Background. Emergency medical service (EMS) personnel are exposed to high levels of psychological, physical and emotional stressors. There has been an increase in stimulant use among healthcare professionals worldwide. There is a paucity of data pertaining to the use of stimulant products among EMS personnel in South Africa (SA).

Objectives. To determine the prevalence of and other aspects pertaining to use of stimulant products among EMS personnel in Gauteng Province, SA.

Methods. A prospective cross-sectional study using a questionnaire-based model was used to survey EMS personnel in Gauteng.

Results. Of the 315 respondents who completed the questionnaire, 310 (98.4%) reported use of stimulant products, 295 (93.7%) consumed tea/coffee, 187 (59.4%) consumed commercial energy drinks, 60 (19.0%) used caffeinated energy-enhancing tablets, 14 (4.4%) used non-caffeinated prescription stimulant medications, 50 (15.9%) used illicit drugs, 134 (42.5%) exceeded the recommended daily allowance (RDA) of caffeine, 201 (63.8%) exceeded the RDA of sugar, 231 (73.3%) experienced difficulty remaining awake during a shift, 148 (47.8%) used stimulants off shift, and 71 (22.5%) experienced insomnia. Common reasons for use of stimulants were enjoyment ($n=218$; 69.2%), to stay awake ($n=125$; 39.7%) and improvement of physical and mental performance ($n=94$; 29.8%).

Conclusions. The high prevalence of stimulant use among respondents is a cause for concern. Strategies to address it should be aimed at promoting awareness and education, improving working conditions, enhancing support structures, and regulating the stimulant content of commercial products.

S Afr Med J 2021;111(6):587-590. <https://doi.org/10.7196/SAMJ.2021.v111i6.15465>

Stimulants such as caffeine, nicotine, methylphenidate, cocaine and methamphetamines are a class of drugs that have the ability to stimulate the central nervous system and thereby enhance cognitive and/or physical functionality.^[1-3] Owing to their dominant psychotropic properties, which include mood enhancement, increased perception and cognition, these substances have also been described as 'psychostimulants'.^[3]

It is estimated that ~85% of adults in the USA consume caffeine daily, with coffee being the most commonly consumed caffeinated beverage.^[2] In 2006, a global increase in energy drink sales and consumption was noted, with ~500 new energy drinks being released into the market.^[1] The consumption of coffee and energy drinks in SA is on the increase as the country adapts to growing trends worldwide.^[4]

The estimated amount of caffeine per serving in commonly consumed products varies considerably, with energy drinks (71 - 422 mg) and over-the-counter stimulant medications (32 - 200 mg) having the highest content, followed by coffee (40 - 108 mg), sodas (25 - 55 mg) and tea (9 - 50 mg). Caffeine consumed in doses between 85 and 200 mg may decrease fatigue and increase alertness; however, the downside of caffeine consumption to combat fatigue is that once arousal from caffeine's effect becomes too high, performance decreases significantly.^[2] Excessive use of caffeine, exceeding 200 mg per serving or 400 mg per day, may result in caffeine toxicity, which manifests with tremors, insomnia, seizures, hypokalaemia and other effects resulting from hyperstimulation of the cardiovascular, gastrointestinal and central nervous systems.^[1,5,6] Other studies have also linked the consumption of energy products

to changes in blood pressure, sudden cardiac death, elevated creatinine, an increase in platelet aggregation, and endothelial dysfunction.^[6-8]

In addition to caffeine, energy drinks and other stimulant-containing products contain large amounts of sugar,^[5,6] with some energy drink brands containing as much as 20 teaspoons of sugar per 500 mL.^[4] This high sugar content far exceeds the World Health Organization's recommended daily allowance (RDA) of 6 - 12 teaspoons of sugar per day for adults.^[9] These high quantities of sugar increase the risk of developing lifestyle-related diseases such as diabetes mellitus, renal insufficiency, obesity and dental decay.^[5,10] Some products also contain a cocktail of other physical and mental enhancers such as guarana, taurine, ginseng and other herbs, which may also potentiate the adverse health effects of excessive caffeine consumption.^[11]

Prolonged and excessive use of stimulants may pose a health risk, and impact negatively on patient management and care.^[12] There has been an increase in stimulant and illicit drug use in the medical fraternity.^[13] The use of caffeine and other stimulant products by healthcare professionals to combat fatigue and maintain physical and cognitive function while on duty has been well documented.^[2,14] In addition, the use of prescription stimulant medications such as methylphenidate, pemoline and modafinil, which mimic the effects of caffeine, is on the increase among medical practitioners and medical students.^[12,15] Stimulant use among emergency medical service (EMS) personnel, the military and other shift workers has been shown to be much higher than in the general population.^[10] In SA, there is no legislation pertaining to the maximum amount

of caffeine that is allowed in stimulant energy drinks, only that the products must have a warning when the amount is over 150 mg/L.^[4]

EMS personnel are regularly faced with high levels of psychological, physical and emotional stressors in their work and personal lives.^[16] Ongoing exposure to these stressors may exacerbate health ailments, predispose to substance abuse and impair work performance, thereby affecting patient care.^[17,18]

Objectives

There is a paucity of data pertaining to the use of stimulant products among EMS personnel in SA. We hypothesised that there is a high prevalence of stimulant use in this group. Our objective was therefore to determine the prevalence of and other aspects pertaining to the use of stimulant products among EMS personnel in Gauteng Province, SA.

Methods

This was a prospective, questionnaire-based cross-sectional study conducted between 1 May and 16 October 2019. The study population comprised EMS personnel employed at one of seven EMS providers in two metropolitan municipalities in Gauteng. Permission to conduct the study was obtained from each of the service providers, while ethics clearance was obtained from the University of Witwatersrand Human Research Ethics Committee (ref. no. M181116).

Data were collected by the primary investigator (L-RvR), who attended continuing medical education events as well as approaching potential participants at the various operation bases. To ensure that

all shifts were adequately represented, data collection was conducted during both day and night shifts. Potential participants were first given a study information sheet that outlined the study objectives, and thereafter a quick response link to the online questionnaire. Study consent was automatically assumed when participants chose to complete the survey.

The questionnaire included questions pertaining to gender, experience, qualifications, difficulty staying awake during a shift, insomnia, and aspects pertaining to stimulant consumption, including the quantity of various stimulant products consumed, use of illicit drugs, reasons for stimulant consumption and increasing frequency of stimulant consumption. Data pertaining to the quantity of stimulant consumption were used to calculate the percentage of the RDA for caffeine and sugar.

Data were electronically captured into a data collection sheet that was created in the RedCap system.^[19] Captured data were thereafter exported to Excel (Microsoft 365, USA) for further analysis. Relevant data were tabulated and described using frequencies and percentages.

Results

Of the total of 501 EMS personnel who were approached, 315 completed the questionnaire, giving a response rate of 62.9%. Table 1 describes the characteristics of the study participants, including perceptions relating to stimulant use. Of note, most participants were male ($n=226$; 71.1%), had >10 years of EMS experience ($n=125$; 39.7%) and had an advanced-level qualification ($n=133$; 42.2%).

Table 1. Characteristics and perceptions of study participants (N=315)

Characteristics	n (%)
Male	226 (71.7)
Experience (years)	
≤5	104 (33.0)
6 - 10	86 (27.3)
>10	125 (39.7)
Qualifications	
Basic-level qualification	76 (24.1)
Intermediate-level qualification	106 (33.7)
Advanced-level qualification*	133 (42.2)
Consumption of stimulant-containing products	310 (98.4)
Caffeinated beverages (tea/coffee)	295 (93.7)
Caffeinated commercial energy drinks†	187 (59.4)
Caffeinated-energy enhancing tablets‡	60 (19.0)
Non-caffeinated prescription stimulant medication§	14 (4.4)
Use of illicit drugs¶	50 (15.9)
Exceeded RDA of caffeine	134 (42.5)
Exceeded RDA of sugar	201 (63.8)
Difficulty staying awake during shift	231 (73.3)
Use of stimulants off shift	148 (47.8)
Experiences insomnia	71 (22.5)
Perceives that insomnia is secondary to stimulant use	33 (10.5)
Perceives that stimulant use among EMS personnel is a problem	252 (80.0)
Unaware that some regularly consumed products contain stimulants	87 (27.6)
Required hospital admission due to excessive stimulant use	5 (1.6)
Experiences withdrawal symptoms if adequate amount of stimulant not consumed	97 (30.8)
Perceived increased risk of health complications from excessive stimulant use	298 (94.6)

RDA = recommended daily allowance.

*Emergency Care Technician, Critical Care Assistant, Advanced Life Support, Dip EMC, National Diploma in Emergency Medical Care, Emergency Care Practitioner.

†Monster, Red Bull, Rockstar, Dragon, Mofire, Wicked, Switch, Play.

‡Regmakers, Bioplus, Stay Awake, Macnabs, Berocca, Rapid Energy.

§Methylphenidate (Ritalin, Concerta), modafinil.

¶Marijuana, cocaine, amphetamines, methamphetamines, methcathinone (cat), 3,4-methylenedioxymethamphetamine (MDMA).

More than half the participants ($n=187$; 59.4%) reported consumption of caffeinated commercial energy drinks, while approximately one-fifth ($n=60$; 19.0%) reported consumption of caffeinated energy-enhancing tablets. Monster was the most commonly consumed caffeinated commercial energy drink ($n=111$; 35.2%). Among the 50 participants (15.9%) who reported use of illicit substances, marijuana was most commonly used ($n=43$; 13.7%). The RDA of caffeine and sugar was exceeded by 134 (42.5%) and 210 (63.8%) participants, respectively.

Almost three-quarters of the participants ($n=231$; 73.3%) reported experiencing difficulty in remaining awake during their shifts, while 252 (80.0%) perceived that stimulant use among EMS personnel was a problem and 87 (27.6%) were unaware that regularly consumed products contained stimulants.

Almost a third of the participants ($n=97$; 30.8%) reported experiencing withdrawal symptoms if adequate amounts of stimulant were not consumed. Overall, most subjects ($n=298$; 94.6%) perceived that excessive stimulant intake increases the risk of developing health complications.

Table 2 describes the reasons for stimulant consumption as well as reasons for the increasing frequency of stimulant consumption over time. Enjoyment ($n=218$; 69.2%) and to stay awake or alert ($n=125$; 39.7%) were the most common reported reasons for stimulant consumption. Among the 111 participants (35.2%) who reported an increase in the frequency of stimulant consumption over time, to combat stress ($n=85$; 76.6%) and to cope with an increase in the intensity of work ($n=54$; 48.6%) were given as the most common reasons.

Discussion

Although studies have reported on caffeine and other stimulant use among healthcare workers in general,^[20-22] there is a paucity of data pertaining to stimulant use among EMS personnel.^[10,23] Like other healthcare professionals,^[24-26] EMS personnel are susceptible to stimulant and drug use as a result of exposure to various work-related stressors.^[27,28]

Although previous studies have not specifically quantified stimulant and sugar consumption among EMS workers, consumption in the present study was excessive, with the RDA for caffeine (400 mg per day)^[29] and sugar (6 - 12 teaspoons per day)^[4,9] being exceeded by 42.5% and 63.8% of study participants, respectively. The high rates of consumption of these products among study respondents

are of concern and call for strategies to increase awareness, improve working conditions and limit use of stimulant- and sugar-containing products.

In a study that investigated predictors of stimulant use among 107 physicians in Nigeria,^[24] 92.5% of respondents were male, 27.1% had >10 years of experience, 89% reported use of stimulants, 26% used stimulants at home, 83% consumed coffee, 35.1% consumed caffeinated energy drinks, and 54.5% consumed kola nut (an edible caffeine-containing nut that is native to tropical rainforests in Africa). Among the reasons given, 55% used stimulants to keep alert, 50% to stay awake, 42% for pleasure and 37% to cope with stress.^[24] Similarly, in a survey that investigated the use of neurocognitive enhancement substances among 716 EMS personnel in San Diego, USA, 86% of respondents were male, 69% reported daily use, 63% consumed marketed energy drinks, 31% consumed tea or coffee, 8% used prescription psychostimulant medications, and 72% used several products in combination. Additionally, 52% of respondents reported the presence of side-effects, while 3% had required medical attention secondary to use of these substances. The most cited reasons for use were to stay awake and to increase energy for recreational activities, while 61% believed that their job performance benefited.^[30] In comparison, in the present study, 71.7% of respondents were male, 39.7% had >10 years of experience, 98.4% used stimulant-containing products, 47.8% used stimulants off shift, 93.7% consumed tea or coffee, 59.4% consumed caffeinated commercial energy drinks, 4.4% used non-caffeinated prescription stimulant medications, 15.9% used illicit drugs, 69.2% used stimulants for enjoyment, 39.7% used stimulants to stay awake, and 29.8% used stimulants to improve their physical or mental performance.

EMS personnel have been shown to have high rates of depression, post-traumatic stress disorder and sleep disturbances, all of which have been associated with substance abuse.^[27,31] Similar to a study that investigated substance use among 206 healthcare workers in 15 health facilities in Kenya, where rates of consumption of illicit stimulants were 9.3% for marijuana and sedatives together, 8.8% for cocaine, 6.4% for amphetamine-like stimulants and 5.4% for hallucinogens,^[25] in our study, marijuana was consumed by 13.7% of respondents, cocaine by 2.5% and methamphetamines and amphetamines by 1%. In contrast, none of the respondents in the Nigerian study^[24] used illicit drugs. The authors of that study attributed this positive finding to local cultural stigmatisation.^[24]

Table 2. Reasons for stimulant consumption and increasing frequency of stimulant consumption (N=315)

	n (%)
Reasons for stimulant consumption	
Enjoyment	218 (69.2)
To stay awake/alert	125 (39.7)
To improve physical or mental performance	94 (29.8)
Cannot function without it	52 (16.5)
Not sure why	25 (7.9)
Because everyone does it	14 (4.4)
Increased frequency of stimulant consumption over time	111 (35.2)
Reasons for increased frequency of stimulant consumption (N=111)	
To combat stress	85 (76.6)
When the intensity of my work is increased	54 (48.6)
To stay awake or alert	51 (45.9)
My shifts are too long	31 (27.9)
I work too many shifts	29 (26.1)
There is no trigger for my increased consumption	13 (11.7)

Prescription stimulant medications such as methylphenidate and modafinil are frequently used by healthcare personnel to improve concentration, memory, wakefulness, motivation, energy, performance and mood.^[12] Compared with a study conducted at a medical centre in the USA, where >50% of healthcare workers tested positive on urine drug screening for prescription stimulant medications used to treat attention deficit hyperactivity disorder,^[32] only 4.4% of respondents in this study reported the use of prescription stimulant medications such as methylphenidate and modafinil. The fact that access to methylphenidate in SA is more restricted (schedule 6 drug)^[33] than in the USA (schedule 2 drug)^[34] is a probable reason for the big difference between the two studies.

As a result of long working hours, high workloads and physical and mental demands, the prevalence of sleep disorders is high among EMS personnel.^[16] Physical and mental fatigue has been shown to affect 50% of EMS personnel in the USA,^[18] while excessive daytime sleepiness was experienced by 39.2% of EMS personnel in a study in Taiwan.^[35] In comparison, in the present study, difficulty staying awake during a shift was reported by 73.3% of respondents and insomnia by 22.5%, while 10.5% perceived that their insomnia was secondary to stimulant use. Similarly, a study investigating energy drink consumption among medical students and junior doctors in Malta reported that 31.9% of respondents experienced insomnia after consuming energy drinks.^[36]

Study limitations

Limitations of the present study are that it was a regional study conducted in Gauteng, so our findings may not be representative of other regions where work stresses, cultural values and access to various products may differ. Furthermore, other limitations that pertain to questionnaire-based studies in general, including recall bias and selective non-disclosure, are also applicable to this study.

Conclusions

This study demonstrates that the prevalence of stimulant use among EMS personnel in Gauteng, SA, is a cause for concern. Strategies that may be useful in curbing the excessive use of stimulant products among EMS and other healthcare personnel should be aimed at promoting awareness and education, improving working conditions, enhancing support structures, and regulating the stimulant content of commercial products.

Declaration. The research for this study was done in partial fulfilment of the requirements for L-RvR's MSc (Emergency Medicine) degree at the University of the Witwatersrand.
