ABSTRACT

For the first time, cuprous oxide nanocubes (Cu₂O NCBs) were successfully combined with chitosan nanoparticles (CS NPs) to generate Cu₂O NCBs/CS NPs composites material with highly optical property and photocatalytic activity using a simple and eco-friendly synthetic approach at room temperature for 30 min. The synthesized Cu₂O NCBs/CS NPs were characterized by Ultraviolet-visible spectroscopy (UV-vis), Fourier transform infrared spectroscopy (FTIR), X-ray Diffraction (XRD), Transmission Electron Microscope (TEM) and Energy-dispersive X-ray spectroscopy (EDX). Results show that the Cu₂O NCBs/CS NPs composites possessed an average particle size of ~ 3 - 5 nm; in which, Cu₂O had the form of nanocubes with a size of ~ 3 - 4 nm and CS NPs had spherical shape with a size of ~ 4 - 5 nm. In addition, the composition percentages of elements presented in Cu₂O NCBs/CS NPs composites material was also investigated for photocatalytic activity applied in *p*-nitrophenol degradation. The obtained results showed that the catalytic capability of Cu₂O NCBs/CS NPs for *p*-nitrophenol reduction reached the highest efficiency of > 55% in the treatment time of 25 min, and this efficiency was higher than that of the ZnO@chitosan nanoparticles catalyst under the same conditions.

Keywords: Cuprous oxide nanocubes (Cu₂O NCBs), chitosan nanoparticles (CS NPs), cuprous oxide nanocubes/chitosan nanoparticles (Cu₂O NCBs/CS NPs) composites, photocatalytic activity, *p*-nitrophenol.

INTRODUCTION

As a side effect of the industrialization, many polluting compounds were discharged into the environment, especially the water environment. To this end, p-Nitrophenol (p-NP) is one of the most refractory and stable nitroaromatic compounds due to its resistance to chemical and biological degradation [1]. This organic toxic is widely used in the synthesis of plenty industrial and agricultural products such as pesticides, herbicides, petrochemicals, explosives, pharmaceuticals, and dyes [2 - 4]. p-NP contamination has significant effects on human and animal health. Thus, p-NP was listed as one of the priority hazardous and toxic pollutant by the U.S. Environmental Protection Agency (EPA) [5]. Various studies have been performed to reduce the content of p-NP in solution, such as photocatalytic hydrogenation [1, 6], photoelectrocatalytic [7, 8], biological degradation

[9], and metal-free catalyst [10]. In recent years, the reduction of p-NP to p-aminophenol (p-AP) have gained attention from the scientific community, since p-AP is a low toxic compound that is useful as an important intermediate in the preparation of pharmaceuticals, lubricants, and dyes [11].

Obviously, metal oxide-based semiconductor nanomaterials have received much attention due to their excellent physical and chemical properties, which can be applied in various practical fields. In particular, cuprous oxide (Cu_2O) is considered as an important *p*-type semiconductor materials because of its attractive optical properties. The bandgap energy of Cu_2O is between 1.95 - 2.2 eV [12]. Therefore, it represents a promising candidate for many applications such as photovoltaic, sensors, superconductors, and especially, photocatalysis [13].

The photocatalytic ability of Cu₂O has been extensively researched the removal of pollutants from aqueous medium such as methyl orange [9], methyl blue [10], brilliant red X-3B [11], and p-NP [12, 13]. Up to now, various studies have been devoted to the synthesis of Cu₂O nanoparticles (NPs) that adopt various morphologies such as: nanocubes [14], octahedra [14, 15], spherical particles [16], and nanowires [17]. The catalytic ability of Cu₂O is influenced by its morphology since the structure-related band gap energy is essential to their photocatalytic performance [7]. The photocatalytic activity of pure Cu₂O is very low because of the easy recombination between photo-generated electrons and holes, be oxidized or easy to aggregate to micron-size [11]. Several methods including the incorporation of Cu₂O composites with noble metal [18] and other semiconductors [19] have been developed to enhance the photocatalytic activity of pure Cu₂O under visible-light radiation. In this work, a substrate that is able to disperse and stabilize the Cu₂O NPs and enhance its photocatalytic performance has been proposed. Chitosan (CS) is one of the most commonly used natural biopolymers [20]. CS is an abundant low-cost raw material with high reproducibility and biodegradability [21]. CS NPs possess surface and interface effect, small size and quantum size effect [22]. In addition, CS NPs can be easily combined with metal ions or metal oxides to form composites (due to the existence of -NH, and -OH functional groups in the molecule). These composites have a stable structure and shape, and higher photocatalytic activity than the original metal oxide properties [23].

To the best of our knowledge, there have been no published reports concerning the synthesis of a composite material comprised of both Cu_2O nanocubes and chitosan nanoparticles (denoted here as Cu_2O NCBs/CS NPs). Herein, Cu_2O NCBs were successfully synthesized and combined with CS NPs to generate Cu_2O NCBs/CS NPs composites by a rapid and simple method. Besides, the properties characterizations of this nanocomposites material have also been analyzed. Moreover, the synthesized Cu_2O NCBs/CS NPs nanocomposites have been used as a catalyst material for the degradation of *p*-nitrophenol.

EXPERIMENTAL

Materials: Copper sulfate (CuSO₄ × 5H₂O; 99.5%), Sodium borohydride (NaBH₄; 99%), Sodium hydroxide (NaOH; 99%), and Hydrazine hydrate (N₂H₄ × 2H₂O; 99%) were purchased from Sigma-Aldrich (Merck). Acetic acid (CH₃COOH; 99%) and D-glucose (C₆H₁₂O₆ × H₂O, 99.5%) were bought from Hemidia, India. Chitosan of Vietnam; and *p*-Nitrophenol (C₆H₅NO₃, 99%) was purchased from Dengfeng Chemical Technology Co., Ltd,. All solutions were prepared with deionized water (DI H₂O) from a MilliQ system.

Preparation of cuprous oxide nanocubes (Cu₂O NCBs): Typically, 70.30 mg of $CuSO_4 \times 5H_2O$ and

0.361 g of D-glucose were dissolved in 100 mL of deionized water under vigorous stirring. After 15 min, 100 μ L of NaOH (10 M) was added dropwise into the copper sulfate solution and stirred for 15 min. Then, 200 μ L of N₂H₄ × 2H₂O (2 M) was added into the mixture and continuous stirred for 20 - 30 min. As a result, the solution color changed from blue to orange-red. Finally, the prepared-solution was centrifuged and washed several times with DI H₂O to neutral pH and re-dispersed in 15 mL of DI H₂O to use for next steps.

Preparation of chitosan nanoparticles (CS NPs): 1 g of chitosan (CS) was added into 100 mL of acetic acid (0.5% in DI H₂O) and stirred at 60 °C for 1 h. Then, 10 mL of sodium triphosphate (STPP) (1 mg/mL in DI H₂O) was mixed with as-prepared CS solution and stirred for 30 min. Finally, the prepared CS NPs solution was centrifuged and washed three times with DI H₂O to obtain CS NPs with high purity and dispersed in 100 mL of DI H₂O to use for next experiments.

Synthesis of Cu₂O NCBs/CS NPs composites: To formulate Cu₂O NCBs/CS NPs composites material, the prepared CS NPs was added to Cu₂O NCBs solution. Various volumes of CS NPs solution of respective: 100 μ L, 200 μ L, 500 μ L, and 1000 μ L was added dropwise into 5 mL of Cu₂O NCBs solution and stirred at room temperature for 30 min to obtain Cu₂O NCBs/CS NPs composites material. This Cu₂O NCBs/ CS NPs composite will be used as a photocatalyst material for *p*-nitrophenol degradation.

Scheme.1. Synthesis of Cu₂O NCBs/CS NPs nanocomposites

Catalytic activity test of Cu_2O NCBs/CS NPs composites: 30 µL of NaBH₄ (3 M) and 750 µL of *p*-nitrophenol (*p*-NP) (25 ppm) were stirred in the dark for 10 min to obtain the adsorption-desorption equilibrium. Then, under UV light (395 nm, OEM, Philips), 1.5 mL of Cu_2O NCBs/CS NPs (0.22 mg of Cu_2O NCBs loading) was added to the prepared-solution under constant stirring. The reaction was determined as soon as the catalyst was added into the solution. Consequently, the material treatment was separated by centrifugation within 2 min. On the other hand, an experiment to investigate the reduction of *p*-NP by NaBH₄ in the absence of catalyst material was also performed for comparison. The amount of lost *p*-NP was determined according to Equation 1.

$$H\% = 100. (\Delta C/C_0)$$
 (1)

Where $\Delta C = C_0 - C$ with C_0 and C are the initial and final concentrations of *p*-nitrophenol, respectively.

Instrumentation: The Cu₂O NCBs/CS NPs synthesis process was observed by recording the absorbance spectra between 200 and 900 nm on the UV-vis spectrophotometer (Thermo Scientific Evolution 60S UV-Vis spectrophotometer, USA). X-ray diffraction (XRD) was performed on a D8-Advance machine (Bruker, Germany) in the 20 range of $10^{\circ} - 80^{\circ}$.

The Fourier transform infrared (FT-IR) spectra were obtained by Perkin Elmer Frontier MIR/NIR (Perkin Elmer, USA) in the range of 4000 - 400 cm⁻¹. Transmission electron microscopy (TEM) characterization was performed on a Jem1010 device (Joel Company, Japan). Chemical properties and constituent components were analyzed via Energydispersive X-ray spectroscopy (EDX H-7593, Horiba, England).

RESULTS AND DISCUSSION

Characterization and morphology of Cu_O NCBs/ CS NPs composites: Fig. 1 shows the UV-vis result of the synthesized Cu₂O NCBs/CS NPs composites with various volumes of CS NPs solution. Obviously, the amount of CS NPs influenced the synthesis of Cu₂O NCBs/CS NPs composites. Fig. 1A (a), (b) indicate that the initial characteristic peak at 470 nm of Cu₂O NCBs shifted to the peak at 500 nm and 480 nm with higher absorption intensity corresponding to the added volume of CS NPs solution of 100 µL and 200 µL, respectively. Moreover, the absorption band in the range from 550 nm to 900 nm of Cu₂O NCBs tends to increase strongly (Fig. 1A). Besides, a band gap with energy level at 2.08 eV of the synthesized Cu₂O NCBs was converted to 2.04 eV when combined with 200 µL of CS NPs solution - as shown in Fig. 1B. Therefore, it can be confirmed that CS NPs have the ability to enhance the optical properties of Cu₂O NCBs.

When the volume of CS NPs solution is excessive, the UV spectra showed the gradual decrease and disappearance of the characteristic peak and optical absorption band of composites material (Fig. 1A (d),(e)). Due to the interaction between the excess acid in the CS NPs solution with Cu₂O NCBs to form Cu²⁺ ion or nano Cu, leading to a significant loss of Cu₂O NCBs, thereby making the optical absorbance of the material decreased.

Thus, the volume of CS NPs solution at 200 μ L was chosen as the optimal condition for the combination of CS NPs with Cu₂O NCBs to generate Cu₂O NCBs/CS NPs composites.

 - B. Graphical determination of direct optical band gap of (a) Cu₂O NCBs/CS NPs and (b) Cu₂O NCBs, respectively.

To study the structure of Cu_2O NCBs/CS NPs composites, the FTIR spectra of pure CS NPs and composites were applied (Fig. 2). The FTIR spectra of the obtained CS NPs showed characteristic oscillations at 3414 cm⁻¹ and 2926 cm⁻¹, attributed to the stretching vibration of -NH₂, -OH, and aliphatic -CH₂ and -CH₃ groups, respectively [24]. The vibration bands at 1641 cm⁻¹ and 1087 cm⁻¹ are corresponding to the bending vibrations of -NH and -OH groups.

The transformation of chemical groups in CS NPs when forming of Cu₂O NCBs/CS NPs composites was shown in Fig. 2(a). The broad absorption band between 3150-3414 cm⁻¹ became a sharp peak at 3428 cm⁻¹ due to the compression of the -OH group, possibly caused by the water molecule adsorbed on the surface of Cu₂O NCBs. Additionally, the peaks at 1641 cm⁻¹ and 1087 cm⁻¹ were shifted to 1611 cm⁻¹ and 1060 cm⁻¹, respectively, indicating that the amine functional group (-NH) and the hydroxyl group (-OH) participated in the complexation process [25]. At the same time, the narrow oscillation range from 1450-1300 cm⁻¹, which was attributed to the fluctuation of C-N bonding in CS NPs and appeared with a sharp peak at 1411 cm⁻¹ in FTIR spectra of Cu₂O NCBs/CS NPs. Besides, the characteristic absorption bands of Cu₂O NCBs were shown at 720 cm⁻¹ and 618 cm⁻¹ [7]. The bands shift in the region from 1700-700 cm⁻¹ is influenced by the absorption peak of Cu-O bonds in this region [15]. As a result, the maximum absorption peak intensity of Cu₂O NCBs/CS NPs composites are significantly changed compared to the pure CS NPs. This result was due to the strong surface interaction between CS NPs and Cu₂O NCBs.

Fig. 2. FTIR spectra of (a) Cu₂O NCBs/CS NPs composites and (b) CS NPs, respectively.

The X-ray diffraction (XRD) results of CS NPs and Cu_2O NCBs/CS NPs composites are clearly shown in Fig. 3. Fig. 3(a) shows that there are a large amounts of hydroxyl and amino groups in the structure of CS NPs. The presence of STPP induces cross-links in CS circuits to form CS NPs with amorphous structure. This result is in complete agreement with a previous work [26]. The synthesized CS NPs structure improves metal ions absorption ability of CS NPs [27].

Fig. 3. X-ray diffraction (XRD) patterns of (a) CS NPs and (b) Cu₂O NCBs/CS NPs composites, respectively.

When CS NPs was added to the Cu₂O NCBs (Fig. 3(b)), the characteristic diffraction peaks of Cu₂O were identified at six clear peaks with 20 values of 29.5°; 38°; 42.1°; 53.2°; 70°; and 76.18°, corresponding to the crystal planes (110); (111); (200); (211); (311); and (222). These diffraction peaks completely coincide with the Cu₂O NCBs structure (JCPDS Card No. 05-0667) [28]. In addition, no other diffraction peaks arising from possible impurities such as Cu, CuO or Cu(OH)₂ were detected, thus, confirming the formation of pure Cu₂O NPs [24]. The increase in the intensity of the diffraction

peak between Cu₂O NCBs/CS NPs composites and CS NPs was caused by diffraction/interlacing between the amorphous structure of CS NPs and the crystal structure of Cu₂O NCBs. This change of CS NPs represents a successful interaction/binding between CS NPs and Cu₂O NCBs to form Cu₂O NCBs/CS NPs composites.

Fig. 4A. TEM image of Cu₂O NCBs/CS NPs composites; B. Particle size distribution of Cu₂O NCBs/CS NPs composites, respectively.

The morphology and size of the product was studied by TEM, Fig. 4A. The result shows that Cu_2O NCBs have the cubic structure with an average particle size ~3 - 4 nm; and CS NPs have spherical shape with an average particle size ~4 - 5 nm. Thus, the synthesized Cu_2O NCBs/CS NPs composites have an average particle size of ~3 - 5 nm (Fig. 4B). Additionally, the Cu_2O NCBs/CS NPs composites particles were uniformly distributed and dispersed without agglomeration.

Fig. 5. Energy dispersive X-ray (EDX) spectra of Cu₂O NCBs/CS NPs composites.

EDX analysis was used to determine the composition of the synthesized Cu_2O NCBs/CS NPs composites sample. Fig. 5 shows that the Cu_2O NCBs/CS NPs composites comprised elemental compositions including: Cu (23.99%), O (38.18%), C (33.61%), and other elements like N and P. These results indicated that the presence of Cu_2O NCBs and CS NPs in the synthesized Cu_2O NCBs/CS NPs nanocomposites sample.

Photocatalytic activity of Cu₂O NCBs/CS NPs composites for p-nitrophenol degradation: The reduction of p-NP by NaBH, without using photocatalytic is presented in Fig. 6. Firstly, the UVvis spectrum (Fig. 6(a)) indicated that the absorption wavelength of the initial p-NP was shifted from 317 to 400 nm immediately upon the addition of NaBH, corresponding to a significant change in solution color from light yellow to yellow-green due to the formation of 4-nitrophenolate ion. The reduction of p-NP by NaBH, is thermodynamically feasible but possesses a high kinetic impediment between negative ions that repel each other between p-nitrophenolate and BH_{4} in the absence of an effective catalyst [29, 30].

Fig. 6. UV-vis spectra of p-nitrophenol (p-NP) reduction without photocatalysts.

Fig. 7. UV-vis spectra of *p*-nitrophenol reduction with various reaction times using Cu₂O NCBs/CS NPs composites as a photocatalyst material.

As showed in Fig. 6(c), the yellow-green decolorization of the *p*-NP solution after 6 h has no significant change

compared to that at the initial time. The decomposition percentage of p-NP after 6 h in the absence of catalyst was only 3.68%. This represented an extremely slow reaction rate in the absence of a catalyst. Using different catalysts in this reaction could yield disparate results due to the fact that many oxides are also unable to degrade p-NP under different reaction conditions [29]. In the presence of Cu₂O NCBs/CS NPs composites catalyst, the results of p-NP degradation (Fig. 7) are significantly different from those of NaBH, without catalytic materials. The absorption peak at 400 nm of *p*-nitrophenolate ions was gradually decreased in intensity. At the same time, there was the formation and intensification of another absorption peak at 300 nm, which is the characteristic absorption peak of p-aminophenol (p-AP). Therefore, it is demonstrated that there was a conversion from p-NP to p-AP in the presence of Cu₂O NCBs/CS NPs.

Fig. 8. Decomposition percent versus reaction time for the reduction of *p*-NP over (a) blank sample without catalyst and (b) using Cu₂O NCBs/CS NPs composites catalyst, respectively.

Meanwhile, the color of solution also showed that p-NP was reduced in the reaction, the characteristic yellow color of p-nitrophenolate ion was lost and changed to a clear solution of *p*-AP. Indeed, the results of the graph in Fig. 8 show that in the presence of Cu₂O NCBs/CS NPs photocatalysts, the higher the reaction time, the greater the percentage loss of *p*-nitrophenolate ions. The percentage (%) of p-NP decomposition in 1 min was 37.92 %. After 25 min, this value was ~55.72 % (Fig. 8). Thus, it is confirmed that the positive charges on the Cu₂O NCBs/CS NPs composites' surfaces facilitated the interaction between nitrophenolate and BH, ions. At the same time, the inactivity of ZnO@CS NPs in this reaction can be attributed to the absence of electron relay process. In addtion, the bandgap energy of Cu₂O NCBs/CS NPs (2.04 eV) is lower than that of ZnO@ CS NPs (3.06 eV) and the existence of copper (Cu) metal on the surface of Cu₂O NCBs made the electron transfer occur faster. This result was completely consistent with previous studies [29].

CONCLUSIONS

Cu_oO NCBs/CS NPs composites have been successfully synthesized by simple physical mixing between Cu₂O NCBs and CS NPs at room temperature for 30 min. Cu₂O NCBs/CS NPs composites have an average particle size ~ 3 - 5 nm; in which, Cu₂O NCBs have the form of cubic particles (Cu₂O nanocubes -Cu_oO NCBs) with a dimension of $\sim 3^{-}$ 4 nm and CS NPs have spherical shape with a particle size of ~ 4 - 5 nm. Besides, the percent (%) composition of elements presented in Cu₂O NCBs/CS NPs composites material are as followed: Cu (23.99%), O (38.18%), C (33.61%) and other elements. Furthermore, the Cu₂O NCBs/CS NPs composite is confirmed as a potential and promising photocatalyst material for *p*-nitrophenol reduction with a treatment efficiency of > 55% at a treatment time of 25 min. Thus, this study has proposed a cheap nanocomposites catalyst instead of an expensive noble material system in the treatment of *p*-nitrophenol for the environmental problems.
