# **Appendix**

Table 1. Overview of selected demographic and clinical moderators

| Selected moderator variables                                  | Justification   |
|---|---|
| Age<br>Level of education<br>Expectation of treatment effects | Older age, higher education, higher expectations associated with better outcomes in pain, quality of life, pain catastrophising, self-efficacy, and fatigue after face-to-face pain coping skills training [1]  |
| Gender  | Being male associated with better outcomes in pain and physical function after supervised strengthening exercises [2]   |
| Pain self-efficacy  | Higher self-efficacy associated with better outcomes in pain and quality of life after supervised neuromuscular exercise [3]  |
| BMI   | Being obese associated with better outcomes in quality of life after supervised aquatic exercise [4]  |
| Employment situation  | Chosen based on theoretical plausibility. An internet delivered intervention could be perceived as being more convenient, flexible and hence more effective by those who are employed than by those who are not employed.   |
| Pain catastrophising  | Chosen based on theoretical plausibility and indirect evidence whereby pain catastrophizing is related to pain severity, psychological and physical disability, walking speed, and poor outcomes after pain treatment [5,6]. People with lower pain catastrophising may be more likely to engage with, and adhere to, a self-management intervention. |

BMI: body mass index
