## INTRODUCTION

Dredging and land reclamation are two of the potentially most damaging activities that man undertakes in estuarine areas. Hampton Roads, the world's largest natural harbor, is a multiple use port, being a major center for fishing and shellfishing, transportation, recreation and industrial sitings. Dredging which is a necessary perpetuation for some of these activities, could be directly or indirectly detrimental to others. It is in such a multiple use situation that environmental alterations, real or potential, must be carefully planned and closely monitored. Projects of the type underway can cause changes in circulation, water depth, turbidity, and patterns of siltation, all of which can be damaging to the living components of the estuarine system. Estuarine species are, by nature, hardy organisms, however, as many live near their limit of tolerance, an additional increase in stress from one or a combination of sources could be disasterous. Besides the obvious physical stresses, there are related ones of a more insidious nature caused by, among other things, an increase in heavy metal exposure. Heavy metals become associated with clay size particles in the substrate, and as these particles are resuspended by bottom disturbances, the organisms' level of exposure can be greatly increased. This becomes of significant economic importance when the affected species is a

marketable shellfish, or a food resource for a commercially valuable species. Presently information sufficient to allow prediction or comprehensive evaluation of the effects of dredging is not available. All heavy metal data collected was presented in the interim report and will not be considered further.

The objectives of this study are to determine the immediate and short-term effects of the Shipyard's current expansion on the aquatic environment of the lower James River estuary and Hampton Roads.

### Methods and Materials

#### Benthic Fauna

Five sampling transects have been placed in the lower James River estuary and Hampton Roads in areas thought to be along the likely route of silt transport. Twenty-five sites on these transects were occupied during December 1972 and June 1973 and were sampled in triplicate using a Ponar grab of 0.05 square meters (Fig. 1).

All samples, after being returned to the laboratory, were refrigerated overnight and then washed through a 1 mm sieve to remove the majority of sediment. The material retained on the sieve was preserved in 10% formaldehyde with 100 mg/l of Phloxine B stain. The Phloxine B stains organic matter red making organisms easier to see and therefore faster to pick out. All organisms were removed from the debris remaining after sieving with the aid of a dissecting microscope or illuminated magnifying glass. The fauna was sorted, identified and enumerated. All information was placed on punch cards for computer analysis.

Community structure was analyzed using species diversity, its components, and similarity analysis to elucidate characteristics of the animal communities represented at the sampling sites. Computer classification of the 25 sites was performed using the Canberra metric dissimilarity coefficient and flexible grouping ( $\beta$  set at -0.25).

### Results

Sediments did not change appreciably from December to June and ranged from clay to medium sand with most areas also containing shell and other debris. The predominant substrate type was fine sand, although sediments at 25% of the stations consisted predominantly of finer grained particles (Table 1).

In December, 111 taxa were taken while June samples yielded 92 (Appendix 1), a decline of 19 taxa (Table 2). One sponge, one anemone, 9 polychaetes, 12 molluscs, and 22 arthropods occurred during only one of the sampling periods. Most of these one-time species occurred in December. Three of the 18 dominant species occurred in only one sampling period. They were Paracaprella tenuis in December and Corophium acherusicum and Macoma balthica in June. There was a great amount of rearrangement of dominant species from December to June (Table 3). Quantitative community structure also changed drastically. The number of species needed to make up 90% of the total number of individuals at each station decreased at two thirds of the stations from December to June (Tables 5 and 6).

Species diversity ( $H'$ ) increased from December to June at all stations except 17, 19, and 23. Diversity values were lowest at station 18 in December and 17 in June and highest at 23 in December and 22 in June (Table 4). The

evenness component of diversity, which gives an indication of how evenly the individuals in a sample are distributed among the species, showed no concordant pattern, with half the stations increasing and half decreasing. The richness component of diversity, which gives an indication of the number of species that occur per number of individuals in a sample, declined from December to June at all stations except six, reflecting the general decline in the number of species taken in June (Table 4).

Computer classification of December data produced two main site groups--one running along the edge of the main channel from the James River Bridge to the Hampton Roads Bridge-Tunnel (Stations 6 to 11 and 19 to 23). The second larger and more dispersed group is composed of three subgroups--stations on Hampton Flats in the Elizabeth River channel, and above the bridge (Fig. 2). Classification of June data also produced two main site groups (Fig. 3). The smaller group included all stations above the bridge, one at the bridge and one on Hampton Flats. The second site group was the more dispersed and consisted of two subgroups--the main channel stations and Elizabeth River channel stations, one station on Hampton Flats, and one station in the main channel. The larger subgroups consists of the remaining stations along the main channel and three Hampton flats stations.

Classification of combined December and June data produced two main site groups (Figure 4)--one above the bridge and another below. The latter is composed of subgroups of stations from the main channel, Hampton Flats, and Elizabeth River Channel. Due to the heterogeneity of the data some misclassifications occurred in the combined analysis (see Boesch, 1973 for detailed explanation of misclassifications). Reallocation of these misclassified groups to form more meaningful site groups is based on subjective reevaluation of the relationships between misclassified stations and the site groups. From the combined data analysis December station 7 and June station 6 were reallocated to the main channel subgroup and December station 14 was put in the above-bridge group.

Biomass showed no concordant trend from December to June, with half the stations increasing and half decreasing (Table 7). However, the total biomass from December to June decreased from 607.7 to 464.7 grams wet weight for all 75 grabs.

### Discussion

There appeared to be no significant increase in additional siltation from the shipyard project; however, this is most likely due to the dynamic nature of the tides and currents in the study area, which would prevent accumulations of fine-grained particles to any great extent.

The large scale change of species from December to June is attributed mainly to normal seasonal changes. The change of Mulinia lateralis from sixteenth in December to first dominant in June was caused by heavy sets in late winter or early spring. At sandy stations (all stations except 7, 8, 11, 23, 24 and 25) faunal changes were more intense with many species not appearing again in June samples (Table 5 and 6).

Another set of sequential winter and summer samples would distinguish seasonal faunal changes from changes due to shipyard activity. Comparing one set of winter and summer samples for changes other than seasonal faunal changes is virtually impossible.

For both December and June samples a gradient in diversity exists with lowest values at the up-river stations (18 in December and 17 in June) and highest near the Hampton Roads Bridge-Tunnel stations (23 in December and 22 in June). This gradient is produced and maintained by the salinity structure of the James estuary. In a gradient estuary, like the James,

diversity decreases with decreasing salinity (Boesch, 1972). The increase in diversity from December to June is attributable to general seasonal trend (Boesch, 1973).

The spring and early summer reproduction and setting of organisms increased the number of individuals of a few species and the decrease in the number of species taken caused the general lowering of species richness (Table 4). Evenness remained essentially the same. Even though the dominant species changed, the degree of dominance did not change. A great increase in evenness at seven stations from December to June was due to decrease in numerical abundance of dominant species. Evenness decreased at seven other stations but this was mainly attributed to an increase in the total numbers of dominant species.

Biomass varied greatly during both seasons and this was due primarily to the patchy distribution of large animals, such as hard clams and oysters. Spring and summer setting of organisms accounted for small increases (less than 10 grams wet weight) at eight stations. Effects of shipyard expansion on biomass are impossible to determine without further more intense sampling.

Computer classification of sample sites produced interesting results. In both December and June those stations along the main channel were the only sites to remain classified in essentially the same group.

Affinities between sites in this group were higher in December reflecting high homogeneity among the species found along the channel transect. In June many species previously taken did not occur again in the channel while several more ubiquitous species did, causing the channel transect to become more heterogeneous. This allowed one station (5) outside of the channel to be included and one channel station (6) to be excluded from the main channel site group (Figure 3). With respect to seasonal variation, the most homogenous group was composed of the above-bridge sites, due primarily to the predominance of Mulinia lateralis, Heteromastus filiformis and Leptocheirus plumulosus in both December and June.

In the combined analysis after reallocation the two main groups reflect the salinity structure of the James, with those stations above the bridge being in mesohaline salinity (5-10‰) and those below in polyhaline salinities (10-18‰). Water of higher and more constant salinity which moves up the channel depths allows the channel to retain a more homogeneous fauna. Stations 1 to 5 and 24 and 25 are rather heterogeneous and show no consistent relationships to either of the two site groups previously mentioned. Within this assemblage there are weak similarities that might form two somewhat related site groups (Figure 5).

Conclusions

The most pronounced characteristics of the benthos from December to June were seasonal changes and the influence of salinity. It is impossible to determine any effects of the shipyard project without replications of seasons. Normal changes from winter to summer may overshadow effects of the ongoing project.

## Appendix 1

### Species list for December 1972 and June 1973 benthic stations

	<u>December</u>	<u>June</u>
<b>PORIFERA</b>		
<u>Microciona prolifera</u>	x	
<b>CNIDARIA</b>		
<u>Bougainvillia rugosa</u>	x	x
<u>Sertularia argentea</u>	x	x
<u>Anthozoans</u>	x	
<b>RHYNCHOCOELA</b>		
<u>Tubulanus pellucidus</u>	x	
<u>Anoplans</u>	x	x
<b>NEMATODA</b>		
<b>ANNELIDA (POLYCHAETA)</b>		
<u>Drilonereis filum</u>	x	x
<u>Heteromastus filiformis</u>	x	x
<u>Spiochaetopterus oculatus</u>	x	x
<u>Cirratulus grandis</u>	x	x
<u>Tharyx setigera</u>	x	x
<u>Marpysa sanguinea</u>	x	
<u>Glycera dibranchiata</u>	x	x
<u>Glycinde solitaria</u>	x	x
<u>Lumbrinereis tenuis</u>	x	x
<u>Clymenella torquata</u>	x	x
<u>Nephtys</u> sp.	x	x
<u>Nereis succinea</u>	x	x
<u>Diopatra cuprea</u>	x	x
<u>Scoloplos fragilis</u>	x	x
<u>Scoloplos robustus</u>	x	x
<u>Aricidea jefferei</u>	x	
<u>Pectinaria gouldi</u>	x	x
<u>Eteone heteropoda</u>	x	x
<u>Sabellaria vulgaris</u>	x	x
<u>Sabella microphthalma</u>	x	
<u>Pseudeurythoe</u> sp.	x	x
<u>Hydroides dianthus</u>	x	x

Appendix 1. (continued)

Species list for December 1972  
and June 1973 benthic stations

	<u>December</u>	<u>June</u>
<u>Polydora ligni</u>	x	x
<u>Polydora websteri</u>	x	x
<u>Parapriionospio pinnata</u>	x	x
<u>Scolecolepides viridis</u>	x	x
<u>Spio sp.</u>	x	x
<u>Spiophanes bombyx</u>	x	x
<u>Streblospio benedicti</u>	x	x
<u>Syllid</u>	x	x
<u>Loimia medusa</u>	x	
<u>Harmothoe sp.</u>		x
<u>Sigambra tentaculata</u>		x
<u>Laeonereis culveri</u>		x

ANNELIDA (Oligochaeta)

<u>Peloscolex</u> spp.	x	x
------------------------	---	---

MOLLUSCA (Pelecypoda)

<u>Nucula proxima</u>	x	x
<u>Anadara transversa</u>	x	x
<u>Anadara ovalis</u>	x	
<u>Brachiodontes recurvus</u>	x	x
<u>Crassostrea virginica</u>	x	x
<u>Mercenaria mercenaria</u>	x	x
<u>Gemma gemma</u>	x	x
<u>Petricola pholadiformis</u>	x	
<u>Mulinia lateralis</u>	x	x
<u>Tellina agilis</u>	x	x
<u>Macoma baltica</u>	x	x
<u>Macoma phenax</u>	x	x
<u>Tagelus plebeius</u>	x	
<u>Mya arenaria</u>	x	x
<u>Cyrtopleura costata</u>	x	x
<u>Lyonsia hyalina</u>	x	x
<u>Epitonium rupicolum</u>	x	
<u>Crepidula convexa</u>	x	x
<u>Yoldia limulata</u>		x
<u>Mytilus edulis</u>		x
<u>Macoma tenta</u>		x
<u>Ensis directus</u>		x

Appendix 1 (continued)

Species list for December 1972  
and June 1973 benthic stations

	<u>December</u>	<u>June</u>
<b>ECHINODERMATA</b>		
<u>Amphiodia atra</u>	x	x
<b>UROCHORDATA</b>		
<u>Molgula manhattensis</u>	x	x
<b>TELEOSTEI</b>		
<u>Gobiosoma boscii</u>	x	x
<b>MOLLUSCA (Gastropoda)</b>		
<u>Urosalpinx cinerea</u>	x	
<u>Mitrella lunata</u>	x	
<u>Busycon canaliculatum</u>	x	x
<u>Nassarius vibex</u>	x	x
<u>Nassarius trivittatus</u>	x	
<u>Nassarius obsoletus</u>	x	x
<u>Odostomia impressa</u>	x	
<u>Pyramidella fusca</u>	x	x
<u>Turbanilla interrupta</u>	x	x
<u>Acteon punctostriatus</u>	x	x
<u>Acteocina canaliculata</u>	x	x
<u>Doridella obscura</u>	x	x
<u>Odostomia bisuturalis</u>	x	x
<b>ARTHROPODA</b>		
<u>Balanus improvisus</u>	x	x
<u>Neomysis americana</u>	x	x
<u>Leucon americanus</u>	x	x
<u>Diastyli polita</u>	x	
<u>Oxyurostylis smithi</u>	x	
<u>Cyathura polita</u>	x	x
<u>Cyathura burbancki</u>	x	x
<u>Crassidionidea lunifrons</u>	x	x
<u>Chiridotea caeca</u>	x	
<u>Edotea triloba</u>	x	x

Appendix 1 (continued)

Species list for December 1972  
and June 1973 benthic stations

	<u>December</u>	<u>June</u>
<u>Ampelisca verrilli</u>		x
<u>Ampelisca abdita</u>	x	
<u>Ampelisca vadorum</u>	x	
<u>Leptocheirus plumulosus</u>	x	x
<u>Corophium lacustre</u>	x	x
<u>Corophium tubesculatum</u>	x	
<u>Unciola irrorata</u>	x	x
<u>Elasmopus levis</u>	x	
<u>Melita nitida</u>	x	
<u>Listrella clymenellae</u>	x	x
<u>Monoculodes edwardsi</u>	x	x
<u>Paraphoxus epistomus</u>	x	x
<u>Symplyctes glaber</u>	x	x
<u>Caprella penantis</u>	x	x
<u>Paracaprella tenuis</u>	x	x
<u>Palaemonete vulgaris</u>	x	
<u>Ogryrides limnicola</u>	x	
<u>Crangon septemspinosa</u>	x	x
<u>Upogebia affinis</u>	x	
<u>Pagurus longicarpus</u>	x	x
<u>Callinectes sapidus</u>	x	
<u>Neopanope sayi</u>	x	x
<u>Panopeus herbstii</u>	x	
<u>Pinnixa sp.</u>	x	
<u>Pinnotheres ostreum</u>	x	x
<u>Rhithropanopeus harrisii</u>		x
<u>Stenothoe sp.</u>		x
<u>Gammarus mucronatus</u>		x
<u>Corophium acherusicum</u>		x
<u>Ampithoe valida</u>		x
<u>Ampithoe longimana</u>		x
<u>Erichsonella filiformis</u>		x
ECTOPROCTA		
<u>Aeuerrillia armata</u>	x	x
<u>Anguinella palmata</u>	x	x
<u>Electra membranacea</u>	x	x
PHORONIDA		
<u>Phoronis architecta</u>	x	x
