avoided, and desired product **143** was obtained with 70% yield. The same reaction condition was also tested for the synthesis of the dA• precursor and gave 72% yield, which was comparable to yield obtained when NaH was used as the base (Scheme 37). The benzyl protecting group was removed by hydrogenolysis while the N-O bond remained intact to generate **144**, and the ensuing desilylation afforded the precursor **7**.

Scheme 39. Synthesis of precursor 7.

3.1.2.4 Photochemical properties of 7

Precursor **7** shows a $\lambda_{\text{max}} = 260 \text{ nm}$ ($\epsilon = 1.22 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$ in water), which tails above 300 nm. The photolysis of **7** was less efficient than that of **6**, and the conversion was only 10% even after 8 h photolysis at 350 nm. The quantum yield of the disappearance of **7** ($\Phi = \sim 0.0018$) was also determined using 2-hydroxy-2-methylpropiophenone (**132**) as an actinometer, and this quantum yield is similar to that of **6**. However, **7** has a lower absorbance than **6** above 300 nm, which exacerbates the inefficient photochemistry. Inspired by the sensitization used during the photolysis of **6**, we used acetone (2% v/v, 150 mM) to sensitize the reaction and achieved 63% conversion after 8 h. The yield of dG and mass balance under different conditions are shown in Table 8. When the precursor was photolyzed in the absence of reducing agents or oxygen, the rate of conversion was doubled, and the mass balance was

~50%. This is consistent with the proposal that the precursor can serve as a reducing reagent for dG(N2-H)•. In contrast to **6** (Table 7), both BME and PhSH trap dG(N2-H)• and form dG. This can be rationalized by the fact that guanine is more electron-rich than dA, and the corresponding nitrogen radical is less electrophilic, thus has a lower energy barrier to react with electronegative hydrogen atom donors, such as thiols. This observation further corroborates our hypothesis regarding the polarity matching between hydrogen atom donors and neutral purine radicals.

Table 8. Effect of reaction conditions on dG (100 μM) yield from the photolysis of 7 in the presence of acetone (2% v/v) as sensitizer.

O ₂	Reducing agent (mM)	% Yield of dG ^a	% Mass balance ^a
-	Fe ²⁺ (10 mM)	85 ± 2 %	90 ± 1 %
-	PhSH	89 ± 3 %	93 ± 1 %
-	BME	87 ± 2 %	91 ± 2 %
-	None	53.2%	53.2%
+	None	35 ± 2 %	44 ± 3 %

^aAverage ± std. dev. of 3 experiments.

Despite the success in utilizing acetone to sensitize the photolysis of **7**, the efficiency of the photochemistry was still too low for LFP studies. In order to improve the photolysis efficiency, we investigated photolysis in the presence of other photosensitizers. Acetophenone was a promising candidate due to its efficient intersystem crossing, long triplet lifetime, and relatively high triplet energy.²⁴⁴⁻²⁴⁶ Anaerobic photolyses were carried out in the presence of acetophenone (1% v/v, 86 mM), and the consumption of the precursor was significantly accelerated. The sensitization efficiency is proportional to the percentage of acetonitrile in phosphate buffer (Table 9). In the presence of 100 mM BME,

the photolysis of **7** quantitatively yielded dG. This suggested that the fidelity of the photochemistry was not affected by the sensitization.

Table 9. Effect of acetonitrile on the conversion of **7 (1 mM) within 30 min in the presence of acetophenone (1% v/v).**

3.1.2.5 Attempts to generate dG(N2-H)• via intramolecular sensitization

Encouraged by the success of the intermolecular sensitization of the Norrish type I photocleavage of **6** and **7**, we set out to explore the possibility of sensitizing the Norrish reaction intramolecularly. Intermolecular sensitization is not suitable for polymer studies due to the generation of diffusible excited ketone molecules. It has been reported that acetone and benzophenone damage DNA photochemically.²⁴⁷⁻²⁴⁸ Intramolecular sensitization limits the possibility of undesirable photooxidation of DNA and thus is potentially useful for polymer studies. There is precedence to suggest that this could work. Intramolecular energy transfer from ketones have been reported.²⁴⁹ For instance, Wagner et al. reported intramolecular photosensitization of the pinene–ocimene rearrangement using a tethered *p*-alkoxy acetophenone.²⁵⁰

Scheme 40. Attempted synthesis of t-butyl ketone moiety in precursor **145**.

We designed precursor **145**, in which the acetophenone moiety is tethered to the *t*-butyl ketone moiety via an oxymethylene linkage. The *p*-hydroxymethyl acetophenone (**148**) was synthesized according to a report in the literature (Scheme 40a).²⁵¹ The *t*-butyl ketone moiety was synthesized from commercially available 2,2,4-trimethyl-1,3-pentanediol (**149**). The secondary alcohol was selectively oxidized via rhenium-catalyzed oxidation using methyl sulfoxide as an oxidant in the presence of ethylene glycol.²⁵² The β -hydroxy ketone (**150**) was brominated and subsequently converted to the corresponding tosylate **152**. The bromination was carried out at this stage to avoid the undesirable bromination of the acetophenone moiety. The nucleophilic substitution was carried out between **148** and **158** in hopes of forming **153** because the primary carbon is less hindered and may be more reactive. However, the bromine-substituted product (**134**) was the only product isolated (Scheme 40b). This observation suggests that the α -bromo group was more prone to react with nucleophiles.

Consequently, we modified our synthetic strategy to form the O-C bond between the guanine moiety (**155**) and the α -bromo- β -tosylate ketone (**152**) prior to installation of the acetophenone moiety (Scheme 41). Since the desired product **156** only has the tosylate to react with **148**, the possibility of the aforementioned side reaction is eliminated. The hydroxylamine functionalized nucleoside was synthesized via a pathway similar to that used in the synthesis of **142** (Scheme 39). However, β -(trimethylsilyl)ethyl was chosen as the protecting group for O6, because we anticipated that the hydrogenolysis condition would be incompatible with the oxymethylene linkage in **145**. The exocyclic amine group of O6- β -(trimethylsilyl)ethyl-2'-deoxyguanosine (**157**) was converted to fluorine via the method reported by Spratt et al.²⁵³ The TBDMS group remained intact during the

fluorination. The 2-fluoro-2'-deoxyinosine derivative **158** was more reactive than the 2-bromo-O6-benzyl-2'-deoxyinosine (**142**, Scheme 39), and the substitution reaction to generate **155** was complete in 12 h. Unfortunately, the reaction between **155** and **152** did not yield the desired product (**156**) but instead provided the cyclized compound **159** (Scheme 41).

Scheme 41. Attempted synthesis of precursor **145**.

Consequently, we pursued an alternative synthetic strategy, in which the construction of the oxymethylene was achieved by reacting the hydroxy group of **163** with *p*-chloromethyl acetophenone (**164**, Scheme 42). The β -hydroxy ketone (**150**) was brominated following the protection of the hydroxyl group as its benzyl ether. The benzyl protection prevented the hydroxyl group from acting as a nucleophile during the substitution reaction between **161** and **155**. However, the bromination was low-yielding because the benzyl protecting group was labile under oxidative conditions. After the *t*-butyl ketone moiety is coupled to **155**, the hydroxy group was unmasked by hydrogenolysis (**163**). The *p*-chloromethyl acetophenone **164** was prepared by Wacker-type oxidation of *p*-chloromethyl styrene.²⁵⁴ The reaction between **164** and **163** generated the protected precursor **165**, which was deprotected using TBAF to afford the precursor **145**.

Scheme 42. Synthesis of precursor **145**.

The photolysis of precursor **145** did not generate dG under any conditions, which included the presence or absence of O₂, as well as hydrogen atom donor (BME, 10 mM). UPLC-MS analysis indicated that the major product generated from the anaerobic photolysis was **166**, which was likely to have resulted from the photoinduced hydrolysis of the benzyloxy group. These results suggest that a more chemically robust linkage is

needed in order to test our proposal regarding the intramolecular sensitization of Norrish type I reaction.

3.1.3 Naphthalimide type precursors for the generation of neutral purine radicals

3.1.3.1 Design and synthesis of precursors for the independent generation of dG(N1-H)•

dG(N1-H)• has two major resonance forms: the oxygen-centered radical **167** and the nitrogen-centered radical **168**. Since reports on installing heteroatom modifications at the N1 position are limited,²⁵⁵ we focused our efforts on developing precursors in which a cleavable group is bonded to the O6 position of the guanine ring.

Based on the photochemistry of alkoxy-4-arylthioazole-2(3)-thiones (**38**) reported by Hartung and co-workers, we designed precursor **169**.¹⁶⁶ The anticipated photochemistry of this precursor is based on the principle utilized by Gimisis (**77** and **79**, Scheme 20).¹⁸⁹ We envisioned that **169** would be more synthetically accessible than **77** because N-hydroxy-thiazolethiones demonstrated better selectivity for O-substitution versus S-substitution compared to N-hydroxypyridine-2(1H)-thione.^{162, 166} In addition, it has been reported that alkoxy-4-arylthioazole-2(3)-thiones are cleaner sources for alkoxy radicals.¹⁶⁸ N-hydroxy-4-(*p*-chlorophenyl)thiazole-2(3H)-thione (**172**) was synthesized according to the literature (Scheme 43a).¹⁶⁶ The nucleophilic aromatic substitution was carried out on O6-sulfonylated 2'-deoxyguanosine (**173**) activated by DABCO. However, the desired product was not formed under this condition (Scheme 43b). Interestingly, **173**, which readily reacts with DABCO to yield a polar salt (**175**), is mostly unreacted under this condition. This result suggests that there is a side reaction, possibly **172** reacting with DABCO. To circumvent this side reaction, O6-benzylthiazole-2'-deoxyguanosine (**176**) was used as the substrate to react with **172**. At room temperature, no reaction was observed after 24 h. When the reaction was carried out at 65 °C, a small amount of side product **177** was generated (Scheme 43c). The assignment of the structure was based on the chemical shift of the proton on the thiazole ring. In the desired product (**174**), the chemical shift of this proton was expected to be around 6.5. However, the observed chemical shift of this proton was 7.66, which was consistent with the reported chemical shift for N-oxides.¹⁶⁶ This is surprising given the reported selectivity of the nucleophilic substitution.¹⁶⁶ However, we cannot rule the possibility that elevated temperature reduces the chemoselectivity. It is also possible that the initially formed **174** tautomerizes to **177** at higher temperature.

Scheme 43. Attempted synthesis of precursor **158**.

After the unsuccessful attempts to synthesize precursor **169**, we turned our attention to the N-aryloxy-naphthalimide **5** because compounds with similar structure (e.g. **44**, Scheme 44) undergo efficient N-O bond cleavage under UV excitation.¹⁷¹⁻¹⁷² Precursor **5** was synthesized by reacting N-hydroxy-naphthalimide (**178**) with **173** activated by DABCO (Scheme 44). When the reaction was carried out in DME, no product was observed. This was attributed to poor solubility of **178** in DME. Switching the solvent to DMF, in which **178** was readily soluble, significantly improved the yield. Upon removing the TBMDs protecting group, precursor **5** was obtained. The UV spectrum of **5** shows absorption at 287 nm ($\epsilon = 1.1 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) which arises from the guanine, and another at 346 nm ($\epsilon = 1.72 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) which is attributed to the naphthalimide moiety.

Scheme 44. Synthesis of precursor **5**.

3.1.3.2 Photochemical properties of **5**

The photochemistry of **5** was investigated under anaerobic and aerobic conditions. When photolyzed in the absence of O₂, **5** is completely consumed in approximately 2 min. The presence of 10 mM BME increased the yield of dG from 52 ± 2% (yield of dG in the absence of reducing agents) to nearly quantitative. UPLC-MS/MS analyses suggested that naphthalimide (**180**) was the other major photolysis product. This observation, as well as the lack of formation of **178** are consistent with homolytic N-O bond cleavage and exclude the generation of dG via hydrolysis (Scheme 45). Interestingly, the yield of naphthalimide determined by HPLC was quantitative and independent of the presence of BME. This observation is important to understand the photochemistry of **5** (see below). The quantum yield of the disappearance of **5** ($\Phi = 0.03$) was determined using N-hydroxynaphthalimide triflate as actinometer.¹⁷¹⁻¹⁷² The quantum yield of **5** is 20 times higher than that of precursors **6** and **7**. This increased quantum yield and the high absorbance around 350 nm ($\lambda_{\text{max}} = 346 \text{ nm}$, $\epsilon = 1.72 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) contribute to the rapid conversion of the precursor **5**.

Scheme 45. Proposed mechanism for the generation of dG(N1-H)• from photolysis of **5** and production of dG in the presence of BME.

The anaerobic photolyses in the absence of BME generated approximately 50% dG. Naphthalimide (**180**) was formed quantitatively. To explain this result, we propose that the precursor served as the reducing agent of dG(N1-H)• and naphthalimidyl radical (**181**, Scheme 46). Furthermore, to balance the equation, we postulated that the remaining 50% of the guanine would be converted into four-electron oxidized guanines, such as dSp and dGh (Scheme 46). We propose that in the absence of reducing agents, UV-excited **5** initially undergoes homolytic cleavage of the N-O bond to generate dG(N1-H)• and naphthalimidyl radical (**181**). The naphthalimidyl radical can oxidize another molecule of

precursor **5** to generate the radical cation **182** and naphthalimide (Scheme 47). However, we cannot rule out the possibility that dG(N1-H) \bullet oxidizes **5**. The fragmentation of **182** and subsequent hydration result in the formation of 8-oxo-dG and naphthalimidyl radical. Given the low oxidation potential of 8-oxo-dG, both dG(N1-H) \bullet and **181** can be reduced by 8-oxo-dG, and 8-oxo-dG is oxidized to generate product such as dGh and dSp. Admittedly, the proposed reaction between 8-oxo-G \bullet with dG(N1-H) \bullet or **181** may not be favorable given the concentration of these species.

Scheme 46. Generation of four-electron oxidized dG during the anaerobic photolysis of **5** in the absence of BME.

To support the proposed mechanism, the photolysis of **5** was carried out in the presence of two equivalents of 8-oxo-dG. Indeed, the addition of 8-oxo-dG restored the quantitative formation of dG observed under anaerobic conditions, and one equivalent of 8-oxo-dG was consumed. This result supports the proposal that 8-oxo-dG is formed as an intermediate during anaerobic photolysis in the absence of reducing agent (BME).

Additional support for the mechanism was obtained by identifying the proposed 4 electron oxidized forms of dG. This was facilitated by Burrow's previous report on the separation

Scheme 47. Proposed mechanism for the generation of dGh and dSp from the anaerobic photolysis of **5** in the absence of BME.

and identification of these products.²⁵⁶ The photolysates were initially analyzed by C₁₈-reversed phase HPLC, and the void volume containing the polar four-electron oxidized guanines was collected. The void volume was then analyzed by UPLC-MS equipped with a Hypercarb column. The UPLC-MS/MS revealed dSp and dGh, which was consistent with the proposed mechanism (Figure 12, EIC of molecular ion of spiroiminodihydroantoin (Sp) was used to improve

signal to noise ratio). The yields of dSp and dGh were qualitatively higher for the photolyses carried out in the presence of 8-oxo-dG as expected (Figure 12b, 12d).

Figure 12. UPLC-MS/MS analysis of the anaerobic photolysis of precursor **5**. (a) Extracted-ion chromatogram (EIC) of Sp (calculated $m/z = 184.0465$, observed $m/z = 184.0468$) generated during the photolysis in the absence of 8-oxo-dG (0.2 mM). (b) EIC of Sp (calculated $m/z = 184.0465$, observed $m/z = 184.0468$) generated during the photolysis in the presence of 8-oxo-dG (0.2 mM). (c) EIC of dGh (calculated $m/z = 274.1146$, observed $m/z = 274.1143$) generated during the photolysis in the absence of 8-oxo-dG (0.2 mM). (d) EIC of dGh (calculated $m/z = 274.1146$, observed $m/z = 274.1143$) generated during the photolysis in the presence of 8-oxo-dG (0.2 mM).

When the photolyses were carried out in the presence of O_2 , the rate of consumption of precursor was significantly decreased. This is consistent with the report that the triplet excited state of naphthalimide is efficiently quenched by O_2 to yield singlet O_2 .²⁵⁷ In the absence of thiol, the precursor was consumed in 4 h, and only about 10% of dG was

generated. We proposed that the low yield of dG was caused by the reaction between singlet oxygen, produced from excitation of the phthalimide, and dG.²⁵⁸ This proposal was supported by the observation that the yield of dG was 37% based on conversion when **5** was photolyzed for 2 h. In the presence of thiol, the precursor was consumed within 1 h, and the yield of dG was essentially quantitative. Extended photolysis in the presence of O₂ led to the reduction of the yield of dG, possibly due to the singlet oxygen generated reacting with dG. These observations also suggested that BME may reduce photoexcited **5**, which led to faster consumption of the precursor (Scheme 45).

3.1.3.3 Synthesis of the precursors for the independent generation of nitrogen-centered neutral purine radicals

Encouraged by these results, we proposed that **183** and **184** (Scheme 48) may serve as more efficient precursors dA• and dG(N2-H)•,

respectively. Precursor **183** was prepared by reacting 1,8-naphthalic anhydride with disilylated *N*6-amino-2'-deoxyadenosine (**185**) in THF at reflux, followed by desilylation (Scheme 48a). Similarly, precursor **184** was prepared by reacting 1,8-naphthalic anhydride with disilylated *N*2-amino-*O*6-*p*-nitrophenylethyl-2'-deoxyadenosine (**187**, Scheme 48b). The *p*-nitrophenylethyl protecting group was removed by treating with DBU, and subsequent desilylation afforded precursor **184**. The UV spectrum of **183** shows UV-absorption maximum at 261 nm ($\epsilon = 2.04 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) which arises from the adenine, and a maximum at 346 nm ($\epsilon = 1.72 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) which is attributed to the naphthalimide moiety. Similarly, **184** shows absorption maxima at 282 nm ($\epsilon = 1.08 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$) and

346 nm ($\epsilon = 1.64 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$). Unfortunately, anaerobic photolyses of **183** and **184** in the presence of hydrogen atom donor for 4 h did not lead to any consumption of the precursors or the generation of their corresponding 2'-deoxynucleosides.

Scheme 48. Synthesis of precursor **183** and **184**.

3.2 Reactivity of dA• in DNA

3.2.1 Synthesis of DNA containing precursors 3 and 6

Precursors **3** and **6** are compatible with solid phase oligonucleotide synthesis conditions. Phosphoramidites **191** and **193** were synthesized according to standard procedures and were incorporated in oligonucleotides (Scheme 49). Commercially available fast deprotecting phosphoramidites were used for the synthesis. Deprotection of oligonucleotides containing **6** was performed with concentrated NH_4OH at room temperature for 16 h.

Scheme 49. Synthesis of phosphoramidite **191** and **193**.

3.2.2 Effects of precursors on the T_m 's of duplex DNA

The T_m of a dodecameric duplex containing **3** (**194a**, 29.2 °C) was decreased significantly compared to an otherwise identical one containing dA (**194b**, 49.6 °C) in place of **3**. Similarly, **6** decreases the T_m of the dodecameric duplex from 49.1 °C (**195b**) to 35.8 °C (**195a**). This will not detract from the utility of **3** and **6** as tools for producing dA• in DNA since the lifetime of the radical (4.0 ± 1.0 ms)²⁵⁹ is long compared to the timescale of conformational changes within the helix.²⁶⁰

3.2.3 Traceless tandem lesion formation initiated by dA•

3.2.3.1 dA• does not initiate hole migration in DNA

Based on pulse radiolysis experiments on single-stranded oligodeoxynucleotides, O'Neill and co-workers propose that dA• oxidizes dG via electron transfer.⁹⁴ This electron transfer is thermodynamically favorable given the redox potential of dA• (1.42 V versus

NHE in water at pH 7) and dG• (1.29 V versus NHE in water at pH 7). However, it is also proposed that the deprotonation of dA^{•+} (pK_a ≤ 1) to dA• attenuates hole transfer.²⁰ Duplexes **196-200** were designed to probe for hole migration from dA• by incorporating a dGGG sequence proximal to the site of radical generation. Damage at the 5'- and central dG's within a dGGG triplet is characteristic of hole migration. Holes that migrate to dGGG triplets predominantly localize at the 5'- and middle-dG.¹⁴² Approximately 10% of these holes react with water and O₂ to form DNA lesions.¹³ These damages are detected by inducing cleavage with reagents known to react at various types of modified nucleotides, followed by denaturing PAGE analysis. Piperidine treatment with or without prior oxidation by Na₂IrCl₆ cleaves DNA at various sugar and nucleobase modifications at different rates.²⁶¹⁻²⁶² To probe the formation of 8-oxo-dG, piperidine treatments are carried out in the presence of BME, which prevents cleavage at 8-oxo-dG by inhibiting further oxidation of 8-oxo-dG to more labile lesions, such as dSp and dGh.^{261,263} The base excision repair enzyme formamidopyrimidine glycosylase (Fpg) cleaves DNA at a variety of modified purines, abasic sites, and some pyrimidines.²⁶⁴⁻²⁶⁶

Applying these diagnostic reactions to photolyzed 5'-³²P-**196** (Figure 13a-b) and 5'-³²P-**197** (Figure 13c-d), the O₂-dependent formation of modified nucleotides was detected, and the yields in 5'-³²P-**196** was 10-fold greater than those in 5'-³²P-**197**. (If not mentioned otherwise, the strands containing the modified nucleotides in each duplex were radiolabeled.) For instance, Fpg yielded 28.2 ± 0.5% strand scission at G₁₁ in photolyzed 5'-³²P-**196** and 2.9 ± 0.3% (G₁₂) in 5'-³²P-**197**. We initially considered the possibility that the triplet excited state of t-butyl ketone was quenched by DNA in a sequence-dependent manner, and the conversion of **6** in **197** is lower than that in **196**, which led to a lower yield of strand damage. However, UPLC analysis following nuclease digestion showed similar conversions of **6** (~80%, Appendix Figure 1, 2) upon photolysis (8 h) of **196** and **197**. This result suggests that the disparity in strand cleavages was not induced by the difference of conversion of precursor **6** in these two duplexes but is caused by sequence-dependent strand damage formation (see below).

Figure 13. PAGE analysis of oxygen-dependent strand damage in 5'-(GT) sequences. Autoradiogram of (a) aerobic photolysis of 5'-³²P-196, (b) anaerobic photolysis of 5'-³²P-196, (c) aerobic photolysis of 5'-³²P-197, (d) anaerobic photolysis of 5'-³²P-197 followed by chemical and enzymatic treatments.

Neither direct strand scission or damage at the 5'- or central dGs in the dG-triplet was observed in either sequence. These results suggested that hole migration did not occur in these two duplexes. In addition, hole migration was not observed in duplexes **198-200** (Appendix Figure 3-5). Oxidation in irradiated **196** and **197** at the 3'-terminal dG within the respective dGGG-triplets is mechanistically significant and eliminates hole injection from dA•, despite thermodynamically favorable dG oxidation by dA•.⁴ In contrast to the proposal by O'Neill, our observations are consistent with computational studies demonstrating that dA• attenuates hole migration.^{21, 267}

3.2.3.2 dA• Initiates tandem lesion formation when flanked by a 5'-d(GT) sequence

The major cleavage site at dG₁₁ in 5'-³²P-**196** was accompanied by smaller amounts of piperidine-induced cleavage at T₁₂ ($8.2 \pm 0.2\%$). This result suggests that the initially formed purine radical may react with the 5'-adjacent pyrimidine, and ultimately give rise to a tandem lesion involving dG. If the observed damage is caused by two separate oxidative damage events, the observed strand cleavage should be independent of which terminus of an oligonucleotide is labeled with ³²P (Figure 14a).

Figure 14. Schematic demonstration of detection of the tandem lesion by labeling the 5'-end or the 3'-end of DNA. (a) Expected cleavage patterns of piperidine (Pip.) treatment if the strand cleavages are caused by two separate damage events. (b) Expected cleavage patterns of tandem lesions induced by piperidine (Pip.) treatment X and Y are alkaline labile and are completely cleaved by piperidine treatment.

If 5'-dGT tandem lesions are formed, greater strand damage at the corresponding thymidine should be observed in $3'-^{32}\text{P}$ -labeled substrates compared to those labeled at their 5'-termini because damage at the 5'-adjacent dG prevents detecting damage at the pyrimidine in $5'-^{32}\text{P}$ substrates (Figure 14b). Indeed, piperidine treatment of photolyzed $5'-^{32}\text{P}$ -196 yielded $11.9 \pm 0.2\%$ cleavage at dG₁₁ and $8.2 \pm 0.2\%$ at T₁₂ (Figure 13a, 16), but the preference is reversed in $3'-^{32}\text{P}$ -196 (dG₁₁, $4.0 \pm 0.2\%$; T₁₂, $14.6 \pm 0.9\%$, Figure 15, 16). These results suggest that the observed strand damage is indeed part of a tandem lesion.

Figure 15. Identification of tandem lesion formation in photolyzed 3'-³²P-196. (a) Autoradiogram of aerobic photolysis of 3'-³²P-196 followed by chemical and enzymatic treatments. (b) Piperidine-induced cleavage in photolyzed 196. The values presented are the ave. ± std. dev. of 3 replicates.

The generality of this sequence requirement for tandem lesion formation was examined using several duplexes in which the local sequence was varied. Tandem lesions were observed in duplexes 201-203 (Figure 16, Appendix Figure 6-9). The yields of

tandem lesion formation in **196**, **201**, and **202**, which only differ by a single base at the position most remote from dA• in a 5-nucleotide span (5'-d(XGG₁₁T₁₂**6**)) correlate with the ionization potential of 5'-d(XGG₁₁) sequences. A plot of the natural logarithm of the strand cleavage against the calculated ionization potentials of the trinucleotide sequence reveals a linear correlation (Figure 17a). Similarly, the amounts of oxidative damages on T₁₂ can be plotted against the trinucleotide ionization potentials if we assume that all the damages on G₁₁ are transferred via T₁₂, and the overall oxidative damage on T₁₂ is the sum of strand cleavage at T₁₂ and G₁₁ detected by PAGE. The correlation between the ionization potential of flanking sequences and the amounts of oxidative damages on T₁₂ is evident (Figure 17b). Overall, these data show that the extended π -system affects the redox properties of DNA.

3.2.3.3 Characterization of the structure of the tandem lesion

3.2.3.3.1 Chemical and enzymatic assays

Insight into the identity of the damaged nucleotides was obtained by a variety of chemical and enzymatic assays. The modification at dG_{11} was labile to Fpg, and the presence of BME prevented piperidine induced cleavage (Figure 13a). These observations suggest that 8-oxo-dG is likely to be the major product at dG_{11} in **196**. The reaction of photolyzed $5'^{32}P$ -**195a** with aldehyde reactive probe (ARP) produced a product (8.1 ± 0.5 %) that migrated more slowly in a denaturing polyacrylamide gel (Figure 18a). Furthermore, $NaBH_4$ treatment of $5'^{32}P$ -**196** photolysate prior to piperidine cleavage eliminated strand scission at this position (Figure 18b, 0.4 ± 0.1 %). These observations are consistent with the formation of a piperidine labile carbonyl-containing compound at the thymidine bonded to the 5'-phosphate of dA^\bullet , and 5-fdU was a good candidate for this

product. The reduction of 5-fdU by NaBH₄ would lead to the formation of 5-hmdU, which is not labile to piperidine and is consistent with observation.²⁶⁸⁻²⁶⁹

Figure 18. Chemical assays to determine DNA lesion(s) formed at T₁₂. (a) aerobic photolysis of 5'-³²P-**195a** followed by derivatization using ARP. (b) aerobic photolysis of 5'-³²P-**196** followed by piperidine treatment and NaBH₄/piperidine treatment.

3.2.3.3.2 Characterization of the structure of the tandem lesion by UPLC-MS/MS

More definitive identification of the tandem lesion was obtained by UPLC-MS/MS analysis of photolyzed **195a**. As discussed in Section 2.4, UPLC-MS/MS is a powerful method for identifying nucleic acid modifications.²⁷⁰ It is most frequently used to identify isolated lesions following enzyme digestion of the DNA.²⁷¹ However, DNA lesion location is lost upon enzyme digestion. Tandem lesions have been identified in this manner as well by taking advantage of their resistance to the enzyme digestion conditions and/or covalent bonding between nucleotides.^{149, 151-152, 156} Analysis of intact oligonucleotides using

collision-induced dissociation (CID) is a powerful yet underutilized method for DNA lesion detection.²⁷²⁻²⁷⁴ The commonly used HOAc-TEA (TEAA) ion-pairing system provides excellent separation of oligonucleotides.²⁷⁵ However, it is not compatible with LC-MS/MS due to the high boiling point of acetic acid, which leads to ion suppression. We took advantage of the HFIP-TEA ion-pairing system.²⁷⁵ The low boiling point and relatively weak acidity of HFIP provides for rapid evaporation during ionization and improves the signal strength in the mass spectrometer. In addition, utilization of collision-induced dissociation (CID) provides oligonucleotide sequence information. DNA molecules mainly fragment to w-series ions and [a - B]-series ions during CID (Scheme 50).²⁷⁴ [a - B]-Series ions start from [a₂ - B₂], because [a₁ - B₁] fragment is essentially furfuryl alcohol, which does not contain any DNA sequence information.

Scheme 50. CID induced fragmentation of DNA generating w-series ions and [a - B]-series ions.

(X = 8-oxo-dG; Y = 5-hmdU)

The crude photolysate of **195a** was analyzed by UPLC-MS/MS, and the major product observed was that resulting from the reduction of $\text{dA}\cdot$ (**204**). This is consistent with the denaturing PAGE analysis of photolyzed **196**, in which a low yield of strand cleavage was observed where **6** resided. Moreover, we observed a product with $m/z = 3688.8921$ (Figure 19) that is consistent with the expected mass for the tandem lesion containing 5'-d[(8-oxo-dG)-(5-fdU)] and dA at the position where $\text{dA}\cdot$ (**207**) is generated (**205**, calculated $m/z = 3688.6137$).

Figure 19. UPLC-MS/MS analysis of the photolysis of **195a**. (a) Total ion chromatogram (TIC) of the photolysate of **195a**. (b) Deconvoluted mass spectrum of **205**.

Furthermore, the treatment of the photolysate with NaBH_4 yielded a new product (**206**) that was two mass units higher than **205** (Figure 20, $m/z = 3690.9253$). This is consistent with the denaturing PAGE analysis (Figure 18b) and further supports the presence of 5-fdU, which is reduced to 5-hmdU by NaBH_4 . We also tried to derivatize 5-fdU using Girard reagent T,²⁷⁶ but the attempts were unsuccessful.

Figure 20. UPLC-MS/MS analysis of the photolysate of **195a** treated with NaBH_4 . (a) Total ion chromatogram (TIC) of the photolysate. (b) Deconvoluted mass spectrum of **206**.

Finally, the collision-induced dissociation (CID) spectrum of the ion corresponding to $z = 3$ of **205** (Figure 21, Appendix Figure 16) was obtained. The fragment containing 8-oxo-dG ($[\text{a}_5 - \text{B}_5]^-$) and the intact tandem lesion ($[\text{a}_6 - \text{B}_6]^-$) was observed. Although the w-series ions containing individual modified DNA lesions were not observed, we detected the fragment containing the entire tandem lesion (w_9^{2-}). The fragmentation is consistent with the proposed structure of the tandem lesion **206** (Table 10).

3.2.3.4 Mechanism of tandem lesion formation

3.2.3.4.1 Hydrogen atom abstraction initiates tandem lesion formation

The strand damage in 5'-³²P-**197** was inefficient despite the presence of a local dGGG sequence that has a relatively favorable oxidation potential.⁶⁵ Furthermore, the fact

that tandem lesion (**207**) contains 5-fdU suggests that the intervening thymidine was essential for propagating the oxidative damage to the 5'-dG.

The requirement of the intervening thymidine and the formation of 5-fdU suggested that $\text{dA}\cdot$ abstracts the hydrogen atom from the C5-methyl group of the 5'-adjacent thymidine (Scheme 51), and the resulting 5-(2'-deoxyuridinyl)methyl radical ($\text{T}\cdot$) ultimately transfers damage to the 5'-adjacent dG. Based upon the approximate BDEs of the N6-H bond (~ 97 kcal/mol) in dA and the allylic C5-H bond ($\text{BDE} \leq 90$ kcal/mol) of thymidine, this process should be exothermic.²³⁸⁻²³⁹ This possibility was explored by examining strand damage in duplexes in which the 5'-adjacent thymidine in **196** was substituted either by 5,6-dihydrothymidine (dHT, **208**) or 2'-deoxyuridine (dU, **209**). The alkyl C-H bond strength of the C5-methyl group in dHT is higher than the that of the allylic C-H bond in dT, and hydrogen atom abstraction from its methyl group by $\text{dA}\cdot$ should be less favorable. Since dHT is cleaved by piperidine or Fpg (Appendix Figure 10), photolysates of 5'-³²P-**208** and 5'-³²P-**196** were treated with hOGG1, followed by NaOH to assay for damage at dG₁₁ (Figure 22a). Strand scission at dG₁₁ was significantly reduced from 26.1 ± 0.2 % in **196** to 2.0 ± 0.6 % in the duplex containing dHT (**208**). The low level of strand damage that is still detected at dG₁₁ in 5'-³²P-**208** could be attributed to hydrogen

Scheme 51. dA• abstracts the hydrogen atom from C5-methyl group generating T•.

atom abstraction by dA• from the C5-methyl group in dHT, but this is uncertain. Replacement of the 5'-adjacent thymidine by dU (**209**) has an even more definitive effect on tandem lesion formation. Strand damage at dG₁₁ in 5'-³²P-**209** photolysates is completely eliminated (Figure 22b). Overall, these observations are consistent with the major pathway for tandem lesion formation from dA• involving initial C5-methyl hydrogen atom abstraction from the 5'-adjacent thymidine (Scheme 51). Additionally, the hydrogen atom abstraction also agrees with the observation that dA• is repaired in **207**.

Figure 22. Effect of 5'-allylic C-H bond on tandem lesion formation. Autoradiogram of aerobic photolysis of (a) 5'-³²P-208 (b) 5'-³²P-209 followed by chemical and enzymatic treatments.

The proposed hydrogen atom abstraction also explains the observation that inverting the sequence from 5'-d(GGG₁₁T₁₂6) (**196**) to 5'-d(6T₁₄G₁₅GG) (**198**) results in no

alkali-labile strand damage at T₁₄ or dG₁₅ upon photolysis of **198**, and only a small amount of piperidine cleavage is observed at T₁₂ (1.7 ± 0.1 %). Since the spin density of dA• is mostly localized at N6,²⁷⁷ the conformational restrictions imposed by the right-handed helix were expected to have a significant effect on tandem lesion formation from dA•. Close inspection of a molecular model revealed that the methyl group of the 5'-adjacent thymidine is approximately 2 Å closer than the corresponding hydrogen in the 3'-adjacent thymidine to the radical at N6 of dA• (Figure 23). Hence, hydrogen atom abstraction from the methyl group of thymidine explains the directional preference for tandem lesion formation.

Figure 23. Molecular modeling demonstrating hydrogen atom abstraction by $\text{dA}\cdot$ in the trinucleotide sequence 5'-T-dA•-T/3'-dA-T-dA.

3.2.3.4.2 Thymidine peroxy radical oxidizes 5'-dG

Formation of 5-fdU and the O_2 dependence of tandem lesion formation suggest that the corresponding peroxy radical of T• ($\text{Tp}\cdot$) is likely formed by oxygen trapping the carbon-centered radical following the generation of T• by hydrogen atom abstraction (Scheme 52). The viability for T• to induce tandem lesion formation was investigated by independently generating T• from **210** (Scheme 53) within DNA (**211,212**).²⁷⁸⁻²⁸⁰ These duplexes were designed to replicate the environment in which T• was produced from $\text{dA}\cdot$.

Scheme 53. Generation of T• and carbocation from **210**.

Indeed, alkali-labile lesions were generated at dG₁₁ in photolyzed 5'-³²P-**211** and 5'-³²P-**212** under aerobic conditions but not under anaerobic conditions (Figure 24, Appendix Figure 11). Yields of alkali-labile lesion products were lower than when dA• was generated from **6** (Figure 24, cleavage at G₁₁ = 6.7 ± 0.7 % in **211** and 1.3 ± 0.2 % in **212**). This observation, along with the generation of interstrand cross-links, is consistent with the generation of carbocation from **210** in addition to T• (Scheme 53).²⁸⁰ The alkali-

labile cleavage yield in the substrate containing the 5'-dGGG sequence (**211**) was considerably higher than that in **212**. This is consistent with the above experiments (Figure 17) in which the oxidation potential of polynucleotide sequences on the 5'-side of dT affected the yield of the tandem lesion. In addition, the lability towards Fpg and the reduction in alkali-induced cleavage at dG₁₁ in **211** by piperidine/BME treatment were consistent with the formation of 8-oxo-dG, as was observed when tandem lesion formation was initiated by dA•. Finally, the elimination of alkali-labile lesions at T₁₂ following NaBH₄ treatment is consistent with 5-fdU formation at this position (Figure 24a). Overall, independent generation of T• at T₁₂ (**211**) within the otherwise identical sequence in which dA• is produced (**196**), supports the proposal that T• generated by hydrogen atom abstraction is trapped by oxygen, and that the peroxy radical (Tp•) oxidizes the 5'-adjacent dG resulting in a tandem lesion (**207**) consisting of 5'-[(8-oxo-dG)-(5-fdU)].

Although peroxy radicals have been suggested to oxidize dG via an outer sphere process (Scheme 54),²⁸¹ studies on related nucleobase peroxy radicals indicate that addition to the purine ring is more likely.²⁸² Outer sphere and inner sphere mechanisms are distinguishable by product analysis. The former involves the formation of dG•+ that gives rise to hole migration.^{16, 18, 283} The absence of strand damage at dG₉ and dG₁₀ in **196** argues against the outer sphere process.¹⁴² Furthermore, the transformation of G•+ into 8-oxo-dG requires incorporation of oxygen from H₂O. However, ¹⁸O-incorporation was not detected by LC-MS/MS following photolysis of **195a** in H₂¹⁸O (Figure 25), which also agrees with the inner sphere mechanism (Scheme 55).

Scheme 54. Oxidation of dG by Tp• via an outer sphere mechanism.

 (X = 8-oxo-dG; Y = 5-fdU)

Figure 25. Mass spectrum of **205** ($z = 3$) generated by photolysis of **195a** in (a) H_2O , (b) H_2^{18}O .

Inspection of molecular models suggested that Tp^\bullet was well positioned to add to C8 of the 5'-adjacent dG (Figure 26). The second one-electron oxidation of dG can be achieved by the addition of O_2 , followed by superoxide elimination (Scheme 55).^{9, 284} We propose that 1,2-hydride migration in **214** generates carbocation **215**, followed by deprotonation from **215** to produce the tandem lesion (**207**).

Scheme 55. Oxidation of dG by Tp^\bullet via an inner sphere mechanism.

Figure 26. Molecular modeling demonstrating the addition of peroxy radical to 5'-dG in the dinucleotide sequence 5'-dG-Tp• /3'-dC-dA.

The rate constant describing Tp• reaction with dG₁₁ was determined by measuring the effect of BME on the yield of alkali-labile lesions at the dG₁₁ in photolyzed 5'-³²P-**196** (Figure 27, Appendix Figure 12, 13). Assuming that the maximum rate constant for trapping T• by BME is $1 \times 10^7 \text{ M}^{-1}\text{s}^{-1}$, even the highest concentration of BME (0.5 mM) employed should not compete with O₂ (0.2 mM), which reacts with alkyl radicals at $\sim 2 \times 10^9 \text{ M}^{-1}\text{s}^{-1}$, for the alkyl radical.²⁸⁵ In addition, BME reacts inefficiently with dA•.⁴² Hence, we are confident that the reduction in cleavage at dG₁₁ as a function of BME concentration is a reflection of the competition between the reaction of Tp• with the purine (Scheme 56, $k_{\text{Add.}}$) and the thiol (Scheme 56, $k_{\text{Red.}}$).

Scheme 56. Competition between the reaction of Tp• with the purine ($k_{\text{Add.}}$) and BME ($k_{\text{Red.}}$).

The amount of Tp• reduction product was calculated to be the difference in alkali-induced cleavage at dG₁₁ in the absence of BME and the presence of a given thiol concentration. The slope of the line ($4.8 \times 10^3 \text{ M}^{-1}$, Figure 27) is the ratio of rate constants ($k_{\text{Red.}} / k_{\text{Add.}}$, eqn. 7), and if we assume that $k_{\text{Red.}} = 2 \times 10^2 \text{ M}^{-1}\text{s}^{-1}$, then $k_{\text{Add.}} = 4.2 \times 10^{-2} \text{ s}^{-1}$.²⁸⁶ The estimated rate constant for addition of Tp• to the 5'-adjacent dG₁₁ is slightly slower than that estimated for other nucleobase peroxy radicals using competitive kinetics.²⁸²

$$\frac{[216]}{[207]} = \frac{k_{Red.}}{k_{Add.}} [BME] \quad \text{eqn. 7}$$

Figure 27. Thiol effect on tandem lesion (**207**) formation in photolyzed 5'-³²P-**196**. The plot of [**216**] versus tandem lesion formation ([**207**]) as a function of [BME].

The trapping of Tp• by BME is further corroborated by UPLC-MS/MS (Figure 28). When **195a** is photolyzed in the presence of 1 mM BME, the tandem lesion is replaced by a product with $m/z = 3674.8979$, which is consistent with the reduction Tp• yielding 5-hydroxymethyl-2'-deoxyuridine (**217**, calculated $m/z = 3674.6344$).

Figure 28. UPLC-MS/MS analysis of photolysis of **195a** in the presence of 1 mM BME. (a) Total ion chromatogram (TIC) of the photolysate of **195a** in the presence of BME. (b) Deconvoluted mass spectrum of **217**.

3.2.3.1 Generation of 2'-deoxyinosine in DNA

During the aerobic photolysis of **6**, 2'-deoxyinosine (dI) was generated. To detect whether dI is also formed in DNA, we treated photolyzed 5'-³²P-**196** with endonuclease V (Endo V, Figure 29a). Endo V is a 3'-endonuclease involved in DNA repair, which initiates removal of deaminated bases from damaged DNA.²⁸⁷ The cleavage site generated by Endo V is at the second phosphodiester bond 3' to a lesion (Figure 29b).

Figure 29. Detection of dI formation by Endo V treatment. (a) Autoradiogram of aerobic photolysis of 5'-³²P-**196** followed by Fpg and Endo V treatments. (b) Schematic demonstration of Endo V activity.

Formation of dI was detected in irradiated duplexes **196**, **197** and **203**. The yields of dI were independent of the sequence ($14.5 \pm 0.3\%$ in **196**, $12.7 \pm 1.5\%$ in **197**, $13.6 \pm 0.6\%$ in **203**, Appendix Figure 14). Treating photolyzed 5'-³²P-**196** with a mixture of Fpg and Endo V does not affect the yield of cleavage induced by either enzyme (Figure 29a). This result suggested the dI formation and tandem lesion formation are two independent pathways. Furthermore, the formation of dI is confirmed by UPLC-MS/MS analysis following nuclease digestion (Figure 30). The yield of dI is determined to be $12.9 \pm 0.1\%$ using the calibration curve,²⁸⁸ which is consistent with the result obtained by PAGE analysis. However, the mechanism for dI formation is not clear at this point.

3.2.3.2 Tandem lesion formation in oligonucleotides containing hydrazine precursor **3**

Duplexes containing the hydrazine precursor **3** (**218** and **219**) were synthesized, and **3** was incorporated within sequence contexts that are similar to **196** and **203**, respectively. Tandem lesion was detected in both duplexes after photolysis, consistent with the formation of dA^\bullet (Figure 31). The yields of the tandem lesion were lower than those

observed in **196** and **203** ($4.4 \pm 0.2\%$ Fpg induced cleavage in $5'$ - ^{32}P -**218** at G_{11} , $0.75 \pm 0.02\%$ Fpg induced cleavage in $5'$ - ^{32}P -**219** at G_{11}), but a similar sequence effect was observed. In addition, alkali-labile lesion formation was detected at the position where the precursor was incorporated. Given that the recombination product **104** is the same oxidation state as 8-oxo-dA and 8-oxo-dG, we propose that **104** is alkali-labile, and its formation leads to the observed strand cleavage. Formation of **104** is consistent with the lower yields of the tandem lesion from **3** compared to ketone **6**. Furthermore, piperidine treatment in the presence of BME significantly reduced the observed strand cleavage at the site where precursor **3** resided. This result agrees with **104** behaving similarly to 8-oxo-dG.

3.2.4 Probing π -stacking induced pK_a increase of dA radical cation

In Section 3.2.3.1, we established that unlike benzotriazinyl radicals and the neutral radical derived from 2-aminopurine,^{64,289} one-electron oxidation of dG to dG^{•+} by dA[•] does not compete with other reaction pathways in duplexes **196-200**, despite thermodynamically favorable dG oxidation by dA[•]. Importantly, dA[•] is not flanked by dA in these duplexes. The pK_a of dA^{•+} has been estimated to be as high as 7 at room temperature when it is flanked by dA in DNA.²¹ Consequently, we anticipated that when flanked by dA, dA[•] will be at least partially protonated to form dA^{•+} and give rise to chemistry in DNA that is attributable to both species. Generation of dA^{•+} was expected to result in direct one-electron oxidation of dG to dG^{•+}. Site-selective, independent dA[•] generation from **6** in oligonucleotides enables us to probe the effects of the flanking sequence directly.

3.2.4.1 Sequence effect on hole migration

We investigated the neutral radical's reactivity when it is flanked by dA (**220-222**). The flanking dA is positioned on the 5' side of dA• to minimize the direct reaction of dA• with 5'-T or dG. In marked contrast to photolyses of **196**, the major sites of strand scission following piperidine or Fpg treatment of 5'-³²P-**220** photolysates are at the 5'- and middle-dG (dG₉ and dG₁₀) of the dGGG sequence, the characteristic damage pattern for hole transfer (Figure 32). The cleavage pattern indicates that as predicted by Sevilla, π -stacking with the adjacent dA increases the pK_a of dA•+ such that the radical cation is produced from initially formed dA• at pH 7.2. The extent of strand damage increases upon reducing the pH from 7.2 to 6 to 5.1, but the general cleavage pattern is unchanged (Figure 32, 33). More favorable hydration compared to deprotonation of G•+ at lower pH may also contribute to increased strand damage.¹⁸⁷ Furthermore, no hole migration is observed in photolyzed 5'-³²P-**196** at pH 5.1, and the majority of strand cleavage is localized at G₁₁

(Appendix Figure 15). The lack of hole migration is consistent with the pK_a of $dA^{\bullet+}$ ($pK_a \approx 4$), and less than 10% of dA^{\bullet} is protonated at pH 5.1. This observation further underscores the effect of the adjacent dA on the the pK_a of $dA^{\bullet+}$.

The absolute amount of strand cleavage detected in **220** ($9.1 \pm 1.2\%$) corresponds to a high level of hole transfer when one accounts for the $\sim 10\%$ efficiency for G \bullet + conversion to alkali-labile lesions at pH 5.¹³ When combined with the aforementioned UPLC analysis following nuclease digestion (see Section 3.2.3.1), which showed that $\sim 80\%$ of **6** is consumed upon photolysis, these experiments indicate that dA \bullet produced from **6** in **220** results in almost quantitative hole transfer ($113.25 \pm 15.5\%$) at pH 5.1. Similar

measurements were carried out on all of the duplexes used in the study (Table 11), and the high level of hole migration is observed for all of the substrates at pH 5.1.

Table 11. Estimated efficiency of hole transfer (pH = 5.1)

Duplexes	Total % cleavage on Gs	% Hole transfer ^{a,b}

^a The yield of trapping reaction of the hole is ~10%.

^b The conversion of **6** is 80% after 8 h photolysis.

^c See Section 3.2.4.2.

^d See Section 3.2.4.3.

The generality of this sequence-dependent phenomenon was explored using established guidelines governing hole transfer in DNA concerning directionality and sequence/distance effects.^{16, 116} For instance, a dGGG triplet is more easily oxidized than a single dG, which provides a driving force for holes to hop short distances from dG^{•+} to dGGG triplets.⁶⁵ Indeed, photolysis (pH 5.1) of 5'-³²P-**221** (Figure 34a, 35) produced 7.6-fold greater strand damage at the dGGG triplet than at the single dG adjacent to the site at which dA[•] was generated (dG₁₂). This is consistent with the fact that dGGG triplets have a lower oxidation potential compared to dG.⁶⁵ In the corresponding sequence lacking a dA stacked with dA[•] (**199**), cleavage was detected only at dG₁₂, and in much lower yield than in **221** (Figure 34b). In another example, generating dA[•] in 5'-³²P-**222** illustrates the expected ability of hole transfer to proceed in the 3'-direction, unlike tandem lesion

formation (Figure 34c). Damage in **222** was detected predominantly at the 5'- and middle dG's of the dGGG triplet; whereas irradiation of the corresponding sequence lacking a stacking dA (5'-³²P-**200**) produced a small amount of damage at the 5'-T₁₂ and none within the dGGG sequence (Figure 34d). The hole transfer efficiency is slightly lower in the 3' direction (Table 11, 72.9 ± 2.6%). There have been conflicting reports on the efficiency of hole migration as a function of migration direction, but it may depend on the nature of the hole injector and local sequences.²⁹⁰⁻²⁹⁴ Overall, these observations are consistent with the well-established paradigm of hole migration.

3.2.4.2 dA^{•+} is the hole carrier

To further support the formation of dA^{•+}, we took advantage of dA^{•+} delocalization over multiple dAs within poly(dA-T) sequences.²⁹⁵ The delocalization of positive charge leads to polaron formation and hole transfer with weak distance dependence.^{12, 296} Generating dA[•] within dA₅ sequences (223, 224) again yielded strand damage at the 5'- and middle-dGs of the dGGG triplet. The damage detected in dGGG triplets in 223 and

224 is the same within experimental error (Figure 36, 37), despite the distances between initial hole injection site and the reporter sequence differing by several angstroms (2 base pairs). This result is consistent with polaron formation in poly(dA-T) sequences, which is unique for $dA^{\bullet+}$, and supports the intermediacy of $dA^{\bullet+}$.

3.2.4.3 pH-dependent switching between hole migration and tandem lesion formation

Finally, we examined the strand damage when $\text{dA}\cdot$ was generated in a sequence where hole transfer or tandem lesion formation is possible (**225**). dG_{11} was the site of greatest damage (Figure 38a, 40) following photolysis of $5'\text{-}^{32}\text{P}\text{-225}$ at pH 7.2. Also, experiments using $3'\text{-}^{32}\text{P}\text{-225}$ showed strand scission at T_{12} , as expected for tandem lesion formation from $\text{dA}\cdot$ (Figure 39). At pH 5.1, the preference switched to G_9 and G_{10} , and the damage pattern was consistent with that of hole transfer. These data suggest that $\text{dA}\cdot$ and $\text{dA}\cdot+$ contribute to the observed strand damage in **225** (Figure 38b) in a manner proportional to their relative amounts. Furthermore, the differences observed between **225** and **220** suggest that at pH 7.2 tandem lesion formation from $\text{dA}\cdot$ competes with radical cation formation. However, we cannot rule out that $\text{dA}\cdot$ is initially formed in a conformation from which tandem lesions are formed more rapidly than $\text{dA}\cdot+$.

3.2.5 An alternative mechanism for strand damage formed during DNA hole migration within DNA that lacks dG

3.2.5.1 Inconsistency in the proposed mechanism for hole migration induced tandem lesion formation

In Section 2.3.2.2, the strand damages induced by hole migration in poly(dA-T) sequences were discussed. Given the fact that the population of the thymidine radical cation

in an A/T base pair will be less than 1% of that at the adenine ($\Delta E_{\text{ox}} \sim 0.3$ V in water), it is surprising that the oxidative reaction occurs at thymidine.⁴ The authors proposed that product ratios depend on differences in the energy of the transition states.²⁹⁷ Thus, the dominant reaction of radical cations at thymidine in DNA suggests a kinetically favorable pathway for a hole to be trapped on this nucleotide.^{24, 298} Computational studies and a kinetic isotope effect experiment suggested that a concerted proton-coupled electron transfer (PCET) process avoided the higher-energy intermediates (Scheme 57).²⁹⁸ The proposed PCET process involves spontaneous deprotonation of the methyl group of the $\text{T}^{\bullet+}$ to form T^{\bullet} (Scheme 57). However, the formation of T^{\bullet} is inconsistent with the formation of Tg which requires trapping of $\text{T}^{\bullet+}$ by O_2 and water when the hole is localized at the 3'-side of TT steps (Scheme 10).

Scheme 57. Generation of T^{\bullet} via PCET from $\text{dA}^{\bullet+}$ in an A/T base pair .

The proposed mechanism does not fully explain the reactivity of $T^{\bullet+}$ localized at the 5'-side of TT steps. The authors propose that this $T^{\bullet+}$ deprotonates to generate carbon-centered radical T^{\bullet} rather than reacts with O_2 and H_2O . However, the author does not rationalize this difference of reactivity depending upon which position within a TT step the radical cation is generated. In addition, the authors also proposed that Tp^{\bullet} generated by oxygen trapping of T^{\bullet} does not induce tandem lesion formation because the distance between the terminal oxygen atom of Tp^{\bullet} and the C5-methyl hydrogen atom of the 5'-T is 4.2 Å. The authors conclude that this distance is sufficient to render hydrogen atom abstraction unlikely.²⁵ However, our molecular modeling (Figure 41) suggests this distance can be as short as 2.6 Å, and the peroxy radical is well-positioned for the hydrogen atom abstraction. Furthermore, the distances between the Tp^{\bullet} terminal oxygen atom and C5 or C6 are 3.0 Å and 2.5 Å, respectively. These distances are comparable to those measured for the addition of 5,6-dihydro-2'-deoxyuridine C-6 peroxy radical (Up^{\bullet}) to a 5'-adjacent T, from which tandem lesion formation has been observed.²⁹⁹ Therefore, we believe that the addition of peroxy radical to the C5-C6 π bond of the 5'-T is also possible.

Figure 41. Molecular modeling demonstrating the addition of peroxy radical Tp^\bullet to 5'-T in the dinucleotide sequence 5'-T- Tp^\bullet .

Moreover, to explain the predominant damage on the central T of TTT sequences, the authors reasoned that two of three possible products (**226-228**) generated have alkali-labile lesions located where the central T resided, which is consistent with the gel results. However, based on the previous discussion concerning PAGE analysis of tandem lesions (Figure 14), Tg in **226** will be detected when the strand is 5'-labeled, which is inconsistent with the gel results.

3.2.5.2 Reproducing tandem lesion formation by independently generating dA•

The inconsistency of the previously reported mechanism in explaining the products observed when holes were injected into poly(dA-T) duplexes via photoexcited anthraquinone led us to consider an alternative mechanism. In Section 3.2.3, it was established that dA• abstracts the C5-methyl hydrogen from the 5'-adjacent thymidine which led to the formation of a tandem lesion in 5'-d(GT) sequences. Tandem lesion formation was inhibited by 5'-d(GU) sequences. Interestingly, similar sequence specificity was also observed in photoexcited anthraquinone induced hole migration. For instance, the strand cleavages were preferentially localized at 5'-T in 5'-d(TTA) sequences when the oligonucleotides were 5'-³²P labeled. In addition, alkali-labile cleavage was observed at 5'-d(TTA) and 5'-d(UTA) steps, but no damage was detected at 5'-d(TUA) sequences.²⁵ The requirement for an intervening thymidine is consistent with the tandem lesion formation initiated by hydrogen atom abstraction (see section 3.2.3.4.1).

Furthermore, as discussed in Section 3.2.4, dA^\bullet and $\text{dA}^{\bullet+}$ equilibrate in duplex DNA in a sequence-dependent manner. In the presence of guanine (**16**), hole transfer outcompetes the deprotonation of $\text{dA}^{\bullet+}$, and the hole is eventually trapped by guanines (Figure 42a).^{12-13, 83, 300-301} In the absence of such hole sinks, such as in poly(dA-T) substrates **17-19**, $\text{dA}^{\bullet+}$ randomly migrates over the dA-T tracts and deprotonates to form dA^\bullet (Figure 42b). Given the possibility of dA^\bullet generation in duplexes **17-19** and the aforementioned sequence specificity of tandem lesion formation, we proposed that the tandem lesion formation may be initiated by dA^\bullet .

Figure 42. Schematic demonstration of hole migration (a) in the presence of guanine; (b) in the absence of guanine

229: X = T Y = T
 230: X = T Y = dU
 231: X = dU Y = T

Consequently, we tested the possibility that dA^\bullet is the species directly responsible for the products observed following hole migration in poly(dA-T) sequences. Substrates

229-231 containing 5'-d(TT), 5'-d(UT), and 5'-d(TU) flanked by a photochemical precursor (**6**) for dA• were prepared. The purpose of these sequences was to reproduce the sequence specificity for tandem lesion formation observed in photoexcited anthraquinone induced hole migration. The dA• precursor was not flanked by dA to minimize dA•+ formation under the reaction conditions. Piperidine treatment of photolyzed 5'-³²P-**229-231** produced cleavage patterns that were fully consistent with those reported when duplexes containing the same dinucleotide steps and anthraquinone were irradiated (Figure 43). Specifically, duplex **229**, containing a 5'-T₁₃-T₁₄-dA• sequence results in predominant cleavage at the 5'-thymidine of the dinucleotide sequence. Similarly, strand damage is detected in approximately equal amounts at dU₁₃ and T₁₄ in 5'-³²P-**230**; whereas no damage is detected in the duplex (**231**) containing 5'-T-dU-dA•.

Figure 43. Strand damage in duplexes (5'-³²P-**229-231**) containing 5'-pyr₁₃-pyr₁₄-dA• induced by piperidine. Three replicates are shown for each substrate.

3.2.5.3 Characterization of the structure of the tandem lesion formation

3.2.5.3.1 Chemical assays

Based on the observations made in 5'-d(GTA•) and Schuster's report on the structure of tandem lesions, we proposed that tandem lesion (**232**) containing 5'-d[Tg-(5-fdU)] was formed.

Similar to the 5'-d[(8-oxo-dG)-(5-fdU)], one would expect greater strand damage at 5-fdU to be observed in 3'-³²P-**229** substrates compared to 5'-³²P-**229** because damage at the 5'-Tg prevents the detection of 5-fdU on the 3' side when the ³²P-label is at the 5'-terminus. Indeed, piperidine treatment of photolyzed 5'-³²P-**229** yielded 10.5 ± 0.2% cleavage at T₁₃ and 1.4 ± 0.1% at T₁₄ (Figure 44b), but the preference is reversed in 3'-³²P-**229** (Figure 44a, T₁₃, 2.8 ± 0.2%; T₁₄, 4.3 ± 0.1%). These results suggest that the observed strand damage is part of a tandem lesion. Cleavage at T₁₃ was still observed in 3'-³²P-**229**, which is consistent with the report that 5-fdU is not completely cleaved by piperidine treatment.³⁰² Additionally, NaBH₄ treatment of 3'-³²P-**229** photolysate before piperidine cleavage resulted in increased strand scission detected at T₁₃ (Figure 44a, 5.9 ± 0.1 %) and

decreased damage at T₁₄. This is consistent with the reduction of 5-fdU to 5-hmdU at T₁₄, which is not labile to piperidine and does not mask the detection of Tg formation at T₁₃.

Figure 44. Denaturing PAGE investigation of the structure of the tandem lesion formed in 5'-TT steps using piperidine and NaBH₄/piperidine treatments. Autoradiogram of aerobic photolysis of (a) 3'-³²P-229 and (b) 5'-³²P-229 followed by chemical treatments.

3.2.5.3.2 Characterization of the structure of the tandem lesion by UPLC-MS/MS

The structure of the tandem lesion was validated via UPLC-MS/MS analysis of photolysates of **233** using the method mentioned previously (see Section 3.2.3.3.2). The usage of a relatively short duplex is crucial for detection of fragments via CID, which is critical for product assignment.^{272-273, 303} The T_m's of dodecameric poly(dA-T) substrates are too low for them to remain hybridized during photolysis. However, since we believe that tandem lesion formation does not involve dA•+, we predicted that sequences containing dGs at distal positions would not affect tandem lesion formation. This was

demonstrated by piperidine treatment following the photolysis of 5'-³²P-**234**, which showed an identical damage pattern compared to 5'-³²P-**229**.

Figure 45. Autoradiogram of aerobic photolysis of 5-³²P-**234** followed by piperidine treatment.

Having established that dGs do not affect the tandem lesion formation, we designed dodecameric substrate **235** for UPLC-MS/MS studies. However, we were unable to separate the products generated by photolysis from the complementary strand **236**. The inclusion of a 3'-TT overhang increased the retention time of the complementary strand (**237**), enabling its separation from the products of interest. Moreover, d(G-C) base pairs stabilized **233** ($T_m = 35.5\text{ }^\circ\text{C}$) against melting during photolysis.

The major product generated by the photolysis of **233** is **238**, which is consistent with the results obtained by UPLC-MS/MS analysis on the photolysate of **195a** (Figure 19). We also observed a product with the expected mass ($m/z = 3666.6240$) and fragmentation pattern that is consistent with the oligonucleotide containing tandem lesion **232** (**239**, Figure 46, Appendix Figure 17, Table 12). Oligonucleotide **239** coeluted with another product **240**, the m/z of which is consistent with an oligonucleotide containing a single 5-hmdU lesion (Figure 46b). Additionally, a product with $m/z = 3648.6965$ (**238** + 30 Da) was detected, but the structure was not assigned.

Figure 46. UPLC-MS/MS analysis of photolysis of **233**. (a) CID mass spectrum of the ion ($m/z = 732.7$, $z = 5$) of the oligonucleotide containing tandem lesion **232** (**239**). X = Tg, Y = 5-fdU. (b) Deconvoluted mass spectrum of oligonucleotide **239** and **240**.

Furthermore, Tg-containing DNA may produce an $[a_n - 143 \text{ Da}]$ fragment instead of $[a_n - \text{Tg}]$ fragments (Scheme 58).³⁰⁴ However, the expected m/z value for the $[a_3 - 143 \text{ Da}]$ fragment ($m/z = 732.1437$) is very close to the m/z of the precursor ion ($z = 5$) chosen in Figure 29. To unambiguously identify this fragment, we used a different precursor ion ($z = 3$) and acquired the CID spectrum (Figure 47, Appendix Figure 18). The fragmentation of the $z = 3$ ion yielded fewer fragments bearing structural information compared to those obtained from the $z = 5$ ion. However, an ion corresponding to $[a_3 - 143 \text{ Da}]$ ($m/z = 732.1434$) was observed, which was consistent with the presence of Tg lesion.

Scheme 58. CID induced fragmentation of DNA containing Tg generating w-series ions, $[a_n - 143 \text{ Da}]$ ion and $[a - B]$ -series ions.

Figure 47. CID mass spectrum of the ion ($m/z = 1221.6$, $z = 3$) of the oligonucleotide containing tandem lesion **232** (**239**). X = Tg, Y = 5-fdU.

3.2.5.4 An alternative mechanism for the tandem lesion formation in poly(dA-T) sequences

3.2.5.4.1 Proposed mechanism for tandem lesion formation

We proposed a mechanism that is consistent with the structure of the tandem lesion (**232**), the sequence specificity of its formation, and previously characterized $\text{dA}\cdot$ reactivity.

The mechanism involves initial hydrogen atom abstraction from the C5-methyl group of the thymidine bonded to the 5'-phosphate of the neutral nitrogen radical (Scheme 59). The initial hydrogen atom abstraction from the thymidine C5-methyl group by dA• explains the lack of tandem lesion formation in 5'-d(TUA) steps. Under aerobic conditions, T• is trapped by O₂ to form Tp•, which reacts with the 5'-adjacent pyrimidine by adding to the pyrimidine double bond. Addition at the C5-position of thymidine is shown in Scheme 59. However, we cannot distinguish between this pathway and addition to the C6-position.³⁰⁵ Photolysis of **233** in the presence of β-mercaptoethanol (1 mM) eliminates the formation of **232** (within **239**) and is replaced by the product containing 5-hmdU (**240**) (Figure 48). This is consistent with the intermediacy of Tp• in tandem lesion formation. To further validate the addition of Tp• to the 5'-adjacent thymidine, photolysis in ¹⁸O₂ was carried out. Unfortunately, the photolysis (8 h) of samples sparged with ¹⁸O₂ resulted in the formation of a complicated mixture, and thus we were unable to identify the incorporation of ¹⁸O by UPLC-MS/MS.

Scheme 59. An alternative mechanism for the formation of tandem lesion **232**.

Figure 48. Deconvoluted mass spectrum of oligonucleotide generated after the photolysis of **233** in the presence of 1 mM BME.

Tp• addition to the 5'-adjacent pyrimidine may also explain the damage pattern observed in the the 5'-d(UT) sequence, which yields nearly identical strand cleavage at the two pyrimidine nucleotides. Peroxide **241** generated at dU gives rise to products such as 5-hydroxy-2'-deoxyuridine (Scheme 60 pathway a, 5-HOdU),³⁰⁶ which does not yield strand scission upon alkali-treatment.³⁰⁷⁻³⁰⁹ Furthermore, previous investigations in which pyrimidine peroxy radicals are independently generated in duplex DNA have shown that alkali-labile lesion formation at a 5'-dU is less efficient than when thymidine is present at this position.²⁹⁹ Tp• resulted from oxygen trapping the initially formed T• may also ultimately convert to 5-fdU yielding the oligonucleotide containing isolated lesions (Scheme 60 pathway b).²⁵

Scheme 60. Formation of the tandem lesion in 5'-d(UT) sequence.

3.2.5.4.2 Distinguishing the alternative mechanism from the published PCET mechanism

Although we successfully reproduced tandem lesion formation in poly(dA-T) via independently generating dA•, these results were not sufficient to disprove the mechanism put forward by Schuster et al.,²⁵ because our experiments did not rule out the potential contributions of dA•+ and T•+ in tandem lesion formation. To distinguish the mechanism involving interstrand charge transfer from dA•+ to T and that proposed herein involving dA•, we designed anthraquinone tethered duplex **241** similar to duplex **18** designed by Schuster and coworkers,²⁴ which contains three 5'-d(TTT) steps and one 5'-d(TTU) step. The photoexcited anthraquinone was used to initiate hole migration, and the three 5'-d(TTT) steps acted as positive controls. As mentioned previously 5'-d(TTT) sequences were preferentially damaged at the central thymidine, followed by the 3'-terminal T, during hole migration initiated by anthraquinone excitation.²⁴⁻²⁵ If the mechanism involves interstrand charge transfer generating T•+, the TT step in 5'-d(TTU) should give rise to a tandem lesion since the hole transferred from the dA•+ on the opposite strand will not be affected by the presence of dU (Scheme 61a). If the alternative mechanism proposed above is responsible for the products, substituting a single dU for thymidine at the 3'-terminus of a 5'-d(TTT) sequence should eliminate strand damage at that location because the 3'-adjacent dA• radical responsible for initiating tandem lesion formation will not have a C5-methyl hydrogen atom to abstract at the 5'-adjacent pyrimidine (Scheme 61b).

Scheme 61. The hypothesized mechanism for tandem lesion formation in a 5'-d(TTU) sequence.

Photolysis of 5'-³²P-**242** led to no strand damage at the 5'-d(TTU) sequence (Figure 49a). Furthermore, the strand damages in 5'-d(TTT) steps were predominantly localized at the central T's (Figure 49a). This observation was consistent with the previous report,²⁹ which suggested that hole migration occurred as expected. Finally, the reactivity disparity between 5'-d(TTT) and 5'-d(TTU) was reproduced by independently generating dA•. Piperidine treatment of photolyzed 5'-³²P-**244** led strand cleavage at T₁₃, the central T of the 5'-d(TTT) sequence. On the other hand, no tandem lesion formation was detected in photolyzed 5'-³²P-**243** (Figure 49b). These observations were consistent with our proposed mechanism (Scheme 61b). The mechanism proposed by Schuster et al. does not explain the reactivity of 5'-d(TTU) sequences.²⁵ Given this result, along with the inconsistency mentioned in Section 3.2.5.1, we disproved the mechanism (Scheme 10) involving the

formation of $T^{\bullet+}$. The alternative mechanism proposed (Scheme 59) is consistent with all of these observations, and dA^{\bullet} is the species that initiates the formation of tandem lesion 232.

Figure 49. Distinguishing the interstrand charge transfer mechanisms and intrastrand hydrogen atom abstraction mechanism using PAGE analysis. (a) Autoradiogram of photoexcited anthraquinone induced strand damage in 5'-³²P-242. (b) Autoradiogram of aerobic photolysis of 5'-³²P-243 and 5'-³²P-244, followed by piperidine treatment.

4. Conclusions

In summary, in response to a dearth of methods for generating aminyl radicals photochemically, we successfully developed photochemical precursors for dA^{\bullet} (**3**, **6**), $dG(N2-H)^{\bullet}$ (**4**, **7**), and $dG(N1-H)^{\bullet}$ (**5**). Product studies reveal that the photolyses of these precursors produce their corresponding neutral purine radicals with high fidelity. In addition, dA^{\bullet} is directly observed via laser flash photolysis under photosensitization conditions. Furthermore, **3**, **4**, **6**, and **7** are compatible with solid phase oligonucleotide synthesis conditions, and thus are potentially useful tools for mechanistic studies of neutral

purine radicals. Incorporation of **3** and **6** into DNA enabled us to investigate the reactivity of $\text{dA}\cdot$ in DNA, of which little was known prior to our studies.

By incorporating **6** in DNA, We examined the proposal based on pulse radiolysis studies that $\text{dA}\cdot$ induces hole migration in DNA.⁹⁴ Hole migration by $\text{dA}\cdot$ was not observed. However, tandem lesion formation was observed in 5'-d(NGGT) sequences. The structure of this tandem lesion was characterized by analyzing intact oligonucleotides using UPLC-MS/MS, a powerful but underutilized method for DNA lesion characterization. Interestingly, $\text{dA}\cdot$ is repaired to dA in the final product. Therefore, the involvement of $\text{dA}\cdot$ is traceless by typical product analysis. We proposed that $\text{dA}\cdot$ initiates the formation of this tandem lesion by abstracting a hydrogen atom from the C5-methyl group of a 5'-adjacent thymidine to form 5-(2'-deoxyuridinyl)methyl radical ($\text{T}\cdot$). The subsequently formed thymidine peroxy radical ($\text{Tp}\cdot$) adds to the 5'-adjacent dG, ultimately producing a 5'-[(8-oxo-dG)-(5-fdU)] tandem lesion (Scheme 55). The proposed mechanism is supported by UPLC-MS/MS, chemical reactivity experiments, isotopic labeling, as well as the

independent generation of $T\bullet$. In addition, tandem lesions from $dA\bullet$ are formed relatively efficiently when flanked on the 5'-side by 5'-d(NGGT) sequences, which based upon statistics will appear $>10^6$ times in the human genome. Tandem lesions pose a greater challenge for base excision repair enzymes, and thus this tandem lesion is potentially relevant to human health.

Independent generation of $dA\bullet$ also allowed us to investigate the impact of flanking sequence on the pK_a of $dA\bullet+$. We demonstrated, for the first time, that a flanking dA dramatically shifts the $dA\bullet+/dA\bullet$ equilibrium and results in the formation of the radical cation ($dA\bullet+$) that is produced from the direct effect (Figure 32b). Support for $dA\bullet+$ formation is based on well-precedented DNA hole transfer chemistry. The experiments presented in this dissertation provide the first experimental evidence in DNA that π -stacking increases the pK_a of $dA\bullet$ at room temperature. It is believed that the direct and indirect effects of γ -radiolysis contribute approximately equally to DNA damage.^{2, 46, 310} By independently generating $dA\bullet$, a radical produced by the indirect effect, for the first time in DNA, we demonstrate that when flanked by another dA , $dA\bullet$ generation leads to DNA hole transfer, a process induced by the direct effect of ionizing radiation.³¹¹⁻³¹² Results presented in this dissertation suggest that the indirect and direct effects γ -radiolysis are closely intertwined, and converge in a sequence-dependent manner.

The insights into $dA\bullet$ reactivity led us to revisit the tandem lesion(s) observed during hole migration in DNA that lacks dG .²⁹ Rather than invoking the higher energy $T\bullet+$, we propose that $dA\bullet$ is responsible for the tandem lesion formation. Holes carried by $dA\bullet+$ migrate throughout the poly(dA -T) sequences and are fixed at a particular location upon deprotonation. The resulting $dA\bullet$ initiates tandem lesion formation via initial hydrogen

atom abstraction from the C5-methyl group of a 5'-adjacent thymidine, a process also observed in tandem lesion formation in 5'-d(GT) sequences (Scheme 59).³¹³ Independent generation of dA• reproduced the sequence specificity of tandem lesion formation when holes are injected by photoexcited anthraquinones (Figure 43).²⁵ The structure of the tandem lesion was determined by UPLC-MS/MS. Furthermore, unlike the previously proposed mechanism, the alternative mechanism also correctly predicted the lack of strand damage in a 5'-d(TTU) sequence using anthraquinone (Figure 49). Finally, in the alternative mechanism proposed by us, dA• is repaired by initial hydrogen atom abstraction, which serves as a second example for the traceless involvement of dA• in the formation of tandem lesions.

The role of nitrogen-centered neutral purine radicals in DNA damage has been overshadowed by other nucleoside reactive intermediates, carbon-centered radicals and radical cations. Unlike radical cations, nitrogen-centered radicals do not react with water.⁷⁷ Nitrogen-centered radicals also do not react rapidly with O₂, unlike carbon radicals.^{157, 299, 314-315} Consequently, nitrogen-centered radicals may not directly yield DNA lesions, and other reaction pathways of nitrogen-centered radicals may be competitive in DNA. Considering the frequent formation of neutral purine radicals, their heretofore minor role in DNA damage is surprising.³¹⁶ With the capability of site-specific independent generation dA•, we demonstrated tandem lesion formation initiated hydrogen atom abstraction by dA•, and sequence-dependent protonic equilibrium of dA•/dA•+. These results raise the possibility that nitrogen-centered neutral purine radicals and other heteroatom-centered radicals may play important, general roles in DNA damage.

5. Future directions

The results presented here suggest several potential future experiments. The acetophenone sensitized photolyses of **6** and **7**, and direct photolysis of **5** is very efficient. We expect to be able to observe the transient spectra of $\text{dA}\cdot$, $\text{dG(N2-H)}\cdot$, and $\text{dG(N1-H)}\cdot$ with sufficient signal strength in aqueous buffer or buffer-acetonitrile mixtures. This will allow us to determine the reactivity of these radicals towards H_2O , O_2 , and other species, such as thiols. Furthermore, with the capability of unequivocally generating $\text{dG(N2-H)}\cdot$ and $\text{dG(N1-H)}\cdot$, the two tautomers of $\text{dG}\cdot$, we will be able to investigate the tautomerization between these two species.^{36-37, 69, 95} We expect to determine whether this tautomerization happens, and measure the rate of tautomerization.

There is no precursor for $\text{dG(N1-H)}\cdot$ or $\text{dG(N2-H)}\cdot$ that can be used in DNA polymer studies at this point. Precursor **7** requires sensitization to achieve photocleavage efficiency that is useful for mechanistic studies. On the other hand, photolysis of precursor **5** in the presence of O_2 leads to the generation of singlet O_2 ,²⁵⁷ which will hamper studies on the reactivity of $\text{dG(N1-H)}\cdot$ in DNA in the presence of O_2 by generating unwanted damage. Furthermore, the reactivity of naphthalimidyl radical (**181**) towards DNA is also unclear. In addition, incorporation of **5** into oligonucleotides might be challenging, considering N-hydroxy-naphthalimide (**178**) is a reasonable leaving group and may not be compatible with common solid-phase synthesis deprotection conditions. For these reasons, precursors based on intramolecular sensitization (e.g. **145**) are particularly attractive. Intramolecular sensitization reduces the possibility of undesirable photooxidation of DNA, and thus is potentially useful for polymer studies.

Lastly, the reactivity of $dC_{im}\bullet$ is unclear.^{40, 71, 75} We propose that the reactivity of $dC_{im}\bullet$ may be similar to that of $dA\bullet$, because the spin density of $dC_{im}\bullet$ also resides in the major groove of B-form DNA, and the BDE of N-H bond is ~ 100 kcal mol⁻¹.³¹⁷ We envision that $dC_{im}\bullet$ can be accessed by photolyzing precursor **245**. It is also worth noting that imino tautomer is favored in **245**, which grants us direct access to $dC_{im}\bullet$ without generating the amino tautomer $dC\bullet$.³¹⁸

6. Experimental

Materials and methods. Dichloromethane, DIPEA, DME, DMF, toluene, and pyridine were distilled from CaH₂. THF and dioxane were distilled from sodium. All other reagents were purchased from commercial sources and were used without further purification unless noted otherwise. T4 polynucleotide kinase (T4 PNK), human 8-oxoguanine DNA N-glycosylase 1 (hOGG1), endonuclease V (Endo V), and terminal transferase were obtained from New England Biolabs. DNA Degradase Plus was obtained from Zymo Research. γ -³²P-ATP and α -³²P-cordycepin 5'-triphosphate were purchased from Perkin Elmer. C18-Sep-Pak cartridges were obtained from Waters. PBS buffer (0.1

M NaCl, 10 mM sodium phosphate, pH 7.2) and water were treated with Chelex® 100 resin (BioRad). All reactions were carried out under a positive pressure of argon atmosphere and monitored by TLC on Silica Gel G-25 UV254 (0.25 mm) plates unless stated otherwise. Spots were detected under UV light and/or by ethanolic solution p-anisaldehyde, or aqueous solution of ammonium molybdate. Column flash chromatography was performed with Silicycle® grade 70–230 mesh, 60–200 µm, 60 Å silica. UV absorbance was measured with a Thermo Scientific NanoDrop® 2000c spectrometer. UV-melting was measured with a Beckman DU® 640 spectrometer. HPLC was performed on a Phenomenex Luna C-18 column (250 × 4.6 mm). ESI-MS was carried out on a Thermoquest LCQDeca. UPLC-MS/MS analyses were carried out on Waters Acquity/ Xevo-G2 UPLC-MS system equipped with an ACQUITY UPLC HSS T3 Column (100 Å, 1.8 µm, 2.1 mm × 100 mm), Oligonucleotide BEH C18 Column (130 Å, 1.7 µm, 2.1 mm × 100 mm), or Thermo Scientific Hypercarb column (130 Å, 5 µm, 2.1 × 100 mm,). Oligonucleotide masses were obtained via deconvolution using MassLynx 4.1 software. CID fragmentation patterns were processed using Microsoft Excel. MALDI-TOF analyses were carried out on a Bruker AutoFlex III Maldi-TOF MS. Quantification of radiolabeled oligonucleotides was carried out using a Molecular Dynamics Phosphorimager 860 equipped with ImageQuant Version TL software.

Procedure for the photolysis of precursors and subsequent HPLC analysis.

Photolyses were carried out in Pyrex tubes using a Rayonet photochemical reactor (Southern New England Ultraviolet) equipped with a merry-go-round apparatus and 16 lamps having a maximum output at 350 nm. Photolyses were carried out at 25 °C. This temperature was maintained by using the fan at the bottom of the unit provided by the

manufacturer and a Dayton® 239 CFM AC axial fan at the top facing such that air flowing through the unit is drawn out through the top. Reaction mixtures (50 µL each) containing precursor (100 µM), internal standard (thymidine, 100 µM), and additives (reducing agents, organic solvent, sensitizers) in buffer (10 mM phosphate, pH 7.2) were photolyzed at room temperature under aerobic or anaerobic conditions. Samples for anaerobic reactions were degassed by three freeze-pump-thaw cycles at 2 mTorr and flame sealed under vacuum. Samples containing acetone or a high percentage of acetonitrile (> 30%) were evaporated to dryness and resuspended in water. Samples using thiophenol as reducing agent were washed with hexanes (3 × 50 µL), evaporated to dryness and resuspended in water before HPLC analysis.

The reaction mixtures (including unphotolyzed controls) were analyzed by reversed-phase HPLC while being monitored at 260 nm and 284 nm. HPLC was performed on a Phenomenex Luna C-18 column (A, water; B, ACN; 3% B from t = 0 to t = 1 min; 3-28% B linearly over 9 min; 28-97% B linearly over 5 min; 97% B from t = 25 to t = 20 min; 97-3% B linearly over 2 min; 3% B from t = 22 to t = 42 min; flow rate, 1 mL/min). The retention times of the internal standard, precursors, and products generated by photolysis are listed in Table 13. The peaks were integrated and quantified against the internal standard (thymidine), and the response factors are reported in Table 13.

Table 13. Retention times and response factors for HPLC analysis.

Compound	Retention time (min)	Response factor (260 nm)
T	8.2	
dA	8.9	0.66

dG	7.4	0.84
dI	5.4	1.12
3	16.1	1.13
4	15.4	0.71
5	15.5	2.2
6	15.4	0.75
7	15.1	0.78
180	16.0	9.1

Cyclic voltammetry.^a A solution of the nucleoside (e.g. **3**) was prepared in acetonitrile containing 0.1 M tetrabutylammonium perchlorate (TBAP). Subsequently, the solution was saturated with nitrogen. A three-electrode system was utilized to carry out cyclic voltammetric studies of these N₂-saturated solutions: glassy carbon as the working electrode, Pt wire as the counter electrode, and Ag wire as the reference electrode. The scan rate was 100 mV/s. The conditioning potential was set at 0 V. The cyclic voltammetric scan was started along with the anodic pathway, followed by the cathodic pathway. This was done to avoid the probable interference from the reduction process. All potentials were calibrated based on Fc⁺/Fc (Fc=ferrocene) toward the normal hydrogen electrode (NHE). The redox potentials of dG and 8-oxo-dG were determined by employing 10 mM of each nucleoside. The redox potentials of **3** and **4** were obtained at 0.15 mM.

Determination of the quantum yield for photoconversion of 6 and 7 in acetonitrile under continuous photolysis. The light flux of the photoreactor was determined by using 2-hydroxy-2-methylpropiophenone actinometry in acetonitrile. 2-Hydroxy-2-

^a The cyclic voltammetry studies were carried out in collaboration with Lu Lin, Ke Qu, Amitava Adhikary, Michael D. Sevilla in the Department of Chemistry at Oakland University.

methylpropiophenone has a 0.38 quantum yield for Norrish type I cleavage.³¹⁹ Solutions containing the actinometer (50 μ L, 320 mM) were degassed using 3 freeze–pump–thaw cycles and sealed under high vacuum prior to photolysis. The extent of reaction of the actinometer was measured using an Agilent 6890N GC equipped with an Agilent HP-5 column (30 m \times 0.320 mm, 0.5 micron film)) from t = 0 to 1 min holding 80 $^{\circ}$ C, from t = 1 to 10 min, from 80 $^{\circ}$ C - 240 $^{\circ}$ C linearly, from t = 10 to 16 min, from 200 $^{\circ}$ C - 310 $^{\circ}$ C linearly over 5 min. The conversion of 2-hydroxy-2-methylpropiophenone (retention time = 4.09 min) was determined after 30 min of photolysis using dodecane (retention time = 3.62 min) as internal standard. The conversion of the actinometer was $30.0 \pm 0.7\%$. The optical density at 350 nm (OD_{350}) changed from 3.2 to 2.4. Therefore, the change of transmittance was negligible during photolysis. Using eqn. 8, the light flux was calculated to be $(4.2 \pm 0.1) \times 10^{-7}$ Einstein \cdot min $^{-1}$. Solutions containing **6** (50 μ L, 100 μ M) had an OD_{350} at 0.016. The OD_{350} of solution containing **7** (50 μ L, 100 μ M) was estimated using a 10 mM solution of **7** to be 0.0009 samples containing were degassed and photolyzed for 60 min using the calibrated photoreactor. The extent of reaction of **6** was determined by HPLC using thymidine as internal standard. The conversion of **6** was $30 \pm 1\%$. The quantum yield for conversion of precursor **6** was calculated using eqn. 9, and determined to be $(1.5 \pm 0.1) \times 10^{-3}$. Similarly, 6 h photolysis of samples containing **7** resulted in $12.4 \pm 0.5\%$ conversion, and the quantum yield of conversion of precursor **7** was determined to be $(1.8 \pm 0.1) \times 10^{-3}$.

$$\text{Light flux} = \frac{n_{\text{actinometer conversion}}}{\Phi_{\text{actinometer}} t_{\text{photolysis}}} \quad \text{eqn. 8}$$

$$\Phi_x = \frac{n_x \text{ conversion}}{\left(1 - \frac{\%T}{100}\right) (\text{Light flux}) \times t_{\text{photolysis}}} \quad \text{eqn. 9}$$

Determination of the quantum yield for photoconversion of 5 in acetonitrile under continuous photolysis. The light flux of the photoreactor was determined by N-hydroxynaphthalimide triflate actinometry in acetonitrile. N-Hydroxynaphthalimide triflate has a 0.23 quantum yield for N-O bond cleavage.¹⁷¹⁻¹⁷² Solutions containing the actinometer (50 μ L, 50 mM) were degassed using 3 freeze–pump–thaw cycles and sealed under high vacuum prior to photolysis. The extent of reaction of the actinometer was measured by UV absorbance at 360 nm. The conversion of the actinometer was 12.4% in 30 s. the % transmittance of actinometer solution was less than 0.1% during the photolysis. Therefore, the change of transmittance was negligible during photolysis. Using eqn. 8, the light flux was calculated to be $(2.5 \pm 0.1) \times 10^{-7}$ Einstein \cdot min⁻¹. Solutions containing **5** (50 μ L, 100 μ M) had an OD₃₅₀ at 1.72. The samples were degassed and photolyzed for 1 min using the calibrated photoreactor. The extent of reaction of **5** was determined by HPLC using thymidine as internal standard. The conversion of **5** was 30.7 ± 0.9 %. The quantum yield for conversion of precursor **5** was calculated using eqn. 9, and determined to be 0.03.

Nanosecond transient absorption.^b Experiments were performed on an LFP-112 spectrometer (Luzchem, Canada) employing an EX10 (GAM Laser, USA) XeCl Excimer laser (308 nm, ca. 12 mJ/pulse, ca. 12 ns pulse width) for excitation. The transient absorption spectra were recorded in acetonitrile or buffer mixtures (phosphate 10 mM, pH 7.4) in a quartz cuvette (1 x 1 cm²) equipped with a septum under a nitrogen atmosphere (bubbled for 10 minutes before measurement).

^b The nanosecond transient absorption was measured in collaboration with Markus Griesser and Derek A. Pratt in the Department of Chemistry & Biomolecular Sciences at University of Ottawa.

Oligonucleotide synthesis. Oligonucleotides were synthesized on an Applied Biosystems Incorporated 394 oligonucleotide synthesizer. Oligonucleotide synthesis reagents were purchased from Glen Research (Sterling, VA). Commercially available CE phosphoramidites were used for synthesizing unmodified oligonucleotides. Deprotection of unmodified oligonucleotides was performed with concentrated aqueous ammonia-methylamine (v/v = 1:1, 1 mL) at 65 °C for 1 h, followed by concentration under reduced pressure.

Commercially available CE phosphoramidites were used for DNA synthesis of oligonucleotides containing **3** or anthraquinone (AQ). A 5 min coupling time was used for the modified phosphoramidites. Deprotection of synthesized oligonucleotides was performed with concentrated aqueous ammonia-methylamine (v/v = 1:1, 1 mL) at 65 °C for 1 h, followed by concentration under reduced pressure.

144

Commercially available UltraMILD CE phosphoramidites were used for DNA synthesis of oligonucleotides containing **6**. A 5 min coupling time was used for the modified phosphoramidite **193**. Deprotection of synthesized oligonucleotides containing **6** was performed with concentrated aqueous ammonia at room temperature for 16 h, followed by concentration under reduced pressure.

Commercially available UltraMILD CE phosphoramidites and UltraMild Cap Mix A (5% phenoxyacetic anhydride in THF/pyridine) were used for DNA synthesis of oligonucleotides containing 5,6-dihydrothymidine (dHT). A 5 min coupling time was used for the dHT phosphoramidite. Deprotection of synthesized oligonucleotides

containing dHT was performed with concentrated aqueous ammonia at room temperature for 2 h, followed by concentration under reduced pressure.³²⁰

Commercially available UltraMILD CE phosphoramidites were used for DNA synthesis of oligonucleotides containing **210**. A 5 min coupling time was used for the modified phosphoramidite. Pivaloyl anhydride/2,6-lutidine/THF (1:1:8) was used as capping reagent and 1 M t-butyl-hydroperoxide in toluene was used as oxidizing reagent. The oxidation time is 40 s, and the capping time is 25 s. Deprotection of synthesized oligonucleotides containing **210** was performed with concentrated aqueous ammonia at room temperature for 5 h, followed by concentration under reduced pressure.^{279, 321}

The oligonucleotides were purified using 20% denaturing PAGE. Oligonucleotides were eluted from polyacrylamide gel with elution buffer (10 mL, 200 mM NaCl, 1 mM EDTA) at room temperature for 12 h and desalted using C18-Sep-Pak cartridges. Oligonucleotides containing **210** were subjected to additional purification HPLC on a Phenomenex Luna C-18 column (A: 0.05 M TEAA (pH 7.0)/MeCN 95:5; B: 0.05 M TEAA (pH 7.0)/MeCN 50:50; 0% B from t = 0 to t = 5 min; 0-15% B linearly over 15 min; 15-22% B linearly over 35 min; 22-80% B linearly over 5 min; 80-0% B linearly over 5 min; 0% B from t = 65 to t = 75 min; flow rate, 1 mL/min).³²² The extinction coefficients at 260 nm of modified oligonucleotide were calculated using IDT OligoAnalyzer® program based on nearest neighbor method,³²³ and the modified nucleotide were treated as their unmodified counterparts. The concentrations of oligonucleotides were determined using their absorbance at 260 nm. Anthraquinone (AQ)-modified oligonucleotide solution concentrations were determined using the absorbance of the anthraquinone at 333 nm ($5.5 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$).¹⁴⁴

UV melting experiments. Solutions containing a single-stranded oligonucleotide (1 μM) and their corresponding complementary oligonucleotide (1 μM) were prepared in hybridization buffer (200 μL , 100 mM NaCl, 10 mM sodium phosphate, pH 7.2) and were hybridized by heating the samples to 90 °C and slowly cooled to 17 °C. Melting studies were carried out in 1 cm path length quartz cells. Absorbance at 260 nm was monitored while the temperature was ramped at a rate of 1.0 °C/min from 20 °C to 70 °C. Experiments were carried out in duplicate.

Photolysis of oligonucleotides. The strand (1 μM) containing the radical precursor was labeled at the 5'-terminus with γ - ^{32}P -ATP using T4 PNK (30 units) in T4 PNK buffer (70 mM Tris-HCl, pH 7.6, 10 mM MgCl_2 , 5 mM DTT, 1 h, 37 °C). Alternatively, the strand (1 μM) containing the radical precursor was labeled at the 3'-terminus with α - ^{32}P -cordycepin triphosphate using terminal transferase (40 units) in CoCl_2 (250 μM) and TdT buffer (20 mM Tris-HOAc, pH 7.9, 50 mM KOAc, 10 mM $\text{Mg}(\text{OAc})_2$, 1 h, 37 °C). The labeled strand was hybridized to the complementary strand (1.5 eq.) in PBS by heating at 90°C for 1 min and slowly cooling to room temperature. The hybridized duplexes were diluted to 0.1 μM in PBS before photolysis. All photolyses were carried out in Pyrex tubes using a Rayonet photoreactor equipped with 16 lamps having a maximum output at 350 nm. All anaerobic photolyses were carried out in sealed Pyrex tubes, which were degassed by freeze-pump-thaw degassing (3 cycles). Samples were sealed while under vacuum at 77 K. Photolyses of DNA containing **3** and **6** were carried out for 4 h and 8 h respectively.

Post-photolysis treatments. Aliquots from photolyzed solutions or unphotolyzed controls were treated with piperidine (1 M, 30 min, 90 °C), Fpg (1.25

μM , 1 μL , 10 mM Bis Tris-Propane HCl (pH 7), 10 mM MgCl_2 , 1 mM DTT, 100 $\mu\text{g}/\text{mL}$ BSA, 1 h, 37 $^{\circ}\text{C}$), ARP (1 mM, 1 h, 37 $^{\circ}\text{C}$), Endo V (10 units, 1 μL , 50 mM KOAc, 20 mM Tris-acetate, 10 mM $\text{Mg}(\text{OAc})_2$, 1 mM DTT, 1 h, 37 $^{\circ}\text{C}$) or Ir^{4+} (0.1 mM of $\text{Na}_2\text{IrCl}_6 \cdot 6\text{H}_2\text{O}$) for 1 h at 25 $^{\circ}\text{C}$, quenched (2 mM Hepes, 10 mM EDTA, pH 7), followed by treatment with piperidine (1 M, 30 min, 90 $^{\circ}\text{C}$). Alternatively, photolysates were treated with piperidine (1 M, 30 min, 90 $^{\circ}\text{C}$) in the presence of 0.25 M BME. In addition, the photolysates were treated with NaBH_4 (100 mM, 1 h, 4 $^{\circ}\text{C}$), prior to piperidine treatment (1 M, 30 min, 90 $^{\circ}\text{C}$), or hOGG1 (8 units, 50 mM NaCl, 10 mM Tris-HCl (pH 7.9), 10 mM MgCl_2 , 1 mM DTT, 100 $\mu\text{g}/\text{mL}$ BSA) for 1 h at 37 $^{\circ}\text{C}$, followed by NaOH (1 M, 30 min, 37 $^{\circ}\text{C}$). NaOH treated samples were neutralized with HCl (1 equiv.). All samples treated with enzymes were precipitated (0.3 M NaOAc, pH 5.2, 0.1 g/mL calf thymus DNA) with ethanol. Piperidine treated samples were evaporated to dryness under vacuum and washed with $2 \times 10 \mu\text{L}$ water, which was also removed under vacuum. Samples were analyzed by dissolving in formamide loading buffer prior to analyzing by 20% denaturing PAGE. BME, piperidine, NaBH_4 , and Ir^{4+} solutions were prepared fresh on the day of the experiment.

Enzymatic digestion of oligonucleotides to 2'-deoxynucleosides for UPLC analysis. Duplexes **179**, **180**, and the corresponding photolysates (10 μL , 2 μM) in 1 \times PBS buffer, 5 μL water, 10 \times DNA Degradase Plus[®] buffer (2.5 μL) and dU (2.5 μL , 100 μM) as internal standard were incubated with DNA Degradase Plus[®] (5 μL , 5 U/ μL) for 4 h at 37 $^{\circ}\text{C}$. The reaction mixture was filtered through a nanosep[®] 3K filter by centrifuging the mixture for 5-10 min at 16000 \times g. The filter was washed once with H_2O (25 μL) and the combined filtrate (50 μL) was analyzed using an Agilent

1290 infinity UPLC equipped with the ACQUITY UPLC HSS T3 Column (A, 10 mM ammonium formate; B, acetonitrile; 5% B from t = 0 to t = 2 min; 5-80% B linearly over 7.5 min; 80% B from t = 9.5 to t = 12.5 min; 80-5% B linearly over 1 min; 5% B from t = 13 to t = 16 min; flow rate, 0.3 mL/min.)

UPLC and UPLC-MS/MS analysis of oligonucleotides. Photolysates (8 μ L) containing 5 μ M of duplex dodecamer were analyzed by UPLC-MS/MS using the Oligonucleotide BEH C18 Column (A, 100 mM HFIP and 8.6 mM TEA; B, Methanol; 2% B from t = 0 to t = 5 min; 2-9% B linearly over 3 min; 9% B from t = 8 to t = 20 min; 9-30% B linearly over 5 min; 30% B from t = 25 to t = 30 min; 30-2% B linearly over 5 min; 2% B from t = 35 to t = 40 min; flow rate, 0.2 mL/min.). The column temperature was 60 °C. The collision energy was set to ramp from 10 to 45 V. MS Conditions: capillary, 2 kV; sample cone, 40 V; extraction cone 4 V; source temperature, 130 °C; desolvation temperature, 500 °C; gas flow, 0.3 mL min⁻¹.

Photolysis of oligonucleotides in the presence of H₂¹⁸O and ¹⁸O₂. For photolyses carried out in H₂¹⁸O, 100 μ L of the double-stranded oligonucleotide in 1x PBS buffer was concentrated using the SpeedVac and redissolved in 100 μ L H₂¹⁸O. For photolyses carried out using ¹⁸O₂, the sample was sparged with ¹⁸O₂ while on ice for 15 min, and the tube was subsequently sealed with a torch. The subsequent photolysis was carried out according to the typical procedures.

Preparation of 85. 2'-Deoxyadenosine monohydrate (673

mg, 2.5 mmol) and imidazole (1.02 g, 15 mmol) were dissolved in anhydrous DMF (10 mL). *t*-Butyldimethylsilyl chloride (1.126 g, 7.5 mmol) was slowly added, and the reaction was stirred at room temperature overnight. The resulting mixture was washed with water and saturated NaHCO₃, extracted with DCM (3 × 50 mL), and dried over Na₂SO₄. Na₂SO₄ was removed via filtration. The organic phase was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 3% MeOH in DCM gave **85** as a white solid (948 mg, 80%). ¹H NMR (400 MHz, CDCl₃) δ 8.35 (s, 1H), 8.13 (s, 1H), 6.45 (t, *J* = 6.4 Hz, 1H), 5.62 (s, 2H), 4.61 (dt, *J* = 5.7, 3.3 Hz, 1H), 4.01 (dd, *J* = 7.3, 3.3 Hz, 1H), 3.87 (dd, *J* = 11.2, 4.2 Hz, 1H), 3.77 (dd, *J* = 11.2, 3.2 Hz, 1H), 2.70 – 2.57 (m, 1H), 2.43 (ddd, *J* = 13.1, 6.2, 3.9 Hz, 1H), 0.91 (s, 9H), 0.91 (s, 9H), 0.10 (s, 6H), 0.09 (s, 3H), 0.09 (s, 3H).

Preparation of 83a. Compound **85** (47.5 mg, 0.1 mmol)

was azeotropically dried 3 times using pyridine (2 mL × 3) and dissolved in pyridine (2 mL). Triphenylmethyl chloride **75** (45 mg, 0.16 mmol) was added to the solution. The reaction was stirred at 100 °C for 12 h, while a water-cooled condenser was attached to the round bottom flask. The reaction mixture was concentrated under vacuum and dissolved using THF (2 mL). Et₃N·3HF (161 mg, 1.0 mmol) was slowly added to the solution. The reaction was stirred overnight at room temperature. The reaction mixture was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 3% MeOH in DCM gave

83a as a white solid (17.8 mg, 36%). ¹H NMR (MeOH-d₄) δ 8.34 (s, 1H), 7.84 (s, 1H), 7.42 – 7.11 (m, 15H), 6.40 (dd, *J* = 7.9, 6.0 Hz, 1H), 4.61 – 4.48 (m, 1H), 4.05 (d, *J* = 2.6 Hz, 1H), 3.82 (dd, *J* = 12.3, 2.9 Hz, 1H), 3.71 (dd, *J* = 12.3, 3.4 Hz, 1H), 2.79 (ddd, *J* = 13.6, 8.0, 5.8 Hz, 1H), 2.39 (ddd, *J* = 13.6, 6.0, 2.7 Hz, 1H).

Preparation of 86. 2'-Deoxyguanosine monohydrate

(1.425 g, 5 mmol) and imidazole (2.04 g, 30 mmol) were dissolved in anhydrous DMF (20 mL). *t*-Butyldimethylsilyl chloride (2.25 g, 15 mmol) was slowly added, and the reaction was stirred at room temperature overnight. The resulting mixture was washed with water and saturated NaHCO₃, extracted with DCM (3 × 200 mL), and dried over Na₂SO₄. Na₂SO₄ was removed via filtration. The organic phase was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave **86** as a white solid (1.83 g, 75%). ¹H NMR (400 MHz, CDCl₃) δ 7.80 (s, 1H), 6.24 (t, *J* = 6.4 Hz, 1H), 5.90 (s, 2H), 4.63 – 4.48 (m, 1H), 3.97 (dd, *J* = 7.2, 3.6 Hz, 1H), 3.80 (dd, *J* = 11.2, 4.1 Hz, 1H), 3.75 (dd, *J* = 11.2, 3.2 Hz, 1H), 2.56 – 2.46 (m, 1H), 2.41 – 2.29 (m, 1H), 0.91 (s, 18H), 0.10 (s, 6H), 0.08 (s, 3H), 0.08 (s, 3H).

Preparation of 84a. Compound **86** (49.4 mg, 0.1

mmol) was azeotropically dried 3 times using pyridine (2 mL × 3) and dissolved in pyridine (2 mL). Triphenylmethyl chloride **75** (45 mg, 0.16 mmol) was added to the solution. The reaction was stirred at 100 °C for 12 h, while a water-cooled condenser was attached to the round bottom flask. The reaction mixture was concentrated under vacuum and

dissolved using THF (2 mL). Et₃N•3HF (161 mg, 1.0 mmol) was slowly added to the solution. The reaction was stirred overnight at room temperature. The reaction mixture was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 3% MeOH in DCM gave **84a** as a white solid (37.8 mg, 74%). ¹H NMR (400 MHz, MeOH-d₄) δ 7.90 (s, 1H), 7.45 – 7.07 (m, 17H), 5.61 (t, *J* = 6.5 Hz, 1H), 4.18 (dt, *J* = 7.0, 3.7 Hz, 1H), 3.80 (q, *J* = 3.7 Hz, 1H), 3.55 (d, *J* = 1.4 Hz, 1H), 3.54 (d, *J* = 1.4 Hz, 1H), 2.02 (dt, *J* = 13.2, 6.4 Hz, 1H), 1.85 (ddd, *J* = 13.2, 6.2, 3.9 Hz, 1H).

3',5'-bis-O-(*t*-butyldimethylsilyl)-2'-deoxyinosine

Preparation of 3',5'-bis-O-(*t*-

butyldimethylsilyl)-2'-deoxyinosine. 2'-

Deoxyinosine (630 mg, 2.5 mmol) and imidazole

(1.02 g, 15 mmol) were dissolved in anhydrous

DMF (10 mL). *t*-Butyldimethylsilyl chloride (1.126 g, 7.5 mmol) was slowly added, and the reaction was stirred at room temperature overnight. The resulting mixture was washed with water and saturated NaHCO₃, extracted with DCM (3 × 50 mL), and dried over Na₂SO₄. Na₂SO₄ was removed via filtration. The organic phase was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave 3',5'-bis-O-(*t*-butyldimethylsilyl)-2'-deoxyinosine as a white solid (1.07 g, 89%). ¹H NMR (400 MHz, CDCl₃) δ 8.18 (s, 1H), 8.16 (s, 1H), 6.44 (t, *J* = 6.4 Hz, 1H), 4.63 (dt, *J* = 5.6, 3.7 Hz, 1H), 4.04 (dd, *J* = 7.2, 3.7 Hz, 1H), 3.87 (dd, *J* = 11.2, 4.1 Hz, 1H), 3.80 (dd, *J* = 11.2, 3.1 Hz, 1H), 2.65 – 2.51 (m, 1H), 2.51 – 2.36 (m, 1H), 0.94 (s, 9H), 0.94 (s, 9H), 0.13 (s, 6H), 0.11 (s, 3H), 0.11 (s, 3H).

Preparation of 91.²⁰⁰ 3',5'-Bis-O-(*t*-butyldimethylsilyl)-2'-

deoxyinosine (481 mg, 1 mmol) and (benzotriazol-1-yloxy)tris(dimethylamino)phosphonium hexafluorophosphate (BOP reagent, 900 mg, 2.03 mmol) were dissolved in THF (10 mL).

DIPEA (194 mg, 262 μ L, 1.5 mmol) were added, and the mixture was allowed to stir at room temperature for 24 h. The mixture was washed with water, extracted with DCM (3 \times 30 mL), and dried over Na₂SO₄. Na₂SO₄ was removed via filtration. The organic phase was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **91** as a white solid (467 mg, 78% yield). ¹H NMR (400 MHz, CDCl₃) δ 8.56 (s, 1H), 8.43 (s, 1H), 8.16 (d, *J* = 8.1 Hz, 1H), 7.53 (dd, *J* = 18.1, 6.0 Hz, 3H), 6.58 (d, *J* = 5.5 Hz, 1H), 4.67 (s, 1H), 4.09 (s, 1H), 3.94 (d, *J* = 11.2 Hz, 1H), 3.83 (d, *J* = 11.2 Hz, 1H), 2.80 – 2.61 (m, 1H), 2.55 (s, 1H), 0.95 (s, 18H), 0.13 (s, 12H).

Preparation of 92. Compound **91** (59.8 mg, 0.1 mmol) was

dissolved in THF (2 mL), and phenylhydrazine (108 mg, 1 mmol) was added. The reaction was stirred at 65 °C for 3 h. The resulting mixture was washed with 10% citric acid solution, extracted with EtOAc (3 \times 10 mL), and dried over Na₂SO₄. Na₂SO₄ was removed

via filtration. The combined organic phase was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 30% EtOAc in hexanes gave **92** as an orange foam (57.0 mg, > 99%). ¹H NMR (400 MHz, MeOH-*d*₄) δ 8.31 (s, 1H), 8.23 (s, 1H), 7.24 – 7.05 (m, 2H), 6.93 – 6.71 (m, 3H), 6.44 (dd, *J* = 7.8, 6.1 Hz, 1H), 4.58 (dt, *J* = 5.5, 2.5 Hz, 1H), 4.07 (q, *J* = 3.1 Hz, 1H), 3.84 (dd, *J* = 12.3, 3.1 Hz, 1H), 3.78 – 3.69

(m, 1H), 2.79 (td, $J = 7.8, 3.9$ Hz, 1H), 2.41 (ddd, $J = 13.4, 6.1, 2.8$ Hz, 1H), 0.92 (s, 9H), 0.87 (s, 9H), 0.12 (s, 6H), 0.07 (s, 3H), 0.06 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 159.0, 153.6, 151.4, 143.6, 143.5, 128.7, 124.8, 120.6, 119.9, 108.7, 88.2, 85.1, 71.7, 62.6, 41.7, 26.0, 25.7, 18.4, 18.0, -4.7, -4.8, -5.4, -5.5. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{28}\text{H}_{47}\text{N}_6\text{O}_3\text{Si}_2)^+$ ($\text{M} + \text{H}$) $^+ = 571.3248$, found $m/z = 571.3239$.

Preparation of 90. Compound **92** (57.0 mg, 0.1 mmol) was dissolved in THF (2 mL), and $\text{Et}_3\text{N}\cdot 3\text{HF}$ (1.0 mmol, 161 mg) was slowly added to the solution, and the mixture is allowed to react at room temperature overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column.

Elution with 3% MeOH in DCM gave **78** as a brown solid (22.9 mg, 67%). ^1H NMR (MeOH-d_4) δ 8.31 (s, 1H), 8.23 (s, 1H), 7.24 – 7.05 (m, 2H), 6.93 – 6.71 (m, 3H), 6.44 (dd, $J = 7.8, 6.1$ Hz, 1H), 4.58 (dt, $J = 5.5, 2.5$ Hz, 1H), 4.07 (q, $J = 3.1$ Hz, 1H), 3.84 (dd, $J = 12.3, 3.1$ Hz, 1H), 3.78 – 3.69 (m, 1H), 2.79 (td, $J = 7.8, 3.9$ Hz, 1H), 2.41 (ddd, $J = 13.4, 6.1, 2.8$ Hz, 1H).

Preparation of 97.³²⁴ 3',5'-Bis-O-TBDMS-2'-deoxyadenosine (**85**, 475 mg, 1 mmol) was dissolved in bromoform (6 mL). The reaction mixture was heated to 40 °C. tBuONO (2.4 mL) was slowly added to the solution, and the reaction was reacted at 40 °C for 45 min.

The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **97** as a white solid (288.3 mg, 53%). ^1H NMR (CDCl_3) δ 8.54 (s, 1H), 8.38 (s, 1H), 6.40 (t, $J = 6.4$ Hz, 1H), 4.52 (dt, $J = 5.7, 3.7$ Hz, 1H), 3.93 (q, $J = 3.3$ Hz, 1H), 3.77 (dd, $J = 11.3, 3.9$ Hz, 1H), 3.67 (dd, $J =$

11.3, 2.9 Hz, 1H), 2.65 – 2.48 (m, 1H), 2.38 (ddd, $J = 13.1, 6.1, 3.9$ Hz, 1H), 0.79 (s, 9H), 0.77 (s, 9H), - 0.01 (s, 6H), - 0.03 (s, 3H), - 0.04 (s, 3H).

Preparation of **98**.²¹¹ 3',5'-Bis-O-(*t*-

butyldimethylsilyl)-2'-deoxyinosine (48 mg, 0.1 mmol) was dissolved in DCM (2 mL). HMPA (0.2 mL), DMAP (0.02 mmol, 2.5 mg), and TEA (200 mg, 0.28 mL, 0.2

mmol) were added. 2-Mesitylenesulfonyl chloride (43.8 mg, 0.2 mmol) was slowly added while stirring, and the mixture was allowed to stir at room temperature overnight. The mixture was washed with water, extracted with DCM (3×10 mL), and dried over Na_2SO_4 . Na_2SO_4 was removed via filtration. The organic phase was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 25% EtOAc in hexanes gave **98** as a white solid (20 mg, 30% yield). ^1H NMR (400 MHz, CDCl_3) δ 8.54 (s, 1H), 8.38 (s, 1H), 6.99 (s, 2H), 6.48 (t, $J = 6.4$ Hz, 1H), 4.61 (dt, $J = 5.9, 3.5$ Hz, 1H), 4.03 (dd, $J = 6.9, 3.5$ Hz, 1H), 3.86 (dd, $J = 11.3, 3.9$ Hz, 1H), 3.76 (dd, $J = 11.3, 3.0$ Hz, 1H), 2.76 (s, 6H), 2.62 (dt, $J = 12.7, 6.2$ Hz, 1H), 2.45 (ddd, $J = 12.7, 6.2, 3.9$ Hz, 1H), 2.31 (s, 3H), 0.91 (s, 9H), 0.89 (s, 9H), 0.10 (s, 6H), 0.08 (s, 3H), 0.07 (s, 3H).

Preparation of **96**. Compound **97** (288.3 mg, 0.53

mmol), Pd_2dba_3 (48.5 mg, 0.053 mmol), *N,N*-diphenylhydrazine (196 mg, 1.06 mmol), Xantphos (47 mg, 0.080 mmol), and Cs_2CO_3 (260 mg, 0.8 mmol) was added to a

dry Schlenk flask. The flask was purged with argon for three times, and toluene (10 mL) was added. The reaction was stirred at 80 °C for 3 h. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 20% EtOAc

in hexanes gave **96** as a red foam (164 mg, 48%). ¹H NMR (400 MHz, CDCl₃) δ 10.29 (s, 1H), 8.46 (s, 1H), 7.60 (s, 1H), 7.33 (d, *J* = 8.0 Hz, 5H), 7.29 – 7.19 (m, 5H), 7.06 – 6.92 (m, 2H), 6.33 (t, *J* = 5.9 Hz, 1H), 4.71 – 4.47 (m, 1H), 4.00 (dd, *J* = 7.5, 4.7 Hz, 1H), 3.73 (dd, *J* = 11.0, 4.8 Hz, 1H), 3.68 (dd, *J* = 11.0, 4.8 Hz, 1H), 2.78 – 2.49 (m, 1H), 2.35 (ddd, *J* = 13.1, 6.0, 3.5 Hz, 1H), 0.93 (s, 9H), 0.89 (s, 9H), 0.12 (s, 6H), 0.06 (s, 3H), 0.04 (s, 3H). ¹³C NMR (101 MHz, CDCl₃) δ 153.6, 146.3, 139.6, 129.2, 122.8, 119.3, 87.9, 84.5, 72.2, 62.9, 40.4, 25.9, 25.8, 18.4, 18.0, -4.7, -4.8, -5.4. HRMS (ESI-TOF) *m/z* calcd for (C₃₄H₅₁N₆O₃Si₂)⁺ (M + H)⁺ = 647.3561, found *m/z* = 647.3567.

Preparation of 3. Compound **96** (164 mg, 0.26 mmol) was dissolved in THF (7 mL). While stirring, Et₃N•3HF (2.6 mmol, 419 mg) was slowly added. The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 1% to 3% MeOH in DCM gave **3** as a light yellow oil (95 mg, 87%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.24 (s, 2H), 7.23 (s, 8H), 6.96 (s, 2H), 6.42 (s, 1H), 4.56 (s, 1H), 4.05 (s, 1H), 3.81 (d, *J* = 11.9 Hz, 1H), 3.72 (d, *J* = 11.9 Hz, 1H), 2.78 (br, 1H), 2.40 (br, 1H). ¹³C NMR (101 MHz, MeOH-d₄) δ 150.6, 147.3, 145.0, 139.4, 127.2, 121.0, 117.7, 117.3, 86.9, 84.1, 70.0, 60.7, 38.6. HRMS (ESI-TOF) *m/z* calcd for (C₂₂H₂₃N₆O₃)⁺ (M + H)⁺ = 419.1832, found *m/z* = 419.1843. UV/Vis λ_{max} (H₂O) = 267 nm, ε = 1.88 × 10⁴ dm³ mol⁻¹ cm⁻¹.

Preparation of 99.²²⁰ 3',5'-Bis-O-TBDMS-2'-deoxyguanosine (**86**, 306 mg, 0.61 mmol), benzyl alcohol (141 mg, 1.3 mmol), and PPh₃ (340 mg, 1.3 mmol) was dissolved in dioxane (10 mL). DEAD (226 mg, 1.3 mmol) and

were slowly added. The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **99** as a light yellow oil (319 mg, 89%). ¹H NMR (400 MHz, CDCl₃) δ 7.90 (s, 1H), 7.54 – 7.43 (m, 2H), 7.37 – 7.17 (m, 5H), 6.30 (t, *J* = 6.5 Hz, 1H), 5.63 – 5.46 (m, 2H), 4.94 (s, 2H), 4.69 (s, 2H), 4.62 – 4.49 (m, 1H), 3.96 (dd, *J* = 7.3, 3.3 Hz, 1H), 3.81 (dd, *J* = 11.2, 4.2 Hz, 1H), 3.75 (dd, *J* = 11.2, 4.2 Hz, 1H), 2.55 (ddd, *J* = 12.9, 8.4, 4.9 Hz, 1H), 2.34 (ddd, *J* = 12.9, 6.1, 3.8 Hz, 1H), 0.91 (s, 9H), 0.90 (s, 9H), 0.44 – -0.19 (m, 12H).

Preparation of 100.²²⁰ Compound **99** (319 mg, 0.54 mmol), SbBr₃ (320 mg, 0.87 mmol) was dissolved in methylene bromide (7 mL). The reaction mixture was cooled to -10 °C. tBuONO (260 μL, 268 mg, 2.17 mmol) was slowly

added to the solution, and the reaction was stirred at -10 °C for 1 h. The reaction mixture was poured into saturated NaHCO₃ and extracted with DCM (3 × 20 mL). The resulting mixture was dried using Na₂SO₄. Na₂SO₄ was removed via filtration, and the solution was concentrated under vacuum. The reaction was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **100** as a light yellow oil (158 mg, 45%). ¹H NMR (400 MHz, CDCl₃) δ 8.16 (s, 1H), 7.50 (dd, *J* = 8.0, 1.4 Hz, 2H), 7.31 (m, 3H), 6.37 (t, *J* = 6.3 Hz, 1H), 5.69 – 5.45 (m, 2H), 4.64 (dt, *J* = 5.7, 4.0 Hz, 1H), 3.98 (dd, *J* = 7.4, 3.5 Hz, 1H), 3.88 (dd, *J* = 11.2, 4.3 Hz, 1H), 3.76 (dd, *J* = 11.2, 4.3 Hz, 1H), 2.63 (ddd, *J* = 13.1, 6.1, 3.8 Hz, 1H), 2.40 (ddd, *J* = 13.1, 6.3, 4.3 Hz, 1H), 0.91 (s, 9H), 0.90 (s, 9H), 0.11 (s, 6H), 0.08 (s, 3H), 0.08 (s, 3H).

Preparation of 101. Compound **100** (91.5 mg,

0.14 mmol), Pd₂dba₃ (13.8 mg, 0.014 mmol), N,N-diphenylhydrazine (36.8 mg, 0.28 mmol), Xantphos (13 mg, 0.021 mmol), and Cs₂CO₃ (75 mg, 0.21 mmol) were

added to a dry Schlenk flask. The flask was purged with argon three times, and toluene (10 mL) was added. The reaction reacted at 80 °C for 3 h. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **101** as an orange foam (66.4 mg, 63%). ¹H NMR (400 MHz, CDCl₃) δ 7.94 (s, 1H), 7.38 (s, 2H), 7.33 (s, 1H), 7.31 – 7.21 (m, 12H), 7.05 – 6.95 (m, 2H), 6.30 (s, 1H), 5.45 (s, 2H), 4.53 (s, 1H), 3.97 (d, *J* = 3.6 Hz, 1H), 3.86 – 3.60 (m, 2H), 2.51 (br, 1H), 2.28 (br, 1H), 0.94 (s, 9H), 0.93 (s, 9H), 0.12 (s, 3H), 0.11 (s, 3H), 0.09 (s, 3H), 0.08 (s, 3H). ¹³C NMR (101 MHz, CDCl₃) δ 161.0, 153.5, 146.4, 138.2, 136.3, 129.0, 128.8, 128.3, 127.9, 122.2, 119.1, 117.0, 87.8, 72.0, 68.1, 62.8, 26.0, 25.8, 25.7, 18.4, 18.0, -3.5, -4.6, -4.8, -5.37, -5.41. HRMS (ESI-TOF) *m/z* calcd for (C₄₁H₅₇N₆O₄Si₂)⁺ (M + H)⁺ = 753.3980, found *m/z* = 753.3983.

Preparation of 4. Compound **101** (66.4 mg, 0.09

mmol) was dissolved in THF (2 mL). Et₃N•3HF (161 mg, 1.0 mmol) was slowly added, and the reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum, and

directly carried on to the next step without purification. The residue was dissolved in MeOH (6 mL), and 20 mg 10% Pd/C was added to the solution. The flask was bubbled with hydrogen using a balloon. The reaction was monitored by TLC and was completed after 30 min. The Pd/C was removed by passing the reaction through a silica plug. The

reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 1% to 3% MeOH in DCM gave **4** as a white foam (24 mg, 61.4%). ^1H NMR (400 MHz, MeOH- d_4) δ 8.02 (s, 1H), 7.34 (dd, J = 8.6, 7.3 Hz, 4H), 7.24 (dd, J = 8.6, 1.0 Hz, 4H), 7.10 (t, J = 7.3 Hz, 2H), 6.28 (t, J = 6.8 Hz, 1H), 4.50 (s, 1H), 3.97 (d, J = 3.3 Hz, 1H), 3.72 (dd, J = 23.3, 11.5 Hz, 2H), 2.68 (dt, J = 13.5, 6.7 Hz, 1H), 2.33 (s, 1H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 156.1, 152.0, 149.2, 145.2, 135.8, 127.4, 122.1, 118.4, 86.4, 82.8, 69.7, 60.4, 38.3. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{22}\text{H}_{23}\text{N}_6\text{O}_4)^+$ ($\text{M} + \text{H}$) $^+$ = 435.1781, found m/z = 435.1788. UV/Vis λ_{max} (H_2O) = 264 nm, ϵ = $1.74 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$.

Preparation of 8- ^2H -3. Compound **3** (42.1 mg, 0.1 mmol) is dissolved in d_3 -acetonitrile- D_2O (3 mL, 1:1). TEA (11 mg, 0.1 mmol) was added to the mixture, and the reaction was stirred at 65 $^\circ\text{C}$ for 48 h. The reaction was concentrated and dried under vacuum overnight to provide 8- ^2H -**3** (42 mg, 99%). ^1H NMR (400 MHz, MeOH- d_4) δ 8.25 (s, 1H), 7.23 (t, J = 6.7 Hz, 8H), 6.98 (dt, J = 8.6, 4.1 Hz, 2H), 6.44 (t, J = 6.7 Hz, 1H), 4.67 – 4.46 (m, 1H), 4.06 (d, J = 2.7 Hz, 1H), 3.82 (dd, J = 12.2, 3.0 Hz, 1H), 3.73 (dd, J = 12.2, 3.0 Hz, 1H), 2.79 (dd, J = 13.0, 6.3 Hz, 1H), 2.40 (d, J = 8.9 Hz, 1H). HRMS (ESI-TOF) m/z calcd for $(\text{C}_{22}\text{H}_{22}\text{DN}_6\text{O}_3)^+$ ($\text{M} + \text{H}$) $^+$ = 420.1894, found m/z = 420.1881.

Preparation of disilylated 106.³²⁵ Racemic 2,2'-bis(diphenylphosphino)-1,1'-binaphthyl (rac-BINAP, 37.4 mg, 0.06 mmol) and $\text{Pd}_2(\text{dba})_3$, 18.3 mg, 0.02 mmol) were suspended in anhydrous DME (2 mL). Bis-TBDMS 8-bromo-2'-deoxyadenosine³²⁶ (**105**, 111 mg, 0.2 mmol), aniline (47 mg, 0.5 mmol), and Cs_2CO_3 (98

mg, 0.3 mmol) were added and the mixture was stirred under reflux for 48 h. The reaction mixture was allowed to cool to room temperature and quenched with saturated NaHCO₃ solution. The mixture was extracted with ethyl acetate (3 × 5 mL). The organic layer was dried with Na₂SO₄. Na₂SO₄ was removed via filtration, and concentrated under vacuum. Purification of the residue by flash chromatography on silica gel (5 to 35% ethyl acetate in hexanes) gave disilylated **106** as a light yellow oil (89 mg, 78%). ¹H NMR (400 MHz, CDCl₃) δ 8.19 (s, 1H), 7.79 (s, 1H), 7.56 (dd, *J* = 8.6, 1.1 Hz, 2H), 7.35 – 7.27 (m, 2H), 7.08 – 6.98 (m, 1H), 6.43 (dd, *J* = 7.9, 5.8 Hz, 1H), 4.58 (dt, *J* = 6.2, 3.1 Hz, 1H), 4.04 (q, *J* = 3.4 Hz, 1H), 3.95 (dd, *J* = 11.4, 3.4 Hz, 1H), 3.83 (dd, *J* = 11.4, 3.5 Hz, 1H), 2.89 (ddd, *J* = 13.2, 7.9, 6.3 Hz, 1H), 2.31 (ddd, *J* = 13.0, 5.8, 3.1 Hz, 1H), 0.92 (s, 9H), 0.82 (s, 9H), 0.11 (s, 3H), 0.11 (s, 3H), 0.01 (s, 3H), -0.01 (s, 3H).

106

Preparation of 106. Disilylated **106** (89 mg, 0.16 mmol) was dissolved in THF (2 mL). While stirring, Et₃N•3HF (1.6 mmol, 258 mg) was slowly added. The reaction was stirred at 25 °C overnight.

The reaction was concentrated under vacuum and purified by flash

chromatography on a silica column. Elution with 1% to 7% MeOH in DCM gave **106** as a colorless foam (44 mg, 80%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.05 (s, 1H), 7.59 (d, *J* = 7.9 Hz, 2H), 7.32 (t, *J* = 7.9 Hz, 2H), 7.05 (t, *J* = 7.4 Hz, 1H), 6.61 (dd, *J* = 9.3, 5.9 Hz, 1H), 4.60 (d, *J* = 6.0 Hz, 1H), 4.09 (s, 1H), 3.93 (d, *J* = 11.8 Hz, 1H), 3.87 (d, *J* = 11.8 Hz, 1H), 2.87 – 2.68 (m, 1H), 2.24 (dd, *J* = 13.4, 5.9 Hz, 1H). ¹³C NMR (101 MHz, MeOH-d₄) δ 151.2, 147.8, 147.2, 146.9, 137.8, 127.1, 121.3, 118.6, 86.3, 82.4, 70.4, 60.0, 37.0. HRMS (ESI-TOF) *m/z* calcd for (C₁₆H₁₉N₆O₃)⁺ (M + H)⁺ = 343.1519, found *m/z* = 343.1510. UV/Vis λ_{max} (ACN) = 292 nm, ε = 1.17 × 10⁴ dm³ mol⁻¹ cm⁻¹.

Preparation of 109. HMDS (3.2 mL, 15.0 mmol) was added to a solution of n-butyl lithium (14.5 mmol, 11 mL) at -78 °C in THF (7 mL), and the mixture was stirred at this temperature for 1 h. Isobutyronitrile (966 mg, 14.0 mmol) in THF (5 mL) was slowly added to the solution. The solution was stirred for 1 h at which time ethyl phenylacetate (2.228 g, 14.0 mmol) in THF (10 mL) was added. The mixture was allowed to warm to room temperature and stirred overnight. The reaction was quenched with MeOH at room temperature, concentrated under vacuum, and purified by flash chromatography. Elution with 20% ethyl acetate in hexanes gave **109** as a colorless oil (597 mg, 22%). ¹H NMR (300 MHz, CDCl₃) δ 7.45 – 7.18 (m, 5H), 4.10 (s, 2H), 1.52 (s, 6H). ¹³C NMR (75 MHz, CDCl₃) δ 201.7, 132.8, 129.7, 128.7, 127.4, 121.9, 45.2, 43.9, 23.9. IR (KBr plate) 2998, 2902, 2856, 2344, 1721, 792, 713 cm⁻¹. HRMS (FAB) C₁₂H₁₄NO⁺ (M + H)⁺ calcd. 188.1075, found 188.1072.

Preparation of 110. A solution of **109** (168 mg, 0.9 mmol) in THF (1 mL) was added dropwise to a suspension of LiAlH₄ (36 mg, 0.95 mmol) in THF (1 mL) over 2 min at 0 °C. The ice bath was removed, and the reaction was stirred at room temperature for 4 h. The reaction mixture was poured into THF/H₂O (1:1, 1 mL) at 0 °C and stirred at 80 °C for 10 min, and then filtered through celite. The filtrate was extracted with DCM (3 × 10 mL). The organic layers were combined and dried over Na₂SO₄. Na₂SO₄ was removed via filtration, and the solution was concentrated under vacuum to give 4-amino-3,3-dimethyl-1-phenylbutan-2-ol. 4-Amino-3,3-dimethyl-1-phenylbutan-2-ol was used without further purification. A solution of di-tert-butyl dicarbonate (207 mg, 0.95 mmol) in DCM (2 mL) was added to a solution of 4-amino-3,3-dimethyl-1-phenylbutan-2-ol in DCM (2 mL) at 0 °C and stirred

at room temperature overnight. The reaction mixture was poured into water and extracted with DCM (3×10 mL), dried over Na_2SO_4 . Na_2SO_4 was removed via filtration, and the solution was concentrated under vacuum. The residue was chromatographed on silica gel and eluted with 25% ethyl acetate in hexanes to give **110** as colorless oil (188.7 mg, 72% over two steps). ^1H NMR (400 MHz, CDCl_3) δ 7.27 (m, 5H), 5.26 (t, $J = 6.2$ Hz, 1H), 3.53 (d, $J = 9.2$ Hz, 1H), 3.39 (dd, $J = 14.1, 7.2$ Hz, 1H), 3.26 (s, 1H), 2.81 (dd, $J = 21.6, 9.1$ Hz, 2H), 2.56 (dd, $J = 13.8, 10.5$ Hz, 1H), 1.44 (s, 9H), 0.97 (d, $J = 7.5$ Hz, 6H). ^{13}C NMR (75 MHz, CDCl_3) δ 146.3, 139.6, 129.1, 122.8, 119.4, 87.9, 84.5, 72.1, 62.9, 40.6, 25.9, 25.8, 18.4, 18.0. IR (KBr plate) 3457, 3398, 2970, 2934, 2859, 1719, 1685, 792, 743, 729 cm^{-1} . HRMS (FAB) $\text{C}_{17}\text{H}_{28}\text{NO}_3^+$ ($\text{M} + \text{H}$) $^+$ calcd. 294.2069, found 294.2065.

Preparation of t-Boc-protected 111. A solution of **110** (153

mg, 0.52 mmol) in DCM (2 mL) was added to a solution of pyridine (60 mg, 0.75 mmol), PCC (162 mg, 0.75 mmol) and celite (1.3 g) in DCM (2.5 mL). The reaction mixture was refluxed for 6.5 h. After quenching excess PCC with isopropanol (5 mL), diethyl ether (20 mL) was added to the solution. The reaction mixture was filtered through celite and concentrated under vacuum. The residue was chromatographed on silica gel and eluted with 25% ethyl acetate in hexanes to give t-Boc-protected **111** as a light yellow oil (137.6 mg, 90%). ^1H NMR (400 MHz, CDCl_3) δ 7.34 – 7.27 (m, 2H), 7.27 – 7.20 (m, 1H), 7.15 (dd, $J = 7.7, 0.9$ Hz, 2H), 4.95 (s, 1H), 3.78 (s, 2H), 3.25 (d, $J = 6.6$ Hz, 2H), 1.41 (s, 9H), 1.22 (s, 6H). ^{13}C NMR (75 MHz, CDCl_3): δ 212.7, 156.3, 134.4, 129.7, 128.5, 126.9, 79.1, 49.4, 48.0, 43.7, 28.4, 22.5. IR (KBr plate) 3387, 2975, 2935, 2849, 1760, 1697, 749, 735 cm^{-1} . HRMS (FAB) $\text{C}_{17}\text{H}_{26}\text{NO}_3^+$ ($\text{M} + \text{H}$) $^+$ calcd. 292.1913, found 292.1905.

Preparation of 111. t-Boc-protected **111** (137.6 mg, 0.47 mmol)

was treated with DCM-TFA (1:1, 2 mL) for 1 h at 25 °C. The reaction mixture was then poured into saturated NaHCO₃ solution, extracted with DCM (3 × 10 mL), dried over Na₂SO₄. Na₂SO₄ was removed via filtration, and the solution was concentrated under vacuum. The residue was chromatographed on silica gel and eluted with 40% ethyl acetate in hexanes to give **111** as a colorless oil (91 mg, > 99%).
¹H NMR (300 MHz, CDCl₃) δ 7.25 (m, 5H), 3.80 (s, 2H), 2.81 (s, 2H), 1.47 (s, 2H), 1.19 (s, 6H).
¹³C NMR (75 MHz, CDCl₃) δ 212.5, 134.6, 129.6, 128.4, 126.7, 53.5, 50.8, 49.9, 44.1, 22.4. IR (KBr plate) 3391 (broad), 2963, 2925, 2854, 1700, 1043, 725, 696, 667 cm⁻¹.
¹. HRMS (FAB) C₁₂H₁₈NO⁺ (M + H)⁺ calcd. 192.1388, found 192.1391.

Preparation of 112. Compound **91** (59.8 mg, 0.1

mmol) and **111** (46 mg, 0.24 mmol) were stirred in THF (1 mL) at room temperature overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 3% MeOH in DCM gave **112** as a white solid (53.9 mg, 83%).
¹H NMR (400 MHz, CDCl₃) δ 8.33 (s, 1H), 8.04 (s, 1H), 7.34 – 7.26 (m, 2H), 7.24 (dd, *J* = 5.1, 3.7 Hz, 1H), 7.18 – 7.12 (m, 2H), 6.42 (t, *J* = 6.5 Hz, 1H), 4.65 – 4.57 (m, 1H), 4.00 (dd, *J* = 7.5, 3.3 Hz, 1H), 3.90 – 3.67 (m, 6H), 2.69 – 2.54 (m, 1H), 2.41 (ddd, *J* = 13.0, 6.1, 3.8 Hz, 1H), 1.32 (s, 6H), 0.91 (s, 9H), 0.91 (s, 9H), 0.09 (s, 6H), 0.08 (s, 3H), 0.08 (s, 3H).
¹³C NMR (75 MHz, CDCl₃) δ 212.2, 155.1, 152.8, 150.6, 138.2, 134.3, 129.6, 128.4, 126.8, 87.8, 84.2, 71.9, 62.8, 49.6, 43.7, 41.2, 26.0, 25.8, 22.6, 18.4, 18.0, -4.7, -4.8, -5.4, -5.5. IR (KBr plate) 2953, 2928, 2855, 1708, 1613, 1471, 1252, 835,

777, 724 cm^{-1} ; HRMS (ESI-TOF) $\text{C}_{34}\text{H}_{56}\text{N}_5\text{O}_4\text{Si}_2^+$ ($\text{M} + \text{H}$) $^+$ calcd. 654.3871, found 654.3871.

Preparation of 107. $\text{Et}_3\text{N}\cdot 3\text{HF}$ (161 mg, 1.0 mmol) was slowly added to **112** (65 mg, 0.1 mmol) in THF (1 mL). The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave **107** as a white solid (37.0 mg, 87%). ^1H NMR (400 MHz, MeOH- d_4) δ 8.29 (s, 1H), 8.23 (s, 1H), 7.34 – 7.03 (m, 5H), 6.43 (dd, $J = 7.8, 6.0$ Hz, 1H), 4.65 – 4.56 (m, 1H), 4.09 (dd, $J = 5.5, 2.9$ Hz, 1H), 3.97 (s, 2H), 3.86 (dd, $J = 12.3, 2.9$ Hz, 2H), 3.75 (dd, $J = 12.3, 3.3$ Hz, 1H), 3.43 – 3.10 (m, 2H), 2.81 (ddd, $J = 13.6, 8.0, 5.8$ Hz, 1H), 2.41 (ddd, $J = 13.6, 6.0, 2.6$ Hz, 1H), 1.32 (s, 6H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 211.1, 153.6, 150.5, 138.2, 133.3, 129.5, 127.9, 126.9, 126.3, 124.6, 87.0, 84.3, 70.2, 60.8, 48.0, 41.9, 38.7, 27.8, 20.0. IR (KBr plate) 3279 (broad), 2928, 1610, 1580, 1473, 1228, 1111, 1071, 836, 774, 728 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{22}\text{H}_{28}\text{N}_5\text{O}_4^+$ ($\text{M} + \text{H}$) $^+$ calcd. 426.2141, found 426.2136.

Preparation of 119. *p*-Toluenesulfonic acid (19 mg, 0.1 mmol), isobutyrophenone (148 mg, 1 mmol) was dissolved in DCM (2 mL). Br_2 (168 mg, 1.05 mmol) was slowly added while stirring. The reaction was stirred at room temperature for 1 h. The reaction was poured into water and extracted with EtOAc (5 mL \times 3). The organic phase was dried over Na_2SO_4 , passed through a silica plug, concentrated under vacuum gave **119** as a yellow oil (178.6 mg, 79%). ^1H NMR (300 MHz, CDCl_3) δ 8.14 (ddd, $J = 7.0, 2.4, 1.2$ Hz, 2H), 7.62 – 7.48 (m, 1H), 7.48 – 7.37 (m, 2H), 2.03 (s, 6H).

Preparation of 120. N-Boc-hydroxylamine (27 mg, 0.2 mmol) was dissolved in DMF (1 mL). NaH (60% in mineral oil, 8 mg, 0.2 mmol) was slowly added while stirring. The reaction was stirred at 0 °C for 30 min, and **119** (17 mg, 0.075 mmol) was then added at 0 °C. The reaction was stirred at room temperature overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **120** as a yellow oil (23.9 mg, > 99%). ¹H NMR (300 MHz, CDCl₃) δ 8.54 – 7.92 (m, 2H), 7.62 – 7.52 (m, 1H), 7.47 (ddt, *J* = 8.3, 6.9, 1.4 Hz, 2H), 6.71 (s, 1H), 1.63 (s, 6H), 1.44 (s, 9H).

Preparation of 121. DCM-TFA (1:1, 1 mL) was added to a dry round bottom flask containing **120** (21 mg, 0.075 mmol). The reaction was stirred at room temperature for 1 h. The reaction was quenched by saturated NaHCO₃ solution and extracted with DCM (5 mL × 3). The combined organic phases were dried over Na₂SO₄. Na₂SO₄ was removed via filtration. The organic phase was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **121** as a white solid (12.5 mg, > 99%). ¹H NMR (400 MHz, CDCl₃) δ 8.61 – 7.97 (m, 2H), 7.49 (m, 3H), 1.55 (s, 6H).

Preparation of 123. TEA (1.01 g, 10 mmol) was added to hydroxylamine hydrochloride (345 mg, 5 mmol) in THF (10 mL). After stirring at room temperature for 30 min **97** (270 mg, 0.5 mmol) was added, and the reaction was refluxed at 65 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 5% MeOH and 1% Et₃N in DCM gave **123** as a light purple

foam. The sample was dissolved in MeOH (10 mL) and Na₂-EDTA (1.7 g, 5 mmol) was added to the solution and the reaction was stirred at 50 °C until the purple color faded. The mixture was cooled to room temperature and filtered to remove Na₂-EDTA. The organic phase was then concentrated under vacuum to give **123** as a white foam (143 mg, 58%). ¹H NMR (300 MHz, MeOH-d₄) δ 8.20 (s, 1H), 8.05 (s, 1H), 6.37 (t, *J* = 6.4 Hz, 1H), 4.69 (dt, *J* = 5.6, 4.0 Hz, 1H), 3.97 (dd, *J* = 7.8, 3.6 Hz, 1H), 3.86 (dd, *J* = 11.2, 4.5 Hz, 1H), 3.76 (dd, *J* = 11.2, 3.6 Hz, 1H), 2.75 (dt, *J* = 13.0, 6.1 Hz, 1H), 2.43 (ddd, *J* = 13.0, 6.2, 4.2 Hz, 1H), 0.93 (s, 9H), 0.87 (s, 9H), 0.17 – 0.00 (m, 12H). ¹³C NMR (75 MHz, MeOH-d₄) δ 149.7, 147.2, 145.9, 140.3, 139.5, 119.8, 89.2, 85.7, 73.4, 64.0, 41.6, 26.6, 26.5, 19.3, 19.0, 9.7, -4.2, -4.3, -5.1. IR (KBr plate) 3408 (broad), 2954, 2929, 2896, 2857, 1691, 1680, 1254, 1110, 837, 778 cm⁻¹. HRMS (ESI-TOF) C₂₂H₄₂N₅O₄Si₂⁺ (M + H)⁺ calcd. 496.2775, found 496.2768.

Preparation of 122. NaH (60% in mineral oil, 20 mg, 0.5 mmol) was slowly added while stirring to **123** (241 mg, 0.5 mmol) in DMF (3 mL) at 0 °C. The reaction was stirred at 0 °C for 30 min at which time **119** (227 mg,

0.55 mmol) was added. The reaction was stirred at room temperature for 4 h, concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **122** as a red oil (209 mg, 64%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.17-8.13 (m, 2H), 7.86 (s, 1H), 7.62 (s, 1H), 7.45-7.38 (m, 1H), 7.38-7.31 (m, 2H), 6.22 (t, *J* = 6.2 Hz, 1H), 4.63 (dd, *J* = 8.9, 3.9 Hz, 1H), 3.92 (dd, *J* = 7.8, 3.7 Hz, 1H), 3.80 (dd, *J* = 11.2, 4.6 Hz, 1H), 3.72 (dd, *J* = 11.2, 3.6 Hz, 1H), 2.69 – 2.55 (m, 1H), 2.35 (ddd, *J* = 13.1, 6.2, 4.3 Hz, 1H), 1.63 (s, 6H), 0.91 (s, 9H), 0.85 (s, 9H), 0.11 (s, 6H), 0.03 (s, 3H),

0.01 (s, 3H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 203.0, 151.5, 145.3, 143.9, 141.1, 140.5, 136.3, 135.4, 131.8, 129.3, 127.6, 118.6, 87.9, 87.8, 86.1, 85.2, 84.1, 71.9, 62.4, 40.2, 25.1, 25.0, 24.9, 24.0, 17.9, 17.5, -5.8, -5.93, -6.65, -6.66. IR (KBr plate): 2934, 1610, 1592, 1494, 1475, 1320, 834, 760, 743, 695 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{32}\text{H}_{52}\text{N}_5\text{O}_5\text{Si}_2^+$ ($\text{M} + \text{H}$) $^+$ calcd. 642.3507, found 642.3503.

Preparation of 117 Et₃N•3HF (530 mg, 3.3 mmol)

was added to **123** (209 mg, 0.33 mmol) in THF (5 mL).

The reaction was stirred at 25 °C overnight, concentrated under vacuum, and purified by flash chromatography on a

silica column. Elution with 5% MeOH in DCM gave **117** as a yellow foam (101 mg, 75%).

^1H NMR (300 MHz, MeOH- d_4) δ 8.23 – 8.06 (m, 2H), 7.91 (s, 1H), 7.63 (s, 1H), 7.45-7.38 (m, 1H), 7.38-7.30 (m, 2H), 6.30 – 6.21 (m, 1H), 4.49 (dt, $J = 5.5, 2.7$ Hz, 1H), 3.99 (dd, $J = 6.2, 3.3$ Hz, 1H), 3.77 (dd, $J = 12.2, 3.3$ Hz, 1H), 3.68 (dd, $J = 12.2, 3.7$ Hz, 1H), 2.63 (ddd, $J = 13.6, 7.7, 6.0$ Hz, 1H), 2.34 (ddd, $J = 13.6, 6.0, 2.9$ Hz, 1H), 1.65 (s, 6H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 203.1, 144.0, 141.0, 140.2, 137.0, 135.3, 131.9, 129.2, 127.9, 127.7, 118.9, 88.2, 86.2, 85.2, 71.4, 62.1, 40.5, 24.0. IR (KBr plate): 3273 (broad), 2928, 1606, 1590, 1494, 1471, 1328, 1252, 1105, 835, 777, 747, 692 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{20}\text{H}_{24}\text{N}_5\text{O}_5^+$ ($\text{M} + \text{H}$) $^+$ calcd. 414.1777, found 414.1770.

Preparation of 128.²³² Methyl trimethylsilyl dimethylketene

acetal (2.61 g, 15 mmol) and pivaloyl chloride (1.44 g, 12 mmol) was dissolved in DCM (30 mL). TiCl₄ (2.845 g, 15 mmol) was slowly added to the reaction at 0 °C. The reaction was stirred at room temperature overnight. The reaction was quenched with water, extracted with DCM (30 mL \times 3). The organic phase was dried

over Na₂SO₄, and Na₂SO₄ was removed via filtration. The mixture was concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **128** as a colorless oil (2 g, 90%). ¹H NMR (400 MHz, CDCl₃) δ 3.66 (s, 3H), 1.32 (s, 6H), 1.12 (s, 9H).

Preparation of 129. Acetic acid-conc. HCl (1:1, 30 mL) was added to **128** (2.0 g, 10 mmol). The reaction was refluxed at 110 °C for 8 h. The cooled reaction was quenched by saturated NaHCO₃ solution and extracted with DCM (30 mL × 3). The organic phase was dried over Na₂SO₄. The organic phase was concentrated under vacuum to give **129** as an orange oil (1.75 g, > 99%). ¹H NMR (300 MHz, CDCl₃) δ 3.12 (hept, *J* = 6.7 Hz, 1H), 1.14 (s, 9H), 1.03 (d, *J* = 6.7 Hz, 6H). ¹³C NMR (75 MHz, CDCl₃) δ 220.1, 44.6, 33.8, 26.0, 20.1. IR (KBr plate) 2973, 2936, 2874, 1732 cm⁻¹.

Preparation of 130. Br₂ (176 mg, 1.1 mmol) was slowly added to **129** (128 mg, 1 mmol) in HOAc (2 mL). The reaction was heated at 70 °C for 5 h, poured into water, and extracted with EtOAc (5 mL × 3). The organic phase was passed through a silica plug and then concentrated under vacuum to yield **130** as a yellow oil (200 mg, 97%). ¹H NMR (400 MHz, CDCl₃) δ 1.91 (s, 6H), 1.36 (s, 9H). ¹³C NMR (75 MHz, CDCl₃) δ 209.2, 62.3, 45.5, 31.9, 29.3. IR (KBr plate) 2981, 2876, 1733, 1699, 1263, 1194, 1145 cm⁻¹.

Preparation of 131. NaH (60% in mineral oil, 28 mg, 0.7 mmol) was slowly added to **123** (335 mg, 0.7 mmol) in DMF (7 mL). The reaction was stirred at 0 °C for 1 h, at which time **130** (290 mg, 1.4 mmol) was added at 0 °C. The reaction was stirred at room temperature for 4 h, and quenched with MeOH. The

mixture was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave bis-silylated **131** as a yellow foam (320 mg, 74%). ^1H NMR (400 MHz, MeOH- d_4) δ 7.94 (s, 1H), 7.62 (s, 1H), 6.28 (t, $J = 6.4$ Hz, 1H), 4.69 (dd, $J = 9.2, 3.9$ Hz, 1H), 3.95 (dd, $J = 7.7, 3.7$ Hz, 1H), 3.84 (dd, $J = 11.2, 4.5$ Hz, 1H), 3.76 (dd, $J = 11.2, 3.6$ Hz, 1H), 2.73 (dt, $J = 13.1, 6.1$ Hz, 1H), 2.40 (ddd, $J = 13.1, 6.3, 4.3$ Hz, 1H), 1.48 (s, 6H), 1.25 (s, 9H), 0.93 (s, 9H), 0.88 (s, 9H), 0.14 (s, 6H), 0.07 (s, 3H), 0.04 (s, 3H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 218.4, 144.1, 140.5, 136.5, 118.8, 87.9, 87.2, 84.2, 71.9, 62.4, 43.8, 40.2, 27.9, 25.1, 24.91, 23.8, 17.9, 17.5, -5.9, -6.0, -6.8. IR (KBr plate) 2927, 1672, 1609, 1474, 1254, 1112, 832, 782, 662 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{30}\text{H}_{56}\text{N}_5\text{O}_5\text{Si}_2^+$ ($\text{M} + \text{H}$) $^+$ calcd. 622.3820, found 622.3820.

Preparation of 6. Et₃N•3HF (0.83 g, 5.2 mmol)

was slowly added to **131** (320 mg, 0.52 mmol) and the reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash

chromatography on a silica column. Elution with 5% MeOH in DCM gave **6** as a yellow foam (163 mg, 59%). ^1H NMR (400 MHz, MeOH- d_4) δ 8.01 (s, 1H), 7.64 (s, 1H), 6.45 – 6.17 (m, 1H), 4.60 – 4.40 (m, 1H), 4.02 (dd, $J = 6.1, 3.2$ Hz, 1H), 3.80 (dd, $J = 12.2, 3.2$ Hz, 1H), 3.75 – 3.67 (m, 1H), 2.77 – 2.62 (m, 1H), 2.39 (ddd, $J = 13.4, 6.0, 2.9$ Hz, 1H), 1.48 (s, 6H), 1.24 (s, 9H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 218.4, 144.2, 140.5, 140.3, 137.1, 119.2, 88.3, 87.3, 85.3, 71.4, 62.1, 43.8, 40.6, 27.9, 23.8. IR (KBr plate) 3278 (broad), 2932, 1669, 1610, 1471, 1254, 1110, 837, 778, 665 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{18}\text{H}_{28}\text{N}_5\text{O}_5^+$ ($\text{M} + \text{H}$) $^+$ calcd. 394.2090, found 394.2085.

Preparation of 138. Et₃N•3HF (323 mg, 2.0 mmol) was slowly added to **123** (99 mg, 0.2 mmol) in THF (2 mL). The reaction was stirred at 25 °C overnight, concentrated under vacuum, and purified by flash chromatography on a silica column. Elution with 10% MeOH in DCM gave **138** as a light purple foam. The sample was dissolved in MeOH (2 mL) and Na₂-EDTA (770 mg, 2 mmol) was added to the solution and the reaction was stirred at 50 °C until the purple color faded. The mixture was cooled to room temperature and filtered to remove Na₂-EDTA. The organic phase was then concentrated under vacuum give **138** as a white foam (37.5 mg, 70%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.36 (s, 1H), 8.20 (s, 1H), 6.44 (dd, *J* = 7.9, 6.0 Hz, 1H), 4.58 (dt, *J* = 5.6, 2.7 Hz, 1H), 4.07 (dd, *J* = 5.8, 3.1 Hz, 1H), 3.84 (dd, *J* = 12.3, 3.0 Hz, 1H), 3.74 (dd, *J* = 12.3, 3.4 Hz, 1H), 2.80 (ddd, *J* = 13.6, 7.9, 5.8 Hz, 1H), 2.42 (ddd, *J* = 13.6, 6.0, 2.8 Hz, 1H). The spectral data matches the literature.³²⁷

Preparation of 140. NaH (60% in mineral oil, 20 mg, 0.5 mmol) was slowly to **123** (241 mg, 0.5 mmol) in THF (3 mL). The reaction was stirred at 0 °C for 30 min, at which time 2-bromopropane (68 mg, 0.55 mmol) was added at 0 °C. The reaction was stirred at room temperature for 2 h and quenched with MeOH. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **140** as a red oil (70 mg, 26%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.03 (s, 1H), 7.69 (s, 1H), 6.31 (s, 1H), 5.50 (d, *J* = 10.6 Hz, 1H), 4.76 – 4.59 (m, 1H), 4.27 (hept, *J* = 6.3 Hz, 1H), 3.95 (dd, *J* = 8.0, 3.7 Hz, 1H), 3.85 (dd, *J* = 11.2, 4.6 Hz, 1H), 3.76 (dd, *J* = 11.2, 3.7 Hz, 1H), 2.80 – 2.67 (m, 1H), 2.40 (ddd, *J* = 13.1,

6.2, 4.2 Hz, 1H), 1.29 (d, $J = 6.2$ Hz, 6H), 0.93 (s, 9H), 0.89 (s, 9H), 0.14 (s, 6H), 0.07 (s, 3H), 0.05 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 156.1, 152.9, 149.8, 142.4, 140.7, 140.1, 139.6, 136.0, 120.1, 118.8, 87.9, 84.4, 83.9, 78.0, 75.1, 71.8, 62.8, 41.5, 41.2, 26.0, 25.8, 21.8, 20.6, 18.4, 18.0, -4.6, -4.8, -5.4, -5.5. IR (KBr plate) 2975, 2920, 1670, 1581, 1412, 1223, 889, 748, 659 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{25}\text{H}_{48}\text{N}_5\text{O}_4\text{Si}_2^+$ ($\text{M} + \text{H}$) $^+$ calcd. 538.3245, found 538.3240.

Preparation of 141. $\text{Et}_3\text{N}\cdot 3\text{HF}$ (122 mg, 0.76 mmol) was added to **140** (40.5 mg, 0.076 mmol) in THF (1 mL). The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave **141** as a yellow foam (19 mg, 80%). ^1H NMR (400 MHz, MeOH-d_4) δ 8.06 (s, 1H), 7.64 (s, 1H), 6.34 (s, 1H), 4.61 – 4.41 (m, 1H), 4.27 (hept, $J = 6.1$ Hz, 1H), 4.04 (d, $J = 2.8$ Hz, 1H), 3.81 (dd, $J = 12.2, 3.1$ Hz, 1H), 3.72 (dd, $J = 12.2, 3.6$ Hz, 1H), 2.72 (m, 1H), 2.39 (ddd, $J = 13.4, 6.0, 2.8$ Hz, 1H), 1.29 (d, $J = 6.2$ Hz, 6H). ^{13}C NMR (101 MHz, MeOH-d_4) δ 153.6, 145.5, 142.6, 138.6, 121.1, 89.73, 86.8, 76.1, 73.6, 63.6, 41.9, 21.9. IR (KBr plate) 3274 (broad), 2973, 2924, 1659, 1589, 1416, 1393, 1327, 1217, 1095, 1058, 967, 942, 893, 753, 653 cm^{-1} . HRMS (ESI-TOF) $\text{C}_{13}\text{H}_{20}\text{N}_5\text{O}_4^+$ ($\text{M} + \text{H}$) $^+$ calcd. 310.1515, found 310.1513.

Preparation of 142. Hydroxylamine hydrochloride (345 mg, 5 mmol) was treated with TEA (1.01 g, 10 mmol) in dioxane (10 mL) for 30 min before **100** (324 mg, 0.5 mmol) was added. The reaction was refluxed at 110 °C overnight. The reaction was cooled to room temperature, concentrated under vacuum, and purified by

flash chromatography on a silica column. Elution with 5% MeOH and 1% Et₃N in DCM gave **142** as a white foam (186 mg, 62%). ¹H NMR (400 MHz, CDCl₃) δ 9.70 (s, 1H), 8.09 (s, 1H), 7.58 (s, 1H), 7.41 (d, *J* = 6.6 Hz, 2H), 7.33 – 7.07 (m, 3H), 6.60 (t, *J* = 6.2 Hz, 1H), 5.48 (q, *J* = 12.3 Hz, 2H), 4.57 (dt, *J* = 7.4, 3.9 Hz, 1H), 4.00 (d, *J* = 3.1 Hz, 1H), 3.83 (dd, *J* = 11.3, 3.1 Hz, 1H), 3.79 (dd, *J* = 11.3, 3.1 Hz, 1H), 2.60 – 2.45 (m, 1H), 2.36 (dt, *J* = 12.7, 6.2 Hz, 1H), 0.91 (s, 9H), 0.90 (s, 9H), 0.11 (s, 6H), 0.08 (s, 6H). ¹³C NMR (101 MHz, CDCl₃) δ 162.3, 160.7, 152.4, 138.0, 136.0, 128.4, 128.3, 128.3, 128.27, 128.25, 128.23, 128.23, 128.22, 128.0, 117.0, 87.6, 84.0, 71.8, 68.4, 62.7, 42.2, 26.0, 25.8, 18.4, 18.0, -4.6, -4.8, -5.4, -5.5. HRMS (ESI-TOF) *m/z* calcd for (C₂₉H₄₇N₅O₅Si₂)⁺ (M + H)⁺ = 602.3194, found *m/z* = 602.3197.

Preparation of 143. Compound **142** (186 mg,

0.31 mmol) was dissolved in DMF (3 mL). Cs₂CO₃ (101 mg, 0.31 mmol) was slowly added while stirring.

The reaction was stirred at 0 °C for 30 min before **130**

(81 mg, 0.39 mmol) was added at 0 °C. The reaction was stirred at room temperature overnight. The reaction was quenched by water and extracted with DCM (3 × 10 mL). The organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The residue was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **143** as a yellow foam (158 mg, 70%). ¹H NMR (400 MHz, CDCl₃) δ 8.03 (s, 1H), 7.60 (s, 1H), 7.38 (d, *J* = 6.7 Hz, 2H), 7.22 (ddd, *J* = 8.5, 7.7, 2.3 Hz, 3H), 6.33 (t, *J* = 6.5 Hz, 1H), 5.57 – 5.40 (m, 2H), 4.60 – 4.41 (m, 1H), 3.95 (dd, *J* = 6.3, 3.1 Hz, 1H), 3.75 (qd, *J* = 11.2, 3.5 Hz, 2H), 2.48 – 2.36 (m, 1H), 2.30 (ddd, *J* = 12.9, 5.8, 3.5 Hz, 1H), 1.48 (s, 7H), 1.32 (s, 10H), 0.86 (s, 18H),

0.04 (d, $J = 2.3$ Hz, 12H). ^{13}C NMR (101 MHz, CDCl_3) δ 215.6, 161.1, 160.6, 153.0, 138.4, 136.1, 128.3, 128.0, 127.9, 117.4, 91.2, 87.8, 84.1, 72.0, 68.1, 62.9, 45.2, 41.7, 26.8, 26.0, 25.9, 25.7, 24.4, 24.3, 18.4, 17.9, -4.7, -4.8, -5.4, -5.5. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{37}\text{H}_{62}\text{N}_5\text{O}_6\text{Si}_2)^+$ ($\text{M} + \text{H}$) $^+$ = 728.4239, found m/z = 728.4245.

Preparation of 144. Compound **143** (158 mg,

0.22 mmol) was dissolved in MeOH (4 mL), and 20 mg 10% Pd/C was added to the solution. The flask was sparged with hydrogen using a balloon. The reaction

was monitored by TLC (3% MeOH in DCM) and was complete after 30 min. The Pd/C was removed by passing the reaction through a silica plug. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 1% to 3% MeOH in DCM gave **144** as a white solid (126 mg, 90%). ^1H NMR (400 MHz, CDCl_3) δ 7.84 (s, 1H), 6.23 (t, $J = 6.5$ Hz, 1H), 4.51 (br, 1H), 3.96 (br, 1H), 3.72 (d, $J = 12.1$ Hz, 2H), 2.55 – 2.21 (m, 2H), 1.54 (s, 3H), 1.52 (s, 3H), 1.33 (s, 9H), 0.89 (s, 9H), 0.88 (s, 9H), 0.08 (s, 6H), 0.06 (s, 3H), 0.05 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 214.9, 157.7, 154.7, 149.6, 136.0, 119.4, 90.9, 87.9, 83.9, 72.2, 62.9, 44.9, 41.4, 27.2, 25.9, 25.7, 24.1, 18.4, 18.0, -4.7, -4.8, -5.4, -5.5. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{30}\text{H}_{56}\text{N}_5\text{O}_6\text{Si}_2)^+$ ($\text{M} + \text{H}$) $^+$ = 638.3769, found m/z = 638.3742.

Preparation of 7. Compound **144** (126 mg, 0.2

mmol) was dissolved in THF (2 mL). $\text{Et}_3\text{N} \cdot 3\text{HF}$ (322 mg, 2.0 mmol) was slowly added while stirring. The reaction

was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 7% MeOH in DCM gave **7** as a

light pink foam (63.8 mg, 78%). ^1H NMR (400 MHz, MeOH- d_4) δ 8.14 (s, 1H), 6.31 (t, J = 6.7 Hz, 1H), 4.56 – 4.42 (m, 1H), 3.98 (dd, J = 7.3, 3.8 Hz, 1H), 3.75 (dd, J = 7.3, 4.0 Hz, 1H), 2.64 (ddd, J = 13.4, 7.1, 6.2 Hz, 1H), 2.39 (ddd, J = 13.4, 6.2, 3.6 Hz, 1H), 1.57 (d, J = 1.1 Hz, 6H), 1.31 (s, 9H). ^{13}C NMR (101 MHz, MeOH- d_4) δ 215.5, 157.2, 155.3, 149.8, 137.4, 118.4, 90.3, 87.8, 84.2, 71.1, 61.7, 44.4, 40.3, 26.4, 23.3. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{18}\text{H}_{28}\text{N}_5\text{O}_6)^+$ ($\text{M} + \text{H}$) $^+$ = 410.2040, found m/z = 410.2038.

Preparation of 146. Methyl 4-acetylbenzoate (2.67 g, 15 mmol), ethylene glycol (1.24 g, 1.1 mL, 20 mmol), and *p*-toluenesulfonic acid (26 mg, 0.15 mmol) were dissolved in toluene (15 mL) was added. A Dean-Stark trap was attached, and the solution was refluxed for 24 h. The solution was washed with saturated NaHCO_3 (50 mL) and extracted with DCM (3×50 mL). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **146** as white solid (3.1 g, 92%). ^1H NMR (400 MHz, CDCl_3) δ 8.01 (d, J = 8.6 Hz, 2H), 7.55 (d, J = 8.6 Hz, 2H), 4.05 (td, J = 6.2, 4.2 Hz, 2H), 3.91 (s, 3H), 3.76 (td, J = 6.2, 4.2 Hz, 2H), 1.65 (s, 3H).

Preparation of 147. A solution of **146** (3.1 g, 14 mmol) in THF (20 mL) was added dropwise to a suspension of LiAlH_4 (1.33 g, 35 mmol) in THF (25 mL) over 10 min at 0 °C. The ice bath was removed, and the reaction was stirred at room temperature for 12 h. The reaction mixture quenched by 10% NaOH and extracted with DCM (3×50 mL). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated

under vacuum to give **147** as a white solid (3.14 g, 99%). $^1\text{H NMR}$ (400 MHz, CDCl_3) δ 7.43 (d, $J = 8.3$ Hz, 2H), 7.29 (d, $J = 8.3$ Hz, 2H), 4.59 (s, 2H), 3.98 (td, $J = 6.1, 4.2$ Hz, 2H), 3.72 (td, $J = 6.1, 4.2$ Hz, 2H), 3.40 (s, 1H), 1.62 (s, 3H).

Preparation of 148. A mixture of THF (2.5 mL), H_2O (1.5 mL) and concentrated HCl (1 mL) was added to **147** (1 g, 5 mmol). The reaction was stirred at room temperature for 30 min. The reaction mixture was extracted with DCM (3×30 mL), dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The residue was chromatographed on silica gel and eluted with 30% ethyl acetate in hexanes to give **148** as white solid (744 mg, 99%). $^1\text{H NMR}$ (400 MHz, CDCl_3) δ 7.90 (d, $J = 8.6$ Hz, 2H), 7.42 (d, $J = 8.6$ Hz, 2H), 4.74 (s, 2H), 3.01 (s, 1H), 2.57 (s, 3H).

Preparation of 150. To a mixture of 2,2,4-trimethyl-1,3-pentanediol (730 mg, 5 mmol), ethylene glycol (1.24 g, 1.1 mL, 20 mmol), dimethyl sulfoxide (470 mg, 425 μL , 6 mmol), and $\text{Re}(\text{O})\text{Cl}_3(\text{PPh}_3)_2$ (210 mg, 0.25 mmol), toluene (25 mL) was added. A Dean-Stark trap was attached, and the solution was heated to reflux. An additional portion of ethylene glycol (2.5 g, 2.2 mL, 40 mmol) was added after 1 h. The reaction was removed from the heat after a total of 3 h. The solution was washed with saturated NaHCO_3 (50 mL) and extracted with DCM (3×50 mL). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **150** as a colorless oil (635 mg, 88%). $^1\text{H NMR}$ (400 MHz, CDCl_3) δ 3.57 (s, 2H), 2.49 (s, 1H),

1.92 (s, 6H), 1.42 (s, 6H). ^{13}C NMR (101 MHz, CDCl_3) δ 209.8, 71.8, 62.4, 50.7, 31.6, 23.75, 23.73.

Preparation of 152. Br_2 (635 mg, 4.5 mmol) was added to a solution of **150** (635 mg, 4.4 mmol) in chloroform (15 mL). The solution was refluxed for 1 h and stirred at room temperature overnight. The reaction was concentrated under vacuum, and the product (**151**) was used for the next step without further purification. *p*-Toluenesulfonyl chloride (1.72 g, 9 mmol) was added to a solution of crude **151** (1 g, 4.5 mmol) in pyridine (10 mL). The reaction was stirred overnight. The solution was washed with saturated NaHCO_3 (20 mL) and extracted with DCM (3×10 mL). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **152** as a yellow oil (1.5 g, 90%). ^1H NMR (400 MHz, CDCl_3) δ 7.73 (d, $J = 8.0$ Hz, 2H), 7.33 (d, $J = 8.0$ Hz, 2H), 4.04 (s, 2H), 2.43 (s, 3H), 1.85 (s, 6H), 1.44 (s, 6H). ^{13}C NMR (101 MHz, CDCl_3) δ 205.76, 144.9, 132.7, 129.9, 127.9, 62.1, 49.1, 31.3, 24.0, 21.7.

Preparation of 154. A mixture of **152** (32.7 mg, 0.1 mmol) and *p*-hydroxymethyl acetophenone (**148**, 15 mg, 0.1 mmol), was dissolved in DMF (1 mL), and Cs_2CO_3 (32.5 mg, 0.1 mmol) was added. The reaction was stirred overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **154** as a colorless oil (35 mg, 88%). ^1H NMR (400 MHz, CDCl_3) δ 7.94 – 7.87 (m, 2H), 7.83 – 7.76

(m, 2H), 7.34 (dd, $J = 8.6, 0.7$ Hz, 2H), 7.27 (dd, $J = 8.1, 0.5$ Hz, 2H), 4.58 (d, $J = 13.4$ Hz, 1H), 4.51 (d, $J = 13.4$ Hz, 1H), 4.14 (d, $J = 9.0$ Hz, 1H), 3.96 (d, $J = 9.0$ Hz, 1H), 2.62 (s, 3H), 2.46 (s, 3H), 1.50 (s, 3H), 1.27 (s, 4H), 1.11 (s, 3H), 1.10 (s, 3H).

Preparation of 157.²⁵³ 3',5'-Bis-O-TBDMS-2'-deoxyguanosine (**86**, 980 mg, 2 mmol), 2-(trimethylsilyl)ethanol (472 mg, 4 mmol), and PPh₃ (1.05 g, 4 mmol) was dissolved in THF (25 mL). DEAD (696 mg, 4

mmol) was slowly added. The reaction was stirred at 25 °C overnight. The reaction mixture quenched with water and extracted with DCM (3 × 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **157** as a light yellow oil (610 mg, 49%).
¹H NMR (400 MHz, CDCl₃) δ 7.85 (s, 1H), 6.30 (t, $J = 6.8$, 1H), 4.92 (s, 2H), 4.59 – 4.39 (m, 3H), 3.95 (dd, $J = 7.4, 3.3$ Hz, 1H), 3.78 (dd, $J = 11.1, 4.3$ Hz, 1H), 3.73 (dd, $J = 11.1, 3.3$ Hz, 1H), 2.54 (ddd, $J = 13.0, 7.1, 5.8$ Hz, 1H), 2.33 (ddd, $J = 13.0, 6.1, 3.7$ Hz, 1H), 1.24 – 1.17 (m, 2H), 0.89 (s, 9H), 0.89 (s, 9H), 0.08 (s, 6H), 0.06 (s, 9H), 0.05 (s, 3H), 0.05 (s, 3H).

Preparation of 158.²⁵³ Compound **157** (610 g, 1.02 mmol) was dissolved in 28 mL anhydrous toluene and cooled to -10 °C. Polyvinylpyridine-HF (3.7 g) and tert-butyl nitrite (850 mg, 0.88 mL, 7.4 mmol) were added. After 1 h, the reaction was poured into cold saturated NaHCO₃ (100 mL). The resulting solid was removed by filtration, and the organic phase product extracted with EtOAc (3 × 30 mL).

The organic phase was dried using Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The reaction was purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **158** as a colorless oil (402.5 mg, 67%). ¹H NMR (400 MHz, CDCl₃) δ 8.13 (s, 1H), 6.32 (t, *J* = 6.4 Hz, 1H), 4.66 – 4.51 (m, 3H), 3.94 (dd, *J* = 7.0, 3.3 Hz, 1H), 3.82 (dd, *J* = 11.2, 4.2 Hz, 1H), 3.71 (dd, *J* = 11.2, 3.1 Hz, 1H), 2.56 (dt, *J* = 13.1, 4.7 Hz, 1H), 2.36 (ddd, *J* = 13.1, 6.1, 3.9 Hz, 1H), 1.30 – 1.14 (m, 2H), 0.84 (s, 9H), 0.84 (s, 9H), 0.04 (s, 6H), 0.03 (s, 9H), 0.02 (s, 3H), 0.01 (s, 3H).

Preparation of 155. A mixture of **158** (402.5 mg, 0.67 mmol), hydroxylamine hydrochloride (467 mg, 6.7 mmol), and triethylamine (1.35 g, 1.9 mL, 13.4 mmol) was dissolved in anhydrous dioxane (7 mL). The reaction was refluxed overnight. The reaction mixture quenched with water and extracted with DCM (3 × 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 30% EtOAc in hexanes gave **155** as a light yellow foam (307.5 mg, 75%). ¹H NMR (400 MHz, CDCl₃) δ 9.61 (s, 1H), 8.04 (s, 1H), 7.40 (s, 1H), 6.58 (t, *J* = 6.3 Hz, 1H), 4.67 – 4.38 (m, 3H), 3.99 (dd, *J* = 6.4, 3.2 Hz, 1H), 3.83 (dd, *J* = 11.2, 3.6 Hz, 1H), 3.77 (dd, *J* = 11.2, 2.8 Hz, 1H), 2.51 (ddd, *J* = 12.9, 5.9, 4.0 Hz, 1H), 2.40 – 2.26 (m, 1H), 1.24 – 1.11 (m, 2H), 0.90 (s, 9H), 0.89 (s, 9H), 0.09 (s, 6H), 0.07 (s, 6H), 0.03 (s, 9H). ¹³C NMR (101 MHz, CDCl₃) δ 162.4, 161.1, 152.0, 137.8, 117.1, 87.6, 84.0, 71.8, 65.4, 62.7, 42.2, 25.9, 25.8, 25.8, 25.7, 18.43, 18.42, 18.04, 18.03, 17.5, -1.4, -1.4, -1.4, -4.5, -4.8, -5.3, -5.5.

Preparation of 159. A mixture of **155** (61.5 mg, 0.1 mmol), **152** (32.7 mg, 0.1 mmol), and Cs₂CO₃ (32.5 mg, 0.1 mmol) was dissolved in anhydrous DMF (1 mL). The reaction was stirred at room temperature overnight.

The reaction was quenched with water and extracted with EtOAc (3 × 10 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave **159** as a light yellow oil (307.5 mg, 75%). ¹H NMR (400 MHz, CDCl₃) δ 8.01 (s, 1H), 6.43 (t, *J* = 6.6 Hz, 1H), 4.70 – 4.63 (m, 2H), 4.61 – 4.51 (m, 1H), 4.06 – 3.97 (m, 3H), 3.84 (dd, *J* = 11.2, 4.3 Hz, 1H), 3.79 (dd, *J* = 11.2, 3.5 Hz, 1H), 2.58 (ddd, *J* = 13.0, 7.0, 5.8 Hz, 1H), 2.42 (ddd, *J* = 13.0, 6.1, 3.7 Hz, 1H), 1.53 (s, 3H), 1.51 (s, 3H), 1.34 (s, 6H), 1.30 – 1.26 (m, 2H), 0.94 (s, 9H), 0.93 (s, 9H), 0.12 (s, 6H), 0.11 (s, 9H), 0.10 (s, 2H), 0.10 (s, 3H).

Preparation of 160. NaH (60% in mineral oil, 168 mg, 4.2 mmol) was slowly added to **150** (576 mg, 4 mmol) in DMF (20 mL).

The reaction was stirred at 0 °C for 30 min, at which time benzyl bromide (718.2 mg, 4.2 mmol) was added at 0 °C. The reaction was stirred at room temperature for 4 h. The reaction was quenched with MeOH, washed with water, and extracted with DCM (30 mL × 3). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **160** as a colorless oil (814 mg, 87%). ¹H NMR (400 MHz, CDCl₃) δ 7.40 – 7.28 (m, 5H), 4.53 (s, 2H), 3.52 (s, 2H), 3.15 (hept, *J* = 6.7 Hz, 1H), 1.21 (s, 6H), 1.08

(d, $J = 6.7$ Hz, 6H). ^{13}C NMR (101 MHz, CDCl_3) δ 218.8, 138.3, 128.3, 127.5, 127.4, 73.3, 49.0, 34.3, 21.7, 19.9.

Preparation of 161. Br_2 (160 mg, 1 mmol) was added to a solution of **160** (230 mg, 1 mmol) in chloroform (3 mL). The solution was refluxed for 1 h and stirred at room temperature overnight. The reaction was washed with water, extracted with DCM (10 mL \times 3). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **161** as a colorless oil (104 mg, 35%). ^1H NMR (400 MHz, CDCl_3) δ 7.43 – 7.25 (m, 5H), 4.50 (s, 2H), 3.59 (s, 2H), 1.96 (s, 6H), 1.51 (s, 6H).

Preparation of 162. Compound **155** (61 mg, 0.1 mmol) was dissolved in DMF (3 mL). Cs_2CO_3 (33 mg, 0.1 mmol) was slowly added while stirring. The reaction was stirred at room temperature for 30 min. The solution was cooled to 0°C and **161** (32 mg, 0.1 mmol) was added. The reaction was warmed to room temperature and stirred overnight. The reaction was washed with water, extracted with DCM (10 mL \times 3). The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **162** as a yellow foam (50.2 mg, 59.5%). ^1H NMR (400 MHz, CDCl_3) δ 8.01 (s, 1H), 7.53 (s, 1H), 7.32 – 7.19 (m, 6H), 6.36 (t, $J = 6.5$ Hz, 1H), 4.61 – 4.46 (m, 5H), 3.96 (d, $J = 3.3$ Hz, 1H), 3.80 (dd, $J = 11.2, 4.0$ Hz, 1H),

3.76 (dd, $J = 11.2, 3.1$ Hz, 1H), 3.72 – 3.60 (m, 2H), 2.50 – 2.38 (m, 1H), 2.33 (ddd, $J = 12.9, 5.9, 3.4$ Hz, 1H), 1.53 (s, 6H), 1.39 (s, 6H), 1.23 (dt, $J = 6.7, 4.5$ Hz, 2H), 0.91 (s, 9H), 0.89 (s, 9H), 0.10 – 0.07 (m, 12H), 0.05 (s, 9H). ^{13}C NMR (101 MHz, CDCl_3) δ 214.2, 161.0, 152.7, 138.3, 138.1, 128.2, 127.7, 127.5, 117.4, 91.0, 87.8, 83.9, 72.0, 65.1, 62.9, 49.8, 41.7, 26.0, 25.8, 24.01, 23.98, 23.2, 23.1, 18.4, 18.0, 17.5, -1.4, -4.6 -4.8, -5.3, -5.5.

Preparation of 163. Compound 162 (50.2

mg, 0.06 mmol) was dissolved in MeOH (1 mL), and 13 mg 10% Pd/C was added to the solution.

The flask was sparged with hydrogen using a

balloon. The reaction was monitored by TLC and was complete after 3 h. The Pd/C was removed by passing the reaction through a silica plug. The combined organic phase was dried over Na_2SO_4 . Na_2SO_4 was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 1% to 3% MeOH in DCM gave **163** as a white solid (11 mg, 25%). ^1H NMR (400 MHz, CDCl_3) δ 8.13 (s, 1H), 7.40 (s, 1H), 6.43 (t, $J = 6.1$ Hz, 1H), 4.65 – 4.58 (m, 2H), 4.56 (dd, $J = 9.9, 4.7$ Hz, 1H), 3.99 (dd, $J = 6.6, 3.4$ Hz, 1H), 3.88 (dd, $J = 11.3, 3.6$ Hz, 1H), 3.80 (dd, $J = 11.3, 2.9$ Hz, 3H), 2.47 (ddd, $J = 13.0, 6.2, 4.7$ Hz, 1H), 2.41 – 2.26 (m, 1H), 1.56 (d, $J = 3.7$ Hz, 6H), 1.33 (s, 6H), 1.30 – 1.24 (m, 3H), 0.94 (s, 9H), 0.92 (s, 9H), 0.12 (s, 3H), 0.12 (s, 3H), 0.11 (s, 9H), 0.10 (s, 3H), 0.10 (s, 3H).

Preparation of 164.²⁵⁴ To the solution of 4-vinylbenzyl chloride

(304 mg, 2 mmol) in CH_3CN (10 mL), Pd/C (5 wt%, 420 mg, 0.1 mmol)

and H_2SO_4 (70 wt%, 25 μL) were added. The mixture was stirred for

about 15 min at room temperature. Then H_2O_2 (30 wt%, 1.36 g, 12 mmol) was added

dropwise, and the mixture was heated to 65 °C for 12 h. The Pd/C was removed by passing the reaction through a silica plug. The reaction was concentrated, washed with water, and extracted with DCM (3 × 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 5% EtOAc in hexanes gave **164** as a light yellow solid (320 mg, 95%). ¹H NMR (400 MHz, CDCl₃) δ 10.03 (s, 1H), 7.89 (d, *J* = 7.8 Hz, 2H), 7.57 (d, *J* = 7.6 Hz, 2H), 4.65 (s, 2H).

Preparation of **165**. NaH

(60% in mineral oil, 0.6 mg, 0.015 mmol) was slowly added to **163** (11 mg, 0.015 mmol) in DMF (0.5 mL).

The reaction was stirred at 0 °C for 30 min, at which time *p*-chloromethyl-acetophenone (**164**, 5.1 mg, 0.03 mmol) was added at 0 °C. The reaction was stirred at room temperature for 2 h. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **165** as a yellow solid (11.5 mg, 87%). ¹H NMR (400 MHz, CDCl₃) δ 8.20 (s, 1H), 7.91 – 7.82 (m, 2H), 7.35 (s, 2H), 6.45 (s, 1H), 5.62 (s, 1H), 5.00 (s, 1H), 4.85 (s, 1H), 4.50 (d, *J* = 7.1 Hz, 3H), 4.07 (s, 1H), 3.99 – 3.94 (m, 1H), 3.88 (s, 1H), 3.80 (dd, *J* = 11.3, 2.4 Hz, 1H), 2.58 (s, 3H), 2.49 (br, 1H), 2.25 (br, 1H), 1.53 (d, *J* = 18.4 Hz, 6H), 1.21 – 1.09 (m, 8H), 0.94 (s, 9H), 0.91 (s, 9H), 0.12 (d, *J* = 1.9 Hz, 6H), 0.10 (dd, *J* = 7.1, 3.6 Hz, 6H), 0.02 (s, 9H).

Preparation of 145. A solution of TBAF trihydrate (95 mg, 0.3 mmol) in THF (0.3 mL) was added to **165** (11.5 mg, 0.013 mmol). The reaction was

stirred at room temperature for 1 h. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 6% MeOH in methanol gave **145** as a white solid (5.6 mg, 82%) ^1H NMR (400 MHz, MeOH- d_4) δ 8.36 (s, 1H), 7.98 – 7.81 (m, 2H), 7.42 (d, J = 8.4 Hz, 2H), 6.44 (t, J = 6.5 Hz, 1H), 4.49 (m, 3H), 3.97 (q, J = 3.8 Hz, 1H), 3.92 – 3.64 (m, 4H), 2.55 (m, 4H), 2.41 (ddd, J = 13.5, 6.2, 4.1 Hz, 1H), 1.56 (s, 6H), 1.26 (s, 6H).

Preparation of 170.¹⁶⁶ ω -Bromo- p -chloroacetophenone (2.3 g, 10 mmol) is dissolved in ethanol (10 mL), and treated with a solution of hydroxylamine hydrochloride (695 mg, 10 mmol) in water (2 mL) at 20°C. The reaction was stirred for 24 h at 20°C and poured into a mixture of ice and water. The precipitate is washed with water (5 mL) and dried under vacuum to afford of **170** as a colorless powder (2.01 g, 82%, as a mixture of E/Z isomers). ^1H NMR (400 MHz, CDCl_3) δ 9.24 (s, 1H), 7.65 (d, J = 8.8 Hz, 1H), 7.42 (d, J = 8.8 Hz, 1H), 4.62 (s, 1.4H), 4.43 (s, 0.6H).

Preparation of 171.¹⁶⁶ Potassium O-ethyl xanthate (1.42 g, 8.8 mmol) is dissolved in acetone (6 mL). A solution of **170** (2.01 g, 8 mmol) in acetone (6 mL) is added dropwise at room temperature. The mixture is stirred for 3 h at 20°C. Solids are removed by filtration using celite plug to afford a clear orange solution. The combined washings and filtrate are

concentrated under vacuum to dryness. The yellow residue is dissolved in diethyl ether (30 mL). This solution was washed with water (10 mL), dried with NaSO₄, and evaporated to dryness to afford of **171** as a yellow amorphous solid (2.06 g, 89%, as a mixture of E/Z isomers). ¹H NMR (400 MHz, CDCl₃) δ 8.94 (s, 0.6H), 8.68 (s, 0.4H), 7.63 – 7.54 (m, 1.2H), 7.50 – 7.45 (m, 0.8H), 7.43 – 7.38 (m, 1.2H), 7.38 – 7.32 (m, 0.8H), 4.71 – 4.57 (m, 2H), 4.51 (s, 1.2H), 4.30 (s, 0.8H), 1.40 (m, 3H).

Preparation of 172.¹⁶⁶ Compound **171** (2.06 g, 7.1 mmol) is dissolved in diethyl ether (5 mL), and the slurry is treated at 0°C in small portions with solid anhydrous ZnCl₂ (2.93 g, 22 mmol) at such a rate that the solvent does not boil constantly. After the addition is complete, the flask is stoppered with a drying tube (CaCl₂) and stirring is continued for 48 h at 20°C. ZnCl₂ is fully dissolved toward the end of the reaction, and resulted in a brown, clear slurry. The flask is immersed in an ice bath and treated dropwise with 5.5 M hydrochloric acid (7 mL). Stirring is continued for 30 min at 0°C, a tan-colored solid separates. This material is collected by filtration. It is washed with small portions of diethyl ether (5 mL) and dried to afford 1.7 g (87.8%) of **172**. The crude material was recrystallized from 2-propanol (25 mL). Precipitation of **172** is completed by immersing the flask for 30 min in an acetone-dry ice bath (-78°C). The product is collected by filtration and dried to afford **172** as yellow crystals (1.2 g, 62%). ¹H NMR (400 MHz, CDCl₃) δ 10.06 (s, 1H), 7.71 – 7.56 (m, 3H), 7.52 – 7.40 (m, 3H), 6.69 (s, 1H).

Preparation of 176.²⁰⁰ Compound **86** (248 mg, 0.5 mmol) and BOP reagent (442 mg, 1 mmol) were dissolved in THF (5 mL). DIPEA (97 mg, 131 μ L, 0.75 mmol) were added, and the mixture was allowed to stir at room temperature for 24 h. The mixture was washed with water, extracted with DCM

(3 \times 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **176** as a white foam (230 mg, 75% yield). ¹H NMR (300 MHz, CDCl₃) δ 8.18 – 8.08 (m, 2H), 7.65 – 7.39 (m, 3H), 6.37 (t, *J* = 6.3 Hz, 1H), 4.77 (s, 1H), 4.64 (s, 1H), 4.03 (s, 1H), 3.87 (dd, *J* = 11.0, 4.0 Hz, 1H), 3.79 (dd, *J* = 11.0, 3.0 Hz, 1H), 2.60 (dt, *J* = 12.5, 6.1 Hz, 1H), 2.51 – 2.36 (m, 1H), 0.95 (s, 18H), 0.13 (s, 6H), 0.12 (s, 6H).

Preparation of 177. Compound **176** (61.2 mg, 0.1 mmol) is dissolved in THF (1 mL). Cs₂CO₃ (65 mg, 0.2 mmol) and **172** (48 mg, 0.2mmol) were added to the solution, and the reaction was stirred at

65 °C overnight. The reaction was washed with water, extracted with DCM (10 mL \times 3). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **177** as a brown oil (12 mg, 16%). ¹H NMR (400 MHz, CDCl₃) δ 8.04 (s, 1H), 7.91 (d, *J* = 8.4 Hz, 2H), 7.66 (s, 1H), 7.42 (d, *J* = 8.4 Hz, 2H), 6.36 (t, *J* = 6.5 Hz, 1H), 4.99 (s, 2H), 4.62 (d, *J* = 2.6 Hz, 1H), 4.02 (d, *J* = 2.6 Hz, 1H), 3.84 (dd, *J* = 11.1, 3.0 Hz, 1H), 3.78 (dd, *J* =

11.1, 3.0 Hz, 1H), 2.61 (dt, $J = 12.9, 6.3$ Hz, 1H), 2.45 – 2.35 (m, 1H), 0.95 (s, 9H), 0.93 (s, 9H), 0.14 (s, 6H), 0.11 (s, 3H), 0.10 (s, 3H).

Preparation of 173.²¹¹ Compound **86** (500 mg, 1 mmol), and DMAP (30 mg, 0.25 mmol) were dissolved in DCM (16 mL), and stirred for 30 min. Et₃N (202 mg, 280 μ L, 0.2 mmol) was added. 2-Mesitylenesulfonyl chloride (436 mg, 2 mmol) was slowly added while stirring, and

the mixture was allowed to stir at room temperature overnight. The reaction was quenched by saturated NaHCO₃ and extracted by DCM (3 \times 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **173** as a white solid (562 mg, 83%). ¹H NMR (400 MHz, CDCl₃) δ 7.98 (s, 1H), 6.97 (s, 2H), 6.28 (t, $J = 6.6$ Hz, 1H), 4.84 (s, 2H), 4.57 (dt, $J = 6.3, 3.3$ Hz, 1H), 3.97 (dd, $J = 7.2, 3.3$ Hz, 1H), 3.79 (dd, $J = 11.2, 4.2$ Hz, 1H), 3.73 (dd, $J = 11.2, 3.2$ Hz, 1H), 2.74 (s, 6H), 2.54 (ddd, $J = 12.9, 7.0, 5.8$ Hz, 1H), 2.37 – 2.26 (m, 4H), 0.91 (s, 9H), 0.89 (s, 9H), 0.09 (s, 6H), 0.07 (s, 3H), 0.06 (s, 3H).

Preparation of 179. Compound **173** (135.4 mg, 0.2 mmol), and DABCO (22.4 mg, 0.4 mmol) were dissolved in DMF (2 mL), and stirred for 30 min. DBU (45 mg, 0.3 mmol) and N-hydroxynaphthalimide (**178**, 213 mg, 1 mmol) were added, and the reaction was kept at room temperature

overnight. The reaction was quenched by water and extracted by DCM (3 \times 10 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and

the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **179** as a yellow solid (64 mg, 46%). ^1H NMR (400 MHz, CDCl_3) δ 8.63 (d, $J = 7.3$ Hz, 2H), 8.27 (d, $J = 8.2$ Hz, 2H), 7.95 (s, 1H), 7.78 (t, $J = 7.8$ Hz, 2H), 6.26 (t, $J = 6.2$ Hz, 1H), 4.55 (dd, $J = 9.2, 4.3$ Hz, 1H), 3.99 – 3.89 (m, 1H), 3.80 (dd, $J = 11.2, 3.0$ Hz, 1H), 3.73 (dd, $J = 11.2, 3.0$ Hz, 1H), 2.50 (dt, $J = 12.4, 6.1$ Hz, 1H), 2.41 – 2.25 (m, 1H), 0.89 (s, 9H), 0.85 (s, 9H), 0.08 (s, 6H), 0.04 (s, 3H), 0.03 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 159.9, 158.7, 155.18, 139.2, 134.7, 131.9, 131.8, 127.7, 127.0, 122.7, 113.8, 87.5, 83.8, 71.4, 62.5, 41.1, 25.9, 25.7, 18.3, 17.9, -4.6, -4.8, -5.4, -5.5. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{34}\text{H}_{47}\text{N}_6\text{O}_6\text{Si}_2)^+$ ($\text{M} + \text{H}$) $^+$ = 691.3096, found m/z = 691.3097.

Preparation of 5. Compound **179** (64 mg, 0.092 mmol)

was dissolved in THF (1 mL). While stirring, $\text{Et}_3\text{N}\cdot 3\text{HF}$ (161 mg, 1 mmol) was slowly added. The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave **5** as a yellow foam (35.7 mg, 84%). ^1H NMR (400 MHz, MeOH-d_4) δ 8.64 (d, $J = 6.8$ Hz, 2H), 8.48 (d, $J = 7.8$ Hz, 2H), 8.20 (s, 1H), 7.90 (s, 2H), 6.37 (s, 1H), 4.57 (s, 1H), 4.03 (s, 1H), 3.83 (d, $J = 10.1$ Hz, 1H), 3.74 (d, $J = 10.1$ Hz, 1H), 2.80 (s, 1H), 2.41 (s, 1H). ^{13}C NMR (101 MHz, DMSO) δ 160.1, 159.8, 140.1, 135.9, 132.1, 132.0, 127.9, 127.4, 122.5, 112.0, 88.1, 83.3, 71.1, 62.0. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{22}\text{H}_{19}\text{N}_6\text{O}_6)^+$ ($\text{M} + \text{H}$) $^+$ = 463.1366, found m/z = 463.1369.

Preparation of 185. Compound **91** (598 mg, 1 mmol) was dissolved in THF (10 mL). Hydrazine (3.2 g, 100 mmol) was slowly added while stirring. The reaction was stirred at 25 °C for 1 h. The reaction was washed with water and extracted by DCM

(3 × 30 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 5% MeOH in DCM gave **185** as a yellow foam (467 mg, 94%). ¹H NMR (CDCl₃) δ 8.42 (s, 1H), 8.13 (s, 1H), 7.96 (s, 1H), 6.44 (t, *J* = 6.5 Hz, 1H), 4.73 – 4.49 (m, 1H), 4.24 (s, 2H), 4.00 (dd, *J* = 7.5, 3.3 Hz, 1H), 3.84 (dd, *J* = 11.2, 4.4 Hz, 1H), 3.75 (dd, *J* = 11.2, 3.3 Hz, 1H), 2.70 – 2.59 (m, 1H), 2.41 (ddd, *J* = 13.0, 6.1, 3.7 Hz, 1H), 0.90 (s, 9H), 0.89 (s, 9H), 0.08 (s, 6H), 0.06 (s, 3H), 0.08 (s, 3H).

Preparation of 186. THF (2 mL) was added to **185** (98 mg, 0.2 mmol). Naphthalic anhydride (44 mg, 0.22 mmol) was added to the mixture, and the reaction was stirred at 65 °C for 24 h. The reaction was quenched by saturated NaHCO₃ and extracted by DCM (3 × 20 mL). The

combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 3% MeOH in DCM gave **186** as a yellow solid (99.7 mg, 74%). ¹H NMR (400 MHz, CDCl₃) δ 9.74 (s, 1H), 8.58 (d, *J* = 7.2 Hz, 2H), 8.38 (s, 1H), 8.21 (dd, *J* = 8.4, 1.1 Hz, 2H), 8.12 (s, 1H), 7.71 (dd, *J* = 8.1, 7.4 Hz, 2H),

6.38 (s, 1H), 4.54 (s, 1H), 3.95 (s, 1H), 3.78 (s, 1H), 3.74 – 3.61 (m, 1H), 2.72-2.52 (m, 1H), 2.47 – 2.27 (m, 1H), 0.86 (s, 9H), 0.76 (s, 9H), 0.05 (s, 6H), -0.03 (s, 6H).

Preparation of 183. Compound **169** (99.7 mg, 0.14 mmol) was dissolved in THF (2 mL). While stirring, Et₃N•3HF (225 mg, 1.4 mmol) was slowly added. The reaction was stirred at 25 °C overnight. The reaction was concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 7% MeOH in DCM gave **183** as a yellow foam (53.1 mg, 85%, as a mixture of imino and amino tautomers). ¹H NMR (400 MHz, MeOH-d₄) δ 8.63 (d, *J* = 7.3 Hz, 2H), 8.45 (d, *J* = 8.2 Hz, 3H), 8.24 (s, 1H), 7.88 (s, 2H), 6.44 (d, *J* = 52.8 Hz, 1H), 4.60 (s, 1H), 4.10 (d, *J* = 9.0 Hz, 1H), 3.81 (d, *J* = 36.1 Hz, 2H), 2.84 (s, 1H), 2.45 (s, 1H).

Preparation of 3',5'-bis-O-TBDMS-O6-2-(*p*-nitrophenyl)ethyl 2'-deoxyguanosine.²⁵³ 3',5'-Bis-O-TBDMS-2'-deoxyguanosine (**86**, 498 mg, 1 mmol), 2-(*p*-nitrophenyl)ethanol (334 mg, 2 mmol), and PPh₃ (525 mg, 2 mmol) was dissolved in THF (10 mL). DEAD (348 mg, 2 mmol) was slowly added. The reaction was stirred at 25 °C overnight. The reaction mixture quenched with water and extracted with DCM (3 × 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 20% EtOAc in hexanes gave 3',5'-bis-O-TBDMS-O6-2-(*p*-nitrophenyl)ethyl 2'-deoxyguanosine as a light yellow oil (391 mg, 60%). ¹H NMR (400 MHz, CDCl₃) δ 8.12

(d, $J = 8.6$ Hz, 3H), 7.88 (s, 1H), 7.45 (d, $J = 8.6$ Hz, 2H), 6.28 (t, $J = 6.7$ Hz, 1H), 4.99 (s, 2H), 4.70 (t, $J = 6.8$ Hz, 2H), 4.59 – 4.51 (m, 1H), 3.95 (d, $J = 3.3$ Hz, 1H), 3.78 (dd, $J = 11.2, 4.1$ Hz, 1H), 3.72 (dd, $J = 11.1, 3.1$ Hz, 1H), 3.24 (t, $J = 6.8$ Hz, 2H), 2.51 (dt, $J = 13.0, 6.4$ Hz, 1H), 2.32 (ddd, $J = 13.0, 6.0, 3.6$ Hz, 1H), 0.88 (s, 18H), 0.07 (s, 6H), 0.05 (s, 3H), 0.05 (s, 3H).

Preparation of 103.²⁵³ 3',5'-Bis-O-TBDMS-

O6-2-(*p*-nitrophenyl)ethyl 2'-deoxyguanosine (391 g, 0.6 mmol) was dissolved in 9 mL anhydrous toluene and cooled to -10 °C. Polyvinylpyridine-HF (1.2 g) and tert-butyl nitrite (275 mg, 0.29 mL, 2.4 mmol)

were added. After 1h, the reaction was poured into cold saturated NaHCO_3 (40 mL). The resulting solid was removed by filtration, and the organic phase product extracted with EtOAc (3 \times 20 mL). The organic phase was dried using Na_2SO_4 , concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 10% EtOAc in hexanes gave **103** as a yellow foam (163 mg, 42%). ^1H NMR (400 MHz, CDCl_3) δ 8.20 (s, 1H), 8.11 (d, $J = 8.8$ Hz, 2H), 7.46 (d, $J = 8.8$ Hz, 2H), 6.35 (t, $J = 6.4$ Hz, 1H), 4.79 (t, $J = 6.8$ Hz, 2H), 4.58 (dt, $J = 5.7, 3.3$ Hz, 1H), 3.97 (dd, $J = 7.0, 3.3$ Hz, 1H), 3.84 (dd, $J = 11.3, 4.1$ Hz, 1H), 3.73 (dd, $J = 11.3, 3.1$ Hz, 1H), 3.28 (t, $J = 6.8$ Hz, 2H), 2.63 – 2.50 (m, 1H), 2.39 (ddd, $J = 13.1, 6.2, 3.9$ Hz, 1H), 0.87 (s, 9H), 0.86 (s, 9H), 0.06 (s, 6H), 0.05 (s, 3H), 0.04 (s, 3H).

Preparation of 187. To a solution of **103** (96 mg, 0.15 mmol) in THF (2 mL), hydrazine (48 mg, 15 mmol) was added to the mixture, and the reaction was stirred at 50 °C overnight. The reaction was concentrated under vacuum and purified by flash

chromatography on a silica column. Elution with 3% MeOH in DCM gave **187** as a yellow solid (98 mg, 99%). ¹H NMR (400 MHz, CDCl₃) δ 8.13 (d, *J* = 8.7 Hz, 2H), 7.94 (s, 1H), 7.47 (d, *J* = 8.7 Hz, 2H), 6.39 (t, *J* = 6.6 Hz, 1H), 6.25 (s, 1H), 4.73 (t, *J* = 6.8 Hz, 2H), 4.64 – 4.55 (br, 2H), 3.99 (dd, *J* = 7.0, 3.3 Hz, 1H), 3.84 (t, *J* = 6.3 Hz, 1H), 3.82 (dd, *J* = 11.1, 4.2 Hz, 1H), 3.77 (dd, *J* = 11.1, 3.3 Hz, 1H), 3.27 (t, *J* = 6.8 Hz, 2H), 2.57 (ddd, *J* = 13.0, 7.1, 5.9 Hz, 1H), 2.37 (ddd, *J* = 13.0, 6.0, 3.5 Hz, 1H), 0.92 (s, 9H), 0.91 (s, 9H), 0.10 (d, *J* = 3.0 Hz, 6H), 0.09 (s, 3H), 0.08 (s, 3H).

Preparation of 188. To a solution of **187** (98 mg, 0.15 mmol) in THF (2 mL), naphthalic anhydride (45 mg, 0.225 mmol) was added, and the reaction was refluxed for 24 h. The reaction mixture was poured into saturated NaHCO₃ and extracted with DCM (3 ×

10 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The product was purified by flash chromatography on a silica column. Elution with 30% EtOAc in hexanes gave **188** as a yellow solid (116 mg, 92%). ¹H NMR (400 MHz, CDCl₃) δ 8.63 (d, *J* = 7.1 Hz, 2H), 8.27 (d, *J* = 8.1 Hz, 2H), 8.01 (s, 1H), 7.91 (s, 2H), 7.77 (t, *J* = 7.7 Hz, 2H), 7.43 (s, 1H), 7.10 (s, 2H), 6.21 (s, 1H), 4.54 (s, 2H), 4.42 (s, 1H), 4.10 (dd, *J* = 14.2, 7.1 Hz, 1H), 3.88 (s,

1H), 3.72 (s, 2H), 3.08 (s, 2H), 2.37 (s, 1H), 2.25 (s, 1H), 2.02 (s, 1H), 0.88 (s, 9H), 0.77 (s, 9H), 0.06 (s, 6H), -0.01 (s, 3H), -0.07 (s, 3H).

Preparation of 189. Compound **188** (86 mg,

0.1 mmol) was dissolved in pyridine (1 mL). While stirring, DBU (76 mg, 0.5 mmol) was slowly added.

The reaction was stirred at 25 °C for 24 h. The reaction

mixture was poured into saturated NaHCO₃ and extracted with DCM (3 × 20 mL). The combined organic phase was dried over Na₂SO₄. Na₂SO₄ was removed by filtration, and the mixture was concentrated under vacuum. The reaction was purified by flash chromatography on a silica column. Elution with 50% EtOAc in hexanes gave **189** as a yellow foam (55.3 mg, 82%). ¹H NMR (400 MHz, CDCl₃) δ 8.68 (d, *J* = 6.9 Hz, 2H), 8.26 (d, *J* = 8.1 Hz, 2H), 7.77 (t, *J* = 7.4 Hz, 2H), 7.57 (s, 1H), 5.84 (t, *J* = 6.5 Hz, 1H), 4.12 (s, 1H), 3.74 – 3.60 (m, 1H), 3.53 (dd, *J* = 11.1, 3.3 Hz, 1H), 3.47 (dd, *J* = 11.1, 4.5 Hz, 1H), 2.20 – 2.05 (m, 1H), 2.03 – 1.88 (m, 1H), 0.67 (s, 9H), 0.57 (s, 9H), -0.15 (s, 3H), -0.18 (s, 6H), -0.32 (s, 3H).

Preparation of 184. Compound **189** (55.3 mg,

0.08 mmol) was dissolved in THF (1 mL). While stirring, Et₃N•3HF (160 mg, 1.0 mmol) was slowly added. The

reaction was stirred at 25 °C overnight. The reaction was

concentrated under vacuum and purified by flash chromatography on a silica column. Elution with 10% MeOH in DCM gave **184** as a yellow oil (32 mg, 90%). ¹H NMR (400 MHz, MeOH-d₄) δ 8.57 (d, *J* = 7.3 Hz, 2H), 8.46 (d, *J* = 7.5 Hz, 2H), 8.04 (s, 1H), 7.93 –

7.76 (m, 2H), 6.03 (t, $J = 6.9$ Hz, 1H), 4.02 (s, 1H), 3.70 (d, $J = 3.4$ Hz, 1H), 2.52 (dt, $J = 13.4, 6.7$ Hz, 1H), 2.15 – 2.00 (m, 1H).

Preparation of 190. Compound **3** (54.3 mg, 0.13 mmol), was azeotropically dried with pyridine (1 mL) three times. Pyridine (1 mL) and DMTCl (53 mg, 0.16 mmol) were added. The reaction was stirred at room temperature overnight.

The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in DCM) on a silica column to give **190** as a light yellow foam (62.5 mg, 65%). ^1H NMR (400 MHz, CDCl_3) δ 9.53 (s, 1H), 8.38 (s, 1H), 7.57 (s, 1H), 7.39 (d, $J = 7.3$ Hz, 2H), 7.33 – 7.13 (m, 15H), 6.99 (t, $J = 7.1$ Hz, 2H), 6.80 (d, $J = 8.8$ Hz, 4H), 6.35 (t, $J = 6.2$ Hz, 1H), 4.61 (s, 1H), 4.12 (d, $J = 4.0$ Hz, 1H), 3.76 (s, 6H), 3.41 (dd, $J = 9.9, 4.7$ Hz, 1H), 3.33 (dd, $J = 9.9, 5.7$ Hz, 1H), 2.77 – 2.65 (m, 1H), 2.51 – 2.38 (m, 1H). ^{13}C NMR (101 MHz, CDCl_3) δ 159.0, 158.6, 153.8, 147.5, 146.1, 145.8, 139.6, 137.8, 131.0, 129.7, 129.2, 127.85, 127.82, 127.7, 119.7, 113.0, 88.2, 84.9, 82.0, 81.5, 71.8, 62.7, 55.3, 55.2. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{43}\text{H}_{41}\text{N}_6\text{O}_5)^+$ ($\text{M} + \text{H}$) $^+ = 721.3138$, found $m/z = 721.3134$.

Preparation of 191. DIPEA (51.6 mg, 0.36 mmol) and DCM (2 mL) were added to **190** (96 mg, 0.14 mmol). The reaction was stirred at 0 °C for 30 min, while 2-cyanoethyl-*N,N*-diisopropylchlorophosphoramidite (28.4 mg, 0.12 mmol) was added dropwise. The reaction was stirred at room

temperature for 30 min. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in hexanes) on a silica column to give **191** as a white

foam (62.5 mg, 77%). ^1H NMR (300 MHz, CDCl_3) δ 9.33 (s, 1H), 8.37 (s, 1H), 7.66 (s, 1H), 7.40 (d, $J = 8.1$ Hz, 2H), 7.35 – 7.13 (m, 15H), 7.00 (t, $J = 7.0$ Hz, 2H), 6.80 (dd, $J = 8.8, 3.8$ Hz, 4H), 6.37 (dd, $J = 11.4, 6.8$ Hz, 1H), 4.73 (s, 1H), 4.29 (s, 1H), 3.75– 3.55 (m, 10H), 3.42 – 3.29 (m, 2H), 2.83 (dd, $J = 12.2, 6.0$ Hz, 1H), 2.62 (t, $J = 6.3$ Hz, 1H), 2.59 – 2.52 (m, 1H), 2.48 (t, $J = 6.4$ Hz, 1H), 1.24 – 1.11 (m, 12H). ^{31}P NMR (121 MHz, CDCl_3) δ 148.84 (s), 148.70 (s). HRMS (ESI-TOF) m/z calcd for $(\text{C}_{52}\text{H}_{58}\text{N}_8\text{O}_6\text{P})^+$ ($\text{M} + \text{H}$) $^+ = 921.4217$, found $m/z = 921.4211$.

Preparation of 192. Radical precursor **6** (104 mg,

0.26 mmol), was azeotropically dried with pyridine (2 mL) three times. Pyridine (2 mL) and DMTCI (106 mg, 0.32 mmol) were added. The reaction was stirred at room temperature overnight. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in DCM) on a silica column to give **192** as a light yellow foam (96 mg, 53%). ^1H NMR (400 MHz, MeOH-d_4) δ 7.87 (s, 1H), 7.55 (s, 1H), 7.38 – 7.31 (m, 2H), 7.30 – 7.20 (m, 4H), 7.16 (t, $J = 7.4$ Hz, 2H), 7.12 – 7.07 (m, 1H), 6.74 (dd, $J = 8.9, 1.4$ Hz, 4H), 6.29 (t, $J = 6.3$ Hz, 1H), 4.56 (dd, $J = 9.4, 4.0$ Hz, 1H), 4.10 (q, $J = 4.3$ Hz, 1H), 3.32 – 3.28 (m, 2H), 2.83 – 2.70 (m, 1H), 2.43 (ddd, $J = 13.5, 6.4, 4.3$ Hz, 1H), 1.47 (s, 6H), 1.22 (s, 9H). ^{13}C NMR (101 MHz, MeOH-d_4) δ 160.0, 146.3, 145.4, 142.1, 137.9, 137.2, 137.0, 131.3, 131.2, 129.3, 128.7, 127.8, 120.4, 114.0, 88.6, 88.0, 87.5, 85.9, 72.7, 65.1, 61.5, 55.7, 45.2, 40.9, 29.3, 25.2, 20.9, 14.5. IR (neat) 3273 (broad), 2932, 1691, 1659, 1592, 1463, 1301, 1250, 1176, 1035, 954, 887, 829, 754, 700, 660 cm^{-1} . HRMS (ESI-TOF) m/z calcd for $(\text{C}_{39}\text{H}_{46}\text{N}_5\text{O}_7)^+$ ($\text{M} + \text{H}$) $^+ = 696.3397$, found $m/z = 696.3392$.

Preparation of 193. DIPEA (66.3 mg, 89.3 μ L, 0.54 mmol) and DCM (3.5 mL) were added to **192** (96 mg, 0.14 mmol). The reaction was stirred at 0 $^{\circ}$ C, and 2-cyanoethyl *N,N*-diisopropylchloro-phosphoramidite (40.5 mg, 0.17 mmol) was added dropwise. The reaction

was stirred at room temperature for 30 min. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in hexanes) on a silica column to give **193** as a white foam (74 mg, 59%). ^1H NMR (400 MHz, MeOH- d_4) δ 7.88 (d, $J = 2.1$ Hz, 1H), 7.53 (d, $J = 2.1$ Hz, 1H), 7.44 – 7.33 (m, 2H), 7.31 – 7.23 (m, 4H), 7.23 – 7.06 (m, 3H), 6.88 – 6.62 (m, 5H), 6.29 (td, $J = 6.4, 3.1$ Hz, 1H), 4.85 (s, 1H), 4.83 – 4.73 (m, 1H), 4.29 – 4.14 (m, 1H), 3.88 – 3.52 (m, 12H), 3.42 – 3.35 (m, 1H), 3.02 – 2.83 (m, 1H), 2.69 – 2.40 (m, 4H), 1.47 (s, 6H), 1.23 (s, 9H), 1.15 (m, 14H). ^{31}P NMR (162 MHz, MeOH- d_4) δ 148.4, 148.3. HRMS (ESI-TOF) m/z calcd for $(\text{C}_{48}\text{H}_{63}\text{N}_7\text{O}_8\text{P})^+$ ($\text{M} + \text{H}$) $^+$ = 896.4476, found $m/z = 896.4471$.

5,6-dihydrothymidine

Preparation of 5,6-dihydrothymidine (dHT).³²⁰ Rhodium on alumina (5%, 24 mg) was added to a solution of thymidine (1.2 g, 5 mmol) in a mixture of MeOH and water (1:1, 9mL) in a sealed tube.

The mixture was stirred under 50 psi of H_2 for 48 h. The catalyst was removed by filtration through of a silica plug, and the filtrate was lyophilized to dryness. The reaction was purified by flash chromatography (3% MeOH in DCM) on a silica column to give **dHT** as a white foam (1.08 g, 90%). ^1H NMR (400 MHz, MeOH- d_4) δ 6.28 (dd, $J = 8.0, 6.4$ Hz, 1H), 4.28 (dtd, $J = 3.8, 3.3, 0.4$ Hz, 1H), 3.77 (dd, $J = 7.8, 4.3$ Hz, 1H), 3.67 (dd, $J = 11.8, 4.0$ Hz, 1H), 3.62 (dd, $J = 11.8, 4.7$ Hz, 1H), 3.51 (dd, $J = 12.8, 5.5$ Hz,

1H), 3.22 (dd, $J = 12.8, 9.7$ Hz, 1H), 2.73 – 2.59 (m, 1H), 2.22 (ddd, $J = 13.6, 8.1, 6.6$ Hz, 1H), 1.99 (ddd, $J = 13.6, 6.4, 3.3$ Hz, 1H), 1.21 (d, $J = 7.0$ Hz, 3H).

5'-O-dimethoxytrityl-5,6-dihydrothymidine

Preparation of 5'-O-dimethoxytrityl-5,6-

dihydrothymidine (5'-O-DMT-dHT).³²⁰

dHT (122 mg, 0.5 mmol), was azeotropically dried with pyridine (2 mL) three times. Pyridine (2 mL) and DMTCI (180 mg, 0.53 mmol) were added. The reaction was stirred at room temperature overnight. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in DCM) on a silica column to give **5'-O-DMT-dHT** as a white foam (220 mg, 80%). ¹H NMR (400 MHz, MeOH-d₄) δ 7.44 (d, $J = 7.2$ Hz, 2H), 7.32 (d, $J = 7.7$ Hz, 4H), 7.25 – 7.17 (m, 3H), 6.81 (d, $J = 9.0$ Hz, 4H), 6.35 (dd, $J = 7.5, 6.6$ Hz, 1H), 4.43 (dt, $J = 6.6, 3.4$ Hz, 1H), 3.94 (q, $J = 3.8$ Hz, 1H), 3.69 (s, 6H), 3.43 (dd, $J = 12.8, 5.6$ Hz, 1H), 3.29 (d, $J = 3.8$ Hz, 2H), 3.08 (dd, $J = 12.8, 9.9$ Hz, 1H), 2.62 – 2.41 (m, 1H), 2.37 – 2.16 (m, 4H), 2.08 (ddd, $J = 13.4, 6.4, 3.4$ Hz, 1H), 0.98 (d, $J = 7.0$ Hz, 3H).

Preparation of 5,6-dihydrothymidine

phosphoramidite (dHT phosphoramidite).³²⁰

5,6-dihydrothymidine phosphoramidite

DIPEA (193.5 mg, 1.5 mmol), DCM (10 mL) was added to **5'-O-DMT-dHT** (220 mg, 0.4 mmol). The reaction was stirred at 0 °C, and 2-cyanoethyl N,N-diisopropylchloro-phosphoramidite (118.5 mg, 0.5

mmol) was added dropwise. The reaction was stirred at room temperature for 30 min. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl

acetate in hexanes) on a silica column to give **dHT phosphoramidite** as white foam (245 mg, 83%). ^1H NMR (400 MHz, MeOH- d_4) δ 7.43 (m, 2H), 7.35 – 7.28 (m, 4H), 7.27 – 7.11 (m, 3H), 6.82 (m, $J = 4\text{H}$), 6.30 (t, $J = 6.8\text{ Hz}$, 1H), 4.69 – 4.56 (m, 1H), 3.97 (m, 1H), 3.84 – 3.65 (m, 8H), 3.64 – 3.45 (m, 4H), 3.30 (m, 2H), 3.19 – 3.07 (m, 1H), 2.64 (m, 1H), 2.61 – 2.51 (m, 1H), 2.51 – 2.44 (m, 1H), 2.34 (m, 1H), 2.28 – 2.09 (m, 1H), 1.16 (t, $J = 7.4\text{ Hz}$, 9H), 1.05 (d, $J = 6.7\text{ Hz}$, 3H), 1.00 (dd, $J = 7.0, 2.7\text{ Hz}$, 3H). ^{31}P NMR (162 MHz, MeOH- d_4) δ 148.08, 147.86.

5'-O-dimethoxytrityl-2'-deoxyuridine

Preparation of 5'-O-dimethoxytrityl-2'-deoxyuridine (5'-O-DMT-dU).

2'-Deoxyuridine (2.3 g, 10 mmol), was azeotropically dried with pyridine (10 mL) three times. Pyridine (10 mL) and DMTC1 (4.1 g, 12 mmol) were added. The reaction was stirred at room temperature overnight. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in DCM) on a silica column to give **5'-O-DMT-dU** as a white foam (5.71 g, > 99% with minor impurities). ^1H NMR (400 MHz, CDCl_3) δ 8.59 (s, 1H), 7.80 (d, $J = 8.2\text{ Hz}$, 1H), 7.40 (d, $J = 7.7\text{ Hz}$, 2H), 7.35 – 7.27 (m, 7H), 6.86 (d, $J = 8.8\text{ Hz}$, 4H), 6.33 (t, $J = 6.3\text{ Hz}$, 1H), 5.42 (dd, $J = 8.2, 1.8\text{ Hz}$, 1H), 4.57 (dd, $J = 10.2, 4.4\text{ Hz}$, 1H), 4.04 (q, $J = 3.5\text{ Hz}$, 1H), 3.82 (s, 6H), 3.51 (dd, $J = 10.6, 3.2\text{ Hz}$, 1H), 3.46 (dd, $J = 10.6, 3.1\text{ Hz}$, 1H), 2.51 – 2.42 (m, 1H), 2.32 – 2.24 (m, 1H).

2'-deoxyuridine phosphoramidite

Preparation of 2'-deoxyuridine phosphoramidite

(dU phosphoramidite). DIPEA (4.18 g, 32.4 mmol), DCM (20 mL) was added to **5'-O-DMT-dU** (5.714, 10.8 mmol). The reaction was stirred at 0 °C, and 2-cyanoethyl N,N-diisopropylchloro-phosphoramidite (3.1 g, 13 mmol) was

added dropwise. The reaction was stirred at room temperature for 30 min. The reaction was concentrated under vacuum, and purified by flash chromatography (50% ethyl acetate in hexanes) on a silica column to give **dU phosphoramidite** as white foam (6.2 g, 78%). ¹H NMR (400 MHz, MeOH-d₄) δ 7.90 (dd, *J* = 10.1, 8.1 Hz, 1H), 7.53 – 7.37 (m, 3H), 7.27 (ddd, *J* = 11.0, 10.6, 6.2 Hz, 10H), 6.87 (dd, *J* = 8.6, 6.1 Hz, 5H), 6.22 (s, 1H), 5.38 – 5.22 (m, 1H), 4.75 – 4.66 (m, 1H), 4.10 (m, 1H), 3.90 – 3.53 (m, 14H), 3.52 – 3.38 (m, 3H), 2.72 (t, *J* = 5.8 Hz, 1H), 2.61 – 2.32 (m, 4H), 1.19 (m, 13H), 1.09 (d, *J* = 6.8 Hz, 6H). ³¹P NMR (162 MHz, MeOH-d₄) δ 147.06, 174.03.

9. Curriculum Vitae

LIWEI ZHENG

Education

- 2013 – 2018 **Johns Hopkins University**, Baltimore, MD. Doctor of Philosophy in Chemistry
Advisor: Professor Marc M. Greenberg.
- 2009 – 2013 **Wuhan University**, Wuhan, Hubei, China. Bachelor of Science in Chemistry.
Advisor: Professor Aiwen Lei.

Awards

- Glen E. Meyer '39 Fellowship, Johns Hopkins University, 2017
- Travel Assistance Awards, The Division of Chemical Toxicology, 2017
- Emmet and Elsie Buhle Fellowship Award, Johns Hopkins University, 2015
- The National Scholarship, Ministry of Education of China, 2010
- The National Scholarship, Ministry of Education of China, 2009

Publications

- Chao Liu, Shan Tang, Dong Liu, Jiwen Yuan, **Liwei Zheng**, Lingkui Meng, and Aiwen Lei, Nickel-Catalyzed Heck-Type Alkenylation of Secondary and Tertiary α -Carbonyl Alkyl Bromides. *Angew. Chem. Int. Ed.*, **2012**, *51*, 3638–3641. DOI:10.1002/anie.201108350
