**20 ABSTRACT**

21 Puberty is a complex process that culminates in the acquisition of psychophysical maturity and  
22 reproductive capacity. This elaborate and fascinating process marks the end of childhood. Behind  
23 it lies a complex, genetically mediated neuroendocrine mechanism through which the gonads are  
24 activated thanks to the fine balance between central inhibitory and stimulating neuromodulators  
25 and hormones with both central and peripheral action. The onset of puberty involves the  
26 reactivation of the hypothalamic-pituitary-gonadal (HPG) axis, supported by the initial “kiss”  
27 between kisspeptin and the hypothalamic neurons that secrete GnRH (the GnRH “pulse  
28 generator”). This pulsatile production of GnRH is followed by a rise in LH and, consequently, in  
29 gonadal steroids.

30 The onset of puberty varies naturally between individuals, and especially between males and  
31 females, in the latter of whom it is typically earlier. However, pathological variations, namely  
32 precocious and delayed puberty, are also possible. This article reviews the scientific literature on  
33 the physiological mechanisms of puberty and the main pathophysiological aspects of its onset.

## 43        **1. INTRODUCTION**

44        The term “puberty” refers to a set of psycho-neuro-endocrine changes that occur between the end  
45        of childhood and the achievement of final height and complete sexual maturation, resulting in  
46        sexual dimorphism and the production of gametes. This process is specific to species that  
47        procreate by sexual reproduction. The normal duration of puberty is about 5-6 years. The onset of  
48        puberty is significantly later in males than in females. In females, the first signs are normally seen  
49        at between 8.5 years and 12.5 years (on average 10.5 years), compared with between 9.5 and 13.5  
50        years (on average 11.5 years) in males. Several factors can influence the timing of puberty onset,  
51        giving rise to precocious puberty or delayed puberty (Marshall & Tanner, 1969 and 1970).

52        All the clinical modifications that occur during puberty are the direct consequence of  
53        hypothalamic-pituitary-gonadal axis (HPG) activation, involving an increase in gonadotropin-  
54        releasing hormone (GnRH) pulsatility and, consequently, in follicle-stimulating hormone (FSH),  
55        luteinizing hormone (LH) and gonadal steroids. The purpose of this paper is to carry out a review  
56        of the literature regarding the physiological mechanisms of the HPG axis that lead to pubertal  
57        activation and the factors that influence the timing of puberty. It is also described a detailed  
58        analysis of the main pathophysiological and clinical aspects of puberty.

59

## 60        **2. WHEN DOES THE ACTIVITY OF THE HPG AXIS BEGIN?**

61        The HPG axis has three activation periods: during foetal life, with a peak between mid-gestation  
62        and subsequent decrease towards the end of pregnancy; after birth, between the first week of life  
63        and six-nine months, the period classically known as mini-puberty; and after childhood, with the  
64        onset of puberty (Guimiot et al., 2012). During embryogenesis, and in particular at around 40 days  
65        of gestation, the neurons that secrete GnRH originate from the epithelium of the medial olfactory

66 pit and migrate along nerve fibres to the foetal hypothalamus (Schwanzel-Fukada et al., 1989;  
67 Crossin et al., 1996).

68 The pituitary hormones FSH and LH, known as gonadotropins, begin to be detectable in the  
69 anterior pituitary and general circulation at 9 weeks of gestation (Kaplan et al., 1976; Clements et  
70 al., 1976). Hypothalamic input is probably required to maintain this secretion and to exert trophic  
71 effects on the pituitary gonadotropes. The regulation of foetal GnRH neuron activity also includes  
72 kisspeptin and KISS1R but the secretion of gonadotropins only becomes GnRH-dependent from 30-  
73 31 weeks of gestation (Guimiot et al., 2012).

74 Changes in LH and FSH concentrations during pregnancy are crucial for the activation of peripheral  
75 hormones involved in the maturation of the ovaries and testicles. Males and females have  
76 different gonadotropin concentrations throughout gestation. The first major difference is that  
77 females have a higher proportion of FSH than LH compared to males (Beck-Peccoz et al., 1991).  
78 During the first half of pregnancy, female foetuses have a greater concentration of both LH and  
79 FSH than males. This is probably due to the greater negative feedback exerted by testicular  
80 hormones in male foetuses (Clements et al., 1976; Kaplan et al., 1976; Reyes et al., 1973), or to a  
81 different sex steroid receptors expression between male and female foetuses. During the first  
82 trimester of pregnancy, placental hCG (peak around 8-12 weeks) plays an essential role in  
83 determining an increase in gonadal production of testosterone in male foetuses, thanks to its LH-  
84 like effect. This placental hCG-dependent testosterone increase allows the male differentiation of  
85 the foetus (i.e. masculinization of genitalia), showing that gonadotropins do not play a decisive  
86 role in sexual differentiation during the first trimester of pregnancy. However, in those rare cases  
87 of congenital absence of LH (LHB subunit), ambiguous genitalia do not occur. Instead, this  
88 condition is present in those rare forms of the receptor (LHCGR) or steroidogenic enzymes  
89 mutations.

90 Subsequently, in mid-pregnancy, female foetuses show a higher peak of FSH and LH levels than  
91 males, comparable to that seen in the menopause or in women with hypergonadotropic  
92 hypogonadism. Peak levels are accompanied by the first maturation of the ovarian follicles, in  
93 females, and the seminiferous tubules, in males. Their concentrations then drop gradually and are  
94 practically suppressed at birth (Massa et al., 1992). However, the maturation of ovarian follicles in  
95 female foetuses does not seem to be linked uniquely and directly to a pituitary stimulation, as a  
96 follicular production in foetuses with anencephaly, a condition in which gonadotropins are not  
97 produced given the absence of the pituitary gland, has been also described (Baker et al., 1980;  
98 Bizzarri & Cappa, 2020).

99 In the final period of gestation, there is a considerable increase in placental secretion of  
100 oestrogens to determine a suppression of the foetal HPG axis, and therefore a decrease of both  
101 gonadotropins (Kuijper et al., 2013). Immediately after birth, the high concentration of placental  
102 hormones endures, and continue to exert a negative feedback action on the hypothalamic GnRH.  
103 After a few days it begins to drop, unlocking the secretion of GnRH itself. Consequently,  
104 gonadotropin levels begin to increase about a week to 10 days after birth (Bergadá et al., 2006;  
105 Schmidt et al., 2000), giving rise to the so-called mini-puberty. As in gestation, the secretion of  
106 gonadotropins and gonadal steroids also differs between males and females during mini-puberty.  
107 Males, unlike females, have higher concentrations of LH than FSH, peaking between the second  
108 and tenth week of life, but also have an earlier reduction in these hormones, which usually return  
109 to suppression values at around 4-6 months (Kuiiri-Hänninen et al., 2011). The trend of  
110 testosterone in males exactly reflects that of LH.

111 In females, gonadotropins peak between the first and the third month of postnatal life, similarly to  
112 males, but remain measurable for up to 3-4 years (Winter et al., 1975; Kuiiri-Hänninen et al., 2011).

113 Oestradiol levels show greater fluctuations than testosterone, and begin to drop at around the

114 sixth month of life (Schmidt et al., 2002; Chellakooty et al., 2003; Bidlingmaier et al., 1987). All  
115 these hormonal variations in both males and females are essential for postnatal gonadal  
116 maturation.

117 After mini-puberty, the HPG axis remains quiescent throughout childhood in both males and  
118 females, through a mechanism which is still unknown. It then reactivates upon the onset of  
119 puberty.

120

### 121 **3. ONSET OF PUBERTY: THE GnRH PULSE GENERATOR, THE KND $\gamma$ SYSTEM, EXCITATORY AND** 122 **INHIBITORY NEUROMODULATORS**

123 The increased frequency and amplitude of GnRH release from the hypothalamus to the  
124 hypophyseal portal system triggers the anterior pituitary secretion, thereby promoting the onset  
125 of pulsatile LH secretion.

126 The hypothalamic neural substrate that generates the pulsatile GnRH release is known as the  
127 “GnRH pulse generator”, a term first coined in the early 80s (Pohl & Knobil, 1982).

128 In 2003, two independent groups reported that a mutation causing loss of GPR54 receptor  
129 (otherwise known as KISS1R) function resulted in hypogonadotropic hypogonadism in both males  
130 and females (De Roux et al., 2003; Seminara et al., 2003). The KISS1R ligand, better known as  
131 kisspeptin, is a peptide of 54 amino acids, first discovered as a tumour suppressor (Ohtaki et al.,  
132 2001). Other studies demonstrated that KISS1 gene inactivation results in the failure of pubertal  
133 progression (Topaloglu et al., 2012), further stressing the importance of this gene in pubertal  
134 development. In 1997, De Roux et al. described a case of familiar idiopathic hypogonadotropic  
135 hypogonadism related to compound heterozygous mutation of the GnRH-receptor gene (GNRHR),  
136 who presented only a partial progression of pubertal development (De Roux et al., 1997). Twelve  
137 years later, another gene, whose homozygous mutation was responsible for idiopathic

138 hypogonadotropic hypogonadism, was identified. Specifically, this gene encoded gonadotropin-  
139 releasing hormone 1 (GNRH1), and its mutation was found in two teenage siblings whose parents  
140 were heterozygous, and therefore not affected (Bouligand et al., 2009).

141 Studies on female rodents allowed the localization of two main groups of kisspeptin neurons in the  
142 hypothalamus. The largest is located in the arcuate nucleus (ARC), while the other is clustered in  
143 the preoptic area of the third ventricle (POA) in non-rodents (including humans), and in the  
144 anteroventral periventricular nucleus (AVPV) in rodents (Lehman et al., 2013). These two different  
145 populations of neurons could play different roles in the activation of the HPG axis (Pinilla et al.,  
146 2012): ARC kisspeptin neurons seem to have a negative feedback control on gonadotropin release,  
147 while POA neurons have a positive feedback.

148 Kisspeptin is a highly powerful GnRH secretagogue released from the ARC through a complex  
149 neuronal network that also involves other neuromodulators, some stimulating its secretion, and  
150 others inhibiting it. The stimulatory neuromodulators include neurokinin B (NKB), encoded by the  
151 tachykinin 3 (TAC3) gene (Herbison, 2015). In 2009, Topaloglu et al. found that mutations involving  
152 loss of function of the genes encoding the TAC3 gene (coding NKB) or the TACR3 gene (coding NKB  
153 receptor) were responsible for the failure of pubertal development and the onset of  
154 hypogonadotropic hypogonadism (Topaloglu et al., 2009). As a result, NKB was thought to  
155 stimulate the release of GnRH through kiss1 neurons.

156 Goodman et al. demonstrated that kisspeptin/NKB neurons in the ARC of sheep co-express a third  
157 peptide called dynorphin (Dyn). This endogenous opioid peptide, encoded by the prodynorphin  
158 gene, inhibits the secretion of kisspeptin (Goodman et al., 2007). This was confirmed by a later  
159 study demonstrating that the administration of a dynorphin receptor antagonist resulted in early  
160 puberty onset (Nakahara et al., 2013).

161 Given the interconnection between the two neuromodulators NKB and Dyn and kisspeptin, in  
162 2010 Cheng et al. coined the acronym KNDy to precisely describe the set of neurons involved in  
163 the onset of puberty (Cheng et al., 2010). So, to summarise, the pulsatile secretion of GnRH is  
164 based on the coordinated activity of the KNDy neuronal network (Cheng et al., 2010), in which  
165 NKB stimulates the release of kisspeptin, while Dyn exerts an inhibitory action (Wakabayashi et al.,  
166 2010).

167 Other kisspeptin inhibitors and stimulants can be found upstream of the KNDy system. One of the  
168 key stimulants is glutamate, the main excitatory neurotransmitter in the brain, while GABA has an  
169 inhibitory effect (Clarkson et al., 2006; Watanabe et al., 2014). Studies conducted on monkeys  
170 confirmed the opposite role of these two neurotransmitters, showing that GABA levels gradually  
171 decrease before puberty, while glutamate levels are high at the beginning of puberty, before  
172 GnRH secretion (Shamas et al., 2015; Brann et al., 2002; Kurian et al., 2012). In particular, Kurian  
173 and co-authors demonstrated that an infusion of a GABA<sub>A</sub> receptor antagonist (bicuculline) within  
174 the stalk-median eminence of pre-pubertal monkeys could cause an increased release of  
175 kisspeptin, and consequently of GnRH secretion. The Authors also showed that the same  
176 stimulatory effect was lacking in the case of contextual infusion of the kisspeptin receptor  
177 antagonist (peptide 234).

178 As for GABA, neuropeptide Y also has an inhibitory effect on the system, whose levels tend to  
179 decrease with increasing GnRH secretion (Livadas & Chrousos, 2016).

180 RFRP, a neuropeptide in the RF amide family, is also a kisspeptin inhibitor. The human homologue  
181 is the RFRP-3 variant, the administration of which induces a clear reduction in LH secretion (Khan  
182 et al., 2011).

183 Recent studies showed that mutations involving heterozygous loss of function of the makorin ring  
184 finger 3 (MKRN3) gene, involved in protein ubiquitination and cell signalling, leads to central

185 precocious puberty (Abreu et al., 2013; Christoforidis et al., 2017; Grandone et al., 2017). MKRN3  
186 is a maternal imprinted gene located on chromosome 15q11-q13, the same region involved in  
187 Prader-Willi syndrome (PWS), in which only the paternal allele is expressed (Jong et al., 1999).  
188 Specifically, loss of function mutations of the paternal allele lead to familial forms of central  
189 precocious puberty (Abreu et al., 2015). It is unknown how MKRN3 blocks puberty, however, it  
190 was found to be highly expressed before puberty within the medial basal hypothalamus of the  
191 arcuate nucleus of mice, which is the same brain areas that contain neurons secreting kisspeptin  
192 and NKB. On the contrary, its expression decreases as puberty advances (Abreu et al., 2015).  
193 Another paper by the same research group confirmed the presence of the expression of MKRN3  
194 also in rats and monkeys, and its decrease during the prepubertal period, independently of  
195 gonadal activation (Abreu et al., 2020). They also demonstrated that MKRN3 represses  
196 transcriptional activity of the KISS1 (encoding kisspeptin) and TAC3 gene (encoding NKB), through  
197 an association with the respective promoters. Another recent study found the microRNA “mir-30”  
198 as a probable repressor of MKRN3, whose increase of expression with the approach of puberty  
199 induces the reduction of the MKRN3 activity and the consequent unblock of puberty (Heras et al.,  
200 2019).

201 All these observations obtained from animal studies along with the evidence of MKRN3 mutations  
202 in humans with central precocious puberty, support the hypothesis of a strong inhibitory role of  
203 this protein on the pubertal onset. However, further studies are needed to better understand this  
204 mechanism.

205 Finally, sex steroid hormones exert inhibitory effects on both GnRH release and kisspeptin  
206 neurons. Studies on rodents showed that neuroestradiol acts in a dual mode, having an inhibitory  
207 effect in the ARC and a stimulatory effect in the AVPV nucleus (Khan & Kauffman, 2012; Kauffman,  
208 2010).

209 The onset of puberty also seems to be linked to metabolic and energy signals. Among the  
210 metabolic cues leptin, an adipocyte-derived hormone, plays a key role in regulating appetite and  
211 food intake and is essential for GnRH pulsatility via the KISS1 system (Sanchez-Garrido & Tena-  
212 Sempere, 2013; Zhang et al., 1994). In fact, states of nutritional deprivation and/or leptin  
213 deficiency reduce hypothalamic KISS1 expression and delay or prevent puberty (Castellano &  
214 Tena-Sempere, 2016). Another important metabolic hormone is ghrelin, a peptide secreted  
215 predominantly by the stomach, whose concentrations increase during fasting. Ghrelin cooperates  
216 with leptin in the control of puberty, but inhibits GnRH and LH release; the exact mechanisms  
217 underlying this regulation are still unknown (Sanchez-Garrido & Tena-Sempere, 2013; Tena-  
218 Sempere, 2013; Zhang et al., 1994).

219 A new neuroendocrine factor, involved in regulating food intake and therefore implicated in the  
220 release of gonadotropins and consequent onset of puberty, is known as pituitary adenylate  
221 cyclase-activating polypeptide (PACAP). The role of this polypeptide is not entirely clear yet, as it  
222 seems to exert both stimulator and inhibitor effects to the release of gonadotropins in rodents  
223 (Szabó et al., 2002). Since PACAP was found in the ventromedial hypothalamus nuclei involved in  
224 metabolic and reproductive functions, it could represent a direct or indirect leptin mediator, and  
225 be involved in its metabolic role (Tanida et al., 2013). Some studies showed that PACAP is also  
226 highly expressed at the ventral pre-mammillary nucleus. In particular, Ross and co-authors  
227 demonstrated that a high percentage of leptin-responsive neurons of the ventral pre-mammillary  
228 nucleus express PACAP, thus highlighting a central role in the direct modulation of neurons  
229 secreting kisspeptin. Its pivotal role on the pubertal onset is confirmed by studies on female mice,  
230 which showed that the PACAP removal from this population of neurons leads to a delay in the  
231 vaginal opening and first oestrus (Ross et al., 2018).

232 Table 1 provides a systematic list of all above-mentioned molecular mediators, with their  
233 respective inhibitory or excitatory effect on HPG axis.

234

#### 235 **4. MECHANISM OF ACTION OF GnRH AND GONADOTROPINS**

236 Once the HPG axis is activated, the GnRH released from the hypothalamus binds a G-protein  
237 coupled receptor (GnRH-R receptor, 60 KDa) on the surface of the pituitary gonadotropin-  
238 secreting cells. The ligand binding and the consequent heterotrimeric G proteins activation  
239 triggers a mechanism that leads to the arousal of a phosphatidylinositol-calcium second  
240 messenger, which results in the synthesis and episodic secretion of both FSH and LH (Flanagan &  
241 Manilall et al., 2017).

242 The pulsatile release of GnRH alters the secretion patterns of pituitary gonadotropic cells. An  
243 increased frequency promotes the secretion of LH, while a lower frequency favours the release of  
244 FSH (Savoy-Moore & Swartz, 1987; Wildt et al., 1981). Continuous exposure to GnRH leads to  
245 downregulation of GnRH receptors and a decrease in gonadotropin synthesis and secretion  
246 (Rispoli & Nett, 2005). Gonadotropin synthesis is controlled by the transcription of the distinct  $\beta$ -  
247 subunits. FSH and LH contain a common  $\alpha$ -subunit, but it is FSH $\beta$  and LH $\beta$  that produce the specific  
248 actions of gonadotropins (Childs et al., 1990). Like FSH and LH secretion, the transcription of the  
249 gonadotropin subunits is dependent on GnRH pulse frequency (Dalkin et al., 1989; Haisenleder et  
250 al., 1991; Kaiser et al., 1997).

251 In males FSH binds to receptors on the surface of Sertoli cells, activating proteins that regulate  
252 gene expression and the production of Sertoli cell proteins. These play important roles in  
253 supporting and regulating spermatogenesis within the seminiferous tubules (Rannikko et al.,  
254 1996). LH acts on Leydig cells to stimulate testosterone production, the main sex steroid hormone  
255 in males (Veldhuis et al., 1987).

256 In females, LH is essential for ovulation and the sustenance of corpus luteum function. It also  
257 contributes to follicular function and plays a key role in androgen production. FSH regulates  
258 oestradiol production in the granulosa cells and is the main promoter of follicular growth; in more  
259 advanced phases of follicular development, it synergizes with LH. (Richards & Pangas, 2010).

260

## 261 **5. EFFECT OF ENDOCRINE DISRUPTOR CHEMICALS ON PUBERTAL ONSET**

262 An endocrine disruptor chemical (EDC) is an exogenous substance or mixture that affects  
263 endocrine system function. Several works published in the early 2000s evaluated the effect of  
264 EDCs on the development of pubertal signs in girls and boys, such as age at menarche in girls,  
265 testicular volume increase in boys, and pubertal Tanner stages in both sexes. Most of these studies  
266 investigated girls, with few addressing male puberty. It is known that the EDCs interact with the  
267 organism through multiple mechanisms related to their hormone-like structural characteristics;  
268 among these, the direct interaction with the hormonal receptor or the post-receptor bio-synthetic  
269 pathways, the suppression of hormonal synthesis, and the direct toxic effects are the most  
270 significant. Regarding their influence on puberty, the androgenic, oestrogenic, anti-androgenic or  
271 anti-oestrogenic effects are crucial. Specifically, androgen-like and anti-oestrogenic effects are  
272 essentially related to the inhibition of aromatase activity; the oestrogen-like effect may occur  
273 through the stimulation of aromatase activity or direct binding to the oestrogen receptor; the anti-  
274 androgenic effect may depend on androgen receptor blockage or steroidogenic enzyme inhibition;  
275 finally, EDCs can have a direct effect on GnRH, resulting in an increased secretion of  
276 gonadotropins. Based on the prevailing activity of the ECD, this can result in an anticipated or  
277 delayed pubertal development.

278 In 2002, Den Hond et al. evaluated 80 boys with a mean age of 17.3 years who were exposed to  
279 Polychlorinated biphenyls (PCBs) and dioxin during the pubertal period. They found a negative

280 association between elevated serum PCB and pubertal stage, particularly genital maturation and  
281 pubic hair growth. There was also an association between higher PCB exposure and lower  
282 testicular volume. In contrast, dioxin had no effect on pubertal stage (Den Hond et al., 2002).  
283 Saiyed et al. and Guo et al. also reported some interesting results. Saiyed showed an association  
284 between pubertal exposure to endosulfan and a low level of pubic hair, testis and penis  
285 maturation (Saiyed et al., 2003), while Guo found reduced penile length in 55 boys living in the  
286 Chinese city of Yucheng who had experienced prenatal exposure to polychlorinated biphenyls and  
287 polychlorinated dibenzofurans, in comparison with 55 healthy subjects (Guo et al., 2004).  
288 Many cross-sectional and longitudinal human studies have evaluated the association between the  
289 onset of puberty and prenatal or pubertal exposure to various potential endocrine disruptors. A  
290 2008 study of 15 girls and 18 boys exposed to dioxin through contaminated breast milk,  
291 demonstrated delayed breast development in the girls and delayed age at first ejaculation for the  
292 boys (Leijs et al., 2008).  
293 More recent reports include a study by Ferguson et al., who longitudinally analysed the prenatal  
294 or infantile effects of phthalates and bisphenol-A on 118 boys (aged 8–14). Prenatal exposure was  
295 negatively associated with the onset of the adrenarche and pubarche (with high SHBG levels),  
296 whilst infantile exposure also caused low testosterone levels, and hence a delay in the main signs  
297 of puberty (Ferguson et al., 2014).  
298 A similar recent study evaluated the impact of in utero phthalate and bisphenol-A exposure on  
299 sexual maturation in 109 peripubertal boys aged 8–14 years. In the first and second trimesters, in  
300 utero exposure to DEHP was linked to increased peripubertal serum oestradiol levels. In the third  
301 trimester, exposure was associated with a delay in the onset of pubarche, with increased SHBG  
302 levels (Watkins et al., 2017).

303 A longitudinal study conducted on 516 boys considered the effects of organochlorine chemicals,  
304 lead (Pb) and non-dioxin-like-PCBs. The authors evaluated EDC concentrations at the age of 8-9  
305 years, and subsequently carried out annual examinations until the age of 18-19. Pubertal stage  
306 and testis volume were evaluated during each clinical investigation. The main finding was that the  
307 persistence of Eds in blood negatively influenced growth during puberty; organochlorines and lead  
308 (Pb) delayed the onset of puberty, while PCBs tended to advance the timing of puberty (Sergeyev  
309 et al., 2017).

310 There are few original papers on the effects of EDCs on puberty in males, as the majority focus on  
311 female puberty. These may be because female puberty is more easily detectable, as the menarche  
312 is an undisputed sign of sexual maturation. However, the main findings from studies that do  
313 investigate the effects of EDC exposure on male puberty indicate that it is delayed. This is probably  
314 due to the oestrogenic-like effects of PCBs, PCDFs, and endosulfan. In any case, research in boys is  
315 more focused on semen quality, which is much more closely related to fertility. Table 2  
316 summarises the main EDCs' characteristics and reports studies on animals or humans about their  
317 putative role on the HPG axis dysfunction.

318

## 319 **6. EVOLUTION OF PUBERTAL STAGES, EARLY AND DELAYED PUBERTY**

320 The onset and progression of puberty are clinically evaluated by the Tanner and Marshall stages in  
321 both males and females, to document the sequence of secondary sexual character modifications  
322 (Marshall & Tanner, 1969, 1970). In males, testicular growth, mainly due to the proliferation of  
323 seminiferous tubules, is often the first sign of puberty. This is indicated when a volume greater  
324 than 3-4 mL is reached together with the growth of the scrotum; this is followed by the  
325 appearance of pubic hair and enlargement of the penis, first in length and then in breadth. The  
326 first conscious ejaculation occurs at an average age of 13.5 years and normozoospermia is

327 obtained at around a bone age of 17 years (Laron et al., 1980). Other changes that occur during  
328 puberty include vocal timbre, pubertal growth spurt and the appearance of axillary and facial hair.  
329 In a paper published in 2005 by our research group, the evolution of the male gonad during the  
330 different pubertal stages (from G1 to G5) was assessed in detail. Changes in gonadotropin, inhibin  
331 B (INHB) and testosterone concentrations were evaluated in relation to Tanner's pubertal stages  
332 and testicular volume. We found a direct correlation between INHB and FSH concentrations during  
333 pubertal stage G1 and, more generally, during the initial stages of testicular maturation. We also  
334 demonstrated a strong biphasic relationship between INHB and FSH during pubertal development,  
335 with inversion of this relationship in the mid-late stages of puberty: at this stage, (G3-G4) INHB  
336 increases as its inverse relationship with FSH is being established, leading to spermatogenesis. In  
337 addition, we found a statistically significant direct correlation between INHB and testicular volume  
338 in all pubertal stages (Radicioni et al., 2005).

339 In females, puberty culminates with the menarche, signalling the end of childhood and the  
340 beginning of reproductive capacity. The average age at menarche is 12.4 years (Lacroix &  
341 Langaker, 2019). However, the first sign of puberty in girls is breast development, that begins  
342 under the control of oestrogen at a mean age of 10 years (Klein et al., 2017). Pubic and axillary  
343 hair growth is controlled by adrenal androgens. The uterus and ovarian volumes increase, the  
344 vagina becomes longer, and the vaginal mucosa thickens and changes colour. The labia majora and  
345 minora become thickened, protruding and wrinkled. The clitoris enlarges and the urethral meatus  
346 becomes more prominent. During the first two years after the menarche, anovulatory cycles are  
347 common.

348 Pubertal growth precedes the final fusion of the growth cartilage. At the beginning of puberty,  
349 there is an acceleration in the growth rate. The peak growth in height, better known as the  
350 pubertal growth spurt, occurs during stage G3-G4 in males and G2-G3 in females. At the end of

351 puberty, gonadal steroids are responsible for the maturation and fusion of epiphyseal discs in both  
352 sexes, leading to the achievement of final height.

353 As previously mentioned, the time of onset of puberty can vary, and both precocious and delayed  
354 puberty are pathological conditions.

355 Precocious puberty (PP) is clinically defined by the appearance of the breast bud at less than eight  
356 years in girls, and by an early increase in testicular volume (cut-off 4 ml) before nine years in boys  
357 (Muir, 2006). PP is characterized by increasing growth rate, an early progression of secondary  
358 sexual characteristics and rapid bone maturation. There are two main forms:

359 Central Precocious Puberty (CPP) or Gonadotropin Dependent Precocious Puberty (GDPP). This  
360 involves early activation of the HPG axis that mimics a physiological pubertal progression. In males  
361 above all, it is associated with central nervous system (CNS) injuries such as tumours, and hence  
362 an MRI is indicated in all male subjects, while in females it is only indicated in cases of pubertal  
363 development occurring before six years of age, progressive PP, or neurologic symptoms such as  
364 headache, visual impairment or seizures (Carel & Léger, 2008);

365 Peripheral Precocious Puberty (PPP) or Gonadotropin Independent Precocious Puberty (GIPP). This  
366 is due to abnormally high production of sex steroids from gonads or adrenal glands (e.g. Leydig cell  
367 tumours, hCG-secreting tumours and ovarian tumours). It involves early development of  
368 secondary sexual characteristics and suppression of gonadotropin release by the pituitary gland.

369 Delayed Puberty (DP) is defined as the absence of breast development at 13 years old for females,  
370 and the absence of testicular volume increase over 4 mL at 14 years old for males (Palmert &  
371 Dunkel, 2012). The most common cause is a constitutional delay of growth and puberty (CDGP),  
372 which can be considered as a common normal variant of pubertal timing. This is more common in  
373 boys than in girls. The bone age (BA) is generally lower than the chronological age by 1 or 1.5  
374 years, and height is lower than normal or within the lower limits of the range considered normal

375 for that age. The Growth rate is usually normal. CDGP has a strong genetic basis, as more than 75%  
376 of patients have a family history of delayed puberty (Wehkalampi et al., 2008). The remaining  
377 cases are considered idiopathic.

378 A major challenge is the differential diagnosis between CDGP and congenital hypogonadotropic  
379 hypogonadism (cHH). Recent works provide clinical and laboratory parameters that may be helpful  
380 for the differential diagnosis, starting with the possible presence of cryptorchidism, micropenis  
381 and several congenital anomalies typically associated with cHH, such as anosmia, renal agenesis,  
382 bimanual synkinesis, cleft lip and/or palate, congenital hearing impairment and optic nerve  
383 hypoplasia (Maione et al., 2018). As regards genetics, even though there seems to be an  
384 overlapping between the two conditions, as some genes seem to be shared (e.g., TAC3 and  
385 GNRHR), it has been recently demonstrated that the genetic patterns of patients with CDGP and  
386 control population are very similar (Young et al., 2019; Howard & Dunkel, 2019). The identification  
387 of new target genes will help in discriminating the two conditions with greater certainty.

388 The use of GnRH challenge to differentiate cHH from CDGP is highly debated. Broadly, CDGP  
389 produces a greater increase in gonadotropin levels, while the response is lower or absent in the  
390 case of cHH (Harrington & Palmert, 2012). Actually, the hypothalamus-pituitary reserve of subjects  
391 with cHH is extremely variable, and this often makes the GnRH test not conclusive in the  
392 differential diagnosis. Some studies evaluated the diagnostic power of both the GnRH test and the  
393 dosage of Inhibin B (Mosbah et al., 2020; Coutant et al., 2010). In particular, Mosbah et al.  
394 demonstrated that, in both cHH and CDGP patients, the increase in LH after GnRH challenge was  
395 very variable and it was correlated to testicular volume in subjects with cHH. Moreover, the  
396 authors showed that 47% of cHH subjects had a peak of LH comparable to CDGP patients, but no  
397 subjects with CDGP presented concentrations of LH below 4.0 IU/l, differently from 53% of  
398 patients with cHH. Finally, Coutant and co-authors studied the discriminating capability of the

399 basal Inhibin B blood level, and they concluded that in subjects with genital stage 1 (testis volume3  
400 ml) there was a sensitivity and specificity of 100% for levels of Inhibin B equal to 35 pg/ml or less.  
401 On the contrary, these parameters lowered considerably when switching to genital stage 2 (testis  
402 volume 3-6 ml). Probably the combination of GnRH challenge, basal Inhibin B testing with clinical  
403 and genetic aspects can provide the best and most reliable results in discriminating between CDGP  
404 and cHH.

405

#### 406 **CONCLUSIONS**

407 The role of numerous inhibitory and stimulatory neuromodulators in the onset of puberty is now  
408 well established. Most of them operate upstream of the so-called KNDy system, which definitively  
409 activates the GnRH pulse generator. The perfect balance between inhibitory and stimulating  
410 factors is crucial for the correct timing of puberty, with inhibitory factors predominating before  
411 puberty, and stimulating factors at its onset. The function of these refined neurophysiological  
412 mechanisms can be disrupted by many factors, especially EDs. It is also very important to diagnose  
413 early changes in the onset of puberty, whether precocious or delayed, because of the possible  
414 psychological and clinical short and long-term consequences.

**Table 1**

Characteristics of mediators involved in the HPG axis function.

<b>MEDIATOR</b>	<b>ENCODING GENE</b>	<b>RECEPTOR</b>	<b>KIND OF ACTION</b>	<b>ROLE ON HPG AXIS FUNCTION</b>
<b>Kisspeptin</b>	KISS1, OMIM 603286	GPR54	Excitatory	GnRH secretagogue
<b>NKB</b>	TACR3, OMIM 162330	NK3R	Excitatory	GnRH secretagogue
<b>Dyn</b>	PDYN, OMIM 131340	KOR	Inhibitory	Inhibitor of kisspeptin secretion
<b>Glutamate</b>	-----	NMDA receptor	Excitatory	Promotion of GnRH pulsatility
<b>GABA</b>	-----	GABA A, B, C	Inhibitory	Inhibitor of GnRH pulsatility
<b>Neuropeptide Y</b>	NPY, OMIM 162640	Y1, Y2, Y4, Y6	Inhibitory	Regulation of GnRH suppression
<b>RFRP-3</b>	RFRP, OMIM 616984	NPFFR1	Inhibitory	GnRH neuronal inhibition
<b>MKRN3</b>	MKRN3, OMIM 603856	MKRN3 receptor	Inhibitory	Inhibitor of GnRH secretion
<b>Neuroestradiol</b>	-----	ESR1	Inhibitory	Negative inhibitory action; ESR1 deletion causes early kisspeptin and/or glutamate activation
<b>Leptin</b>	LEP, OMIM 614962	LEP-R	Permissive role	Leptin deficiency reduces KISS1 expression
<b>Ghrelin</b>	GHRL, 605353	GHS-R	Inhibitory	Inhibitor of GnRH and LH secretion
<b>ACAP</b>	ADCYAP1, OMIM 102980	ADCYAP1R1	Inhibitory or excitatory	stimulatory or inhibitory effect to gonadotropins' release

Abbreviations: GPR54, G-protein coupled receptor; GnRH, Gonadotropin-releasing hormone; NKB, Neurokinin B; TACR3, Tachykinin 3 gene; NK3R, Neurokinin 3 receptor; Dyn, Dynorphin; PDYN, Prodynorphin gene; KOR,  $\kappa$ -opioid receptor; NMDA, N-Methyl-d-aspartate; GABA,  $\gamma$ -aminobutyric acid; NPY, Neuropeptide Y gene; Y1, Y2, Y4, Y6, Neuropeptide Y receptor type 1, 2, 4, 6; RFRP-3, RFamide-related peptide 3; NPFFR1, Neuropeptide FF receptor 1; MKRN3, Makorin ring finger protein 3; ESR1, Estrogen receptor 1; LEP, Leptin gene; LEP-R, Leptin receptor; GHRL, ghrelin and obestatin prepropeptide; GHS-R, Growth hormone secretagogue receptor; ACAP, pituitary adenylate cyclase-activating polypeptide; ADCYAP1, Adenylate Cyclase Activating Polypeptide 1; ADCYAP1R1, adenylate cyclase activating polypeptide 1 receptor 1

Table 2

Main properties and hypothetical role on the HPG axis of the most common EDCs.

EDCs/GROUP	ABBR.	ORIGIN	OVERALL PATHOLOGICAL EFFECT	EFFECT ON HPG AXIS	REFERENCES
<b>Bisphenol A/Bisphenols</b>	BPA	Plastic bottles, epoxy resins, polycarbonate plastics and plastic toys	Estrogenic	The exposure of adult female mice to BPA disrupts the HPG axis, by enhancing AVPV-kisspeptin expression and release	Wang et al., 2014
<b>Dichlorodiphenyl-Dichloroethylene/ Organochlorides</b>	DDE	Pesticides (and contaminated fish, soil products and water)	Anti-androgenic, estrogenic	p,p'-DDE, a potent antiandrogen, increases secretion of GnRH and consequently of LH and testosterone	Martin et al., 2002
<b>Per-and poly-fluoroalkyl substances/ Fluorosurfactant</b>	PFAS	Commercial household products and electronics manufacturing. Contaminated fish, soil products and water	Anti-androgenic, anti-estrogenic	There are no studies available	-----
<b>Phthalates/ Plasticizers</b>	-----	Cosmetics and personal care products, medical devices, PVC products and toys	Anti-androgenic	The female rats exposure to high doses of DEHP results in a significant reduction of the Kiss1 mRNA expression in the anteroventral periventricular but not in the arcuate nucleus	Zhen et al., 2020
<b>Polychlorinated Biphenyls/ Organochlorides</b>	PCBs	Flame retardants, pesticides and contaminated fish, soil products and water	Variable (estrogenic, antiestrogenic or antiandrogenic)	Pre-natal exposure to PCDD/Fs (dioxins) and PCBs results in an alteration of the HPG axis, which occurs with a reduction of testosterone in females and estradiol in males	Cao et al., 2008
