## **Abstract**

Improving the expression level of recombinant mammalian proteins has been pursued for production of commercial biotherapeutics in industry, as well as for biomedical studies in academia, as an adequate supply of correctly folded proteins is a prerequisite for all structure and function studies. Presented in this dissertation are different strategies to improve protein functional expression level, especially for membrane proteins. The model protein is neurotensin receptor 1 (NTSR1), a hard-to-express G protein-coupled receptor (GPCR). GPCRs are integral membrane proteins playing a central role in cell signaling and are targets for most of the medicines sold worldwide. Obtaining adequate functional GPCRs has been a bottleneck in their structure studies because the expression of these proteins from mammalian cells is very low.

The first strategy is the adoption of mammalian inducible expression system. A stable and inducible T-REx-293 cell line overexpressing an engineered rat NTSR1 was constructed. 2.5 million Functional copies of NTSR1 per cell were detected on plasma membrane, which is 167 fold improvement comparing to NTSR1 constitutive expression.

The second strategy is production process development including suspension culture adaptation and induction parameter optimization. A further 3.5 fold improvement was achieved and approximately 1 milligram of purified functional NTSR1 per liter suspension culture was obtained. This was comparable yield to the transient baculovirus-insect cell system.

The third strategy is high throughput miRNA screening. MiRNAs are a novel class of small, non-coding RNAs that can simultaneously silence multiple genes. The

NTSR1-expressing cell line was subjected to human miRNA mimic library screening and nine miRNA mimics were identified to improve functional expression of NTSR1 by as much as 48%. Interestingly, five out of nine identified miRNA mimics were effective in improving the functional expression of other proteins, including luciferase (cytosolic protein), serotonin transporter (membrane protein) and glypican-3 hFc protein (secreted protein). These indicated that the identified miRNAs could have a wide role in enhancing production of proteins with biomedical interest.

As genome-wide siRNA screens has emerged to be a powerful methodology for deducing gene functions in various diseases, we applied this technology on HEK293 cells constitutively expressing luciferase reporter to generate a genome-wide profile for recombinant protein expression process. Up to 362 genes associated with significantly enhanced luciferase expression were discovered and 28 of them were found to be enriched in spliceosome pathway. Moreover, top 10 genes leading to greatest improvement of luciferase production were validated and tested with secreted and membrane proteins.

Investigation of these genes/pathways may provide profound information to understanding protein biosynthesis process in mammalian cells. *Oaz1* gene for example, was chosen for further investigation. *Oaz1* encodes ornithine decarboxylase (ODC) antizyme 1, a major negative regulator of ODC and cellular polyamines. In our study, it is found that when antizyme was depleted, ODC enzyme and cellular polyamines levels were up-regulated, leading to enhanced luciferase translation.

Advisors: Michael J. Betenbaugh and Joseph Shiloach

## **Preface**

It has long been pursued by pharmaceutical and biotechnology industry to enhance the quality and quantity of recombinant proteins produced from host cells by traditional (e.g. media and bioprocess conditions optimization) and cell engineering approaches. In academia, the expression of recombinant proteins in general and mammalian proteins in particular, is also at the heart of current medical and structural studies.

This dissertation consists of six chapters and is mainly focused on the improvement of functional expression of a hard-to-express membrane protein-neurotensin receptor (NTSR1).

Chapter 1 provides a review on the ongoing effort to target bottlenecks along transcription, translation, protein processing and secretion pathways, as well as cell growth and survival to improve expression of low yielding proteins in a variety of hosts including bacterial, fungal, insect, and mammalian cells. The contents of Chapter 1 have been published in the *Current Opinion in Structural Biology* journal. Permission for its use was granted by the publisher, Elsevier (license number 3606050366032).

Chapter 2 describes the construction of a stable HEK293 cell line with high-level functional NTSR1 expression and a quantitative comparison with NTSR1 produced from insect cells. The text and illustrations used in Chapter 2 have been published in the *PLOS ONE* journal and *Methods in Molecular Biology* journal. Permission was granted by Springer (license number 3606050761810).

Chapter 3 features the identification of five microRNAs (hsa-miR-22-3p, hsa-miR-22-5p, hsa-miR-18a-5p, hsa-miR-429 and hsa-miR-2110) that can further improve NTSR1 functional expression in HEK293 cells. Their wider application was demonstrated by expression enhancement of other cytosolic, secreted and membrane proteins. The contents of Chapter 3 have been published in the *Biotechnology and Bioengineering* journal. Permission for its reuse was granted by John Wiley and Sons (license number 3606050872125).

Chapter 4 extends the scope to system biology of HEK293 cells and identified 10 significant influential genes for heterologous protein production by genome-wide loss-of-function studies.

Chapter 5 focuses on one of the identified top 10 genes (*oaz1*) and investigated the mechanism of improved protein expression upon *oaz1* gene knockdown. A manuscript is being prepared based on contents of chapter 4 and 5.

Finally, Chapter 6 concludes this dissertation and suggests the future work to extend the efforts.

## **Acknowledgements**

First of all I would like to thank my family, for their encouragement and support in my journey to pursue a doctoral degree. I would like to thank my father, who ignited my dream of becoming an engineer and encouraged me to apply for doctoral education. He has always been an inspiring example of pursuing his dream through thick and thin, and of building his success from ground up. He has always been a strong source of mental support and motivation which carried me through the moments of discouragement and irresolution. I would love to thank my mother, who instilled in me the mind of independence and self-acceptance. She has always been very understanding, supportive and caring along this long journey. Words alone cannot express my deep love and appreciation for her.

I would like to express my sincere appreciation to my advisors, Dr. Michael J. Betenbaugh and Dr. Joseph Shiloach for their wisdom, mentorship and support. Their vision and commitment to research has inspired and will keep motivating me to excel in my scientific research. Their guidance in the past five years helped me to mature professionally and personally. It was an great honor and privilege to get to know them and work with them.

I would also like to thank all my colleagues both at Johns Hopkins University and NIDDK Biotechnology Core Laboratory for their guidance and advices. Especially, I would love to thank Dr. Loc Trinh, Dr. Alejandro Negrete, Dr. Alex Druz, Dr. Bojjiao Yin, Dr. Melissa St Amand, Joseph Priola, Amit Kumar and Sarah Inwood for their help

and advices in designing and carrying out experiments, data analysis and troubleshooting.

I would also like to thank our collaborators at the Membrane Protein Structure and Function Unit at NIH, especially Dr. Reinhard Grishammer and Jim White, for their training and guidance towards neurotensin receptor field. Sincere appreciation is also given to Dr. Christopher Tate and Dr. Juni Andréll at MRC Laboratory of Molecular Biology in UK, for sharing with me their insightful understanding and passion for membrane protein studies. I would also like to thank all staffs from NIH Chemical Genomics Center, especially Dr. Scott E. Martin and Yu-Chi Chen, as well as Dr. Myung Hee Park and Dr. Swati Mandal at National Institute of Dental and Craniofacial Research for their commitment as well as intelligent and technical input into our study. It has been truly a rewarding experience working with all of them.

Finally, I would like to acknowledge that all funding for the work presented here was provided by the Intramural Research program at the National Institute of Diabetes and Digestive Kidney Diseases at the National Institutes of Health and the Department of Chemical and Biomolecular Engineering at Johns Hopkins University. We are grateful to Dr. Philip J. Reeves (University of Essex, Colchester, UK) for the kind gift of pACMV-tetO plasmid and to Dr. Mitchell Ho (National Cancer Institute, Bethesda, US) for HEK-GPC3-hFc cell line.

## **Chapter 1: Engineering cells to improve recombinant protein expression**

### **Abbreviations**

MABs: monoclonal antibodies; CHO: Chinese Hamster Ovary; CMV, Cytomegalovirus; MAR, matrix attachment region; SEAP: secreted alkaline phosphatase; ER: endoplasmic reticulum; SERT: serotonin transporter; SRP: signal recognition particle; TF: trigger factor, ORF, open reading frame; eIF, eukaryotic initiation factor; HSA, human serum albumin; t-PA, tissue-plasminogen activator; NTSR1, neurotensin receptor type I.

### **1.1 - Summary**

Improving the expression level of recombinant mammalian proteins has not only been pursued by biotechnologist for production of commercial biotherapeutics, but has also been at the heart of numerous biomedical studies in academia, as an adequate supply of correctly folded proteins is a prerequisite for all structure and function studies. In industry, there have been consistent efforts made towards process development for recombinant protein therapeutics production, especially on culture medium optimization and feeding strategies. In addition, significant progress has been achieved for the past decades in engineering and development of new cell lines to improve recombinant protein production for structural, biochemical, and commercial applications.

This chapter is a review on recent advances of improving recombinant protein production by engineering a variety of expression host including bacteria, fungi, insect cells and mammalian cells. With increased understanding of the host organism biology,

engineering strategies were developed targeting bottlenecks in transcription, translation, protein processing and secretory pathways, as well as cell growth and survival. A combination of metabolic engineering and synthetic biology has been used to improve the properties of cells for protein production, which has resulted in enhanced yields of multiple protein classes.

## **1.2 - Introduction**

With hundreds of billion dollar global market[1] and 10-20% annual increases in revenue worldwide[2], protein-based therapeutics have received unprecedented recognition of success and great potential. Since the production of the first approved recombinant protein (insulin) in the early 1980s, there have been continuous efforts to improve recombinant protein productivity and quality, especially for monoclonal antibodies (mABs), which accounts for approximately half of the sales[1]. Process development is very effective to improve productivity, especially the optimization of culture medium and feeding strategy. In industry, up to 10 grams of mAB or Fc fusion proteins can be produced in optimized fed-batch process with chemically-defined media[3]. In parallel, cell line engineering and development is also vital for cell-based production process. Development of cell lines with improved stability and protein productivity, quality, and biosimilarity has been pursued for decades.

Expression of recombinant mammalian proteins is also at the heart of medical and structural studies in academia. Although cloning, expression and production methods are

available for many hosts [4-6], and significant progress has been achieved to produce thousands of recombinant proteins for structural and biochemical studies, it has been challenging to produce many difficult proteins, such as membrane proteins, large protein complexes and post-translationally modified proteins [7, 8].

A critical area is mammalian integral membrane proteins such as receptors, ion channels and transporters which are encoded by 20-40% of all open reading frames (ORFs) in the mammalian genome[9] and are targets of most of the medicines sold worldwide[10]. Even though more than 100,000 structures have been deposited in Protein Data bank, the overexpression of membrane protein remains difficult [8, 11] and only 952 membrane protein structures are available as of April, 2015 (<http://blanco.biomol.uci.edu/mpstruc/>). Rational attempts to improve membrane protein expression may not lead to expected results as membrane proteins involve particularly complex folding, assembly, and processing pathways, and there is only limited information for the bottlenecks that may reside in the protein production steps, such as transcription, translation, protein folding, secretion and cell viability.

This chapter will summarize the most recent successful cases where the protein productivity was improved through different cellular engineering strategies. Presented here are a variety of host cells, e.g. bacteria, fungi, insect cells and mammalian cells. Different protein types are all included, e.g. secreted, cytosolic and hard-to-express membrane proteins. Cellular engineering strategies reviewed in this chapter were categorized by the biological process engineered, including transcription, translation, protein processing and secretory pathways, as well as cell growth and survival.

### **1.3 - Choice of host cell line**

The first step in any strategy to over-produce proteins is the selection of the expression host. Table 1.1 includes 11 biopharmaceutical products selected from GEN's top 25 best-selling drug list from 2013. Seven out of eleven products were produced from mammalian expression system (mostly from Chinese Hamster Ovary cells) and the annual revenue generated using mammalian system took up 74% of overall revenue from the 11 top-selling biopharmaceutical products.

However in academia, especially in crystallography studies, mammalian cells are not widely used. According to statistics from the Protein Data Bank (<http://www.rcsb.org>) and the 'Membrane Proteins of Known Structure Database' (<http://blanco.biomol.uci.edu/mpstruc/>), of all the proteins that had their structures determined between 2004 and 2014, 78% were expressed in *Escherichia coli* and only 1.8% in mammalian cells (Fig.1.1A). For the overexpression of membrane proteins, *E. coli* was utilized on average less (61%) and eukaryotic expression systems were used comparatively more (Fig. 1.1B). Notably, there is an increasing trend in the use of more complex eukaryotic hosts (insect and mammalian cells, Fig. 1.1C), which reflects an increase in the number of mammalian membrane proteins being crystallized, particularly G protein-coupled receptors (GPCRs) [12].

### **1.4 - cell engineering strategies**

#### **1.4.1. Optimizing transcription**

One of the most important choices in planning a strategy for overexpression of proteins is the type of promoter to use, and it is often the case that the strongest promoter will be the best for producing large amounts of correctly folded protein. Thus the most commonly used promoters are the T7 promoter in *E. coli*, the polyhedrin promoter in the baculovirus expression system and the Cytomegalovirus (CMV) promoter in mammalian cells. If transcription is the rate limiting step in protein production, even after choosing a strong promoter, then increasing further the strength of the promoter may be effective. For example, Quilici *et al.* constructed a strong *CMV* promoter variant through introducing a 200-nucleotide deletion of intron A that increased luciferase expression up to 2 fold in mammalian cells [13]. However, recent studies have shown that increasing the amount of mRNA encoding the protein of interest does not necessarily lead to improved protein production in *E.coli*[14] or insect cells [15]. In these instances, it is possible that the rate limiting step is protein folding, perhaps due to limitations in host cell factors, such as molecular chaperones. Enhancements in protein expression can be achieved through reducing the rate of transcription, either by substituting a strong promoter with a weaker one [14, 15], or by weakening a strong promoter by introducing a point mutation[16]. An alternative approach is to reduce the levels of polymerase in the host cell. For example, the levels of the T7 DNA polymerase expressed in *E. coli* can be modulated by altering the expression levels of the natural inhibitor T7 lysozyme, which is under the control of a tightly regulated inducible promoter, hence fine-tuning the rates of transcription. Wagner *et al.* improved expression of 14 membrane proteins using this methodology [17].

Even when strong promoters are used, host cell factors can result in low rates of transcription. For example, during the construction of stable mammalian cell lines with the gene of interest expressed from the CMV promoter, poor expression could result from epigenetic silencing of the promoter. This can be alleviated by engineering the nuclear matrix attachment region (MAR) [18] or by combining a MAR with a mammalian replication initiation region (IR) [19, 20], consequently improving recombinant protein production in mammalian cell lines.

#### **1.4.2 Enhancing translation**

Translation of the gene of interest may also be inhibited by host cell silencing processes during protein production. For example, eukaryotic translation initiation factor 2(eIF2) may become phosphorylated after DNA plasmid transfection or upon virus transduction, which will inhibit translation and thus decrease protein expression. However, viruses have evolved mechanisms to circumvent this. Gantke *et al.* co-expressed the Ebola virus protein 35, which is a viral protein that prevents translational silencing, and increased recombinant protein production by 10-fold [21]. An alternative approach to circumvent translational silencing in insect cells following baculovirus infection is to co-express eIF4E, which resulted in a 2-fold increase in the production of a secreted alkaline phosphatase (SEAP)-EGFP fusion protein (SEFP)[22].

#### **1.4.3 Folding and secretory pathway engineering**

Molecular chaperones have been applied to improve protein production in various systems, where they act to preserve nascent proteins in a folding-competent conformation

and prevent aggregation [23]. The most extensively used chaperone systems that have facilitated protein production in *E.coli* are DnaK-DnaJ-GrpE and GroEL-GroES[24, 25]. In insect cells, host protein biosynthesis shuts down as a result of infection by the recombinant baculovirus, which can adversely affect levels of molecular chaperones important for the folding of secreted proteins and membrane proteins in the endoplasmic reticulum (ER), particularly in relation to the high levels of protein synthesis resulting from high mRNA levels produced from the polyhedrin promoter. Hence, co-expression of the membrane-bound molecular chaperone calnexin enhanced the expression of functional serotonin transporter (SERT) by nearly 3 fold [26], and co-expression of the soluble molecular chaperone calreticulin increased secretion of SEAP-EGFP fusion protein in insect cells [22]. Whether a lack of appropriate molecular chaperones in heterologous systems contributes to low levels of functional protein sometimes is difficult to assess. However, overproduction of mammalian calnexin in the yeast *Hansenula polymorpha* did increase production of the truncated glycoprotein of rabies virus[27], suggesting that at least in this case the folding environment in the yeast ER was not optimal for folding large amounts of glycoprotein.

However, co-expression of molecular chaperones is not a panacea and does not often give a 10-fold or more improvement in expression levels. Part of the problem is that overexpression of ER resident chaperones such as calreticulin might burden the ER and activate an unfolded protein response [22]. Another more challenging issue is that molecular chaperones may act in a concerted fashion to promote protein folding in a poorly understood process, suggesting that it may be best to overexpress multiple chaperones simultaneously. However, expression levels will need to be tightly controlled

to prevent overwhelming the cells protein production resource and also the stoichiometry between chaperones will have to be regulated. Another problem associated with engineering the chaperone and secretory pathway is that it can be protein and host specific. For example, co-expression of protein disulfide isomerase increased yields of albumin fusion proteins in the yeast *Pichia pastoris*[28] but did not improve functional SERT expression in insect cells [26]. Similarly, SRP 14 overexpression led to a substantial improvement of IgG production in CHO cells, but the strategy was ineffective in human cell lines producing alkaline phosphatase [29, 30].

An alternative strategy to overexpressing molecular chaperones is to delete endogenous competing chaperones in order to channel the nascent peptide chain to the desired signal recognition particle (SRP) secretory pathway. Indeed, Nannenga *et al.* showed that membrane protein insertion in *E. coli* improved and expression levels increased through eliminating competition between trigger factor (TF) and the SRP for the nascent polypeptide chain [16, 31].

Another strategy to improve secretion is to improve vesicular trafficking from the ER to the cell surface. Co-expression of secretory proteins which modulate vesicle trafficking, such as soluble NSF receptor (SNARE) proteins (SNAP-23 or VAMP8), improved production of SEAP and monoclonal antibodies by 2-3 fold in mammalian CHO-K1 cells [32]. Likewise, overexpression of SNARE-interacting Sec1p and Sly1p proteins improved expression of  $\alpha$ -amylase and human insulin precursor in *Saccharomyces cerevisiae*[33]. In addition, the ceramide transfer protein S132A mutant

improved production of tissue-plasminogen activator (t-PA) [34], human serum albumin (HSA) and monoclonal antibodies in CHO [35].

#### **1.4.4 Protein sequence mutagenesis**

Mutating the sequence of the protein target can also improve expression levels of the target protein. Sometimes this may be achieved through rational approaches such as analyzing the structure of the protein, as in the D500G mutation of laccase in *E.coli* [36] and the cysteine mutation of coagulation factor VIII [37]. However, in many instances there is insufficient evidence to suggest why a protein does not overexpress, so high-throughput mutagenic strategies can be used. For example, directed evolution coupled with random mutagenesis, followed by screening and selection was used by Sarkar *et al.* to evolve a GPCR, the rat neurotensin receptor type I (NTSR1) in *E. coli*. A mutant with 14 nucleotide substitutions retained the biochemical properties of the wild type receptor together with a 10-fold increase in functional expression and slightly increased thermostability [38]. Similarly, Heggeset *et al.* applied combinatorial mutagenesis and selection based on ampicillin tolerance in *E.coli* to evolve the signal sequence of  $\beta$ -lactamase and improved SEAP production up to 8-fold [39].

In theory, a more elegant and simple strategy would be to use *in vivo* mutagenesis coupled to screening or selection to improve expression. This approach was used by Majors *et al.* to evolve an anti-apoptotic gene *Bcl-x<sub>L</sub>* in a mammalian expression system by harnessing the somatic hypermutation capability of human Ramos B-cell line. The *Bcl-x<sub>L</sub>* gene, coupled to the yellow fluorescent protein reporter, was mutated “*in situ*” and

subjected to rounds of staurosporine treatment to identify mutants with reduced apoptosis activation and higher YFP-Bcl-x<sub>L</sub> expression levels [40].

#### **1.4.5 Cell proliferation and survival engineering**

The delay or prevention of the apoptosis cascade activation has been successful in preventing cell death and improving protein production in CHO cells under stress conditions [41]. Co-expression of the anti-apoptotic protein Bcl-x<sub>L</sub> in CHO cells improved the expression of epidermal growth factor receptor, fibroblast growth factor receptor 3 and receptor tyrosine kinases proteins [42]. Knock-out of the genes encoding the pro-apoptotic factors Bax and Bak in a CHO-K1 cell line improved cell viability, reduced levels of transfection-induced apoptosis and led to up to 4 fold higher antibody titers [43]. Similarly, stable inhibition of the pro-apoptotic microRNA mmu-miR-466h-5p in CHO cells delayed the onset of apoptosis, increased the maximum viable cell density and enhanced expression of SEAP [44].

Enhanced cell proliferation represents another potential approach to increase biomass and obtain higher volumetric yield during large scale production processes. For example, a metabolically engineered respiratory strain of *S. cerevisiae* (TM6\*) doubled volumetric yield of Fps1 and at least quadrupled the yield of two human GPCRs (A<sub>2a</sub>R and CNR2)[45]. Overexpression of the mammalian target of rapamycin (mTOR) simultaneously improved cell growth, proliferation, viability and specific productivity of antibody, SEAP and secreted  $\alpha$ -amylase in CHO cells [46]. Similarly, overexpression of miR-7 in CHO cells enhanced cell proliferation, leading to higher Epo-Fc titer [47]. However, accumulated biomass does not always lead to increased production as

demonstrated by chemical inhibition of autophagy in CHO cells, which led to decreased cell concentration but a 2.8 fold increase in t-PA [48].

#### **1.4.6 Other strategies:**

In cases where the heterologous proteins are toxic to the host cells, the presence of inhibitors can protect the host by sequestering proteins and keeping them in an inactive state. For example, co-expression of lysozyme together with its inhibitor Ivy, repressed lysozyme lytic activity in cytoplasm, and, along with transcription enhancement and chaperone co-expression, remarkably improved soluble lysozyme production in *E.coli*[49].

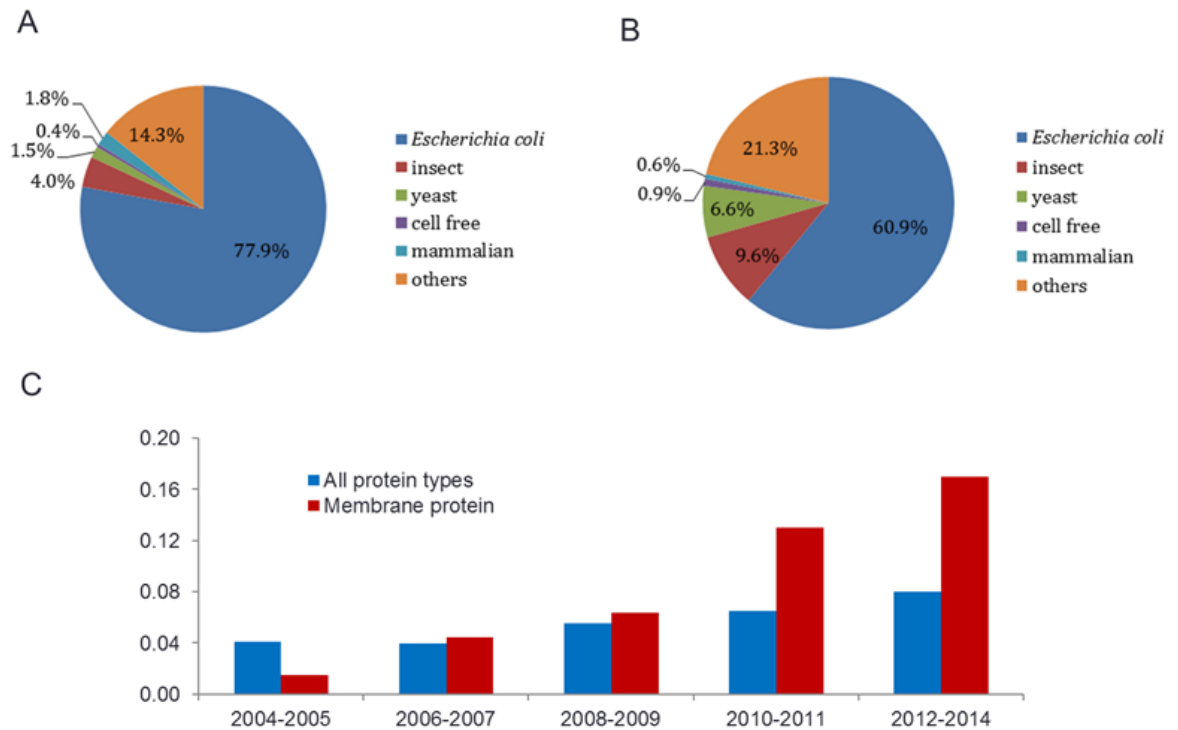

### **1.4 - Conclusion**

Recombinant protein expression has facilitated biochemical and structural studies of thousands of naturally low abundance proteins. Methodologies that improve expression levels can be particularly advantageous for many difficult-to-produce proteins or if the protein is being produced for therapeutic or industrial purposes. To improve expression levels further through cell engineering requires an understanding of both the host organism and the biology of protein expression. In this chapter, we reviewed some recent successful cases that target potential bottlenecks in protein production, using strategies focused on optimizing transcription, translation, engineering the folding and secretory pathways, mutating the target protein sequence, and enhancing cell proliferation and/or survival. Considerable effort has been focused on engineering *E.coli* and yeast

strains, and now there is an expanding effort to engineer insect and mammalian hosts such as HEK293 and CHO cell lines[50, 51], especially for functional expression of mammalian membrane proteins that include particularly complex folding, assembly, and processing pathways [52-54].However, in many instances there is only limited information on the factors that affect expression of any particular protein, so current strategies are often piecemeal and focus on only one or two aspects of the protein production process. A goal for the future is to identify limiting bottlenecks in the protein expression process such as transcription, translation, protein folding, secretion and cell viability and construct robust cell factories through a holistic approach that considers all the bottlenecks and engineer these through an integrative process to enable high-level expression of a wide spectrum of target proteins.

## **Chapter 2: Stable expression of the neurotensin receptor NTSR1 with T-REx-293 cells and comparison with baculovirus- insect cell system**

### **Abbreviations used:**

GPCR, G protein-coupled receptor; NTSR1, neurotensin receptor type 1; NT: neurotensin; HEK, human embryonic kidney; CHO, Chinese hamster ovary; tetO<sub>2</sub>, tandem tet operator; TetR, tet repressor protein; GnTI, N-acetylglucosamine transferase I; DMEM, Dulbecco's modified Eagle's medium; PBS, phosphate-buffered saline; FBS, fetal bovine serum; DM, *n*-Decyl- $\beta$ -D-maltopyranoside; DDM, *n*-dodecyl- $\beta$ -D-maltopyranoside; CHS, cholesteryl hemisuccinate Tris salt; CHAPS, 3-[(3-cholamidopropyl) dimethylammonio] -1- propanesulfonate; NaBu, sodium butyrate; CMV, cytomegalovirus; MOI, multiplicity of infection;

### **2.1 - Summary**

G protein-coupled receptors (GPCRs) are associated with a wide array of diseases and are targets of most of the medicines sold worldwide. Despite their clinical importance, only 62 unique GPCR structures have been determined as of December 2014. The first step for structural studies is to establish the expression of correctly folded, functional receptors in recombinant host cells at quantities to allow subsequent purification and crystallization trials. Baculovirus- insect cell and tetracycline- inducible mammalian cell lines (T-REx-293) are intensively used for GPCR production. Here a stable and inducible T-REx-293 cell line overexpressing an engineered rat neurotensin receptor type 1 (NTSR1) was constructed. With proper clone selection, suspension

culture adaptation and induction parameter optimization, approximately 1 milligram of purified functional NTSR1 per liter suspension culture was obtained. This stable inducible mammalian expression system was also quantitatively compared with the transient baculovirus-insect cell system throughout a milligram-scale expression and purification process. The two systems were comparable on aspects of functional NTSR1 expression level and receptor binding affinity for ligand [<sup>3</sup>H]NT. However, NTSR1 surface display on T-REx-293 cells determined by radio-ligand binding assays was 2.5 fold higher than that on insect cells. This work demonstrates two approaches for preparing milligram-scale quantities of NTSR1 purified enough for structural studies and provides useful input to users in choosing and optimizing an appropriate expression host for other GPCRs.

## **2.2 - Introduction**

As was discussed in Chapter 1, there have been numerous efforts in improving the expression level of recombinant proteins for production of commercial biotherapeutics as well as for biomedical studies in academia. A critical and difficult area is the expression of mammalian integral membrane proteins such as receptors, ion channels and transporters. GPCRs are a superfamily of integral membrane proteins that have seven transmembrane domains. They play a central role in cell signaling by transmitting extracellular chemical signals across membranes to intracellular effector pathways. Closely associated with a wide array of physiological diseases, these proteins are targets of most of the medicines sold worldwide [10]. As of December 2014, structures of 62 unique GPCRs are available (<http://blanco.biomol.uci.edu/mpstruc/listAll/list>).

Crystallographic studies of GPCRs are very rewarding because they provide insight into mechanistic aspects of cell signaling at high resolution, thus opening the pathway to ultimately improve drugs and medicines targeting a wide variety of diseases[10]. In the past few years, we started to see an explosion in the field of GPCR structure determination. This exciting progress is based on a tremendous amount of methods development, such as advances in crystallization methods, the development and implementation of the concept of conformational thermostabilization of GPCRs, and the development of microfocus x-ray synchrotron technologies[55]. Yet, the supply of ample amounts of correctly folded receptors is the key prerequisite for successful structural studies.

The goal of this research is to improve expression level of functional neurotensin receptor type 1 (NTSR1), a difficult-to-express GPCR. Its agonist is neurotensin (NT), a 13 amino acid residue peptide that is found in the nervous system and in peripheral tissues [56]. NT displays a wide range of biological activities and plays important roles in Parkinson's disease, in pathogenesis of schizophrenia, in modulation of dopamine neurotransmission, hypothermia, antinociception and in promoting the growth of cancer cells [57-61]. Three neurotensin receptors have been identified. NTSR1 and NTSR2 belong to the class A GPCR family, whereas NTSR3 is a member of the sortilin family with a single transmembrane domain [62-64]. Most of the known effects of NT are mediated through NTSR1[60].

Wild-type rat NTSR1 has previously been expressed in *Escherichia coli* fused with maltose-binding protein (MBP), and large-scale purification has been accomplished [65]. Recently, systematic scanning mutagenesis of NTSR1 has been performed using *E.*

*coli* as the expression host to identify stabilized NTSR1 mutants suitable for crystallization [66, 67]. The structure of stabilized NTSR1 mutant (GW5) with T4 lysozyme replacing most of the third intracellular loop, was determined with receptors transiently expressed in baculovirus-insect cell system in 2012 [67].

In this work, mammalian cell line HEK293 was chosen as the expression host despite it's not a popular choice for structural studies[7], likely as the result of the high cost associated with serum needed for cell culture and the lengthy process of stable cell line construction. However, mammalian cells are ideally suited for efficient expression of functional membrane proteins because of the near-native environment they provide, such as N-glycosylation, a machinery for post-translational modification, molecular chaperones, and a suitable lipid environment [7]. In addition, the continuous production capability is yet another advantage which the baculovirus-insect cell system cannot provide.

As constitutive mammalian expression systems sometimes fail to provide adequate amounts of membrane proteins for structural studies, a tetracycline-inducible expression system [68] was demonstrated to be advantageous for high-level expression of GPCRs in functional form [50-52]. In tetracycline-free medium, mammalian cells are allowed to reach high cell density without the stress from leaky GPCR expression; after addition of tetracycline and thus GPCR production for typically 24 –72 hrs, cells are harvested.

The tetracycline-inducible expression system developed for recombinant mammalian cell expression hosts contains two components of the tetracycline-resistance determinants of gram-negative bacteria: The tandem tet operator sequence (tetO2)[69],

which is positioned upstream of the gene of interest; and the Tet repressor protein (TetR)[70]. In the absence of tetracycline, the TetR homodimer binds with high affinity to the tetO2 sequence downstream of the TATA element of the human cytomegalovirus (CMV) major immediate-early promoter, thus blocking transcription of the gene of interest (Fig.2.1A). Upon addition of tetracycline, TetR abolishes its association with tetO2, allowing transcription of the gene of interest under the control of the strong CMV promoter [70] (Fig.2.1B).

This system, developed by Yao *et al.*[68], has been commercialized as the T-REx system (Life Technologies) and several tetracycline-inducible mammalian cell lines (HEK293, CHO, HeLa, *etc.*) are now available. Those cell lines have been stably transfected with the pcDNA6/TR regulatory vector which leads to high level, constitutive expression of TetR [70]. The gene of interest is cloned into pcDNA<sup>TM</sup>4/TO (or an equivalent plasmid), which contains the complete CMV enhancer-promoter sequence, with the tetO2 operator region starting 10 nucleotides downstream of the last nucleotide of the TATA element [68].

The successful application of the tetracycline-inducible system for GPCR expression was first demonstrated by Reeves *et al.* [51]. A tetracycline-inducible and suspension adaptable HEK293S-TetR cell line successfully overproduced milligram quantities of opsin mutants per liter of culture in bioreactors. Meanwhile, a HEK293S-GnTI-TetR cell line, which lacks the N-acetylglucosaminetransferase I (GnTI) enzyme, was developed and gained increasing popularity for membrane protein production for structural studies [52-54], owing to the homogeneously N-glycosylated proteins produced by this cell line [51].

Here we report the expression of NTSR1-GW5-Δi3 in a stable, inducible T-REx-293 cell line and in baculovirus infected insect cells. NTSR1-GW5-Δi3 has six stabilizing mutations[67], truncated N- and C-termini, and parts of the third intracellular loop deleted. We provide a quantitative comparison between the two production hosts regarding aspects of functional NTSR1-GW5-Δi3 expression levels and receptor yield after purification, as well as binding properties and cell surface display of the receptors. The scale-up of NTSR1-GW5-Δi3 production using T-REx-293 suspension cultures in a bioreactor allows the continued production of the receptor suitable for the application of biophysical analyses such as *Nuclear magnetic resonance* (NMR) spectroscopy.

## **2.3 - Materials and Methods**

### **2.3.1. Materials**

The tritiated agonist [<sup>3</sup>H]NT ([3,11-tyrosyl-3,5-3H(N)]-pyroGlu-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ile-Leu) was purchased from Perkin Elmer. Unlabeled NT was synthesized by the Center for Biologics Evaluation and Research (Food and Drug Administration). The detergents n-dodecyl-β-D-maltopyranoside (DDM), 3-[(3-cholamidopropyl) dimethylammonio] -1- propanesulfonate (CHAPS) and cholesteryl hemisuccinate Tris salt (CHS) were obtained from Anatrace.

### **2.3.2. The NTSR1 construct used for expression in insect cells and T-REx-293 cells**

The construct NTSR1-GW5-Δi3 consisted of the hemagglutinin signal peptide and the Flag tag [71], followed by the stabilized rat neurotensin receptor NTSR1 (T43-K396 containing the mutations A86L, E166A, G215A, L310A, F358A, V360A) with the

intracellular loop 3 residues G275-E296 deleted [67]. A deca-histidine tag was present at the C-terminus. We refer to this construct in the following as NTSR1. For expression using the baculovirus-insect cell system, NTSR1 was subcloned into the transfer vector pFastBac1 (Invitrogen) thus placing NTSR1 under the control of the strong polyhedrin promoter. For stable expression in T-REx-293 cells, NTSR1 was subcloned into the plasmid pACMV-tetO (a kind gift from Dr. Philip J. Reeves) downstream of the tetracycline-controlled CMV promoter [51] (Fig.2.2).

### **2.3.3. Transient expression of NTSR1 in the baculovirus-insect cell system**

Recombinant baculoviruses were generated using the pFastBac1 transfer plasmid system (Invitrogen). *Trichoplusia ni* cells were infected at a cell density of 0.8-1 million cells/ml with recombinant virus at a multiplicity of infection (MOI) of 5, and the temperature was lowered from 28°C to 21°C. Cells were harvested by centrifugation 48 hours post infection, resuspended in hypotonic buffer (10 mM Hepes pH 7.5, 10 mM MgCl<sub>2</sub>, 20 mM KCl), flash-frozen in liquid nitrogen and stored at -80°C until use.

### **2.3.4. Stable expression of NTSR1 in the T-REx-293 system**

The T-REx-293 cell line was maintained as an adherent culture in DMEM containing 10% certified FBS and 5 µg/ml blasticidin (Invitrogen). The cells were transfected with the plasmid pACMV-tetO-NTSR1 (Fig.2.2). using Lipofectamine 2000 according to the manufacturer's protocol (Life Technologies). One day after transfection, cells were transferred into fresh DMEM medium containing 800 µg/ml Geneticin (Cellgro) and the medium was replaced every three days. Two weeks later, fourteen cell

clones were separately expanded into two T-flasks each. Cells in one T-flask were harvested during the exponential growth phase and frozen in 10% DMSO for storage. Cells in the other T-flask were induced with 2 µg/ml tetracycline for 24 hrs, after reaching 80% confluency. Cells were then detached from the flask and washed with cold PBS. After adjusting the cell density to around one million cells per ml, protease inhibitors (Roche) were added and the cell suspension was frozen on dry ice in 1ml aliquots. NTSR1 expression levels were determined by [<sup>3</sup>H]NT binding and the clone with the highest expression level was selected for further experiments.

#### **2.3.5. Adaption of NTSR1-expressing T-REx-293 cells in to suspension culture**

Three different medium were tested for suspension culture of NTSR1-expressing T-REx-293 cells: Freestyle™ 293, CD OptiCHO™ (Gibco) and pro293 CD™ Medium (Lonza). The adherent growth medium (DMEM supplemented with 10% certified FBS, 5µg/ml blasticidin and 500µg/ml G418) was gradually replaced with suspension growth medium during subculture in T-flask. With the displacement of the media, increasing amount of viable detached cells can be collected and transferred into shake flask and maintained in suspension growth media supplemented with 1% certified FBS, 5 µg/ml blasticidin and 500 µg/ml G418 for suspension culture. The optimal media giving highest cell density and viability was chosen for further culture.

#### **2.3.6. Growth of T-REx-293 cell line suspension culture in a bioreactor**

The suspension-adapted T-REx-293 cells were grown in 5L of CD OptiCHO medium supplemented with 4 mM L-glutamine, 1% certified FBS, 100 unit/ml penicillin,

100 µg/ml streptomycin and 0.1% pluronic F-68 (Gibco), using a 10L glass bioreactor equipped with a pitch blade impeller connected to a Sartorius BDCU controller. The growth parameters were set to 37°C, pH 7, and 30% dissolved oxygen. The latter two parameters were maintained by interactive control delivery of air and CO<sub>2</sub> through direct sparge (up to 10 ml/min). The speed of the impeller was 80 rpm. The cell density at inoculation was 3×10<sup>5</sup> cells per milliliter. On day 5 after inoculation, expression of NTSR1 was induced by addition of 2 µg/ml tetracycline and 2.5 mM sodium butyrate (NaBu). Cells were harvested 36hrs after induction, re-suspended in hypotonic buffer (10 mM Hepes pH 7.5, 10 mM MgCl<sub>2</sub>, 20 mM KCl), flash-frozen in liquid nitrogen and stored at -80°C until use.

### **2.3.7. Analytical solubilization of NTSR1**

Cell pellets from 10 ml of suspension cultures were suspended in Tris-glycerol-NaCl buffer. Then the detergent DM and CHS was added to give a final buffer composition of 50 mM TrisHCl pH 7.4, 200 mM NaCl, 30% glycerol, 1% DM, and 0.1% CHS in a total volume of 2.5 ml. The samples were placed on a rotating mixer at 4°C for 1 hour. Cell debris and non-solubilized material were removed by ultracentrifugation (TL100 rotor, 60k rpm, 4°C, 30 min in Optima Max bench-top ultracentrifuge, Beckman), and the supernatants containing detergent-solubilized NTSR1 were used to determine the total number of expressed receptors by a detergent-based radio-ligand binding (see below).

### **2.3.8. Purification of NTSR1 produced in T-REx-293 and insect cells**

All buffer volumes relate to 1L of original cell culture. T-REx-293 cells were thawed and the volume was brought to approximately 200 ml with hypotonic buffer. The cells were then re-suspended using a Turrax T-25 (IKA) homogenizer at 8,200 rpm for 2 min. After centrifugation (45Ti rotor, 40,000 rpm, 45 min, 4°C, Optima L90K, Beckman), the membranes were resuspended (Turrax T-25) in approximately 120 ml of high-salt buffer (10 mM Hepes pH 7.5, 1 M NaCl, 10 mM MgCl<sub>2</sub>, 20 mM KCl) supplemented with DNaseI (final concentration 10 µg/ml) and AEBSF (100 µM), and centrifuged again. The high-salt washes were repeated 4 more times with the DNaseI addition omitted after the 2<sup>nd</sup> wash. All subsequent steps were performed at 4°C or on ice, and AEBSF (100 µM final concentration) was repeatedly added throughout the procedure. The washed membranes were resuspended in a final volume of 40 ml of buffer (62.5 mM TrisHCl pH 7.4, 625 mM NaCl, 37.5% glycerol) containing 10 µM neurotensin peptide. NTSR1 was extracted by drop-wise addition of 10 ml of a 5% DM / 0.3% CHS solution. After 2.5 hours, the sample was clarified by centrifugation (45Ti rotor, 40,000 rpm, 1 hour, Optima L90K, Beckman), adjusted with imidazole to a final concentration of 20 mM, and then passed through a 0.2 µm filter (Stericup). Next, the sample was loaded at a flow rate of 0.2 ml/min onto 2 ml Talon resin packed into an XK16 column (GE Healthcare) equilibrated with Talon-A buffer (50 mM TrisHCl pH 7.4, 30% glycerol, 500 mM NaCl, 20 mM imidazole, 0.1% DM / 0.01% CHS) containing 1 µM neurotensin peptide. After washing with 29 column volumes of buffer Talon-A, NTSR1 was eluted with Talon-B buffer (50 mM TrisHCl pH 7.4, 30% glycerol, 500 mM NaCl, 200 mM imidazole, 0.1% DM / 0.01% CHS) containing 5 µM neurotensin peptide.

Peak fractions were collected (5 ml) and analyzed. The purification of NTSR1 from insect cells was performed in a similar manner.

### **2.3.9. Protein analysis and radio-ligand binding assays**

The protein content was measured according to the Amido Black method of Schaffner and Weissmann [72] with bovine serum albumin as the standard. Western blot analysis was performed as described [73] using the INDIA HisProbe-HRP reagent (Pierce) and the substrates 3,3'-diaminobenzidine tetrahydrochloride and H<sub>2</sub>O<sub>2</sub>.

[<sup>3</sup>H]NT ligand-binding assays with intact cells were carried out in 500 µl of TEBB assay buffer (50 mM Tris-HCl pH 7.4, 1 mM EDTA, 0.1% bovine serum albumin, 40 µg/ml bacitracin) containing 10 nM [<sup>3</sup>H]NT and about 100,000 cells. After incubation for 2-4 hours on ice, separation of bound from free ligand was achieved by rapid filtration through GF/B glass fiber filters (Whatman) pretreated with polyethylenimine. The amount of radioactivity was quantified by liquid scintillation counting (Beckman LS6500). Non-specific [<sup>3</sup>H]NT binding of 4160 dpm was subtracted from total binding to calculate the receptor density at the cell surface. The concentration of [<sup>3</sup>H]NT used in these assays was four-fold above the apparent dissociation constant for membrane-bound NTSR1 [67] to allow high receptor occupancy, but it kept nonspecific [<sup>3</sup>H]NT binding to a minimum.

Ligand-binding assays with detergent-solubilized receptors were carried out in TEBB assay buffer containing 0.1% DDM, 0.2% CHAPS, 0.04% CHS. For one-point assays, receptors were incubated with 2 nM [<sup>3</sup>H]NT on ice for 1 hour in a volume of 150

$\mu$ l. Separation of the receptor-ligand complex from free ligand (100  $\mu$ l) was achieved by centrifugation-assisted gel filtration using Bio-Spin 30 Tris columns (BioRad), equilibrated with RDB buffer (50 mM Tris-HCl, pH 7.4, 1 mM EDTA, 0.1% DDM, 0.2% CHAPS, 0.04% CHS). Non-specific [ $^3$ H]NT binding of 220 dpm was subtracted from total binding, and the amount of specifically bound [ $^3$ H]NT was then corrected for fractional occupancy (apparent dissociation constants of 0.22 nM and 0.57 nM for receptors produced in HEK-293 cells and insect cells, respectively).

For saturation binding experiments, the [ $^3$ H]NT concentration was varied from 0.2 nM to 10 nM. Non-specific [ $^3$ H]NT binding was determined in the presence of 50  $\mu$ M unlabeled NT. Data were analyzed by nonlinear regression using GraphPad Prism software (version 4, GraphPad Software) and best fit to a one-site binding equation to determine the apparent dissociation constants for NTSR1 produced in insect and HEK-293 cells. Note that the saturation binding experiments using the NTSR1 mutant did not reach equilibrium within the incubation time because of the very slow agonist off-rates determined in a previous study [67]. Individual experiments were conducted as single data points.

## **2.4 - Results**

### **2.4.1. NTSR1 expression in suspension T-REx 293 cells**

For our study, we used the engineered rat neurotensin receptor NTSR1-GW5- $\Delta$ i3 (here referred to as NTSR1). This construct consists of the hemagglutinin signal peptide and the Flag tag, followed by the conformationally thermostabilized rat neurotensin

receptor NTSR1-GW5 (T43-K396 containing the mutations A86L, E166A, G215A, L310A, F358A, V360A)[67, 74] with the intracellular loop 3 residues G275-E296 deleted. A deca-histidine tag was present at the C-terminus. The NTSR1 DNA was inserted into pACMV-tetO [51] using standard molecular biology techniques. The resulting expression vector pACMV-tetO-NTSR1 (Fig. 2.2) allows tetracycline inducible expression of NTSR1.

The N-terminally truncated rat NTSR1 with 6 stabilizing mutations was stably expressed in the tetracycline-regulated T-REx-293 cell line. A high-expressing clone was selected and adapted step-wisely to suspension culture for scaling-up purposes. This clone grew to a density of 4 million cells /ml in shake flask with viability higher than 95% and a doubling time of 48 hours.

To maximize the production of NTSR1, a preliminary orthogonal array design[75] was carried out investigating three induction parameters: tetracycline concentration (1-4  $\mu\text{g/ml}$ ), sodium butyrate (NaBu) concentration (0.5-10 mM) and induction time (24-60 hrs). Initial variance analysis showed negligible impact from higher tetracycline doses, significant effect of NaBu, and considerable cell death with induction time longer than 48hr (data not shown). Therefore, further optimization efforts were focused on the NaBu dose with induction time of 24 or 36 hours. As shown in Fig.2.3, NTSR1 expression was undetectable in the absence of tetracycline, while in the presence of 2  $\mu\text{g/ml}$  tetracycline, 2.5 million plasma membrane localized receptors were produced. The expression of functional NTSR1 improved with increasing NaBu concentrations (0.5-10 mM) and optimal production was achieved by the addition of 2  $\mu\text{g/ml}$  tetracycline and 10 mM sodium butyrate when the viable cell density reached 2

million cells/ml, with harvest 36 hrs later. These optimized conditions resulted in 8.8 million copies of NTSR1 localized at the plasma membrane per cell (Fig. 2.3), a 3.5-fold increase of cell surface expression compared to the induction with tetracycline alone.

Pilot-scale production of NTSR1 was then carried out in a 5L bioreactor. 2µg/ml tetracycline and 2.5 mM NaBu were added to T-REx-293 cells when viable cell density reached 1.5 million cells/ml. Cells were harvested 36 hrs after induction and plasma membrane localized receptors were determined to be 5.6 million per cell with [<sup>3</sup>H]NT binding assays on intact cells. To determine the total amount of functional NTSR1 (i.e. receptors residing in the endoplasmic reticulum, the Golgi apparatus and plasma membrane), cells were solubilized with detergent and the number of receptors were determined by a detergent-based radio-ligand binding assay. This resulted in 18.2 million receptors per cell and a yield of 1.5 mg of functional NTSR1 per liter culture (Table 2.1).

#### **2.4.2. NTSR1 expression in insect cells**

Both Sf9 and *T. ni* cells were tested as insect hosts for NTSR1 expression and all subsequent pilot-scale expression experiments were performed using *T. ni* cells due to their higher viability after infection (we considered cell viability an essential factor as only healthy cells have an intact machinery for insertion and folding of membrane proteins). *T. ni* cells were infected at an MOI of 5 followed by the reduction of temperature to 21°C and cells were harvested at 48 hrs post-infection. NTSR1 was produced at a total number of 17.8 million receptors per cell or 1.7 mg receptor per liter culture as determined by ligand binding assays (Table 2.1).

### **2.4.3. Purification of NTSR1 from T-REx-293 cells and insect cells**

The presence of neurotensin enhance the stability of NTSR1-GW5- $\Delta$ i3 [67], therefore, all purification steps were conducted in the presence of the agonist peptide. The purification of NTSR1 produced in T-Rex-293 and insect cells was done in one step by immobilized metal affinity chromatography (Talon resin) in the presence of the detergent DM/CHS. The yield of NTSR1 per liter of cell culture, as calculated from the cell density at harvest and [ $^3$ H]NT binding assays on detergent-solubilized cells, was similar for both expression hosts (Table 2.1). The protein yield of the Talon column eluates was determined by the Amido Black method, as the presence of NT during the purification procedure prevented a radio-ligand binding analysis. Note that because of background contaminants (Fig.2.4), the Amido Black method overestimates the content of purified NTSR1.

### **2.4.4. Characterization of NTSR1 produced in insect cells and T-Rex-293 cells**

To quantify the total amount of NTSR1 and the amount of plasma membrane localized NTSR1, [ $^3$ H]NT binding assays on detergent-solubilized cell extracts and on intact cells were conducted. The total number of functional NTSR1 per cell, produced in T-Rex-293 cells and insect cells, was similar (Fig. 2.5A). T-Rex-293 cells produced 12.8 million receptors per cell, while insect cells produced 15.8 million receptors per cell. However, the percentage of NTSR1 molecules that had trafficked to the cell surface was 2.5-fold higher in the case of T-Rex-293 cells compared to insect cells (Fig. 2.5B).

Gel electrophoresis of the solubilized protein from T-Rex-293 and insect cells

was performed and analyzed using INDIA HisProbe reagent, which detected all histidine tagged NTSR1. Equivalent amount of correctly folded NTSR1 (as determined by [<sup>3</sup>H]NT binding assays) from the two hosts were applied and the comparable band intensity indicated comparable total NTSR1 expression (including correctly folded and misfolded ones), thus suggesting similar propensity for receptor misfolding in T-Rex-293 and insect cells (Fig.2.4, lane 4 and 5).

The ligand binding property of the receptors produced in the two hosts were comparable according to saturation binding assays using detergent-solubilized receptors. The dissociation constants for NTSR1 from both hosts were not statistically different (Fig. 2.6).

## **2.5 - Discussion**

Unveiling the protein structure of GPCRs by crystallography will help to elucidate the mechanism of many diseases and enhance potential drug discovery and development. In order to accomplish this, milligram amounts of functional receptors are needed. Seeking an appropriate expression host is vital, as the host can affect the quantity and quality of the starting material [76]. Possible host choices include bacteria [77], yeast [78], baculovirus- insect cell system [79], and mammalian cells[80]. The baculovirus- insect cells system and inducible T-REx- 293 system were intensively investigated in recent years because of their lipid composition, translocation machinery and protein folding capabilities [11]. In this study, NTSR1 served as a model GPCR and the

baculovirus- insect cell and mammalian T-REx- 293 system were compared throughout NTSR1 expression and purification process in a quantitative way.

By using inducible expression strategy, 2.5 million functional copies of NTSR1 per cell were detected on plasma membrane of T-REx cells; this level of expression is 167 fold higher than the NTSR1 constitutively expressed in HEK-293T cells [38]. Optimization of induction parameters led to a further increase in expression level to 8.8 million functional receptors per cell on plasma membrane. Among the three induction parameters tested (tetracycline concentration, NaBu concentration and time length of induction) the concentration of sodium butyrate (NaBu) had the most impact. This compound has been successfully applied together with tetracycline for synergistic induction of many GPCRs expression [81, 82]. NaBu is routinely used at low concentration (1-5mM[83]), possibly because of its cytotoxic effects on cell growth[84]. In the experiments reported here, NaBu was applied at a concentration of 10mM resulting in improved receptor expression. The enhancement of NTSR1 gene transcription by inhibition of histone deacetylase may be a possible explanation. It is also possible that NaBu led to growth arrest of host cells, allowing available energy be channeled to the NTSR1 expression pathway.

Expression levels and binding properties of functional NTSR1 from the T-REx-293 and baculovirus insect cells systems were comparable. For both systems, the yields were approximately 15 million total functional receptors per cell or 1 milligram per liter culture after purification. This indicates that a 10L culture will provide approximately 10mg of high-quality material, a sufficient amount for structural studies. From production

point of view, a significant difference was observed in the surface-presentation of the receptors. In T-REx-293 cells, 2.5 times more NTSR1 were trafficked to the plasma membrane than insect cells as determined by ligand binding assays. The assumption was that higher surface-presentation is correlated with more properly folded receptors which were found to be the case for the serotonin transporter [76]. However, when equal amount of functional NTSR1 from both hosts were analyzed by western blot where INDIA HisProbe reagent would capture histidine tag of functional and non-functional NTSR1, the bands have similar intensity. This indicated comparable NTSR1 folding efficiency in both systems. Also, the fact that NTSR1 from insect cells could crystallize [67] suggested the difference between surface and internal receptors could be subtle. More studies will be needed in order to understand the implications of difference in receptor surface- presentation.

Another difference between the transient expressions in the insect cells and the stable expression in the T-REx-293 cells is the timeframe required for process development and for establishing the expression conditions (Fig. 2.7). The estimated time for expression with baculovirus-insect cells is around 6 weeks while it can take up to 12 weeks to obtain products from the stable T-REx-293 expression system. Based on this time frame the transient expression system is better at an early stage of the research when the GPCR of interest is subject to frequent sequence modifications for identifying constructs which are suitable for crystallization. Whereas stable expression in suspension T-REx-293 cells may be preferable for production of GPCRs of a specified construct due to its superior processing capabilities. The well-established scale-up methods for suspension cultures in a bioreactor will allow for one-step large scale production of

sufficient amounts of receptors for other applications of biophysical techniques such as NMR spectroscopy. Cost-wise, the medium prices for T-REx-293 and insect cells are comparable. It is likely possible that improvement in high density suspension culture of T-REx-293 cells will further reduce cost per milligram of protein.

In conclusion, we generated a suspension stable T-REx-293 cell line capable of expressing 1.5 milligram functional NTSR1 per liter. This cell line was found to be comparable to the transient baculovirus-insect cell expression system in regard to functional NTSR1 expression level and receptor binding properties. It provides a superior receptor surface display of the target proteins which may be advantageous for certain applications.

**Contributions from collaborators:**

Dr. Reinhard Grisshammer contributed to drafting and revising the manuscript and Jim White carried out ligand binding assays and NTSR1 purification from T-REx-293 cells and insect cells. Both collaborators contributed to conceiving and designing of experiments.

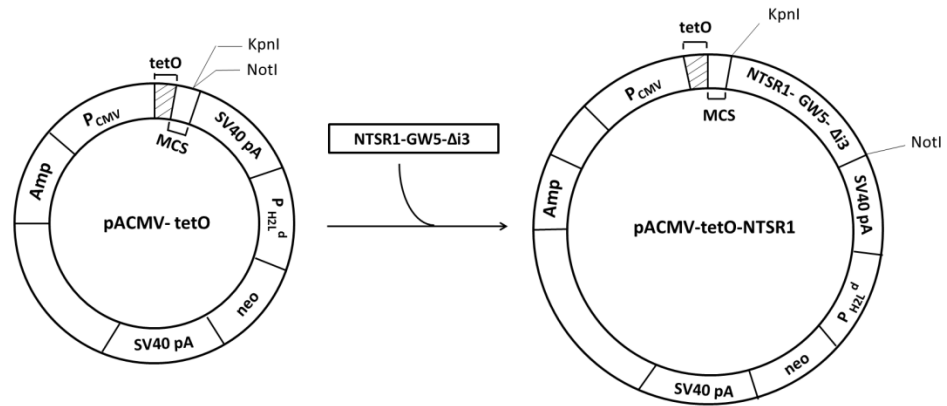

## Figures and tables

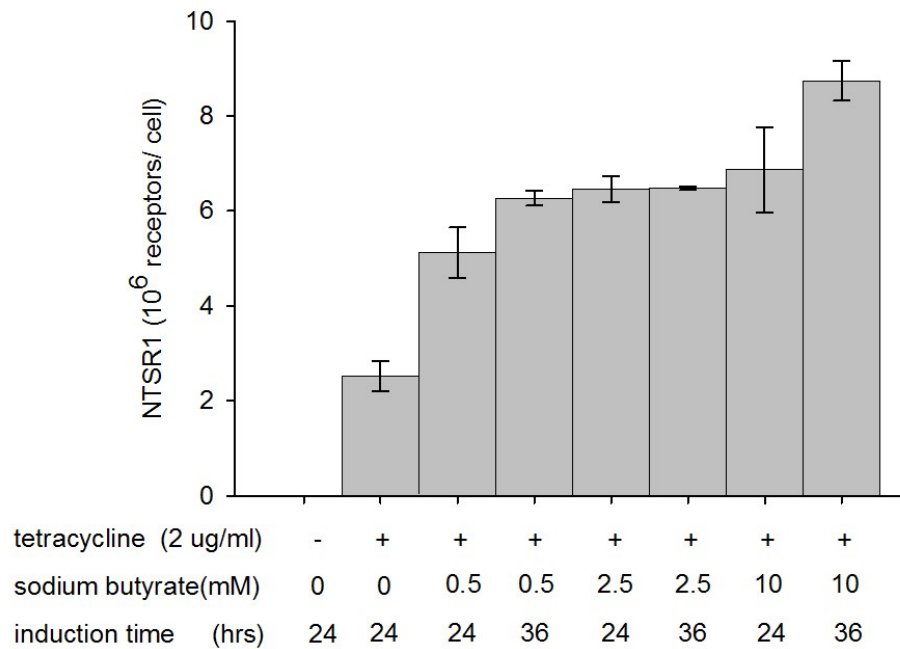

**Fig.2.1.** Illustration of the tetracycline inducible expression system. (A) In the absence of tetracycline, TetR binds to tetO2 downstream of the TATA element, thus blocking transcription of the gene of interest. (B) The interaction of tetracycline with TetR causes its conformation to change, resulting in the dissociation of TetR from tetO2, thus initiating transcription.

**Fig.2.2.** Construction of the NTSR1 expression vector. The NTSR1 DNA was inserted into pACMV-tetO using standard molecular biology techniques. The resulting expression vector allows tetracycline inducible expression of NTSR1 under control of CMV promoter.

**Fig.2.3.** Optimization of NTSR1 expression under different induction conditions using a stable T-REx-293 cell line. The data were collected from a selected high-expressing clone. Cells were grown in suspension and were induced in the late exponential growth phase (at a viable cell density of 2 million cells /ml) with tetracycline. The addition of sodium butyrate enhanced expression levels. Intact cells were subjected to [<sup>3</sup>H]NT binding assay to determine the number of receptors located at the cell-surface.

**Fig.2.4.** Purification of NTSR1. The progress of purification was monitored by SDS-PAGE (NuPAGE 4–12% Bis-Tris gel, Invitrogen, 1x MES SDS buffer) and SimplyBlue staining. Lane 1: Novagen Perfect Protein Marker (15–150 kDa); lane 2: Talon eluate of NTSR1 produced in T-REx-293 cells (3.5µg); lane 3: Talon eluate of NTSR1 produced in insect cells (6 µg); Western blot analysis of total cell extract was performed using the HisProbe-HRP reagent recognizing the histidine tag. Lane 4: NTSR1 produced in T-REx-293 cells (122,000 lyzed cells with 113 ng functional NTSR1); lane 5: NTSR1 produced in insect cells (110,500 lyzed cells with 107 ng functional NTSR1).

**Fig.2.5.** Expression of NTSR1 in the transient insect cell system and inducible T-REx-293 system. (A) Total functional NTSR1 numbers were determined by [<sup>3</sup>H]NT binding assays using detergent solubilized cells (B) Surface localized NTSR1 numbers were determined by [<sup>3</sup>H]NT binding assays using intact cells and combined with data from (A) to calculate percentage of surface localized NTSR1. (baculovirus insect cell system: 7 independent expression experiments; T-REx-293 system: 3 independent measurements on one 5L expression experiment). The expression of NTSR1 in insect cells was conducted as described in Materials and Methods. Expression of NTSR1 in the T-REx-293 system was induced by the addition of 2 µg/ml tetracycline and 10 mM sodium butyrate, with harvest and analysis 48 hours later.

**Fig.2.6.** [<sup>3</sup>H]NT saturation binding of NTSR1 expressed in (A) T-REx-293 cells and (B) insect cells. NTSR1 was extracted from membranes with the detergent DM/CHS and subjected to radio-ligand binding analysis. Inset: Scatchard transformation. Representative experiments conducted as single data points are shown. (C) Table summarizing the values of the apparent dissociation constants values for [<sup>3</sup>H]NT binding. These values were not statistically different (P = 0.2, unpaired two-tailed t-test). Data were collected from three repeated experiments.

C

Receptor source	Apparent dissociation constant (nM) (n=3)
T-REx-293 cell	0.22 ± 0.06
Insect cell	0.57 ± 0.22

**Fig.2.7.** Timeframe for establishment of transient baculovirus- insect cells system and stable expression with inducible T-REx-293 system for GPCR expression.

**Table.2.1.** Purification of NTSR1 from different host cells. Average data for insect cells were from four purification experiments using 1L (3 experiments) or 4L (1 experiment) of cell culture as starting material. Average data for T-REx-293 cells were from two purification experiments using 1L of culture as starting material. All purification procedures were performed in the presence of neurotensin. The theoretical yield was calculated from the cell density at harvest and [<sup>3</sup>H]NT binding assays on detergent-solubilized cells. The protein yield of the Talon column eluate was determined by the Amido Black method, as the presence of NT during the purification procedure prevented a radio-ligand binding analysis. Because of minor contaminants in the Talon column eluate, the content of NTSR1 is overestimated. <sup>a</sup> average data from three 5L expressions, <sup>b</sup> data from one 5L bioreactor run.

Host cell	Functional receptor produced		Functional receptor purified (mg/L)
	(10 <sup>6</sup> /cell)	(mg/L)	
Insect cells	17.8 <sup>a</sup>	1.7 <sup>a</sup>	1.5
T-REx-293 cells	18.2 <sup>b</sup>	1.5 <sup>b</sup>	0.9

## **Chapter 3: Large-scale miRNA mimic screen for improved functional expression of neurotensin receptor**

### **Abbreviations:**

NTSR1, neurotensin receptor type 1; GPCR, G protein-coupled receptor; HEK, human embryonic kidney; CHO, Chinese hamster ovary; ORF, open reading frame; pri-miRNA, primary miRNA; pre-miRNA, precursor miRNA; RISC, RNA-induced silencing complex; 3'-UTR, three prime untranslated region; CMV, cytomegalovirus; DMEM, Dulbecco's modified Eagle's medium; PBS, phosphate-buffered saline; FBS, fetal bovine serum; GFP, green fluorescent protein; MAD, median absolute deviation; DMSO, Dimethyl sulfoxide; NT, neurotensin; DDM, n-dodecyl- $\beta$ -D-maltopyranoside; CHS, cholesteryl hemisuccinate Tris salt; CHAPS, 3-[(3-cholamidopropyl) dimethylammonio] -1- propanesulfonate; GPC3, glypican-3; BSA, bovine serum albumin; MOF, mean of fluorescence.

### **3.1 - Summary**

To explore the possibility of enhancing protein expression using miRNA, a stable T-REx-293 cell line was constructed to over-express the neurotensin receptor type 1 (NTSR1) fused with green fluorescent protein (GFP) to its C-terminal. The cell line was then subjected to high-content image-based human miRNA mimic library screening. Five microRNA mimics: hsa-miR-22-5p, hsa-miR-18a-5p, hsa-miR-22-3p, hsa-miR-429 and hsa-miR-2110 were identified to improve functional expression of NTSR1 by as much as 48%. In parallel, an HEK293 cell line expressing luciferase was also screened with the

same human miRNA mimic library. All five identified microRNA mimics were also found to enhance the luciferase expression up to 239%. Interestingly, all five miRNAs improved glypican-3 hFc fusion protein secretion up to 120%, which indicated that these molecules could have a wide role in enhancing production of proteins with biomedical interest.

### **3.2 - Introduction**

As discussed in chapter 2, the HEK293 cells were demonstrated advantageous for NTSR1 expression in many aspects. They have high functional expression level and surface display ratio of the receptor. They can reach high cell density (4-8 million cells/mL) in bioreactors and have continuous production capability. In addition, the high cost associated with FBS has been brought down by serum-free suspension culture, making the using of the expression system cost-effective. In all, the HEK293 expression system is a good choice for large-scale production of proteins for medical or structural studies, especially for expression of mammalian integral membrane proteins such as receptors, ion channels and transporters [7].

In this chapter, the goal is to use NTSR1 as a model integral membrane protein and to engineer the preferred HEK293 expression system to improve its production capability of heterologous membrane protein. As discussed above and in chapter 1, rational engineering of the host cells may be trial and error due to the lack of thorough understanding in membrane protein biogenesis process. Thus, we chose a bottom-up approach, where host cells were treated by an entire library of engineering tools available to us (miRNAs in this chapter, siRNAs in chapter 4), in a high-throughput

format, for identification of the best sequences that significantly enhanced NTSR1 expression. These top sequences can be investigated in-depth in the future, to decipher the complex membrane protein expression process and provide reference for synthetic biology studies.

The powerful engineering tools used in this chapter are miRNAs. They have been used for engineering cells with desirable properties[85], such as improved protein production capabilities[86] and enhanced anti-apoptotic properties under stress conditions[44, 87]. MiRNAs are a novel class of small, non-coding RNAs that can simultaneously silence multiple genes by binding to their 3'-untranslated regions(3'-UTR)[88]. The miRNA development process starts in the nucleus. Following transcription, the several kb long primary miRNA (pri-miRNA) with a stem-loop structure is cleaved by an endonuclease III (Drosha) to generate a 70-nucleotide long precursor miRNA (pre-miRNA)[89]. After being transported to the cytoplasm, the stem-loop pre-miRNAs is cleaved by another endonuclease III (Dicer), to generate the final mature miRNA duplex with a length of 18-25 nucleotides. The guide strand of the miRNA duplex is then loaded into the RNA-induced silencing complex (RISC) and guides the complex to the complementary 3'-UTR of targeting mRNAs. The degree of complementarity determines the mechanism of the post-transcriptional inhibition function. With high complementarity, target mRNA is degraded via RNA interference process, whereas insufficient complementarity is predictive of a translational repression mechanism.

MiRNAs exhibit a broad spectrum of regulatory effects in eukaryotic cellular processes including cell growth and apoptosis, cell differentiation and metabolism, cancer

development and progression[85]. Their capacity to globally regulate entire gene networks[90] and to introduce no additional translational burden (compared to gene overexpression strategies)[91] makes them particularly advantageous for cell line development.

In this chapter, we explore the ability to improve the receptor expression by applying the powerful miRNAs tool. The NTSR1-GFP-expressing HEK293 cells were subject to a high-throughput image-based screen with a human miRNA mimic library comprising 875 miRNA mimics. Excitingly, 5 top miRNA mimics identified from the screen not only improved NTSR1 functional expression level, but also significantly enhanced production of luciferase (intracellular protein) and an Fc fusion chimeric protein in HEK293 cell lines.

### **3.3 - Materials and Methods:**

#### **3.3.1 Construction of expression plasmid pJMA-NTSR1-GFP**

Truncated wild type NTSR1 (T43-K396) was subcloned into the tetracycline inducible plasmid pJMA111(a kind gift from Dr. Christopher G. Tate) replacing the serotonin transporter construct using KpnI and NotI restriction sites. Thus NTSR1 was placed downstream of the tetracycline-controlled CMV promoter and had an eGFP-deca-histidine tag fused to its C-terminal (Fig. 3.1)[92].

#### **3.3.2 Construction of stable NTSR1-GFP-expressing T-REx-293 cell line**

The T-REx-293 cell line was maintained as an adherent culture in DMEM containing 10% certified FBS and 5 µg/mL blasticidin (Invitrogen). The cells were

transfected with the plasmid pJMA-NTSR1-GFP using Lipofectamine 2000 according to the manufacturer's protocol (Life Technologies). One day after transfection, cells were transferred into fresh DMEM medium containing 200 µg/mL zeocin (Invitrogen) and the medium was replaced every three days. Two weeks later, ten cell clones were separately expanded into two T-flasks each. Cells in one T-flask were harvested during the exponential growth phase and frozen in 10% DMSO for storage. Cells in the other T-flask were induced with 1 µg/mL tetracycline for 24 hrs, after reaching 80% confluency. Cells were then detached from the flask and washed with cold PBS. After adjusting the cell density to  $\sim 1 \times 10^6$  cells per mL, protease inhibitors (Roche) were added and the cell suspension was frozen on dry ice in 1mL aliquots. NTSR1 expression levels were determined by [<sup>3</sup>H]NT binding and the clone with the highest expression level was selected for further experiments. The selected stable T-REx-293-NTSR1-GFP high expressor was then routinely maintained in DMEM containing 10% certified FBS, 5 µg/mL blasticidin and 200 µg/mL zeocin.

### **3.3.3 High-throughput miRNA screen**

T-REx-293-NTSR1-GFP cells were screened with a miRNA mimic library (Qiagen) based on Sanger miRBase 13.0 and consisting of 875 miRNAs mimics. For transfection, 0.8 pmol of each mimic was spotted to 384 well plate wells (Corning) and 20 µL of serum-free DMEM containing 0.1 µL of Lipofectamine RNAiMax (Life Technologies) was then added to each well. This lipid-miRNA mixture was incubated at ambient temperature for 30 min prior to adding 2000 cells in 20 µL of DMEM containing 20% certified FBS (Gibco). Transfected cells were incubated at 37°C in 5% CO<sub>2</sub> for 72

hours and induced with 1 µg/mL tetracycline for 24 hours for NTSR1-GFP expression. Cells were then fixed with 2% paraformaldehyde (Electron Microscopy Sciences), stained with Hoechst 33342 (Life Technologies) for 45 minutes and gently washed with PBS. Plates were imaged with an ImageXpress Micro XL (Molecular Devices). Total cell number and per cell green fluorescence intensity were calculated using MetaXpress software (Molecular Devices) employing the Multi-Wavelength Cell Scoring application module. All screening plates had a full column (16 wells) of Silencer Select Negative Control #2 (Life Technologies) and the median value of each plate's negative control column was used to normalize corresponding sample wells. A full column of positive control siRNA targeting GFP (GFP-22 siRNA, Qiagen) was also used as on-plate reference for transfection efficiency. The median absolute deviation (MAD) - based z-score was calculated for each sample [93].

### **3.3.4 Validation transfection**

Validation transfections were performed in 12-well plates with miScript miRNA mimics (Qiagen, Cat.No. 219600-S0), SilencerSelect Negative Control #2 and with lethal control siRNA (Qiagen AllStars Cell Death Control) served as a control for transfection efficiency. Cells were transfected as described for screening except 0.15 million cells were transfected with 40nM miRNA using 6.25ul Lipofectamine RNAiMax in a total volume of 1mL of media. 72 hours after transfection, cells were induced with 1 µg/mL tetracycline. 24 hours later, cells from each well were detached with non-enzymatic cell dissociation buffer (Gibco, Cat. No. 13150-016) and washed twice with cold PBS. Cell densities and viability were determined by trypan blue exclusion using a CEDEX cell

quantification system (Roche, Mannheim, Germany). Based on the counts, cell densities were adjusted to 0.5 million cells/ml with PBS and then subject to flow cytometry analysis. The remaining cells were pelleted and frozen on dry ice for [<sup>3</sup>H]NT binding assays.

### **3.3.5 Flow cytometry analysis**

Cells harvested from validation transfection step were diluted to 0.2 million cells/ml with cold PBS for flow cytometry analysis. Green fluorescence was measured with Guava EasyCyte 5HT and InCyte software (Millipore). The green fluorescence signal and cell gating were adjusted using uninduced T-REx-293-NTSR1-GFP cells, with more than 99.5% of the cells in low fluorescence range (<100). The setting was kept same for acquisition of all cell samples.

### **3.3.6 Analytical solubilization of NTSR1**

The detergents *n*-Dodecyl-β-D-maltoside (DDM), 3-[(3-cholamidopropyl) dimethylammonio] -1- propane sulfonate (CHAPS) and cholesteryl hemisuccinate Tris salt (CHS) were obtained from Anatrace. Cell pellets from 2 mL of suspension culture were suspended in Tris-glycerol-NaCl buffer. Then the detergents DDM, CHAPS and CHS were added to give a final buffer composition of 50 mM TrisHCl pH 7.4, 200 mM NaCl, 30%(v/v) glycerol, 1% (w/v) DDM, and 0.6%(w/v) CHAPS and 0.12%(w/v) CHS in a total volume of 0.5 mL. The samples were placed on a rotating mixer at 4°C for 1 hour. Cell debris and non-solubilized material were removed by ultracentrifugation (TL100 rotor, 60k rpm, 4°C, 30 min in Optima Max bench-top ultracentrifuge,

Beckman), and the supernatants containing detergent-solubilized NTSR1 were used to determine the total number of expressed receptors by a detergent-based radio-ligand binding assay.

### **3.3.7 Ligand binding assay**

Tritiated neurotensin agonist [<sup>3</sup>H]NT ([3,11-tyrosyl-3,5-<sup>3</sup>H(N)]-pyroGlu-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ile-Leu) was purchased from Perkin Elmer. Ligand-binding assays with detergent-solubilized receptors were carried out in TEBB assay buffer (50mM Tris pH 7.4, 1mM EDTA, 40µg/mL bacitracin, 0.1% BSA) containing 0.1% (w/v) DDM, 0.2% (w/v) CHAPS and 0.04% (w/v) CHS. For one-point assays, receptors were incubated with 2 nM [<sup>3</sup>H]NT on ice for 1 hour in a volume of 150 µL. The concentration of [<sup>3</sup>H]NT used was at least 5-fold above the apparent dissociation constants for detergent-solubilized NTSR1 to allow high receptor occupancy. Separation of the receptor-ligand complex from free ligand (100 µL) was achieved by centrifugation-assisted gel filtration using Bio-Spin 30 Tris columns (BioRad), equilibrated with RDB buffer (50 mM Tris-HCl, pH 7.4, 1 mM EDTA, 0.1% (w/v) DDM, 0.2% (w/v) CHAPS, 0.04% (w/v) CHS). Non-specific [<sup>3</sup>H]NT binding of 220 dpm was subtracted from total binding to calculate the total amount of receptors in T-REx-293-NTSR1-GFP cells. The number of functional NTSR1 was estimated by specific [<sup>3</sup>H]NT binding assuming one ligand-binding site per receptor molecule. The number of cells in the assay was derived by cell counting at cell harvest. This approach led to the calculation of the parameter “receptors/cell”.

### **3.3.8 Application with luciferase-expressing cells**

HEK-CMV-Luc2-Hygro cell line constitutively expressing luciferase is purchased from Promega. Transfections were performed in 12-well plates with miScript miRNA mimics (Qiagen, Cat.No. 219600-S0), SilencerSelect Negative Control #2 and lethal control siRNA (Qiagen AllStars Cell Death Control) served as a control for transfection efficiency. Cells were transfected in duplicates as described for screening except 0.1 million cells were transfected with 40nM miRNA using 6.25ul Lipofectamine RNAiMax in a total volume of 1mL of media. 72 hours after transfection, 500µL of ONE-Glo™ Reagent (Promega) was added to one set of replicates for luciferase activity quantification and 500µL of CellTiter-Glo™ Reagent (Promega) was added to the second set of replicates for viable cell density measurement. All plates were incubated at room temperature for 20 minutes to stabilize luminescent signal and then measured with SpectraMax i3 plate reader (Molecular Devices). Per cell luciferase production can be calculated from overall luciferase activity and viable cell number.

### **3.3.9 Application with GPC3-hFc-expressing cells**

HEK- GPC3-hFc cell line constitutively secreting glypican-3 hFc-fusion protein (GPC3-hFc) is a kind gift from Dr. Mitchell Ho's group from National Institutes of Health. Cells were grown in DMEM supplemented with 10% FBS in a humidified incubator set at 37°C and 5% CO<sub>2</sub>. Cells were transfected in 12-well plates as described for screening except 0.15 million cells were transfected with 40nM miRNA using 6.25ul Lipofectamine RNAiMax in a total volume of 1mL of media. 7 days after transfection, cell culture supernatant was collected and cleared using centrifuge for GPC3-hFc concentration determination with ELISA and cells were detached and counted by trypan

blue exclusion using a CEDEX cell quantification system (Roche, Mannheim, Germany). Per cell GPC3-hFc production can be calculated from overall GPC3-hFc yield and viable cell number.

### **3.3.10 ELISA for GPC3-hFc concentration determination**

AffiniPure F(ab')<sub>2</sub> Fragment Goat Anti-Human IgG (min X Bov, Ms, Rb Sr Prot, Cat. 109-006-170, Jackson Immunology) was used to coat a 96-well plate at 5µg/mL in PBS buffer, 50 µL per well, at 4 °C overnight. After the plate was blocked with 2% BSA in PBS buffer, pre-diluted cell culture supernatant was added, and the plate was incubated at room temperature for 1 h to allow binding to occur. After the plate was washed twice with PBS buffer containing 0.05% Tween 20, Peroxidase-conjugated AffiniPure Goat-anti-uman IgG (Cat. 109-035-098, Jackson Immunology) was added at 1:4000 dilution, 50ul/well. Following incubating at room temperature for 1 h, the plate was washed 4 times and detected with Peroxidase Substrate System (KPL).

## **3.4 - Results**

### **3.4.1 Construction of inducible T-REx-293-NTSR1-GFP cell line for image-based screen**

A stable cell line expressing wild type functional NTSR1-GFP fusion was constructed using the inducible T-REx system[68] by transfecting T-REx-293 cells with the pJMA-NTSR1-GFP plasmid (Fig.3.1). Ten clones were isolated and their neurotensin

receptor expression level upon tetracycline induction was measured by [<sup>3</sup>H]NT binding assay (data not shown). A high-expressing clone producing 8.4 million receptors per cell was selected for further experiments. As seen in Fig.3.2, the receptors for this clone are located mostly on the plasma membrane as expected.

### **3.4.2 High-throughput miRNA screen for enhanced NTSR1-GFP expression**

To identify miRNAs that improve NTSR1 expression in T-REx-293-NTSR1-GFP cells, the cells were screened with a library comprised of 875 human miRNA mimics. Cells were transiently transfected with mimics in 384-well format for 72 hours followed by tetracycline-induced expression of NTSR1-GFP fusion protein (Fig.3.3A). Twenty four hours after induction, the cells were fixed followed by nuclear staining. Each well was then imaged to obtain total cell number and per cell mean green fluorescent intensity (Fig.3.3B). Sample values were normalized based on the median value of each plate's negative control column. A column of positive control siRNA capable of silencing *gfp* gene was also used as on-plate control for transfection efficiency. GFP-directed siRNA consistently provided a > 80% decrease in green fluorescence intensity. To assess reproducibility, the screen was performed in duplicate, resulting in a correlation coefficient of 0.92 (Fig.3.3C). Furthermore, the screen was completed again in replicate using cells from a different passage. The correlation between the two independent screen was 0.73. The median absolute deviation (MAD) - based z-score[93] was calculated for each sample, and the distribution of miRNA activity is plotted in Fig.3.3D. 40 miRNAs were shown to significantly increase NTSR1-GFP productivity (MAD-based z-score > 2.0. Table 1) in both biological replicates and 26 of them (two thirds of total 40) were selected for follow up analysis. All screen data for the four replicates can be found in

Table S1.

### **3.4.3 Validation of the selected miRNA candidates by flow cytometry analysis**

The expression level of NTSR1-GFP following transient transfection of the cells with the top 26 microRNA was measured by flow cytometry (Fig.3.4). The uninduced cells exhibited basal GFP expression with only 1% of cells exceeding the background fluorescence ( $10^{-1}$ ) (Fig.3.4A). Following transfection with negative control siRNA (siN.C.) and tetracycline induction, the expression of NTSR1-GFP caused a significant shift in the fluorescence intensity, resulting in a geometric mean of fluorescence (MOF) of 138. A further shift was observed when the cells were transfected with various miRNA mimics followed by tetracycline induction, including miR-129-5p, which led to a MOF of 197. Compared with negative control siRNA, 14 of the 26 miRNAs resulted in an increased MOF. From this group, top 9 miRNAs were selected for further investigation (Fig.3.4B). Following the transfection with the 26 selected miRNAs, a large variance was seen in viable cell density (ranged from 54% to 135%, normalized to negative control) but not in viability (ranged from 84% to 97%) (Fig.3.4C).

### **3.4.4 [<sup>3</sup>H]NT binding assay validation for improved functional expression of NTSR1**

The effect of the top 9 miRNAs on the functional expression of NTSR1 was also evaluated by measuring the functional activity of the receptor through the binding of labeled neurotensin (<sup>3</sup>H]NT). Although all top 9 miRNAs were shown to improve NTSR1-GFP expression based on GFP fluorescence, only 5 of them (miR-22-5p, miR-18a-5p, miR-22-3p, miR-429 and miR-2110) led to improved functional activity levels of NTSR1 (Fig.3.5A). Of these, miR-2110-transfected cells expressed 13.8 million functional neurotensin receptors per cell, which was 48% higher than that from siN.C. In

addition, miR-22-5p and miR-22-3p improved functional expression of NTSR1, by 30% and 21% respectively. As seen in Fig.3.5B a number of the top 9 miRNAs had negative effect on cell growth and viability.

### **3.4.5 MiRNA screen for enhanced luciferase expression**

The human mimic miRNA library was also evaluated for its effects on the expression of luciferase in HEK293 cells constitutively expressing luciferase under control of a cytomegalovirus (CMV) promoter. Transfection was performed in duplicate in 384-well format. Seventy two hours post- transfection, one set of plates was assayed for luciferase and the other set was used for viable cell density (Fig.3.6A). Both luciferase activity and viable cell density were normalized to the median value of each plate's negative control column and the luciferase expression per cell was calculated for each miRNA. Though luciferase and NTSR1 screen exhibited a limited correlation ( $R=0.31$ , Fig.3.6B), seven out of nine top hits identified from NTSR1 screen (Fig.3.6C) also significantly improved per cell luciferase productivity on a per cell basis (MAD-based z-score $>2.0$ ).

### **3.4.6 Validation of common hits**

The top 9 miRNAs identified from the NTRS1 screen were examined for their effects on luciferase activity in a 12-well plate format. Seven miRNAs improved luciferase activity from 50% to 239% (Fig.3.7A). MiR-892b and miR-22-3p showed the largest effect on luciferase expression with a 239% and 207% improvement respectively. Although these microRNAs inhibited cell growth (Fig.3.7B), the overall production of luciferase from cells transfected with miR-892b and miR-22-3p was still 188% and 127% higher, respectively, than the negative control siN.C. level (Fig.3.7C). Interestingly, both

miR-22-3p and miR-22-5p showed up as top common hits for NTSR1 and luciferase screen.

### **3.4.7 Application of top common hits on secreted protein**

To investigate the impact of top common hits on secreted protein production, the five identified miRNAs (hsa-miR-22-5p, hsa-miR-18a-5p, hsa-miR-22-3p, hsa-miR-429 and hsa-miR-2110) were independently transfected into HEK293 cell line stably expressing secreted hFc-fusion protein: glypican-3 hFc-fusion protein (GPC3-hFc) [94]. All five miRNAs enhanced per cell GPC3-hFc secretion (up to 120% improvement, Fig. 7A), while three miRNAs (hsa-miR-22-5p, hsa-miR-18a-5p and hsa-miR-22-3p) effectively enhanced overall GPC3-hFc (up to 62%, Fig. 3.8C).

## **3.5 - Discussion:**

Integral membrane proteins such as mammalian receptors, ion channels and transporters are vital for medical research. However, obtaining large amounts of functional membrane proteins for medical research, especially structural studies, has been difficult and therefore been a barrier for productive research towards better understanding of their mechanisms and potential medical use [7, 8, 11]. So far, a tetracycline-inducible mammalian expression system [68] has been shown to be an effective method for functional expression of membrane proteins [50, 51, 76]. This inducible system together with optimized production conditions led to a yield of 1 milligram per liter of purified NTSR1 in chapter 2. Compared with well-developed prokaryotic hosts such as *E.coli*, the production of membrane proteins from higher eukaryotic hosts is still in the stage of “trial and error”[95] since engineering tools are limited and the membrane protein synthesis,

insertion, folding and trafficking are not completely understood.

To improve the production of these proteins, a bottom-up screening approach using human miRNA mimics library was implemented to identify candidates that lead to improved expression of the GPCR from the T-Rex-293 cells. This approach has previously proven effective for apoptosis screening[87] and recombinant secreted protein screening[96, 97] in CHO cells. In this study, we developed an image-based high-throughput screening method to detect per cell green fluorescence signal, which is applied as a proxy for the number of molecules of NTSR1 protein expressed per cell. In addition to its high reproducibility (0.92 correlation between technical replicates), this method is cost-effective for protein labeled with fluorescent, as no secondary reagent is needed for protein quantification. . It is also high throughput and high-capacity, as cells are fixed and the screening is not time-sensitive compared to live-cell processes such as flow cytometry. This screen methodology can be applied to other membrane or intracellular protein candidates when the targeted protein is fused with GFP. Although GFP fusion has been widely used for membrane protein overexpression screen and purification in a variety of hosts [98-100], it is possible that the N-terminal GFP fusion may mask signal sequence essential for protein insertion. This may compromise folding or correct localization of the desired membrane protein [101, 102]. C-terminal GFP fusion, on the other hand, is preferable as it is generally better in maintaining the localization and function of the native protein [101] with exceptions when C-terminal contains an essential functional segment [103, 104].

Among the 875 human miRNA mimics tested, 40 mimics consistently led to significant improvement in per cell green fluorescence levels, exhibiting an average

MAD-based-z-score higher than 2.0. Among the top 40 candidates, miR-892b, miR193b-3p and miR-193a-3p share the same seed sequence (ACUGGC), indicating that they may comprise an overlap in target genes. Similarly, miR-129-3p and miR-129-1-3p also share a same seed sequence (AGCCCU).

The activity of two thirds of the 40 mimics was confirmed further by flow cytometry and the 9 mimic candidates contributing to the highest per cell green fluorescence signal were further tested in the [<sup>3</sup>H]NT binding assay. Five out of the nine mimics showed up to 48% improvement in functional expression of NTSR1. From these five, miR-2110 is a novel miRNA that has been identified but not studied[105]. The other four miRNAs (miR-429, miR-18a-5p, miR-22-5p and miR-22-3p) have been associated with cancer research in which they have exhibited contradicting effects on cell proliferation, cell growth, and protein production depending on the cell type and stage of cell development[86, 106-111]. For example, miR-429, a member of the miR-200 family, was shown to suppress tumor growth in human osteosarcoma[107], while in non-small cell lung cancer (NSCLC), the same miRNA is suggested as a potential target for NSCLC due to its promotion of cell proliferation[106]. miR-18a-5p is part of the miR-17-92 precursor sequence cluster, which is also named Oncomir-1. This miR-17-92 cluster was studied in depth regarding its effect on recombinant EpoFc protein production in CHO cells. Although over-expression of the entire cluster decreased productivity while having no effect on cell growth, the over-expression of miR-17 and miR-92 were shown to increase production[86].

Of the nine miRNAs that enhanced the expression of the NTSRI-GFP fusion protein, four (miR-129-5p, miR-221-5p, miR-892b and miR-639) were not associated

with enhanced binding activity of the agonist in the [<sup>3</sup>H]NT assay. This may be an indication that NTSR1 could be misfolded in these cells following the enhanced expression. Another observation is that eight of the nine top hits (except miR-129-5p) caused a decrease in the viable cell number. One possible reason for this behavior is that overexpression of NTSR1-GFP could be toxic to the cells. Another possibility is that the introduction of a specific miRNA to the cells is associated with a growth arrest, leading to improved protein production[85, 112]. Since multiple pathways and genes can be targeted by one miRNA, it will be worthwhile to examine which specific genes are down-regulated in these cells and to investigate the mechanism that improved NTSR1 functional expression.

In parallel to the analysis of the miRNA effect on the NTSR1 expression, an HEK293 cell line constitutively expressing luciferase under the control of CMV promoter was subjected to screening of the same miRNA mimics library. This screen showed low degrees of correlation (R= 0.31) with the NTSR1-GFP screen. The low correlation may be the result of the difference between biogenesis process of integral membrane proteins and intracellular soluble proteins; the difference between constitutive expression elements and the inducible expression system; and clonal differences between the two HEK293 cell line used. Despite the overall low correlation between the screens, seven out of nine top miRNAs (except miR-129-5p and miR-639) identified from NTSR1-GFP screen, improved luciferase activity from 50% to 239%. All the final five miRNAs (miR-429, miR-18a-5p, miR-22-5p and miR-22-3p and miR-2110) capable of improving NTSR1 functional expression were also relevant for improving luciferase expression.

These five miRNAs affecting both model proteins were expected to have wider

application for other types of proteins. Therefore, they were tested with HEK293 cell line constitutively secreting an Fc fusion proteins with medical importance [94]. Interestingly, all of the five miRNAs were effective in enhancing per cell Fc fusion protein secretion. However, the overall Fc fusion protein yield varied from 10% decrease to 62% increase, partially depending on the viable cell number after miRNA transfection.

**Contributions from collaborators:**

Dr. Scott Martin contributed to conceiving and designing of RNAi screen experiments, data analysis and revising the manuscript. Yu-Chi Chen carried out luciferase miRNA mimic screening.

## **Chapter 4: High-throughput genome-wide siRNA screen identifies important genes for improved heterologous protein expression**

### **Abbreviations:**

RNAi, RNA interference; siRNA, small interfering RNAs; RISC, RNA-induced silencing complex; FBS, fetal bovine serum; KEGG, Kyoto Encyclopedia of Genes and Genomes; MAD, median absolute deviation; RSA, redundant siRNA activity; NTSR1, neurotensin receptor type I; SERT, serotonin transporter; GFP, green fluorescent protein; RNP, ribonucleoprotein; snRNA, small nuclear RNA; hnRNP, heterogeneous nuclear ribonucleoprotein.

### **4.1 - Summary**

Large-scale RNA interference has been developed and utilized as a revolutionary tool in deducing gene functions in many diseases. However, the genome-wide loss-of-function data is very limited for heterologous protein production process. In this chapter, HEK293 cells constitutively expressing luciferase reporter were subject to a genome-wide siRNA screen. Among the 21,585 genes that were individually knocked down, 56 genes were selected for validation screen and top 10 genes leading to the greatest improvement of luciferase production were identified. Interestingly, from KEGG pathway analysis, genes significantly improving luciferase expression were found to be highly enriched in splicesome pathway. In addition, the effects of top 10 genes on secreted and membrane proteins were investigated and the co-transfection of different top 10 siRNAs was also explored.

## **4.2 - Introduction**

RNA interference (RNAi), firstly discovered as a natural biological process of eukaryotic cells to protect the genome against foreign nucleic acids [113, 114], has been developed and utilized as a revolutionary tool in deducing gene functions and in combating genetic defects, viral diseases, autoimmune disorders, and cancers [115]. Following the discovery of double strand RNAs in *Caenorhabditis elegans*[116], chemically synthesized small interfering RNAs (siRNA) were shown to efficiently silence endogenous genes in mammalian cells [117, 118], providing the foundation for developing RNAi applications. SiRNAs are 21-25 nucleotide double strand RNA fragments with symmetric 2-nucleotides 3'-end overhangs [119]. The guide strand of siRNA can be incorporated into RNA-induced silencing complex (RISC), which brings about sequence-specific degradation of the homologous single stranded mRNAs[120].

In recent years, large-scale genetic screens were made possible by the availability of genome-wide siRNA library as well as the development of sophisticated new instrumentation and bioinformatics approaches for data analysis [121, 122]. They have been used to interrogate the biological functions of specific genes and pathways in various diseases[123] and important biological process including signal transduction, cell aging or death, cell or organelle organization, protein localization and responses of host cells to pathogens[124-128]. However, the genome-wide loss-of-function data is very limited for heterologous protein production [124, 129], an important process being intensively investigated by pharmaceutical and biotechnology industry using genetic or metabolic engineering approaches.

In this work, we performed a genome-wide siRNA screen to identify genes involved in recombinant protein production using *Photinus pyralis* (firefly) luciferase as a reporter protein. Luciferase is a 62kDa large multidomain enzyme that has been widely used as a reporter in cell biology[130]. As one of the first described large, multidomain proteins, luciferase has been intensively used to study co-translational folding of polypeptide and the role of chaperones in protein folding [131, 132]. Here, with high-throughput format, 21,585 genes were individually knocked down with three different siRNAs in HEK-CMV-Luc2-Hygro cells constitutively expressing firefly luciferase. The results from end-point viable cell number and luciferase activity measurement were cooperated into genome-wide loss-of-function data. Statistical data analysis was executed followed by validation screen, where top 10 genes leading to greatest improvement of luciferase production were confirmed. In this chapter, a brief overview of these top 10 genes was provided and their effects on secreted and membrane proteins were also investigated.

### **4.3 – Materials and Methods:**

#### **4.3.1. High-throughput genome-wide screen for luciferase expression**

HEK-CMV-Luc2-Hygro cells constitutively expressing *P. pyralis* luciferase (Progenia) were maintained in DMEM containing 10% fetal bovine serum (FBS) in a humidified incubator set at 37°C and 5% CO<sub>2</sub>. The library for primary screen is the Silencer® Select Human genome siRNA library (Ambion), which targets 21,585 human genes with 3 siRNAs per gene. Each siRNA is arrayed in an individual well. The

transfection was done in duplicates: 0.8 pmol of each siRNA was spotted to 384 well plate wells (Corning) and 20  $\mu$ L of serum-free DMEM containing 0.15  $\mu$ L of Lipofectamine RNAiMax (Life Technologies) was then added to each well. This lipid-siRNA mixture was incubated at ambient temperature for 30 min prior to adding 4000 cells in 20  $\mu$ L of DMEM containing 20% FBS (Gibco). After incubating transfected cells at 37°C in 5% CO<sub>2</sub> for 72 hours, 20  $\mu$ L of ONE-Glo™ Reagent(Promega) was added to one set of replicates for luciferase activity quantification and 20  $\mu$ L of CellTiter-Glo™ Reagent(Promega) was added to the second set of replicates for viable cell density measurement. All plates were incubated at room temperature for 20 minutes to stabilize luminescent signal and the signal was then measured with PerkinElmer Envision 2104 Multilabel plate reader. All plates had a full column (16 wells) of Silencer Select Negative Control #2 (Life Technologies) for data normalization and a full column of AllStars Hs Cell Death Control siRNA was also used as on-plate reference for transfection efficiency.

#### **4.3.2. Statistical analysis of primary screen data and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis**

For each plate, the median value of negative control column was set as 100% and was used to normalize corresponding sample wells. The luciferase activity and viable cell density was exported as % of negative control and the median absolute deviation (MAD) - based z-score was calculated for each sample [93]. The redundant siRNA activity (RSA) analysis was performed as described[133] to rank candidate genes that enhance luciferase activity. Briefly, luciferase activity data for each sample was subject to

iterative hypergeometric test and p-values indicating the statistical significance of all wells targeting a single gene distributed toward the top ranking slots were generated for each gene. All genes with  $p < 0.005$  were imported for KEGG pathway analysis. For the pathway enrichment map, red color indicates lower p-value ( $p < 0.001$ ) thus higher rank of the genes; while pink color denotes lower rank ( $0.001 < p < 0.005$ ).

#### **4.3.3. Validation screen**

For each of the top 54 genes selected from the primary screen, 3 independent Silencer® siRNAs (Ambion) with different sequences from the primary screen were seeded into 384-well plates. The transfection and assay process is the same as the primary genome-wide screen.

#### **4.3.4 Validation with GPC3-hFc-expressing cells**

HEK- GPC3-hFc cell line constitutively secreting glypican-3 hFc-fusion protein (GPC3-hFc)[94] is a kind gift from Dr. Mitchell Ho's group from National Institutes of Health. Cells were grown in DMEM supplemented with 10% FBS in a humidified incubator set at 37°C and 5% CO<sub>2</sub>.

Validation transfections were performed in 12-well plates with Silencer or SilencerSelect siRNAs and SilencerSelect Negative Control #2 (Ambion). AllStars Cell Death Control (Qiagen) was used as lethal control for transfection efficiency. Cells were transfected in 12-well plates as described except 0.15 million cells were transfected with 40nM siRNA using 3.75ul Lipofectamine RNAiMax in a total volume of 1mL of media.

5 days after transfection, cell culture supernatant was collected and cleared using centrifuge for GPC3-hFc concentration determination with ELISA and cells were detached and counted by trypan blue exclusion using a CEDEX cell quantification system (Roche, Mannheim, Germany).

#### **4.3.5. ELISA for GPC3-hFc concentration determination**

AffiniPure F(ab')<sub>2</sub> Fragment Goat Anti-Human IgG (min X Bov, Ms, Rb Sr Prot, Cat. 109-006-170, Jackson Immunology) was used to coat a 96-well plate at 5µg/mL in PBS buffer, 50 µL per well, at 4 °C overnight. After the plate was blocked with 2% BSA in PBS buffer, pre-diluted cell culture supernatant was added, and the plate was incubated at room temperature for 1 h to allow binding to occur. After the plate was washed twice with PBS buffer containing 0.05% Tween 20, Peroxidase-conjugated AffiniPure Goat-anti-uman IgG (Cat. 109-035-098, Jackson Immunology) was added at 1:4000 dilution, 50ul/well. Following incubating at room temperature for 1 hr, the plate was washed 4 times and detected with Peroxidase Substrate System (KPL).

#### **4.3.6. Validation with cells producing membrane proteins in fusion with GFP**

HEK293 cell lines producing neurotensin receptor (NTSR1)-GFP fusion protein and serotonin transporter (SERT)-GFP fusion protein were independently tested with top 10 siRNAs. The stable SERT-GFP-expressing cell line is a kind gift from Dr. Chris Tate [92](Andréll & Tate unpublished), and NTSR1-GFP-expressing T-REx-293 cell line was previously constructed. Both cell lines were maintained as an adherent culture in DMEM

containing 10% certified FBS and 5  $\mu\text{g}/\text{mL}$  blasticidin and 200  $\mu\text{g}/\text{mL}$  zeocin (Invitrogen).

Cells were transfected as described except 0.15 million cells were transfected with 40nM siRNA using 6.25ul Lipofectamine RNAiMax in a total volume of 1mL of media. 72 hours after transfection, cells were induced with 1 $\mu\text{g}/\text{mL}$  tetracycline. 24 hours later, cells from each well were detached with non-enzymatic cell dissociation buffer (Gibco, Cat. No. 13150-016) and washed twice with cold PBS. Cell densities and viability were determined by trypan blue exclusion using a CEDEX cell quantification system (Roche, Mannheim, Germany). Based on the counts, cell densities were adjusted to 0.5 million cells/ml with PBS and then subject to flow cytometry analysis.

#### **4.3.7. Flow cytometry analysis**

Cells harvested from validation transfection step were diluted to 0.2 million cells/ml with cold PBS for flow cytometry analysis. Green fluorescence was measured with Guava EasyCyte 5HT and InCyte software (Millipore). The green fluorescence signal and cell gating were adjusted using uninduced T-REx-293-NTSR1-GFP cells, with more than 99.5% of the cells in low fluorescence range (<100). The setting was kept same for acquisition of all cell samples.

#### **4.3.8. Co-transfection with two of top 10 siRNAs**

HEK-CMV-Luc2-Hygro cells (Progema) were transfected in quadruplicate in 96-well plates as described except  $2.4 \times 10^4$  cells were transfected using 0.9 $\mu\text{l}$  Lipofectamine RNAiMax in a total volume of 120 $\mu\text{l}$  media. Each well contains two of top 10 siRNAs,

each with final concentration of 40nM. Luciferase activity was measured by ONE-Glo™ assay and viable cell density was measured by CellTiter-Glo™ assay. Wells containing 80nM of Silencer Select Negative Control #2 siRNA were used to normalize all sample wells.

## **4.4 - Results**

### **4.4.1. Primary genome-wide screen identifies a number of genes that enhance CMV driven luciferase expression in HEK293 cells.**

We conducted a human genome siRNA screen to identify genes and pathways associated with CMV driven luciferase activity. Screening employed a siRNA library targeting 21,585 human genes with 3 separately arrayed siRNAs per gene in HEK-CMV-Luc2-Hygro cells. For the screen, the transfection was done in duplicates: one set of plates was used for overall luciferase yield measurement and the other set was used for viable cell number determination, from which the per cell luciferase expression can be calculated (Fig. 4.1A). Based on overall luciferase yield, the distribution of siRNA activity is illustrated in the histogram (Fig.4.1B). 1,778 siRNAs were able to significantly enhance luciferase expression (MAD-based z-score>3, or 40% to 178% increase than negative control), and they were categorized as ‘strong enhancers’. From the 1,778 siRNAs, we identified 56 genes, which were targeted by at least two independent siRNAs from this ‘strong enhancer group’ and they were subject to validation screen.

The overall luciferase yield could be resulted from either improved viable cell number, or improved per cell expression, or both. We found that 11,207(17.3%) siRNAs

improved per cell luciferase expression by more than 20% (Fig. 1C quadrant I&II), while only 254(0.4%) siRNAs achieved more than 20% enhancement in viable cell number (Fig. 4.1C quadrant I&IV). Surprisingly, only 2 siRNAs were capable of improving both per cell luciferase expression and viable cell density by more than 20%.

#### **4.4.2. Validation screen for top 10 gene confirmation**

To further investigate many of the top candidates, additional three siRNAs were tested for the 56 ‘strong enhancer’ genes selected from 4.4.1 (Fig. 1B). The primary screen and validation screen data for the 56 genes were combined and top 10 genes (Table 4.1) were identified based on the criteria that least 3 out of 6 siRNAs tested had led to MAD-based z-scores higher than 3.0. Viable cell number was also taken into consideration to remove candidates with significant toxicity. The overall luciferase yield, per cell luciferase yield and viable cell numbers associated with the 6 siRNAs targeting one of the top 10 genes were summarized in Supplemental Table 4.S1. The median value of the overall luciferase yield for each gene was calculated from the 6 siRNAs (Table 4.1). In summary, the median value of overall luciferase yield was improved by 24% to 72% than negative control cells and the median of MAD-based z-scores range from 2.13 to 4.55.

Interestingly, 4 out of top 10 genes (*ints1*, *ints2*, *hnrnpc* and *prpf19*) are involved in mRNA splicing process. They all encode important proteins for spliceosome formation, e.g. integrator complex, heterogeneous nuclear ribonucleoprotein and pre-mRNA processing factor 19. The rest of top genes encode proteins covered a wide span of biological functions, including cell growth and division, signal transduction, apoptosis,

regulation of cellular polyamine concentration, protein translation and folding (Table 4.1).

#### **4.4.3. KEGG pathway analysis identifies spliceosome as a statistically significantly enriched pathway for top genes**

To identify the pathways where the top candidate genes are enriched in, the redundant siRNA activity (RSA) analysis [133] was performed to rank genes enhancing luciferase activity. Then 362 genes with  $p < 0.005$  from RSA analysis (Supplemental Table.4.S2) were imported for KEGG pathway analysis. Among the 362 genes, 28 were involved in spliceosome pathway ( $p=6.4^{-23}$ , Fig. 4.2). The genes with higher rank ( $p < 0.001$ , red) encode for important spliceosome components, e.g. small nuclear ribonucleoprotein (Sm), splicing factor 3A (SF3a), heterogeneous nuclear ribonucleoproteins (hnRNPs), pre-mRNA-processing factor 19 (Prp19), etc.(Fig. 4.2).

#### **4.4.4. Test of top 10 genes with secreted and membrane proteins**

In order to investigate if the knock-down of identified genes will contribute to similar improvement in HEK293 cell lines expressing other proteins, three cell lines were tested. HEK- GPC3-hFc cell line can constitutively secrete glypican-3 hFc-fusion protein (GPC3-hFc) [94] and was tested in this study as a representative of antibody secreting cell lines. T-REx-293-NTSR1-GFP cell line has been constructed previously for production of functional neurotensin receptor type I (NTSR1) in chapter 3. T-REx-293-SERT-GFP [92]( Andr ell & Tate unpublished) is an inducible cell line for high level expression of serotonin transporter (SERT), a hard-to-express 12 transmembrane domain

protein. Both NTRS1 and SERT were fused with GFP to their C-terminal, allowing proximal protein quantification with flow cytometry. As shown in Fig4.3, the top 10 siRNAs demonstrated various effects on secreted and membrane proteins. Notably, the knocking down of *ints1*, *hnrhpc*, *oaz1* and *ppp2r1a* consistently improved the expression of all proteins tested. However, the knocking down of *ints1* and *hnrnpc* led to significantly reduced viable cell number, indicating these genes may be essential for cell survival or cell growth. Silencing of *oaz1* and *ppp2r1a* gene showed minimal negative effects on viable cell number.

#### **4.4.5. Co-transfection with top 10 siRNAs**

To investigate the combinatorial effect of top siRNAs, HEK-CMV-Luc2-Hygro cells were transfected with two of top 10 siRNAs, each siRNA with final concentration of 40nM. Per cell luciferase production upon co-transfection was calculated from overall luciferase activity and viable cell density and was summarized in Fig. 4.4. Cells transfected with 80nM of negative control siRNA were used for normalization and their per cell luciferase expression level was set as 100. Depending on the genes of choice, the combinatorial effect can be positive or negative. For example, 80nM of siRNA against *hnrnpc* and *ppp1r2a* independently led to luciferase level of 299 and 251. When 40nM of both siRNAs were co-transfected while keeping the overall siRNA concentration at 80nM, the luciferase level went up to 435. The negative effects can be observed with the co-transfection of siRNAs for *casp8ap2* and *eef1b2*. They each independently led to luciferase level of 121 and 170 but the combination brought luciferase expression down to 94.

We chose the best combination from binary co-transfection (*hnrnpc* and *ppp1r2a*) and added a third siRNA to explore further improvement. Maintaining the overall siRNA concentration at 80nM, 27nM of each siRNAs were co-transfected and the best combination is *ints1* with *hnrnpc* and *ppp1r2a*. Altogether, they led to luciferase level of 463 and the addition of a fourth siRNA didn't improve the expression level further (data not shown).

#### **4.5 - Discussion:**

Genome-wide RNAi screening has emerged to be a revolutionary and powerful tool for interrogating gene functions and for target discovery in various diseases [124-128]. However, it has been scarcely used to identify targets for enhancement of recombinant protein production process. The screening in CHO cells was limited to miRNA library [87, 96, 97], as a proper synthetic hamster siRNA library is still lacking. To our knowledge, there have been two publications investigating protein secretion using human whole-genome siRNA libraries [124, 129]. However, both were focusing on disruption of secretory pathway with siRNA-mediated gene depletion as their goal was to identify genes required for protein secretion process. To the contrary, we identified genes that need to be down-regulated for improved recombinant protein production. Besides, our screening is not limited to secretion process. Indeed, the identified gene targets covered a variety of functions, including DNA replication, mRNA splicing, translation, apoptosis mediation, cell growth arrest, etc. (Table 4.1).

In contrast to miRNA screening from chapter 3, which requires intensive follow-up work on gene targets identification through microarray or next-gen sequencing studies, siRNA screening gives direct correlation between the arrayed siRNAs and gene targets. This allows faster gene identification and construction of stable knock-out cell lines for industry.

In this work, in order to aid in the discovery of new genes that are potential engineering targets for improved production of biopharmaceuticals in mammalian expression system, a HEK293 reporter cell line expressing luciferase reporter was subject to interference with 64,755 siRNAs targeting 21,585 human genes. 1,778 siRNAs strongly improved luciferase expression by having MAD-based  $z\text{-core} > 3$ , which corresponded to 2.7% of the library. In order to exclude the ‘false positives’ introduced by off-target effects, gene hits were only considered ‘true positive’ if 2 or more single siRNAs targeting this gene passed the MAD-based  $z\text{-core} > 3$  requirement. 54 genes were selected with this stringent requirement and were subject to validation screen with 3 more siRNAs for each gene. Finally, data generated from 6 siRNAs for each of the 54 genes (3 siRNAs from primary screen and 3 siRNAs from validation screen) were combined for the selection of top 10 genes. The gene is selected if 3 or more siRNAs yield  $> 3$  MAD-based z-scores. This high statistical significance also corresponds to biological relevance, which is 40% increase in luciferase activity.

To identify cellular functions or biological pathways correlated with improved luciferase expression, KEGG pathway analysis was done to discover important pathways where top gene hits were enriched. The top genes list and their statistical significance

were generated from the RSA analysis, a probability-based approach to circumvent off-target effects by analyzing the collective behavior of all wells targeting the same gene [133]. While  $p < 0.05$  in RSA analysis indicates statistical significance of a single gene being distributed toward the top ranking slots, we chose a more stringent cutoff,  $p < 0.005$ . Then, 362 genes (supplemental table.4.S2) were selected based on this criteria and were used for KEGG pathway analysis. Surprisingly, 28 out of 362 genes were involved in spliceosome, a multimegadalton ribonucleoprotein (RNP) complex for pre-mRNA splicing [134]. The 28 genes encode many important spliceosome components such as splicing factors (sf3a3, sf3b2, sf3b3, sf3b4) and small nuclear ribonucleoproteins (snrnp200, snrpb, snrpd2, snrpd3, snrpe, snrpf, snrpg). This finding is counter-intuitive as the knock-down of these genes should theoretically compromise mRNA-splicing and could negatively regulate recombinant protein production.

In good agreement with primary screen pathway analysis, spliceosome was also highlighted by validation screen result (Table 4.1). Four (*ints1*, *ints2*, *hnrnpc* and *prpf19*) out of top ten genes were associated with spliceosome pathway. *Ints1* and *ints2* encode two subunits of integrator complex, which indicates the involvement of this complex in influencing protein overexpression. Indeed, the integrator complex contains at least 12 proteins in humans [135] and based on primary screen data, knocking down of *ints1*, *ints2*, *ints3*, *ints4*, *ints5*, *ints8* and *ints12* all resulted in significantly improved luciferase reporter expression (Supplemental Table.4.S3). Integrator complex mediates small nuclear RNAs (snRNAs) 3' processing [135] and snRNAs are essential for the removal of introns, proper expression of histone mRNA and biosynthesis of ribosomal RNA [136]. Thus the interference of the complex is found to disrupt pre-mRNA processing [135].

The knocking-down of *ints1*, *ints5*, *ints6*, *ints9* and *ints11* has been reported. RNA interference of *ints1*, *ints5* or *ints11* resulted in the accumulation of misprocessed snRNA and ultimately splicing defects in pre-mRNAs for multiple genes [135, 137]. *Ints6* is presumed to be tumor-suppressor gene as overexpression of *ints6* in a prostate cancer cells reduces colony formation and causes a cell-cycle arrest[138]. RNAi-mediated down-regulation of *ints11* leads to G1 arrest in human cells [139]. It is not clear why the down-regulation of integrator complex genes, which would presumably inhibit snRNA biosynthesis, leads to higher recombinant protein production. It could be resulted from splicing defects in specific genes, who are negative regulators of protein expression. Another possibility is that the depletion of integrator complex leads to growth arrest, thus allowing more energy and resources to be channeled to protein production process [85, 112].

The other two genes in spliceosome pathway are *hnrnpc* and *prpf19*. They encode Heterogeneous Nuclear Ribonucleoprotein C (C1/C2) and Pre-mRNA Processing Factor 19 respectively and are both associated with pre-mRNA splicing. Heterogeneous Nuclear Ribonucleoprotein C is a core component of heterogeneous nuclear ribonucleoproteins (hnRNPs) and is one of the most abundant proteins in the nucleus[140]. It's well known that it's involved in alternative splicing of pre-mRNA[141] and stabilization of mRNA[142]. However, its exact role in splicing regulation remained contradictory and unresolved[143]. Pre-mRNA Processing Factor 19 is a component of the prp19p-associated complex (or NTC), which activates spliceosome for pre-mRNA splicing [144]. It is also found to be essential for cell survival and damage DNA repair [145]. *Prpf19* up-regulation has been demonstrated to expand life span of human endothelial cells while its

depletion led to reduced resistance to apoptosis [146, 147]. In our luciferase primary and validation screen, the siRNA-mediated knocking-down of *prpf19* gene didn't lead to significant cell death.

The rest of top genes encode proteins covering a wide range of biological functions.

*Casp8ap2* encodes caspase 8 associated protein 2, which is highly similar to the mouse apoptotic protein FLASH. It is shown to regulate caspase 8-induced activation of NF-kappa-B and it's required for S-phase progression and histone gene transcription [148, 149].

*Oaz1* encodes ornithine decarboxylase antizyme 1, which down-regulates cellular polyamine level by binding to and inhibiting ornithine decarboxylase [150]. This gene will be investigated in detail in the next chapter.

*Ppp2r1a* encodes an alpha isoform of the constant regulatory subunit A (PR 65) of protein phosphatase 2A(PP2A) and it serves as a scaffolding molecule[151]. PP2A is an important regulator in cell proliferation, signal transduction and apoptosis and it is implicated in the negative control of cell growth and division [152].

*Chaf1a* encodes subunit A of chromatin assembly factor 1 (CAF-1), which assembles histone octamers onto replicating DNA [153]. CAF-1 is a histone chaperone that plays important roles in chromatin restoration after DNA synthesis, cell cycle progression, heterochromatin maintenance and asymmetric cell division[154].

*Cct2* encodes beta subunit of cytosolic chaperonin-containing t-complex polypeptide-1(CCT), which is a molecular chaperone important for folding of actin, tubulin and numerous other proteins eukaryotic cytosol[155]. Depletion of CCT were

associated with growth arrest and perturbation of actin-based cell motility in mammalian cells and it is believed to be required for cell cycle progression and cytoskeletal organization[156].

*Eef1b2* encodes beta subunit of eukaryotic translation elongation factor 1. The protein is a guanine nucleotide exchange factor involved in recruitment of aminoacyl-tRNAs onto the ribosome, which is the first step of elongation[157].

To test the effect of silencing top genes for expression of other proteins, one secreted protein(GPC3-hFc) and two hard-to-express membrane proteins (neurotensin receptor type I and serotonin transporter) were investigated. For each cell line, at least 6 out of 10 siRNAs tested improved the recombinant protein production. Notably, 4 genes were always improving protein production in all three cell lines: *ints1*, *hnrhpc*, *oaz1* and *ppp2r1a*. It is found that *ints1* or *hnrhpc* depleted cells consistently have growth disadvantages (Fig. 4.3, viable cell number), indicating they could be essential genes. Indeed, targeted disruption of *ints1* in mouse embryos results in growth arrest followed by apoptotic cell death[158]. Taken together, *oaz1* gene was chosen for follow-up studies in the next chapter since its knock-down was associated with minimal cell growth disadvantage.

#### **Contributions from collaborators:**

Dr. Scott Martin contributed to conceiving and designing of RNAi screen experiments and data analysis. Yu-Chi Chen carried out luciferase siRNA primary screening.

## Figures and tables

**Fig. 4.1.** Genome-wide human siRNA library screen with HEK-CMV-luc2-Hygro cell line. (A) Workflow of the screen; (B) Distribution of siRNA activity on improved overall luciferase expression; top hits (MAD-based z-score>3.0) are highlighted; (C) For each siRNA sample, the relative per cell luciferase yield is plotted against relative viable cell number. The 20% increase cutoffs are highlighted and they divide the entire population into four quadrants (I, II, III and IV).

**Fig.4.2.** Illustration of spliceosome pathway enriched with primary screen top hits. All 362 genes significantly improved luciferase expression ( $p < 0.005$  in RSA analysis) were imported for KEGG pathway mapping. 28 genes were found in spliceosome pathway and were highlighted in red or pink in the map. Red color indicates genes with  $p < 0.001$  thus higher rank; while pink color denotes lower rank ( $0.001 < p < 0.005$ ).

**Fig.4.3.** Test of top 10 siRNAs with (A) luciferase, (B) GPC3-hFc, (C) NTSR1-GFP and (D) SERT-GFP expressing HEK cell line. All protein expression was normalized to cells transfected with the negative control (siN.C.). The experiment was performed twice with different passages of cells. For each biological sample, the measurement was done in duplicates. Error bars indicate SEM.

**Fig.4.4.** Co-transfection of binary siRNA mixtures from top 10 siRNAs. HEK-CMV-Luc2-Hygro cells were transfected with two of top 10 siRNAs, each with final concentration of 40nM. Luciferase level of cells transfected negative control siRNA(siN.C.) was set at 100 and all co-transfection result was normalized. Subscripts indicate SEM. The experiment was performed twice with different passages of cells. For each biological sample, the measurement was done in duplicates.

## **Chapter 5: knockdown of ornithine decarboxylase antizyme1 causes increased polyamine accumulation and improved luciferase translation in HEK293 cells**

### **Abbreviations used:**

ODC, ornithine decarboxylase; OAZ, ornithine decarboxylase antizyme; AZI, antizyme inhibitor; HEK, human embryonic kidney; CMV, cytomegalovirus; DMEM, Dulbecco's modified Eagle's medium; FBS, fetal bovine serum; PBS, phosphate-buffered saline; TCA, trichloroacetic acid; EDTA, ethylenediaminetetraacetic acid; DMFO, difluoromethylornithine.

### **5.1 - Summary**

Polyamines are essential molecules intimately involved in the regulation of cell proliferation, transformation and tumorigenesis and their homeostasis is tightly maintained at multiple levels. Ornithine decarboxylase (ODC) is the rate-limiting enzyme in polyamine biosynthesis and is probably the most highly regulated protein in mammalian cells. *Oaz1* gene encodes ODC antizyme, a major negative regulator of ODC and polyamines. In this chapter, we investigated the mechanisms why luciferase expression is enhanced in antizyme depleted cells. By comparing ODC, antizyme and cellular polyamines concentrations between *oaz1*-knockdown and negative control cells, it is found that when antizyme was depleted, ODC enzyme and cellular polyamines levels were up-regulated, leading to enhanced luciferase translation.

## **5.2 - Introduction**

Polyamines (putrescine, spermidine, and spermine) are essential polycations that affect many biochemical processes [159, 160]. They interact with negatively charged molecules such as DNA, RNA, protein and phospholipids [160, 161], exerting a wide range of effects on replication, transcription, translation and post-translational modification processes as well as on membrane stability[161]. Even though the exact physiological functions and the precise mechanisms of polyamines in mammalian cells have remained unclear, it has been shown that polyamines are largely involved in regulation of cellular proliferation, transformation, differentiation, apoptosis, and tumorigenesis [162, 163]. Elevated polyamine accumulation has been associated with cell proliferation and transformation while decreased polyamines level inhibits cellular growth, migration, and embryonic development [164]. As dysregulation of cellular polyamine is associated with various cancer pathology, polyamine pathways have been explored intensively as targets for cancer chemotherapy and chemoprevention[163, 165].

Ornithine decarboxylase (ODC), spermidine synthase and spermine synthase are three major enzymes in the polyamine biosynthesis pathway and ODC is the first and rate-limiting enzyme (Fig.5.S1 ). Firstly, ornithine is decarboxylated by ODC to form putrescine. Then, catalyzed by spermidine synthase, putrescine receives the amino propylic group from decarboxylated s-adenosylmethionine (dcSAM) to form spermidine. Spermine is formed by obtaining one more amino propylic group from dcSAM (Fig. 5.S1).

Cellular polyamines are highly regulated by antizyme (OAZ) and antizyme inhibitor (AZI)-mediated regulation of ODC (Fig.5.S2). Antizymes are naturally occurring negative regulators of ODC[166]. They can inhibit ODC activity by forming heterodimers with ODC [167] and can lead to fast ubiquitination –independent ODC degradation by 26S proteasome[168]. ODC has a half-life of one to two hours in the absence of antizyme and the presence of antizyme reduces the half-life to minutes [169]. Antizyme levels are very low in most tissues [170], but they are rapidly increased in response to elevating polyamine levels via a mechanism that is not completely understood[171]. Antizyme inhibitors can inactivate antizyme by binding to antizymes with higher affinity than ODC, thus allowing release of ODC from antizyme inhibition. [172].

In humans, antizymes comprise of a family of at least 3 members[173]. Antizyme 1 is distributed in all tissues. It promotes ODC degradation via the 26S proteasome [168], inhibits polyamine uptake into the cell and stimulates polyamine export [174, 175]. Mammalian antizyme 2 is also distributed in all tissues but is less abundantly expressed [176]. It lacks ODC degradation capability but can inhibit polyamine uptake [177]. Antizyme 3 is only expressed during spermatogenesis in testis tissues [178]. Antizyme 1 is most intensively studied due to its effective regulation on cellular polyamine levels and it is directly referred to as “antizyme”. It has been shown that antizyme mRNA level does not change with cellular polyamine concentration[179]; but polyamine level influences antizyme expression on translational level. Elevated polyamine concentration induces a +1 ribosomal frameshift, which is needed for functional antizyme expression [180]. As a result, functional antizymes capable of binding ODC are rapidly produced [171].

In chapter 4, we have identified *oaz1* gene as a top candidate to knock-down for enhanced luciferase expression. As *oaz1* gene encodes ODC antizyme 1, it is speculated that the *oaz1* gene knock down may lead to elevated cellular ODC and polyamine concentrations, resulting in improved protein production. In this chapter, ODC, antizyme and cellular polyamines concentrations are compared between *oaz1*-knockdown and negative control cells. The results showed that in antizyme depleted cells, ODC enzyme and cellular polyamines levels were up-regulated, leading to enhanced luciferase translation.

### **5.3 - Materials and Methods**

#### **5.3.1. Cell culture and transfection**

Silencer siRNA for *oaz1* gene (Catalog number: AM51331, assay ID: 46078) and Silencer Select Negative Control #2 were purchased from Life Technologies. AllStars Hs Cell Death Control was purchased from Qiagen. HEK-CMV-Luc2-Hygro cells constitutively expressing *P. pyralis* luciferase (Progema) were grown in DMEM supplemented with 10% FBS in a humidified incubator set at 37°C and 5% CO<sub>2</sub>.

The transfection was done in 6-well plate format: 0.12 nmol of each siRNA was added to each well (Corning) and 1.5mL of serum-free DMEM containing 11.25 µL of Lipofectamine RNAiMax (Life Technologies) was then added to each well. This lipid-siRNA mixture was incubated at ambient temperature for 30 min prior to adding 2×10<sup>5</sup> cells in 1.5mL of DMEM containing 20% FBS (Gibco). The transfected cells were

incubated at 37°C in 5% CO<sub>2</sub> and were harvested at 24hours, 48hours, 72 hours and 96 hours. Cells transfected with Silencer Select Negative Control siRNA were used for data normalization and cells transfected with AllStars Hs Cell Death Control siRNA was used as transfection efficiency control.

### 5.3.2. Isolation of RNA and real-time qRT-PCR

Cells were trypsinized from 6-well plates, washed with PBS twice and cell pellets were flash frozen on dry ice and then stored at -80°C until extraction. RNA was extracted from the HEK-CMV-Luc2-Hygro cell pellet using the RNeasy kit (Qiagen) and then treated with DNase using TURBO DNA-free™ Kit (life technologies). CDNA was generated from the RNA using the Maxima First Strand cDNA Synthesis Kit for qRT-PCR (Thermo Scientific). The *real-time qPCR* was done using *Fast SYBR® Green* Master Mix (*life technologies*) in 7900 HT Fast Real Time PCR System (*Applied Biosystems*). The  $2^{-\Delta\Delta C_t}$  method was used for relative expression analysis[181] with *gapdh* as reference gene. Cells transfected with negative control siRNA and harvested at 24hr was set as calibrator. Primer used for each gene: *luc* (Promega), 5'-TCACGAAGGTGTACATGCTTTGG-3' and 5'-GATCCTCAACGTGCAAAGAAGC-3'; *odc1*, 5'-TAAAGGAACAGACGGGCTCT-3' and 5'-CCATAGACGCCATCATTAC-3'; *oaz1*: 5'-GGAACCGTAGACTCGCTCAT-3' and 5'-TCGGAGTGAGCGTTTATTTG-3'; *gapdh*: 5'-CATCAATGGAAATCCCATCA-3' and 5'-TTCTCCATGGTGGTGAAGAC-3'.

### 5.3.3. Luciferase concentration and viable cell number measurement

Overall luciferase activity was determined by ONE-Glo™ Reagent (Promega) and the number of viable cells was determined with CellTiter-Glo™ Reagent (Promega). Upon addition of assay reagent, all plates were incubated at room temperature for 20 minutes to stabilize luminescent signal before reading with SpectraMax i3 plate reader (Molecular Devices). Cells transfected with Silencer Select Negative Control siRNA was used for normalization. Per cell luciferase production was calculated from overall luciferase activity and viable cell number.

#### **5.3.4. Western Blotting**

Transfected cells were lysed in buffer containing 50 mM Tris-HCl, pH 7.4, 5 mM EDTA, 150 mM NaCl, 1% Nonidet P-40, and protease inhibitor mixture. Proteins (~20 µg) were separated by SDS-PAGE (4–12% gel) in MES buffer and transferred to 0.2-µm nitrocellulose membrane for immunodetection using mouse anti-ODC (Sigma, catalog number O1136) and mouse anti-β-actin (BD biosciences, catalog number 612657) primary antibodies and HRP conjugated anti-mouse secondary antibodies (abCAM, catalog number ab20043). Signals were detected with an ECL Plus chemiluminescence reagent.

#### **5.3.5. Cellular polyamine concentration measurement**

Cells in six-well plates were washed with PBS twice, harvested, and precipitated with 0.1 mL cold 10% (vol/vol) trichloroacetic acid (TCA). A total of 50µL of the TCA supernatant was used for polyamine analysis by ion exchange chromatographic system as described [182]. TCA precipitates were used for protein determination as above.

## **5.4 - Results**

### **5.4.1. Effective knocking-down of *oaz1* gene with siRNA**

Of the three mammalian antizyme genes, *oaz1*, *oaz2*, and *oaz3* encode three antizyme isoforms. We tested several siRNAs designed against three *oaz* genes (Supplemental Table 5.S1). Five of six *oaz1* siRNA significantly enhanced luciferase expression. In contrast, none of the siRNAs against *oaz2* or *oaz3* caused an increase in luciferase expression, probably due to the fact that antizyme 2 is a minor form and that antizyme 3 is expressed only in testis.

Among the six siRNAs targeting *oaz1* gene, one was chosen for further studies (siOAZ1: GCUAACUUAUUCUACUCCGtt), as it caused significant increase in luciferase without reducing cell viability. In order to examine the efficacies of antizyme 1 knockdown using siOAZ1, qRT-PCR was executed to determine *oaz1* mRNA level (Fig. 5.1). In the first 72 hours, the relative expression of *oaz1* mRNA was less than 3% upon siRNA transfection compare to negative control siRNA transfected cells, confirming good silencing effect of the siRNA. The 96 hour sample showed 7% relative expression level.

### **5.4.2. The improved luciferase expression is not due to improved transcription of *luc* gene**

To investigate if the enhanced luciferase expression is resulted from transcription or translation step, the mRNA level of *luc* gene was also determined. While cells transfected with siOAZ1 had significantly higher production of luciferase (Fig. 5.2A),

their *luc* mRNA levels remained consistently comparable to negative control cells throughout the 96 hour period (Fig. 5.2B). In addition, there is significant cell growth improvement in the first 48 hours upon siOAZ1 transfection (Fig. 5.2A).

#### **5.4.3. Ornithine decarboxylase is over-expressed in *oaz1*-depleted cells**

As antizyme 1 inhibit ornithine decarboxylase (ODC) and render it for degradation, ODC protein and mRNA levels in siOAZ- and siN.C.- transfected cells were also determined. Western blot showed limited ODC enzyme level in un-transfected and siN.C. transfected cells. Upon silencing of *oaz1* gene, ODC level was significantly elevated, from 48 to 96 hours post siOAZ1 transfection (Fig. 5.3A). However, the elevated ODC protein level is not due to enhanced *odc1* gene transcription. To the contrary, qRT-PCR demonstrated consistent reduction of *odc1* mRNA levels after silencing of *oaz1* gene (Fig. 5.3B).

#### **5.4.4. Cellular putrescine concentration is highly up-regulated in *oaz1*-depleted cells**

To investigate if the knocking-down of *oaz1* gene influence cellular polyamine concentration, the levels of three major polyamines, putrescine, spermidine and spermine were determined in siOAZ1- and siN.C- transfected cells. As shown in Fig.5.4, polyamines concentrations were normalized with total protein and presented as nmol/mg total protein. In *oaz1*-depleted cells, putrescine concentration is 10 fold as high as that in negative control cells. Spermidine concentration was also up-regulated, but to a lesser degree of up to one-fold increase in the first 72 hours. Spermine, the last product down the polyamine pathway, was reduced upon *oaz1* depletion.

#### **5.4.5. Exogenous addition of polyamine into culture media improves luciferase expression**

To further verify whether elevated polyamine concentration can lead to improved luciferase expression, different titers of putrescine, spermidine and spermine were independently added into cell culture media and their impacts on luciferase expression level and viable cell number were determined. With putrescine addition, up to 40% increase of luciferase expression was observed (at 100 $\mu$ M) and the cell growth was enhanced up to 10% (at 50  $\mu$ M). Higher concentrations could not generate further improvements (Fig.5.5.A). For spermidine addition, the best effects were reached at a lower titer: a 36% increase in luciferase expression was obtained at 20  $\mu$ M spermidine while a 24% increase in cell growth was achieved with 10  $\mu$ M spermidine. In addition, reduction in both luciferase expression and viable cell number were observed with >100  $\mu$ M spermidine (Fig.5.5.B). The addition of spermine is not beneficial when the titer is >20  $\mu$ M. At a lower concentration (10  $\mu$ M), a 16% increase in luciferase expression was observed (Fig. 5.5.C).

### **5.5 - Discussion**

In chapter 4, we identified *oaz1* gene encoding ornithine decarboxylase antizyme 1 to be a promising target for detailed investigation, as the siRNA-mediated knocking-down of *oaz1* gene can consistently improve expression of multiple model proteins without significantly reducing cell viability. This provides highlights on the importance of cellular polyamines in protein synthesis and cell growth.

Polyamines are essential molecules, intimately involved in the regulation of cell proliferation, transformation and tumorigenesis [183]. Dysregulation of polyamine metabolism has been implicated in the pathogenicity of several human diseases, including cancer [183]. As polycations, they specifically bind to nucleic acids, proteins and phospholipids and regulate the stability, synthesis and activities of the macromolecules [150, 161, 184]. The most critical cellular function of polyamines appears to be the promotion of translation, because depletion of cellular spermidine and spermine by overexpression of a key polyamine catabolic enzyme, spermidine/spermine N1-acetyltransferase 1 (SSAT1) leads to a total suppression of protein synthesis without inhibition of synthesis of DNA and RNA [185]. The current data also suggest that, in a reciprocal situation, increased cellular polyamines can enhance reporter protein synthesis without increasing their transcription. In spite of abundant evidence for the critical function of polyamines, ODC and antizyme in cellular transformation and proliferation [186-188], their mechanism of action and the sequence of events are poorly understood at the molecular level.

In this chapter, we firstly examined the efficacies of antizyme 1 knockdown using siOAZ1. It is confirmed from real time qPCR results that this siRNA effectively down-regulated *oaz1* mRNA by 97% and the depletion extended to 96 hours post transfection (Fig. 5.2A). Upon antizyme depletion, luciferase expression was significantly improved from 48hrs to 96hrs but luciferase mRNA levels were slightly reduced compared to cells transfected with non-complementary siRNA (siN.C.). This finding indicates that the enhanced expression of luciferase occurred without an increase in transcription of

luciferase gene and that antizyme depletion enhanced luciferase expression at the level of translation.

As expected from the known function of antizyme in down-regulation of ODC by inducing its proteosomal degradation, ODC enzyme level was found increased in antizyme-depleted cells (Fig.5.3A). As a highly regulated protein with an extremely short half-life, ODC level fluctuates depending on cellular proliferative status, cellular polyamine level and external stimulus. The significantly higher ODC level in *oaz1* knockdown cells indicates the stabilization of ODC protein upon depletion of antizyme 1. Interestingly, ODC mRNA levels were significantly reduced upon siOAZ1 transfection in a time-dependent manner. Judging from the nucleotide sequence of ODC mRNA, siOAZ1 is not predicted to bind to ODC mRNA to cause its degradation. Thus a decrease in ODC mRNA may be an indirect effect of *oaz1* knockdown.

Consistent with the ODC enzyme level, cellular putrescine level was sharply increased by 24 hrs of transfection with siOAZ1. Spermidine level also increased, but spermine level was lower than in the control siRNA-transfected cells. The sum of three polyamines was higher in OAZ1 knockdown cells, mainly due to a large increase in putrescine.

It has been reported that addition of polyamines in serum free medium increased production of recombinant proteins in mammalian cells [189] and polyamines can be included as components of commercial serum-free medium used for recombinant protein production. Our data is in accordance with these findings. It was found that exogenous addition of 50-100 $\mu$ M putrescine led up to 40% increase of luciferase expression and up

to 10% increase of cell growth. The best effects with spermidine and spermine were observed at a much lower titer, 20  $\mu$ M and 10  $\mu$ M respectively. Higher concentration led to significant proliferation inhibition, probably due to ruminant plasma amine oxidase which generates toxic acrolein[190].

Taken together, our studies suggest that in *oaz1* knocking-down cells, ODC enzyme and cellular polyamines levels were found to be up-regulated, leading to enhanced translation of luciferase and other reporter proteins. This is the first report to our knowledge to have improved recombinant protein production by engineering ODC enzyme or its antizyme.

ODC and antizymes were mostly investigated for their impact on cell proliferation and transformation, especially in cancer research. For example, overexpression of ODC caused enhancement of proliferation and transformation of immortalized mouse fibroblasts NIH3T3 cells [191, 192]. In transgenic mice overexpressing ODC under a keratin promoter, tumor incidence increased after a variety of stimuli, including chemical carcinogens, UV radiation, and an activated Ras, whereas treatment with ODC inhibitor difluoromethylornithine (DFMO) prevented tumor development [193, 194]. In contrast to ODC, lots of research confirmed the anti-proliferative effect of antizyme 1 and suggest a role for antizyme as a potential tumor suppressor[195]. For example, in several human oral cancer cell lines, the expression level of the *oaz1* gene was down-regulated [196, 197]. Overexpression of antizyme in different cell culture models abolishes ODC activity, suppresses cellular levels of polyamines, inhibited the cell proliferation rate, induced G0/G1 arrest and led to

apoptosis [164, 198-201]. *In vivo*, overexpression of an *oaz1* mutant clone under a keratin promoter reduced tumor formation in mouse skin, suggesting its tumor suppressive effects [202].

In addition to inhibition of ODC, antizymes also inhibit transport/uptake of polyamines [174, 203]. Since ODC and antizyme have opposite effects on polyamine levels, they would have opposite effects on reporter gene expression. Indeed, ODC siRNA reduced expression of luciferase (Supplemental Table 5.S2). In this regard, it would be interesting to determine whether overexpression of ODC would stimulate reporter protein production as antizyme knockdown does. This will provide interesting insights on the translational regulation of gene expression by polyamines in mammalian cells.

**Contributions from collaborators:**

Dr. Myung Hee Park contributed to drafting of results and discussion part and Dr. Swati Mandal carried out western blot for ODC, cellular polyamine concentration measurement and corresponding data analysis.

## Figures and tables

## **Chapter 6: Conclusion and future work**

### **6.1 – Final Remarks**

The goal of this study is to develop strategies to improve the functional expression of mammalian membrane proteins. Neurotensin receptor type I (NTSR1) was utilized as a model protein, as it's a hard-to-express G protein-coupled receptor (GPCR) and its structure was not solved. We proposed that by engineering of the host organism and production process, we would be able to produce adequate amounts of purified receptors, to aid the crystallography studies of NTSR1. In addition, the successful strategies can be transferred to improving the production of other difficult proteins.

This dissertation demonstrated three effective strategies, including the adoption of mammalian inducible expression system, production process development and high-throughput RNA interference screening.

The utilization of human embryonic kidney (HEK) cell line harnessed the near-native environment of mammalian cells for protein translation, modification, folding and trafficking, thus contributed to the ideal quality of the membrane proteins produced. The adoption of the tetracycline inducible system allowed the external switching-on of protein production process, making it possible to manipulate temporally the event of cell growth and toxic protein production. This first strategy remarkably improved NTSR1 production comparing to constitutive expression approach.

The process development strategy in this dissertation included suspension culture adaptation for high-density cell culture and induction parameter optimization. The nature

of this strategy is fine-tuning of the production procedures to push the NTSR1 production to the extent of host organism's limit.

Once the host organism's capacity has been reached, further cell line engineering will be necessary to expand the host organism's limit. This dissertation focused on a bottom-up high throughput screening approach, to prove that this strategy can efficiently enhance membrane protein production and can lead to identification of limiting factors that need to be reserve-engineered.

Indeed, the polyamine studies in chapter 5 served as a proof of concept that the genome-scale loss-of-function data is valuable for understanding the protein expression process and can lead to exciting findings and applications. For example, even though the polyamine biosynthesis pathway and its regulation have been studied for decades, there were no reports on engineering any factors in this pathway for the purpose of enhancing protein production. The screen result shed light on this pathway, leading to targeted investigation followed by fast and efficient application of pre-existing biological research results.

## **6.2 – Future work**

Continuation and expansion of the work detailed in this dissertation is currently underway. Firstly, five miRNAs (hsa-miR-22-5p, hsa-miR-18a-5p, hsa-miR-22-3p, hsa-miR-429 and hsa-miR-2110) have been identified in chapter 3 and the identification of target genes of these miRNAs are in progress. Combined with our whole-genome screen

data, it will contribute to our understanding of the mechanism behind improvement of protein expression. Secondly, a HEK293 cell line stably over-expressing hsa-miR-22 is being constructed and tested. This experiment will allow us to investigate stable inhibition and combinatorial effects of miRNAs (hsa-miR-22 is composed of hsa-miR-22-5p and hsa-miR-22-3p arms). Thirdly, CRISPR cell lines knocking out each of identified top 10 genes (*ints1*, *ints2*, *hnrnpc*, *casp8ap2*, *oaz1*, *ppp2r1a*, *prpf19*, *cct2*, *chaf1a*, *ee1b2*) will be constructed to investigate if the gene deletion can intensify the effects. This will also serve as a proof of concept for industrial application of screen hits. Finally, as discussed in chapter 5, as ODC and antizyme has opposite effects in cellular polyamine concentration, it would be interesting to determine whether overexpression of ODC would stimulate reporter protein production as antizyme knockdown does. The comparison of the two system is especially interesting because antizyme not only inhibit ODC but also regulate polyamine transport /update.

In addition, there are many more interesting project candidates derived from this study.

First of all, as large-scale transient gene expression with HEK293 cells has been widely applied in contract manufacturing organizations (CMO) for fast preparation of secreted medical proteins, is it possible to establish a similar strategy for membrane protein production? Such expression strategy will greatly benefit crystallography society as it will generate correctly-folded proteins while keeping a fast turn-over rate.

Secondly, as all of the work in this dissertation is based on loss-of-function studies, our dataset is not complete. It will be very interesting to carry out gain-of-function studies with the same reporter protein and same human genome library [204].

With a two-sided story, we will be able to understand better the positive or negative involvement of different genes in protein biosynthesis and cell growth.

Thirdly, from production point of view, it will be more beneficial to execute genome-scale siRNA screen with Chinese Hamster Ovary cells (CHO). Since the hamster siRNA library is still lacking, murine library could be used instead. Or top hits from this HEK293 screen can be tested with CHO cells.

Additionally, the spliceosome pathway has been high-lighted in chapter 4 and the clear involvement of integrator complex is very intriguing. It'll be worthwhile to look into luciferase mRNA level upon the transfection of these siRNAs, to investigate if the altered spliceosome pathway changed luciferase transcription level. Specifically for integrator complex, it'll be interesting to check U1/U2 snRNA level.

Apart from genes involved in mRNA splicing process and polyamine pathway, there are many others worth further investigation(*casp8ap2*, *ppp2r1a*, *cct2*, *chaf1a*, *eef1b2*) for mechanistic studies. The knocking down of *ppp2r1a* for example, can enhance the expression of cytosolic, secreted and membrane proteins tested, and also introduced minimal cell growth disadvantage. As an important serine/threonine phosphatase with diverse cellular functions, protein phosphatase 2 (PP2) has been intensively studied for years. It will be interesting to decipher how this global regulator can be engineered for a host cell line with improved protein expression capability.

## **Education**

Ph.D. Chemical and Biomolecular Engineering, **Johns Hopkins University** GPA 3.8 May, 2015  
(expected)

Joint program with **National Institutes of Health (NIH)**

Advisors: Michael J. Betenbaugh and Joseph Shiloach

Thesis title: cellular and process engineering to improve mammalian membrane protein expression

B.S. Chemical Engineering, **Tsinghua University**, China GPA 3.3 July, 2010

## **Professional experience**

**Jan. 2011-present: pre-doctoral research fellow, NIDDK Biotechnology Core Laboratory, National Institutes of Health, Bethesda, MD.**

## **Research**

### • 10L-scale production and purification of hard-to-express membrane protein

\* Designed and constructed vectors for inducible neurotensin receptor (NTSR1) expression in HEK293 cells

\* Constructed stable HEK293 cell clones for inducible NTSR1 expression

\* Selected production clones using flow cytometry and ligand-binding assay

\* Adapted production clones into high density serum-free suspension culture

\* Designed and optimized NTSR1 manufacturing method

\* Operated 10L bioreactor followed by immobilized metal ion affinity chromatography for manufacturing of NTSR1

\* Determined the quality and quantity of NTSR1 product

\* Quantitatively compared NTSR1 production from HEK293 and baculovirus-insect cell expression system

### • High-throughput microRNA screen for improved recombinant protein expression

\* Developed and optimized a high-content imaged-based assay for RNAi screening with GFP tagged proteins.

- \* Fine-tuned workflow and solved technical difficulties in the automated screening procedure
- \* Screened human microRNA library with NTSR1-GFP expressing cells
- \* Proposed to combine NTSR1-GFP data with luciferase data to identify common hits improving protein production
- \* Verified the effectiveness of identified common hits (microRNAs) with other secreted and membrane proteins
- \* Constructed stable microRNA over-expressing cell line for enhanced phenotype
- High-throughput whole-genome siRNA screen for improved cell growth and recombinant protein expression
- \* Fine-tuned workflow and solved technical difficulties for whole-genome siRNA screening
- \* Screened human whole-genome siRNA library with NTSR1-GFP expressing cells
- \* Statistically analyzed large-scale whole genome data for both NTSR1-GFP and luciferase screens
- \* Executed pathway analysis to obtain biological interpretation of the screen result
- \* Identified and validated top molecules (siRNAs) for improved cell growth and protein expression
- \* Verified the effectiveness of identified top molecules (siRNAs) with other secreted and membrane proteins
- \* Investigated the mechanistic explanation for improved protein overexpression
- \* Designed CRISPR array screening for construction of stable cell line knocking out identified genes
- Transient overexpression and purification of Respiratory syncytial virus (RSV) fusion protein
- \* Investigated four expression vectors for optimal secreted expression of RSV F0 protein.
- \* Optimized transient transfection parameters and produced RSV F0 protein accordingly.
- \* Purified RSV F0 protein with immobilized metal ion affinity chromatography.
- Rotavirus amplification in Madin-Darby canine kidney (MDCK) cells
- \* Amplified four strains of rotavirus in MA104 cells and determined rotavirus titer in cell culture lysate
- \* Adapted rotavirus to MDCK cells
- \* Determined virus titer change during adaptation using classical plaque assay and ELISA test

**Collaborative/ supervisory/ technical work**

- \* Collaborated with students, postdocs, staff scientists and technicians from both domestic and international locations. Collaborative effort includes setting up regular meetings, transferring of cell lines and reagents, coordinating and travelling to different sites to use shared facilities, data sharing and

editing manuscripts, etc.

\* Served as a teaching assistant for bioseparation course (90 undergraduate students) for 2 semesters. Work includes delivery lectures, holding office hours to answer questions, establishing and troubleshooting new equipment for lab, organizing students for lab practicing, etc.

\* Supervised two graduate students and two undergraduate students on cell culture, cell engineering, virus amplification, data analysis and thesis writing.

\* In charge of preventive maintenance and calibration of analytical instruments.

\* Maintained updated inventory of analytical instrument, lab equipment, consumables and cell lines.

\* Searched for state-of-the-art analytical instruments for purchasing recommendations.

\* Created bacterial and mammalian cell banks

**June- Sept. 2014: managerial internship at Center for Drug Evaluation (CDE), China Food and Drug Administration, Beijing, China.**

\* Investigated Good Review Practices (GRP) and Quality Management System(QMS)

\* Proposed to CDE on implementing ISO 9000 QMS with Six Sigma or Lean methodologies for continuous improvement

\* Led a group of interns to search, translate and compile USFDA QMS/GRP documents

\* Interviewed and worked with consulting firms on implementing QMS/GRP in CDE

**October 2008- June 2010: Undergraduate research at Department of Chemical Engineering, Tsinghua University, Beijing, China**

\* Produced violacein through microbial fermentation, extraction and purification.

\* Characterized and analyzed violacein product.

\* Introduced the entire violacein synthetic pathway from *Duganella sp.* B2 into *C. freundii* to achieve high efficient biosynthesis of violacein.

\* Explored possible impact factors on efficient biosynthesis of violacein by integrating the information on transcription/translation level of violacein biosynthesis gene cluster, fermentation characteristics and intracellular pH.

**July-Sept. 2009: summer training program at Technical University of Denmark, Novozymes and Nordic Sugar, Denmark**

\* Received training on large-scale unit operation, including liquid-liquid extraction, thermal-fluid heat

exchange, fluid bed powder processing and filtration.

\* Studied the bioprocess of enzyme and sugar production and inspected equipment in each section.

## **Scientific meetings/ presentations**

**Xiao S**, Chen YC, White JF, Betenbaugh MJ, Martin SE, Grisshammer R, Shiloach J, 'Engineering towards improved functional expression of neurotensin receptor'. 11th Annual Graduate Student Research Symposium, Bethesda, US, Jan. 2015 (poster, travel award winner)

**Xiao S**, Chen YC, Betenbaugh MJ, Martin SE, Shiloach J, 'Systems and Synthetic Biotechnology Platform for Characterizing and Designing HEK293 Cells'. IBC's 10<sup>th</sup> Annual Cell Line Development & Engineering conference, Berkeley, CA, US, Sept. 2014 (Oral)

**Xiao S**, White JF, Betenbaugh MJ, Grisshammer R, Shiloach J, 'High throughput RNA interference for improved functional expression of neurotensin receptor'. Cell Culture Engineering XIV, Quebec city, Canada, May 2014 (poster)

**Xiao S**, White JF, Betenbaugh MJ, Grisshammer R, Shiloach J, 'Transient and stable expression of the neurotensin receptor NTSR1: a comparison of the baculovirus-insect cell and the T-REx-293 expression systems'. 10th Annual NIDDK Conference, Bethesda, MD, US, Apr. 2013 (poster)

**Xiao S**, White JF, Betenbaugh MJ, Grisshammer R, Shiloach J, 'Transient and stable expression of the neurotensin receptor NTSR1: a comparison of the baculovirus-insect cell and the T-REx-293 expression systems'. Delaware Membrane Protein Symposium, Newark, DE, US, May. 2012 (poster)

## **Awards and Honors**

- \* 2015 NIH Graduate Student Research Award (4%), National Institutes of Health, 2015
- \* 1<sup>st</sup> Prize in National Competition of Chemical Process Design for College Students (2%), Chemical Industry and Engineering Society of *China*, 2009
- \* Scholarship for Scientific Innovation, Tsinghua University, 2009
- \* 1<sup>st</sup> Prize in “Challenge Cup” Scientific and Technological Contest (2.5%), Tsinghua University, 2009
- \* 1<sup>st</sup> Prize in *Chemical Product Design Contest* (3%), *Tsinghua University*, 2008

## **Skills**

### **Laboratory techniques**

- \* Mammalian cell culture (CHO, MDCK, HEK293, Vero, MA104), insect cells (sf9), yeast and bacteria.
- \* Gene and primer design, plasmid DNA cloning, bacterial transformation, transient and stable mammalian transfection, virus infection
- \* Gene overexpression, siRNA and shRNA knock-down, CRISPR knockout
- \* DNA, RNA extraction and purification, DNA and RNA gel electrophoresis, cDNA synthesis, qRT-PCR
- \* Protein expression and IMAC purification, SDS-PAGE, western blotting, ELISA, BCA, Bradford protein assay, ligand binding assay, other enzymatic assays (SEAP, luciferase, etc.)
- \* metabolites analysis with YSI and HPLC
- \* Flow cytometry, fluorescent microscopy, confocal microscopy, ImageXpress Micro.
- \* Virus amplification, plaque assay, TCID50 assay, virus isolation and identification
- \* Large-scale fermentation, process optimization, design of experiment
- \* high-throughput RNAi and compound screening, genome scale data analysis and pathway analysis

### **Personal skills**

Excellent problem-solving, organizational and interpersonal skills, able to multi-task, work independently or as a part of a team, good time management and **prioritization** skills, creative, fast-learning, able to identify existing bottleneck and implement new protocols.

### **computer**

Proficient OFFICE, ORIGIN, ENDNOTE, MATLAB, ASPEN Plus, IPA, DNASTAR, PATBASE
